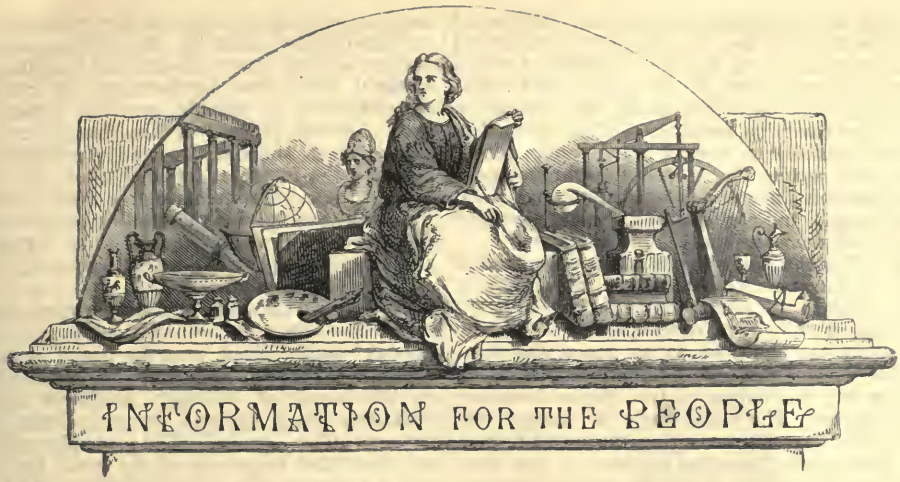
CONTENTS.



ANTHROPOLOGY.

THOUGH there is nothing more hackneyed than Pope's dictum, that 'the proper study of mankind is man;' there is no study we have, from a scientific point of view, more habitually neglected. The moral nature and constitution of man, his hopes, aspirations, passions, and ever-varying humours, have been the subjects of much speculation on the part of metaphysicians and poets; but, till very lately, the study of man in all his relations—'the proper study of mankind'—never had cast on it the dry white light of positive science, which can alone illuminate the mysteries of Nature. So little did we know that was worth knowing about this subject, that till very lately a controversy raged in this country, not as to what the 'science of mankind' taught us, but as to what it should be called. The terms 'Ethnology' and 'Physical History of Mankind' were in general use when we were content to take our notions on the subject from no other work than that of Dr Prichard. Now, however, the term Ethnology is seldom used as a general name for the whole subject, owing to the new school protesting against the science being vitiated at the outset by having a name applied to it that homologated a hotly disputed theory. Ethnology and Ethnography were terms of too limited meaning for a science that professes to study the phenomena of the human group, in its *tout ensemble*, however well they might fit a science which limited itself to the bare description and classification of *races*. Ethnology as the science of races is only a branch of the great science that investigates all the phenomena presented by man as an inhabitant of the globe. Many authorities, too, protested that there were no such things in nature as the 'races of man;' so a new term was introduced, viz. *anthropology*, which is not only of wider meaning than ethnology, but, being of neutral significance, traverses nobody's pet theories, and so gives offence to none. It is derived from the Greek *anthropos*, man, and *logos*, a discourse.

Anthropology is the natural history of man, the words 'natural history' being used in their real meaning, to signify not merely the study of the physique, and the dry descriptive classification of the members of a zoological group, but also the study of whatever of their mental nature finds expression in the phenomena of their physical organisation, and how that and their general environment act and react on each other. The most recent and logical division of the science is as follows:

(1.) *Zoological Anthropology*, discussing man's relations to the brute creation. (2.) *Descriptive Anthropology*, or ethnology proper, describing the divisions and subdivisions of mankind. (3.) *General Anthropology*, or, as M. Paul Broca, in his recent article on the subject in the *Nouveau Dict. Encyclopédique des Sciences Médicales*, puts it, the 'biology of the human race,' which borrows and collates from all sciences facts and phenomena usually investigated in men as individuals, but which relate to groups and numbers of men; comparing these with other facts (got in the same way) relating to other groups of human individuals. For example, the study and bare description of a single skull belonging to any race, is human anatomy; but the study and description of a series of skulls belonging to that race, and of their peculiarities, compared with groups of skulls belonging to other races, is not part of human anatomy, but of general anthropology.

METHODS AND TERMINOLOGY.

The methods of investigation are identical with those of other natural sciences, save when modified by the distinctive peculiarity of anthropology, viz. that its facts refer not to individuals, but to *groups of individuals*. Investigation by measurements is one of the most valuable

methods of anthropological research. By means of it we find out the comparative development of different regions of the skull in different tribes, the various proportions of the trunk and extremities, and, most important of all, the capacity of the cranial cavity or brain-case. The facts got at by this method are only of value—and, indeed, only come within the scope of anthropology—when they refer, not to individuals, but to *groups* of individuals, and are capable of being expressed in tables of maxima, minima, and averages.

As each anthropologist has his own method of measurement, which often differs from those of his brethren, the results obtained by different observers are too often contradictory. The way to measure the skull, so as to get at the comparative development of different regions, is to measure the inclination of two planes bounding those regions. The facial angle of Camper was got in this way, by measuring the angle formed by a line drawn from the forehead to the most projecting part of the jawbone, meeting another drawn from the base of the nose to the external ear. When it was nearest a right angle, it was held to indicate superior intellectual development in a race. Unfortunately, M. Jacquart, of the Natural History Museum in Paris, shewed that it came very near a right angle in comparatively stupid people; and that even in the homogeneous population of Paris, it varied within much wider limits than those Camper held to be a good test of distinct species. It is now held of little account; indeed, cranial measurements are now considered of little use to science, unless they are far more exact and elaborate than this. Instead of using one cranial measurement, as did Camper, Dr Barnard Davis, in his recent work, *Thesaurus Craniorum*, the best authority on this subject, gives us no less than ten. We may briefly sum them up as follows: (*a*) internal capacity of the skull expressed in ounces avoirdupois; (*b*) circumference of skull round forehead, taken by a tape at junction of the forehead and nose, and over the most prominent part of the occiput; (*c*) the arch of the skull, from the junction of forehead and nose to the edge of the foramen magnum; (*d*) the intermastoid arch, from the tip of one mastoid process to another; (*e*) longitudinal diameter, or length from forehead to occiput; (*f*) transverse diameter, noting whether the greatest breadth is between the parietal or temporal bones on opposite sides; (*g*) height from the plane of the foramen magnum to that of the vertex; (*h*) length of face from nasal suture to tip of chin; (*i*) breadth of face or interzygomatic diameter, or space between the two cheek-bones; and lastly, (*j*) a measurement expressing the proportion of the greatest length to breadth of face, taking the latter as 1·00. Dr Davis determines the capacity of the brain-case by filling it with fine sand of specific gravity 1·425; but this is objectionable, for the sand gets into crevices and sutures and little cavities where no brain-matter lodged in life, and gives a false indication of the cerebral capacity of the skulls so measured. Professor Wyman of Harvard University, in the *Proc. Boston Nat. Hist. Soc.* for 1868, suggests a better method. According to him, you first fill the brain-case with fine shot, which cannot get into crevices, &c. and then weigh the cranium. Then convert the weight of material into cubic measurement by determining the cubic measurement of an ounce of the material (shot), and multiplying this by the whole number of ounces. Then you convert the weight of the material (shot) into brain-weight by correcting the difference in specific gravities between the two. Another process of his, though less accurate, is much simpler. Instead of weighing, you *measure* the contents of the brain-case. You convert the cubic contents of the skull into brain-weight, by multiplying the number of cubic inches by the weight of a cubic inch of water (252·5 grs.), and allowing 4 per cent. for difference of specific gravities of brain and water.

Philological methods of research were once the prime favourites of anthropologists. Professor Huxley would indeed base the grand separating distinction between man and the lower animals on the faculty of language, doubtless agreeing with Aristotle in saying: 'Animals have voices, but man alone speaks.' The principles on which the diversified languages of the world are classified, are treated of in another number. The study of this new science of comparative philology made at the outset so many revelations of unexpected affinities among nations, that it seemed at one time as though anthropologists were about to reject all other more laborious methods of research. But of late years, the value of language as a test of race has lost a good deal of its prestige. It is only one amongst many tests; and evidence derived from it must be corroborated by evidence derived from history, physical structure, religion, customs, &c. before it can be regarded with respect. Nations have been known to change their language, and adopt that of nations that conquer them or enslave them; and Sir E. Tennent mentions one tribe, the Veddahs of Ceylon, that are not believed to have any language at all. Such being the case, language is of too fluctuating a character to be relied on as an infallible basis for racial classifications. Next to grammatical structure, similarity in the words denoting the simplest and most necessary things, those most closely interwoven with the home-life of the people, are studied as being likely to afford the clue to the racial affinities of the tribes in whose dialects they occur. As Dr Prichard said: 'Tribes and families separated from each other have been known to have preserved such similar words for thousands of years in a degree of purity that admitted of an easy recognition of this sign of a common origin.'

The study of the myths, customs, weapons, implements, &c. of different tribes has greatly displaced philology as a means of discovering racial relationships. But identity of this sort can never, any more than language, be relied on as an infallible test. Mr Tylor says, in his recent work on the *Early History of Mankind:* 'The principle, that man does the same thing under the same circumstances, will account for much, but it is very doubtful whether it can be stretched far enough to account for even the greater proportion of the facts in question. The other side of the argument is, that the resemblance is due to connection, and the truth is made up of the two, though in what proportion we do not know.'

There are a few anthropological terms liable to considerable ambiguity, owing to their being used by different writers in different senses. These

terms are—(1.) Race, (2.) Species, (3.) Variety. '*Race*,' says M. Broca, 'affirms the existence of a parental bond between the individuals forming a race; but it neither affirms nor denies a similar relationship between that race and other races.' *Species* affirms diversity of origin; so that, if we were to talk of the African species, the European species, &c., we should imply that these several groups sprang from separate origins. *Varieties* is a term the use of which, as applied to mankind, implies that the whole group of mankind form but *one* single species, which many deny. It will be seen that the use of the terms 'variety,' 'species,' implies that we are partisans of those who hold the rival theories regarding the unity and plurality of races; so that it is more convenient to use the term 'race,' in the sense of 'a persistent modification of mankind,' which enables us to preserve our neutrality between the two hostile sects into which anthropologists are divided.

I. ZOOLOGICAL ANTHROPOLOGY.

For the full discussion of the physical differences between man and the lower animals, we refer to treatises on zoology. We may say that the skull presents well-marked differences. For instance, the ridges above the eyebrows are, as a rule, never developed in man as in the higher apes. 'The orbits and jaws are relatively smaller, and situated less in front of, and more below, the fore part of the brain-case. . . . In the profile view of the face, the nasal bones project more beyond the level of the ascending process of the maxilla than they do in any ape.'—*Huxley*. Then we have the erect posture in progression, the non-prehensile nature of the feet, the greater size of the brain, the greater number and complexity of its convolutions, the greater size of the cerebrum as compared with the cerebellum, and of the brain as a whole, as amongst the principal features distinguishing man from the higher apes. Whilst some authorities would place man in an order by himself, later writers, such as Huxley, reverting, to a certain extent, to the ideas of Linnæus, the Father of natural history, would simply make him the only genus and species of a group of higher animals, the group Anthropidæ, which belongs to the family of the Catarrhini, one of the divisions of the order Simiadæ. The most striking distinction between man and the higher apes is in the *volume* of the brain. Professor Schauffhausen holds that the difference in this respect between the highest ape and the lowest man (excluding diseased or abnormal brains from consideration) is so very much greater than any differences of the sort among the anthropomorphic apes themselves, as to create an almost impassable gulf between them. The higher apes and the lowest races of man are gradually tending to extinction, and it may be, that in the ages that have elapsed since man first appeared on the earth, many intermediate forms that might have bridged this gulf have died out, though as yet geologists have not discovered any positive traces of their fossil remains.

II. DESCRIPTIVE ANTHROPOLOGY.

The principles upon which we classify the races of mankind must be the same as those that guide us elsewhere. The value of a character must mainly depend on its permanence and power of resisting change. Hence it is, that though men differ from each other more in brain-power than physical characteristics, yet the latter, being the less ductile, and the most persistent in resisting change, are of most value as a means of classification. Hence it is that even Professor Max Müller has given up the notion of classifying mankind by means of language alone—language being of all human products the one least capable of withstanding change. Blumenbach's popular classification divided mankind into—

1. The *Caucasian Variety*—the characters of which are: white skin, straight oval face, large broad forehead and skull, narrow nose, and thin

Fig. 1.—Caucasian.

Fig. 2.—Mongolian.

Fig. 3.—African.

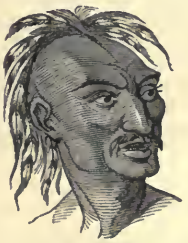


Fig. 4.—American.

Fig. 5.—Malay.

lips. It includes all the people of Europe (except the Finns), high-caste Hindus, Persians, Assyrians, Arabians, Jews, inhabitants of Asia Minor, Caucasus, Egypt, Abyssinia, and Morocco. This is the highest race of all as regards moral feeling and intellect.

2. *Mongolian Variety*.—Characters are: yellow skin, long black *straight* hair, scanty beard, short broad nose, broad flat cheek-bones and prominent, skull flattened at the side, with forehead low. The eyes are rather obliquely set. The Chinese, Tatars, Turks, Finns, Lapps, &c. are good examples.

3. *African Variety*.—Characters: Skin black, hair woolly, forehead low and retreating, jaws

projecting, lips large and thick, nose thick and flat.

4. *American Variety.*—Skin reddish brown, hair long, black, and lank, scanty beard, black eyes, high cheek-bones, aquiline nose, small skull with high apex, and flat occiput.

5. *Malay Variety.*—Characters: Tawny dark-brown skin, coarse black hair, short broad nose, large mouth, broad flat faces with projecting upper jaws, skull high, and the forehead low and broad. This race inhabits the Malay Archipelago.

The most recent classification is the highly ingenious one of Huxley, which is founded on the hair. There are two primary divisions—I. the *Ulotrichi* (crisp or woolly haired people), and II. the *Leiotrichi* (with smooth hair). In the Ulotrichi, the colour varies from yellow to black, and they are dolichocephalic (or possess skulls longer than they are broad). The Negroes, Bushmen, Malays, are members of this *Negroid* stock. The Leiotrichi he divides into—(1) the Australoid group, 'with dark skin and eyes, wavy black hair, and eminently long prognathous skulls, with well-developed brow ridges, who are found in Australia and the Dekhan;' he considers the ancient Egyptians to belong to this group; and Colonel Lane Fox's recent discoveries of the resemblances in the weapons used by these races confirms this somewhat startling view; (2) the Mongoloid group, including Chinese, Tatars, Polynesians, Eskimos, and American Indians; (3) the Xanthochroic group, with pale skins, blue eyes, fair hair, including Sclavs, Teutons, Scandinavians, and the fair Celtic-speaking peoples; (4) lastly, the Melanochroi, or dark whites, with pale complexions, dark hair and eyes, including Iberians, 'black Celts' of Europe, and the dark-complexioned white peoples of the shores of the Mediterranean, Western Asia, and Persia. This group he thinks the result of a mixture of Australoids and Xanthochroi.

To every classification (the most recent one of Huxley's not excepted) grave objections may be made; but as it is necessary to have *some* classification to work from, we recommend, as most popular, simple, and at the same time least inadequate, the following summary of Dr Latham's. He adopts three primary varieties, the Mongolian, African, and European, to which he gives the technical names of (1) Mongolidæ, (2) Atlantidæ, (3) Japetidæ.

I. MONGOLIDÆ.

This is by far the largest division, embracing the nations of Asia, Polynesia, and America, and takes its name from the Mongols of Central Asia, who are considered as typical of the whole. The general characters are—a broad flat face; the skull wide rather than long, and square rather than round; forehead retiring or depressed, rarely approaching the perpendicular; jaw moderately projecting, rarely orthognathic; eyes often oblique; skin rarely a true white or a jet black; eyes generally dark; hair straight, and lank, and black. The languages are either without inflections, or agglutinate. Their influence on the history of the world has been rather material than moral. They fall into the following groups:

(A.) ALTAIC MONGOLIDÆ, which are composed of two stocks, the Seriform and the Turanian.

1. The *Seriform* stock embraces the nations nearly allied to the Chinese (Lat. *Seres*)—namely, Chinese, Tibetans, Anamese, Siamese, Cambodians, Burmese, and other tribes. These all agree in having languages that are monosyllabic and without inflections. The prevailing religion is Buddhism. The Chinese are specially characterised by *oblique* eyes, which, however, occur in other Mongolidæ.

2. The *Turanian* stock, which extends over an immense area, has four branches—the Mongolian, Tungusian, Turk, and Ugrian. The languages of these tribes have inflections of the agglutinate kind. Their physical structure is typically Mongolian. The Mongolian branch of the stock is composed of the Mongols proper of the Desert of Shamo, the Buriats about Lake Baikal, the Kalmucs, &c. The Tungus inhabit about the Lena and the Sea of Okhotsk. The Mantshu conquerors of China were Tungus. The Turk branch includes, among others, the Turks of the Sandy Desert, Kirghis, Uzbeks, Turkomans, Ottoman or Osmanli of the Turkish Empire, and Turks of the Russian Empire. It is probable that a large portion of ancient Scythia was Turk, and that that race furnished some of the most famous conquerors of antiquity. Among the Osmanlis of Turkey, and in other cases, the Mongolian features have become modified by intermixture and other causes. The Turk of Constantinople has a round head, oval face, a regularly formed eye, and a long beard.

The Ugrian branch has its locality along the Arctic Ocean from Norway to the Yenisei, with a detached area in Hungary. A variety of Ugrian tribes inhabit Russia on both sides of the Ural Mountains, and on the Volga, as far south as Astrakhan. The Finlanders of Finland, the Esthonians of Esthonia, the Laplanders of Sweden and Norway, and the Magyars of Hungary, are all Ugrians. With the exception of the Magyar intrusion, the Ugrian frontier is a receding one. The ancient barrows of Scandinavia give evidence that the race at one time had a wider area. The older tombs contain, along with implements, *not* made of iron, skulls that are broad rather than long, and therefore Ugrian. Many Ugrian tribes retain their ancient paganism, called Shamanism.

(B.) DIOSCURIAN MONGOLIDÆ.—The ancient seaport of Dioscurias, at the east end of the Black Sea, was the chief mart of commerce with the inhabitants of the Caucasus, and was remarkable for the multiplicity of languages spoken. This is still a characteristic of these regions, and hence the name. It is startling to find the inhabitants of the Caucasus, so long held to be types of the European variety, excluded from it altogether, and classed with the sallow flat-faced Mongols. Yet the nature of their languages, and other facts, are considered to overbalance the symmetry of their shape and their complexion. The languages of the Caucasus seem to have more resemblance to the monosyllabic and non-inflectional languages of the Chinese and other Seriform peoples, than even to the Turanian. The nature of the climate may account for the physical transformation of the Caucasians, if their personal beauty is really true to the extent generally believed.

The narrow basis on which the theory was formed which makes the Caucasians the type of all that is highest in humanity, is very remarkable.

Dr Latham gives this account of it : 'Blumenbach had a solitary Georgian skull; and that skull was the finest in his collection—that of a Greek being the next. Hence it was taken as the type of the skull of the more organised divisions of our species. More than this; it gave its name to the type, and introduced the term *Caucasian*. Never has a single head done more harm to science than was done in the way of posthumous mischief by the head of this well-shaped female from Georgia.' The chief Circassian tribes are the Georgians, Lesgians, Mizjeji, Iron or Ossetes, and Circassians.

(C.) OCEANIC MONGOLIDÆ.—With a few exceptions, all the islands in the Indian and Pacific Oceans are inhabited by one race—the Oceanic race. The exceptions are—Mauritius, Isle of Bourbon, Ceylon, Maldives and Laccadives, Japan and adjacent islands. This race is not found anywhere on the continent, except in the peninsula of Malacca. It exhibits two types—the Malay, whose colour is yellow, olive, brunette or brown, rather than black, with long black and straight hair; and the Negrito, of a black colour, resembling the negro, and with hair always long, sometimes straight, but in other cases crisp, frizzy, or even woolly. The Negritos, or blacks, are lower in point of civilisation than the Malays. The Negritos extend over New Guinea, Australia, Tasmania, New Ireland, and the islands between it and New Caledonia. The brown division occupy the rest of the oceanic area—Sumatra, Borneo, Java, Moluccas, South Sea Islands, &c. Each of these divisions falls into a great number of subdivisions. The Malays are distinguished for their enterprising and commercial tendencies, and have been called the Phœnicians of the East. Many of the Polynesian section of this type approach Europeans in conformation.

(D.) HYPERBOREAN MONGOLIDÆ.—This class contains three divisions—Samoeids, Yeniseians, and Yukahiri, inhabiting the coasts of the Arctic Ocean. Of all the Siberian tribes, the Samoeids are the nearest to the Eskimos.

(E.) PENINSULAR MONGOLIDÆ, inhabiting the peninsulas of Kamtchatka and Corea, and the islands that form a continuation of them. The divisions are the Coreans, Japanese, Koriaks, and Kamtchadales. One marked distinction between these peoples and the Chinese is, that their languages are anything but monosyllabic; according to Dr Latham, they are the nearest to the languages of America.

(F.) AMERICAN MONGOLIDÆ.—The Eskimos who inhabit the northern coasts of America from Greenland to Alaska, are also found on the Asiatic side of Behring's Strait; and this naturally suggests the idea that America was peopled from Asia by that line. The chief difficulties attending this view are two. The first lies in the physical differences between the Eskimos and the American Indians. 'Stinted as he is in stature,' says Dr Latham, 'the Eskimo is essentially a Mongol in physiognomy. His nose is flattened, his cheek-bones project, his eyes are often oblique, and his skin is more yellow and brown than red or copper coloured. On the other hand, in his most typical form, the American Indian is not Mongol in his physiognomy. With the same black, straight hair, he has an aquiline nose, a prominent profile, and a skin more red or copper coloured than either yellow or brown.' The second difficulty is philological. The Eskimo language is very unlike the better known languages of Europe and Asia, and, *in grammatical structure at least*, is American. The two tests are thus in antagonism; 'physically, the Eskimo is a Mongol and Asiatic; philologically, he is American.' As to the physical differences, though there is a strong contrast between the Eskimos on the east side of the continent and the conterminous tribes on the south, there is no marked line on the west side; the Eskimos of Alaska pass gradually into the Indians proper. In fact, the red colour is little marked, except in a few typical nations, chiefly the Iroquois and Algonkins. The languages of the New World differ from one another in respect of their roots and single words far more completely than is the case in the Old World; yet they are all constructed on the same principle, and have, as it were, one physiognomy. On this and other grounds, the unity of the American peoples is considered established.

(G.) INDIAN MONGOLIDÆ.—These embrace the natives of Hindustan, Cashmere, Ceylon, the Maldives and Laccadives, and part of Beloochistan. They present two types of physical form—one dark, approaching to black, and with a Mongol, or even African physiognomy; the other, brunette, sometimes delicate and clear, and with a profile and oval face approaching the European. The first type prevails in the Deccan and south generally—the last in Northern India. The languages of the northern Hindus, or Indo-Gangetic tribes, are full of Sanscrit vocables, so that they are generally held to be of Sanscrit origin; but Dr Latham and others believe that in respect of grammar they are not Sanscritic. The prevailing religion is Brahminism. The darker tribes—as the Tamuls of the Deccan—retain in a great measure their ancient heathenism, and their language has fewer Sanscrit words in proportion.

II. ATLANTIDÆ.

Under this term, Dr Latham classes all the tribes of Africa, and along with them those of Syria and Arabia. This seems startling; but the transition from the lowest to the highest of these nations is so gradual, that the affinities of language are held to justify the arrangement. The general characters of this variety are a projecting maxilla, retiring forehead, and flat nose. The skull is narrow, and developed in length rather than breadth. The eyes are rarely oblique; the skin is often jet black, very rarely approaching pure white; the hair crisp, woolly, rarely straight or light. The languages are agglutinate, rarely amalgamate. Circumcision is prevalent. The group has seven divisions.

(A.) NEGRO ATLANTIDÆ.—These have, in an exaggerated form, the black unctuous skin, woolly hair, projecting jaws, flat nose, and thick lips characteristic of the whole variety. But it is important to observe the comparatively narrow area to which the Negroes proper are confined. They occupy Western Africa from the Senegal to the Gaboon, Soudan in the centre, and the low parts of the Upper Nile. The dusky or brown hue of the Arab and Australian is more prevalent through Africa as a whole than the jet black of the Negro; which seems nearly coincident with river valleys and deltas lying within the tropics.

(B.) KAFFRE ATLANTIDÆ.—In physical conformation, they are modified Negro; the profile less prognathic; their language has some singular peculiarities. They occupy from north of the equator to south of the Tropic of Capricorn.

(C.) HOTTENTOT ATLANTIDÆ.—These, according to Dr Latham, have a better claim to be considered a second species than any other section of mankind. Their colour is brown rather than black; the hair grows in tufts. The stature is low, and the bones of the pelvis peculiar. Their language has a characteristic *click*. They inhabit the south of the continent, and are divided into Hottentots and Saabs, or Bushmen.

(D.) NILOTIC ATLANTIDÆ, occupying the water-system of the Upper and Middle Nile. The leading tribes are the Gallas, Agows, Nubians, and Bishari, forming the population of Abyssinia, Adel, and Nubia. It connects by imperceptible gradations the Coptic and Semitic groups with the rest of the African.

(E.) AMAZIRGH ATLANTIDÆ, usually called Berbers. In conformation, they vary from the Negro to the Arab type. The language is *sub*-Semitic. They inhabit the ranges of the Atlas, the Sahara, and the Canary Isles.

(F.) EGYPTIAN ATLANTIDÆ, or old Egyptians, represented by the modern Copts. Both language and physical conformation connect them, on the one hand, with Berbers and Nubians; on the other, with the Assyrians, Jews, &c.

(G.) SEMITIC ATLANTIDÆ.—The area of this division lies chiefly in South-western Asia; and to it belong the Syrians, Assyrians, Babylonians, Phœnicians, Carthaginians, Edomites, &c. Jews, Arabs, Ethiopians (Abyssinia). The Semitic nations are light-complexioned, with capacious, elongated skulls, the nasal profile straight or prominent, the maxillary prognathic. Their influence on the world has been eminently moral. All the alphabets of Europe are undoubtedly of Semitic origin; and probably those of the whole world are so. In the early period of their history, their religion was paganism; in the later, it has been eminently monotheistic. The Jewish and Christian Scriptures, and the Mohammedan Koran, are the rules of life to the most advanced peoples of the species. The first builders of cities and organisers of empires seem to have been the Assyrians and Babylonians on the Tigris and Euphrates.

The chief modern Semitic types are the Jew and the Arab; the first being characterised by thicker lips, more aquiline nose, and larger head; the last, by a more oval face, thinner lips, sparer limbs, and brown complexion—in Africa, often nearly black.

The present inhabitants of Madagascar seem to be of Malay origin, and to have exterminated an aboriginal African—probably Hottentot—population.

III. JAPETIDÆ.

The chief nations of Europe belong to this variety, which is generally known by the term Indo-European. Dr Latham prefers to call them Japetidæ, as being traditionally descended from Japheth; probably because he dissents from the theory of the European nations having migrated from Asia, which is implied in the usually received name.

The physical characteristics of the Japetidæ are those of the so-called Caucasians. There are two divisions of them.

(A.) OCCIDENTAL JAPETIDÆ, including the Celtic nations. The Celtic area is now confined to Brittany, Wales, the Highlands of Scotland, the Isle of Man, and Ireland, but at one time it undoubtedly extended over the whole of Britain, the north of France or Gaul, and part of Switzerland, and probably over Baden, Bavaria, the north of Italy, &c. The Celtic languages have the appearance of having broken off from the common mother-tongue at an earlier stage than the other European stocks; they retain an agglutinate character. The modern representatives of the Celtic are divided into two branches—the Cambrian, consisting of Welsh, Cornish, and Armorican; and the Gaelic, consisting of Scotch Gaelic, Irish Gaelic, and Manx.

In physical conformation, the Celts are pre-eminently long-headed, with prominent cheek-bones. Black hair and eyes, and a dark complexion, prevail in South Wales; the Hibernian type has gray eyes, light complexion, and hair yellow, red, or sandy.

(B.) INDO-GERMANIC JAPETIDÆ.—The European part of this division falls into three stocks.

1. The *Gothic* or *German* stock.—This stock exhibits two physical types—one with blue eyes, flaxen hair, and ruddy complexion; the other with gray, dark, or hazel eyes, brown or black hair, and sallow or swarthy complexion. It has two branches—the Teutonic or German proper, and the Scandinavian.

a. The *Teutons* are again divided into High Germans and Low Germans, distinguished chiefly by certain peculiarities of language. The High German area is Hesse and parts of Thuringia and Bavaria. The Low Germans are the Dutch or Batavians of Holland, the Saxons, and the Frisians. The original Saxons of Hanover and Westphalia are now extinct or incorporated with the other Germans. The Anglo-Saxons of England are the most important representatives of the Saxon tribes.

b. The *Scandinavian* branch occupy Denmark and Scandinavia, Iceland and the Faröe Isles. One marked difference in point of language between the Scandinavian Germans and the Teutonic is, that the former place the definite article after the noun, and incorporate the two; as, *bord-et*, 'the table,' from *bord*, 'table,' and *hitt* (neuter), 'the.'

2. The *Sarmatian* stock, comprising the Slavonic and Lithuanic nations. In physical conformation, these often approach the Turanian type.

a. The *Lithuanians* are now confined chiefly to the Baltic provinces of Russia, but were once more extensively spread. The old Prussian language, now extinct, was Lithuanic. The Lettish of Courland, Livonia, Wilna, &c. is a Lithuanic dialect. The great interest attaching to the Lithuanians arises from the fact, that their language is the nearest to the Sanscrit or sacred language of India that is known. They also retained their original paganism longer than any other member of this variety.

b. The *Slavonic* peoples form an extensive group, comprising Russians, Servians, Illyrians, Tsheks (of Bohemia, Moravia, &c.), Poles, Serbs. Large tracts of Northern Germany, now occupied

by Germans, were apparently Slavonic within the historic era.

3. The *Mediterranean* or *Classic* stock, comprising the ancient Greeks and Romans, with their modern representatives. The modern Greeks speak a language far closer to ancient Greek than any modern tongue is to Latin. How far their blood is pure Hellenic, it is difficult to say. The blood of the modern Italians is in the main of Roman descent, with Gothic admixture. The Romans, along with their language and civilisation, contributed important elements to the population of the Spanish peninsula and to France. Distinct traces of Rome also remain among the Swiss of the Grisons and the Walachians. The peoples, therefore, speaking Italian, Spanish, Portuguese, French, Romane (Walachia), and Rumonsch (Grisons), are classed as Romanic. The affinities of the ancient tribes inhabiting these countries are in many respects unsettled. The close relation between the Greek and Latin tongues has always been felt. Dr Latham brings them together geographically by making the Hellenes emigrants from the south of Italy.

Dr Latham dissents from the opinion that classes Persians, Afghans, and even Hindus, with Europeans, but it is generally received by students of language and ethnologists. That opinion rests on affinities of language, and arose about the beginning of the present century in the study of Sanscrit. Sanscrit is the language in which the religious books of the Hindus are preserved, and is of great antiquity. Its similarity in structure to Greek and Latin is so striking, that it was maintained at one time to be a factitious or artificial language, constructed by the Brahmins on the model of the Greek, for the purpose of giving an air of mystery and sanctity to their religious records. But this theory did not long stand examination. Striking coincidences had previously been pointed out between Greek, Persian, and German. The subject was taken up by the scholars of Germany, who are specially qualified for such a research; and the affinity of Sanscrit and Persian, not only with Greek and Latin, and their descendants, but with the other principal languages of Europe—Slavonic, Lithuanic, and all the Germanic languages, including English—soon became a received doctrine. It was generally admitted as beyond doubt that all these languages must have had a common origin, and might, therefore, be fitly designated a family, to which the name of Indo-German was given, as indicating its extremities. The Celtic of Wales, Ireland, and Scotland, continued for some time to be looked upon as foreign to this family—as the remains of the primitive language of Europe before the arrival of the Indo-German races. It was reserved for Dr Prichard to vindicate more recently the claims of the Celtic dialects to be numbered in the sisterhood. This he is allowed to have successfully done; so that Indo-European, instead of Indo-German, is now thought by many to be the more appropriate name for the group.

Along with the affiliation of tongues went that of the peoples speaking them; and the modern languages of Northern India (Hindustani, Bengali, &c.), being held descended from Sanscrit, as Italian is from Latin, and those of Persia similarly related to the ancient Zend—a form very similar to the Sanscrit—Hindus, Afghans, and Persians, were classed as eastern cousins of the European nations. To account for the connection, the European branches of the family were assumed to have migrated from the East before the historic period—a migration to which many traditions are believed to point.

The diversity of appearance in language, features, and physique, found in the existing European descendants of the great Aryan, or Indo-Germanic stock, is, as we have said, due to the fact, that the Aryan race did not find Europe empty when it came to it. The Aryans not only subdued the European *autochthones* (aborigines or primitive people), but intermixture took place between conqueror and conquered, and as the latter may have consisted of a great many varieties, the diversities noticeable in the present inhabitants of Europe are easily accounted for. Indeed, prehistoric investigators tell us that before the Aryan invasion, in the Stone Age, there *must* have been at least two different races in Europe: a race with skulls longer than they were broad (dolichocephalic), that inhabited the shores of Provence; and a race with skulls broader than the former (brachycephalic), inhabiting Scandinavia. The Basques and the Finns have skulls which are respectively dolichocephalic and brachycephalic, like those of the European *autochthones*, and they are the only two nations whose languages shew not the remotest affinity to other European languages, or to the Sanscrit. They are thought to be the last traces of the primeval human fauna of Europe, which was swamped by the tide of Aryan migration from the East.

III. GENERAL ANTHROPOLOGY.

PHYSICAL PECULIARITIES.

Skin, Hair, and Eyes.

The skin varies much in colour and texture in different races—from the pale reddish brown of the 'white' or Xanthochroic races to the black tint peculiar to the Negro. The true skin is the same in all races. The cuticle or scarf-skin, which covers it, varies according to the amount of pigment deposited in the flattened epidermal cells of which it is composed. The pigment is formed in the deeper layer of the cells of the cuticle, sometimes called the *rete mucosum*. Exposure to solar heat is the most popular explanation of the coloration of the skin, but it cannot be shewn that there is any absolute relation between this and the amount of skin pigment. Dark-skinned races exist in the cold arctic regions; and though in the Old World we find a gradual darkening of the skin occurring as we proceed southward from Northern Asia, yet in the New World we find an almost unvarying shade of dusky brown prevailing amongst the aborigines, through every variation of temperature and climate—from the icy regions of Hudson's Bay to the sun-dried Pampas of South America. In corresponding latitudes in Africa, we find the natives not brown, but black. Some have tried to explain this by saying that Africa is an older continent than America, and that its inhabitants, having been so much longer exposed to extreme solar heat, have consequently become proportionately darker in colour. If this theory were reliable, we should have in colour a valuable indicator of the relative

antiquity of races. In India, the darker races are the oldest, and the dark races of the Malay Archipelago inhabit the remains of a continent probably older than that of Asia. Professor Laycock of Edinburgh, in his oral lectures on the practice of medicine, has lately advanced an ingenious theory of skin-pigmentation. The pigment consists of carbonaceous matter, and the skin is an excretory organ; he therefore thinks that where the lungs, as excretors of carbon, are not equal to the demands made on them by the system, as we might suppose the case in hot climates, the skin comes in to aid them, and a vicarious excretion of carbon goes on, through the agency of the epidermal cells, resulting in the deposit of black pigment in these structures. It is assumed by some that the black skin of the Negro gives him an advantage in a hot climate. But if the Negro derives advantage from his skin, it is not because of its colour; for it is now known—though the contrary was long believed—that two surfaces of the same material, the one black and the other white, radiate heat equally. When exposed naked to the sun, the Negro must feel the colour of his skin a disadvantage; for black absorbs bright rays better than white does. The advantage of the Negro lies in the more vigorous excretory power of his skin, and its freer perspiration, which produces cooling. The Negro at birth is not black, but light gray or brown. The skin of the Negro emits a most disagreeable odour, which in some can be smelt at a great distance, and in others is not very perceptible. Foissac says it corresponds to the smell characteristic of black feathers of birds, and black hair of the dogs in New Guinea. We have no evidence of an aboriginal black race having ever existed in Europe, or of a white race having ever existed in Africa. In Asia and Africa, apes and men manifest similar peculiarities as regards colour of skin.

The hair is an appendage of the skin; its pigment is of the same sort, and is not confined to the pith of the hair, for hairs without pith possess pigment. In the hair of red-haired people, traces of sulphur may be discovered by analysis. Hair varies much in form and appearance, as well as colour—sometimes exhibiting a circular, or an oval, or a flattened transverse section. In some races, it is long and straight; in others, short and crisp, like wool. It usually, but not always, is of greater length in the female. In most races, it is scanty on the face and body; in some, almost absent, except on the scalp and eyebrows. When hair is developed to any great extent on the limbs, it is curious to note that the points of the hairs of the arm and fore-arm are directed to the elbow, and those of the leg and thigh slope away from the knee—as in the anthropomorphic apes.

The colour of the eye usually corresponds with that of the hair—though not always—light-coloured eyes being associated, as a rule, with a fair complexion—the exceptions being most numerous in what are called mixed races.

Albinos, Prichard and the old ethnologists held to be mere morbid products of humanity; and in cases where dark-skinned people got their colour blanched by disease, examples of which we find amongst the Tatars and natives of Malabar, the opinion was tenable enough. But the albino Australian described by Bennett in his *Wanderings in New South Wales*, i. 437, who had flaxen hair, light-blue eyes, and white skin, with occasional black spots, can be no more a 'morbid product' than a piebald pony is one. Albinism of this sort is now held to be an individual variation from the racial type, which, though not at all morbid, being out of harmony with external circumstances, rarely becomes permanent; except in the Isthmus of Darien, where albinos are said to be so numerous as to have been described by Coreal (*Voy. aux Indes Occ.* vol. ii. p. 140) as a distinct race. In white races, albinos have reddish eyes and white hair; the want of pigment in the lining membrane of the eye rendering the red blood-vessels that play upon it visible, and greatly impairing the capacity of the organ for absorbing light. The eyes in most European races are set horizontally in the sockets. In the Chinese and Tatar races, they are set obliquely, the inner angle being depressed, and the outer elevated.

Voice.

Very recently, Sir D. Gibb, M.D. drew attention to the varying character of the voice in different races—a subject that had been hitherto greatly overlooked. It would appear that, as we proceed from east to west, the power of the voice tends to increase. The Chinese have a voice feeble in power and compass, its peculiarity being a whining metallic twang. In the races inhabiting Tatary, Tibet, and Mongolia, the voice is strong and loud, though it still has a slight metallic twang. In India and Burmah, the voice is soft and womanly, shrill rather than strong—the hill tribes having stronger voices than the dwellers on the plains; in the Negro, the voice is bellowing and noisy, rather than powerful; it is also indistinct and husky. The Europeans have most powerful sonorous voices, the Germans having the strongest of all, being in this respect excelled by the Tatars only, who have the most powerful voices in the Old World. It is remarkable that in both nations short broad skulls (brachycephaly) prevail. The American Indians excel even the Tatars in vocal power. The Hottentots have peculiar 'clicks' in their speech (which, by the way, Van der Kemp differentiated into six distinct speech-sounds). Sir D. Gibb is hardly justified in describing this as a racial peculiarity, for it is not an inherent one. Hottentot children, reared amongst the whites, on returning to their savage home, can as little acquire the art of 'clicking' as the missionaries (Waitz, *Int. Anthrop.* vol. i. p. 136). The Eskimos are said to have remarkable powers of ventriloquism.

It is probable these variations in vocal powers are due to, as yet, unstudied or unnoticed structural variations in the larynx peculiar to different races. In the Negro, for example, the peculiar position of the larynx prevents the tones of the voice from reverberating so well as they do in the cavern-shaped ventricles of the vocal apparatus in the European; and the shallowness of the larynx characteristic of the Chinese may cause their voices to assume an effeminate type.

Trunk and Extremities.

In the Bushmen, especially in the females, enormous deposits of fat are observed on the buttocks. Cuvier compared these cushions of fat to similar formations in female monkeys (Mandrills), but

Desmoulins denies there is any strict analogy between them. These deposits of fat are seen in many Negresses—for example, in Congo women, often among Nubian and Somali women—and it is curious to note that the Negro race seem to consider these cushions marks of superior beauty. Hence it is that women about Cape Coast Castle imitate this envied peculiarity when they have it not, and wear artificial cushions of cloth to simulate the fat-cushions—a custom which seems strangely enough to survive in a modified form even in the highest races, as a glance at any recent Parisian book of fashions will prove. 'In the lower races, the forearm and hand, and foot and leg, are often longer than in Europeans' (Huxley). As shoes are not worn by them, the great toe is more movable, and the foot more capable of prehension than in higher races. The apelike form of the Negro foot is much exaggerated. Some writers noticing that the Negro often uses the great toe as a thumb, attempt to relegate him to a much lower place in the scale of classification than is justifiable. Many other aboriginal races exhibit the same peculiarity. The Indians, for example, in Yucatan and on the Orinoco can, we are told, pick up money and throw stones with their feet (Waitz, *Int. Anthrop.* vol. i. p. 102). Indeed, Bory (*L'Homme*, vol. i. p. 45) shewed that in the higher races this peculiarity might be acquired: *e. g.* in the gum-gatherers of Marrensin, Department des Landes, who have the great toes on the feet developed in many cases, by habitual climbing, into a closer resemblance to the Simian structure than even the Negro has. It is a popular delusion that the heel is longer in proportion to the foot in Negroes than in other races. The spines in the middle of the back-bone of the neck cease more or less to be bifurcated in the lower races, in whom also, *e.g.* the Australians, the pelvis of the male is less in many of its dimensions, and differs more from that of the female, than in higher races.

Skull.

Here we have the most marked and most important variations in the different races; and of late, our knowledge of these has been so much extended as almost to make the study of them rank as an independent science under the name of Craniology. The most striking differences exist in skulls between the proportions of length and breadth. Taking 100 to represent the length of a skull from before backwards, the breadth or transverse diameter varies from 99 to 62. The *cephalic index* is the number which gives us the proportion the breadth bears to the length. When the cephalic index is 80 and upwards, that is, when the breadth is to the length as 80 to 100, the skull is *brachycephalic* (*brachys*, short, and *kephalē*, head). When the length from front to back is to the breadth as 100 to 68, *i.e.* where the skull is markedly elongated from front to back, it is *dolichocephalic* (*dolichos*, long, and *kephalē*, head); and races possessing crania belonging to these two great typical forms are called respectively *dolichocephali* and *brachycephali*. In fig. 6 may be seen a drawing of a fine specimen of a brachycephalic skull. The calvarium (bones of the head without those of the lower jaw) is short, equable, and well formed—and the great breadth of the cranium in relation to its length is very characteristic. It is a good example of the typical ancient

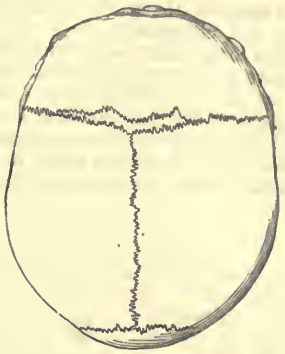

Fig. 6.—Brachycephalic Skull.

British cranium, and was taken from Green-gate Hill Barrow, Yorkshire, in July 1852. Fig. 7 is a good specimen of the dolichocephalic skull of an East Angle, taken from Linton Heath Cemetery.

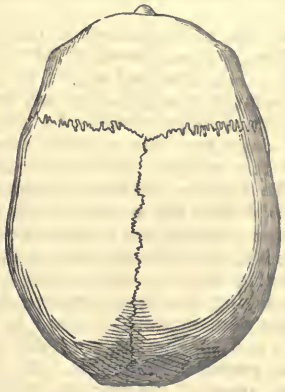

Fig. 7.—Dolichocephalic Skull.

Dolichocephaly is the primitive and lowest type in development, and it tends to disappear with the advance of civilisation (Broca). The old Germans whom the Romans fought were dolichocephalic, differing in this respect but little from their contemporaries the Celts; but Welcker lately shewed that the modern Germans, as a race, are tending towards brachycephaly. Ecker also shews that the same change of type has taken place in the skulls of the old dolichocephalic Alemanni, whose descendants, the modern Swabians, are nearer the brachycephalic type. Professor Herman Schauffhausen, in a lecture delivered before the Archaic Anthropological Congress of Paris, on the 30th August 1867, says, that the 'human skull, during its growth, continues longest to extend in breadth, whence it follows that the *breadth diameter* of the cranium corresponds most with the intellectual development of the brain;' and it is certainly a curious fact that, on comparing the brain of a savage with that of a European, the difference lies less in length than in breadth. In the man-like apes, it is notable that the same cranial types occur—those of Asia, *e.g.* the orang, being brachycephalic,

those of Africa, *e.g.* the chimpanzee, being dolichocephalic. Dolichocephaly may be due to the greater amount of muscular pressure brought to bear on the sides of the skull constantly tending to compress and elongate it; and this would be greatest in the lower races, where the muscles that act on the jaws are more highly developed than in races that eat less and think more. Some races artificially alter the form of the skull by flattening the forehead in infancy by means of pressure. A good example of this is shewn in fig. 8, representing a Peruvian skull. Here we can, from marks

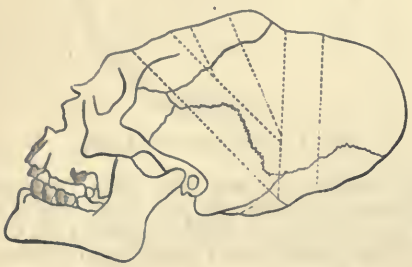

Fig. 8.—Artificially Distorted Skull.

on the skull, trace the course of the bandages used for flattening it, as shewn in the dotted lines of the figure. The forehead seems to have been squeezed downwards and backwards by a compress, probably of folded cloth. To keep it in its place, a bandage has been carried over it from the base of the occiput, and thence across the forehead. To confine the lateral portions of the skull, and to produce the symmetrically elongated form, the same bandage has been carried over the top of the head, immediately behind the coronal suture (probably with an intervening compress), and the bandaging has been repeated over these parts till they were immovably fixed in the position desired, and the head permitted to develop only in the posterior direction. This practice was common amongst the ancient Mexicans and Peruvians, and though it is unknown amongst their modern Indian descendants, yet Dr Robert Brown, in his *Races of Mankind*, says the practice is still continued in some of the lower races of the north-west Pacific coast. His theory of it is, that the American aborigines borrowed the idea from the Mexicans and Peruvians, who had a notion that a flattened retreating forehead was a sign of divine greatness, and whose gods are always represented with this peculiarity.

In the latest and greatest work on craniology, Dr Barnard Davis's *Thesaurus Craniorum*, published by subscription in 1867, a series of most elaborate tables of cranial measurements are given, which, being based upon a much more extensive series of observations than the old tables of Morton, are of greatly more value. The measurements indicating internal cranial capacity, supposed to indicate brain-power, are most interesting, as might be expected, and are of value as correcting the comparatively limited series of observations Morton made in the infancy of the science. Dr Davis finds that the largest average of internal capacity prevails in European skulls, these reaching 90 cubic inches and upwards. In Germans, Russians, and Cossacks, it was 98·5 cubic inches, in Finns 98, ancient Britons 97·5, Welsh 94·8, Turks 93·3, Merovingian Franks 93, Italians 93, Dutch 92·5, Swedes 92, Scotch and Irish 91·2, English 90·9, Lapps 90·6, ancient Gauls 90·3. In Morton's tables, the capacity of the English skull is set down at 96 cubic inches, but his averages were made up from only 58 observations, whereas Dr Davis's are the result of probably ten times that number. In Asiatic skulls, we find few with an internal capacity above 90. Amongst the few are Mishnees 92·7, Chinese 92·6, Siamese 92·1, Bodos 90. Morton's limited observations gave the Asiatic skull an internal capacity under 90 cubic inches. In the African races there are only three whose skulls shew over 90 cubic inches of internal capacity—these are, Kaffirs 92·6, Zulus 91·2, Dahomans 90·7. The mean of Morton's Negro group is 82·25 only. Of the American skulls, Dr Davis finds the Araucanians with internal capacity of 94·1 cubic inches, the Eskimos 90·6; the average of the American group being 89, whereas Morton's tables make it only 80·3. The Australians have an internal cranial capacity of 80·9, Tasmanians 82·5; the general average being 81·7, as compared with Morton's average 75. Dr Davis found the internal cranial capacity of the Oceanic races to be as follows: Mathuans 98·6, Tidonese 98·4, Javans 93·3, Papuans 91·6, Loyalty Islanders 91·3, Marquesans 91, Sumatrans 90·8, Amboynese 90·5, Celebeans 90·2. In Dr Davis's unrivalled craniological collection, few races shewed an internal cranial capacity under 90. Of the few, we may mention, amongst African races, Eboes 85·1, Hottentots 83·9, Bushmen 85·7; amongst American races, Caribs 86·3, Nians 83·5.

It must be remembered that these observations, though more valuable than Morton's, are merely *contributions* to the ultimate absolute truth. Averages obtained from measuring a series of skulls will be affected by the extent of the series, by the proportion of male to female specimens, by the proportion of microcephalic, or idiot crania in the collection, and perhaps by the class of the population from which the skulls are taken. The internal cranial capacity is of use to give us an idea of the contained brain-volume—but it must be borne in mind that the volume of the brain in relation to the brain-case changes greatly at different periods of life. In childhood, when development is going on, the brain presses outwards on all sides of the cavity of the skull, whose bones, by means of the un-united dovetailed joinings called sutures, yield. But as development is completed, the brain-pressure diminishes, and the bone-pressure or cranial resistance increases, as the sutures close. It is held by many that in middle age, the brain, having reached its highest development, begins to shrink; but the space left in the cranial cavity in consequence is filled by serous fluids, which are effused in the ventricles of the organ and between its membranes. We do not, however, know with any exactness the rate at which this shrinking goes on. In a rough way, craniologists say that 10 per cent. requires to be deducted from the brain-volume, as indicated by measurements of internal cranial capacity, on account of this shrinking.

The bones of the face vary in different races. When the facial bones jut forward to excess, the face is *prognathous* (*pro*, forward, *gnathos*, jaw). When the face and jaws are upright, the face is

orthognathous (*orthos*, straight, *gnathos*, jaw). Prognathism may be single or double. In the latter case, the teeth in *both* upper and lower jaws jut forward; in the former, those in the upper jaw only. Double prognathism is very rare. The skulls of the Stone Age are more prognathous than those of the present-day savages, in whom, as in apes, prognathism increases as the development of the individual goes on. Prognathism is the exception in white races, though it is met with in the more degraded portion of the population in England, in the peasantry in Ireland, in the women in Paris, and it is quite a prominent feature in the Esthonians, by some anthropologists held to be the remains of a primitive Mongolian race that first peopled Europe. Professor Owen, in his *Anatomy of Vertebrates*, ii. 566, says prognathism is 'probably concomitant with late weaning of the infant.' It is certainly true that Negro mothers suckle their children longer than any others. Bosman, in his *Description of the Coast of Guinea*, says they give their infants suck for even two or three years. But it seems to us that late weaning of this sort is a characteristic, not of African savages, but of all aboriginal races, whether prognathous or not. Amongst the North American Indians, boys of four years of age may be seen still unweaned. The late Captain C. F. Hall, in his *Life with the Esquimaux*, says (ii. 93): 'As I stood gazing upon the scene before me, Annawa's big boy was actually *standing* by his mother and sucking at the breast, she all the time continuing her work.' Yet we do not find well-marked prognathism amongst the flat-faced races of the arctic circle.

The human skull is slow of ossification compared with that of apes, and it is slowest in the highest races. Quick ossification and straight linear sutures indicate inferiority of race. The sutures or dove-tailed joinings of the cranial bones remain longest open in the higher races, because their brains have a superior impetus of development *ab initio*, and go on developing much longer than they do in lower races.

Stature and Proportions.

Dolichocephaly is usually associated with high stature, brachycephaly with the reverse. The Celts of the past were a tall race. The natives of Scandinavia in the reindeer age were a short race. The Malays and the Mongols are brachycephalic, and they are shorter than the northern Europeans, and Negroes, who are rather dolichocephalic. So we find the dolichocephalic gorilla taller than the brachycephalic orang. The observations that have as yet been made on stature have been trifling and limited. The old notions of the gigantic height of the Patagonians are overthrown by the extensive and accurate measurements lately made by Musters and Cunningham. The tallest Patagonian they could get was only six feet four, and the average height was five feet ten. The most dwarfish races seem to be those at the extremities of great continents—*e. g.* the Eskimos, Lapps, Tierra del Fuegians, and Bushmen. The average height of the Bushmen is variously stated—Barrow described it in one tribe as about four feet four. The Negroes of the South Seas (Austral Negroes, Negritos, &c.) are not much bigger—being on an average about four feet eight in height. The results of Broca's recent investigations as to the proportions of Europeans and Negroes are (1) the length of the upper, as compared with the lower limb, is less in the Negro than European; (2) the length of the humerus or arm-bone, compared with that of the radius or fore-arm bone, is less in the Negro; (3) that though the upper limb of the Negro, by greater length of radius, approximated him more closely to the ape type, the comparative shortness of the humerus removed him even further from that type than the European. Mr David Forbes (*Ethnological Society's Transactions*, 1870) shewed, from the results of sixty measurements of typical specimens of the Negro, European, and Aymara Indian, that the lower extremities of the last are exactly one half the total height; whilst in the European and Negro they were 522-thousandths and 540-thousandths respectively, or much more. The Aymara had the shortest, the Negro the longest, arms of the three. The leg is longest in the Aymara, and shortest in the European; and the European foot was also the shortest of the three. The chest in the Aymara was the most voluminous, and least in the Negro. The excessive length of the trunk in the Aymara Indians may be due to their living in the high table-lands of Bolivia and Peru, where the air is so rarefied that it requires a much greater development of lungs to take in the necessary amount of oxygen. This saves them from suffering from the oppressed breathing that affects the white (Hispano-American) officers of the Bolivian troops on the march, a symptom the privates (half-breeds or pure Indians) do not manifest. Recent explorers do not think the Negroes are under the European average of stature; but the Chinese are. Dr Beddoe finds that the stature of the Scots is highest of all the British people; that of the English comes next; and that of the Irish comes lowest of all. Quetelet's observations shewed that, between eighteen and twenty-three years of age, the average stature of the English was higher than that of the French.

As in the case of animals, the temperate zone is that in which, as a rule, the greatest bodily growth occurs in the different races; the same rule may be held to apply to man. Wherever the greatest quantity of the most nutritious food can be got without over-exertion, the human body will attain the greatest development; for, as Milne Edwards shewed (*Eléments de Zoologie*, p. 254), the size of the body depends essentially on nutrition. Hence, the warmth and luxury of cities develop rapidly the growth of all but the poorest classes.

Weight and Strength.

Regarding weight, the observations yet made are also very trifling; and as this and strength are important elements in the calculations of military leaders in the field, a comparative view of the height, weight, and strength of different races would be most valuable if it were got. Principal Forbes of St Andrews, from observations made on students, found, both as regards height and weight, the Irish were first, the Scots second, the English third, and the Belgians lowest of all.

As regards strength, we may say, when the capacity for great physical effort is a characteristic of any race, it is usually associated with great digestive powers. Examples of vast strength in *individuals* of all races are numerous

enough, but as they are not *racial* peculiarities, they are of little interest to the anthropologist. Peron's dynamometrical observations on muscular power shewed that the natives of Van Diemen's Land were inferior to the Australians in this respect, and these again to the Timorese, and all were inferior to the Europeans (Peron, *Voy. de Découv. aux Terres Australes*, ii. p. 417, 2d ed. 1824). The weakness of the Timorese, he says, is due, not to want of food, but their laziness and hot climate; that of the Australians, to bad nourishment. Freycinet's observations are more recent. He found—

	Kilogrammes.
Creoles (white) from Ile de France could lift	64·4
Frenchmen in " "	60·3
Sandwich Islanders	66·2 and 58·3
Mozambique Negroes	57·1
Malagasches	56·9
Natives of the Carolines	54·2
New Zealanders	51·4
Timorese and Papuans	40·0
Australians	45·6

Buckton (*Western Australia*, p. 91, 1840) gives different results:

	Mean Strength of Arms. Kilogrammes.	Mean Strength of Hips. Myriagrammes.
12 Tasmanians	50·6	—
17 Australians	50·8	10·2
56 Timorese	58·7	11·6
17 Frenchmen	69·2	15·2
14 Englishmen	71·4	16·3

That the Tasmanian race was degenerating, by the time Buckton made his observations, faster than the others, may in part explain the difference between his and Freycinet's statistics.

PHYSIOLOGICAL PECULIARITIES.

It is not to be expected that the various races should have each physiological peculiarities that would enable us to classify them into distinct groups; for it is a general law in biology that all animals—and we include under this term man—belonging to the same species have the same arrangements as regards animal functions and economy. We find in varieties of the same species a pretty general similarity existing as regards animal heat, frequency of pulse, fecundity, duration of life, gestation, &c. In fact, it has always been one of the very strongest arguments against those who maintain the doctrines of polygeny or the specific distinctness of the different races of mankind, that no corresponding physiological differences could be found in these races. Physiological differences and peculiarities there are; but they are only such as could be easily acquired by the operation of widely differing conditions of life or existence. These conditions may be, of course, internal or external, arising from culture, progress in refinement, and civilised modes of life, and the nature of climate and surrounding environment. As regards duration of life, there are few observations that can be called reliable. All over the animal kingdom there would seem to be a relation between reproductive power and longevity. Where the former is high, and greatly exercised, the length of life perhaps on the whole tends to be less. In the races of mankind, all we know on the subject leads us to infer in the meantime that the duration of life is greatest in the highest races, and that life is shortest in the savage and more primitive ones. Just as there is in the higher races greater power of acclimatisation, less death from epidemic disease, and greater muscular strength, so there is greater longevity. The causes may be the same in both cases, and may be chiefly traced to better nutrition, greater ingenuity in warding off the attacks of disease and injurious influences of all sorts. The duration of life is longest in the temperate zone, and becomes less as we approach the tropics. Examples of centenarians, more or less well authenticated, might be adduced in all races, from the highest to the lowest. According to the United States census of 1850, examples of advanced age (*i. e.* from eighty to one hundred) occurred more frequently among the free coloured population, and still more among the Negroes, than among the whites. The duration of life is of course intimately connected with the question of the influence of disease on different races. Some of the American anthropologists, who are sticklers for the plurality of races, have tried to shew that the various races suffer from different specific diseases. The attempt was a signal failure; and no one believes more in this direction than that different races vary as regards their predispositions to diseases. It has been held that the specific distinctness of the Negro from the white race was proved by the fact, that the Negro was not liable to be attacked by yellow fever as the white was in south-western parts of North America. But this is due more to acclimatisation than to any specific racial peculiarity; for even white people in the West Indies who have become acclimatised, enjoy a certain immunity from yellow fever as well as the Negroes. Then, again, Negroes of the third generation, who were sent from America to Africa, suffered from the diseases peculiar to the African climate, as did white unacclimatised persons. There is one strange physiological peculiarity that seems pretty well authenticated, and that is, that what physicians call the *vix medicatrix naturæ*, or innate healing power, is much greater in the lower than in the higher races. The Malays are said to have this high healing power particularly well marked in consequence of their strictly vegetable diet, which reduces the tendency to inflammatory attacks. Parkyns (*Life in Abyssinia*, vol. ii. p. 268) relates instances of people being punished by the most horrible mutilations, and yet recovering simply by their own innate healing power, without any treatment at all. Yet it would appear that from the mere contact of different races, though both may be in good health at the time of meeting, destructive epidemics are originated, which seem much more fatal to the aborigines than to the higher race who came in contact with them.

There is no proof that sexual development is so much affected by race as by the influence of climate. Hence it is that in races inhabiting the torrid zones, women arrive at the age of puberty much sooner than in temperate regions, though it must be noted that there are many exceptions to this general statement. Yet it is clear that Jewish women arrive at puberty much earlier than the women of the nations amongst whom they live; and it is difficult to resist the conclusion, that this

physiological peculiarity is a truly racial one. As a consequence of the early advent of puberty, we may say that women marry at much earlier ages amongst aboriginal races in hot climates, than they do in the higher races inhabiting temperate latitudes, and this as a rule tends to lessen their prolificacy. The fecundity of different races varies. That of the Negroes seems to be far above the average; indeed, it is difficult to understand how, if this were not the case, Africa could have survived the drain on her population, caused by the devastation, horrors, and barbarities of the slave trade. The greatest fecundity known is associated with the most abject demoralisation, and is that of Guanaxuato, in Mexico. The North American Indians, on the other hand, are not a prolific race. The same may be said of the natives of Australia, and the islands in the South Seas. The scanty prolificacy of many aboriginal tribes may be due to the severe labours imposed on women, the practice of abortion so common in savage races, and the custom of long suckling, to which reference has already been made in our remarks on prognathism.

The proportion of male to female births has been, by some, held to differ in different races. In Europe it is as 106:100, there being in European races a preponderance of male births; due, say some, to the fact, that in Europe the male is generally five or six years older than the female at the time of marriage. Quetelet says that at the Cape of Good Hope, amongst the colonists, the female births preponderate—a remarkably exceptional circumstance. In Central America, among the Indians, male and female births are as nearly as possible equal. In Yucatan, the proportion of women to men is said to be 2:1; and in Cumena it is asserted there are seven women to every man in the district. Some authorities think it may turn out that there is a general law that the further you go from the equator the preponderance of female births gradually declines, and when you go far enough north, the preponderance is reversed. It is said, however, that on the Gold Coast, the preponderance of female births only prevails on the coast, and not in the interior. In Australia, on the other hand, Sturt says the smaller tribes in the interior have an excess of women, in the proportion of 2:1, or even more (*Narrative of an Expedition into Central Australia*). The Jews are remarkable for the great excess in the male births as compared with the female, it being in Berlin as 208:100 (Waitz, *Int. Anthrop.* vol. i. p. 112), and as 100:111 in Prussia generally.

The mean animal heat and frequency of the respiration vary hardly at all in different races. Gmelin, Ross, and Parry found even in 74° lat. north that the heat of the body was as great as it is in warm climates. Dr Livingstone, however, found that the heat of his body, taken by applying the thermometer to his tongue, was 100°; whilst the same instrument registered only 98° when applied to the Negroes amongst whom he was living.

We have referred to the peculiarly offensive odour characteristic of the exhalations of the skin in the Negro. This has been by some dwelt on as one proof of the specific distinctness of the African from the other races of mankind. Chemical examination of the sweat of the Negro does not shew it to be different from that of the European; indeed, both are alkaline; whereas it is said the sweat of the aboriginal Indian is acid, though it can be rendered alkaline by continuous animal diet. Again, not only do the Negroes vary amongst themselves in regard to intensity of skin-odour, but some American Indians, *e.g.* the Araucanians, who live on animal food greatly, manifest a similar peculiarity. Rengger even says that Europeans, when acclimatised in Paraguay, have a peculiarly rank skin-odour, and in consequence are, like Negroes, less liable to be pestered with mosquitos. Then we may remark that it is probable that every individual, white or black, has a distinctive skin-odour, and if our senses were as keen as those of dogs, we should, like them, be able to distinguish it in every instance. There is no good proof that the pulse beats quicker in southern races than in northern. Congenital deformities are rarer amongst savage than among civilised races. It is alleged that the capacity for *blushing* is peculiar to white races—that Negroes have it not. But in Mulatto women, it has been proved that where the complexion is delicate, blushing is seen; and Monrad, quoted by Waitz, in his *Introduction to Anthropology*, p. 135, asserts that Negresses become darker when under the influence of a sense of shame. The idea that blushing is peculiar to white races, seems to have originated in careless observation; for the slight deepening of colour that occurs in dark-skinned races when influenced by a sense of shame is not so easily noticed. As regards the senses, it seems clear that savage races have them developed in greater perfection than the higher races. However, it would appear there is one exception, viz. the sense of taste, which in inferior races is but poorly developed. The savage who gluts himself with food for no other purpose than to quench the cravings of an animal appetite, is not a gourmand. The inferior races have, in the struggle for existence, to rely more on their senses than have the civilised; hence they have them by use developed into wonderful acuteness. The power of 'following the trail,' possessed by savage hunters is well known. The Bedouin can discern objects at infinitely greater distances than the European. Rengger says that Indians can distinguish a riderless horse from a mounted one by the difference in the sounds made by its hoofs afar off. Then the Bushmen—a race very low in the scale of civilisation—have the sense of sight so highly developed, that travellers assert they can see things with the naked eye which white men would need a telescope to perceive. Illustrative of what we said about the high state of development of all the senses except taste in the inferior races, we may mention that Freycinet tells a story of a Papuan of New Guinea who actually swallowed up the contents of a pepper-box, and thought it very pleasant to taste—yet the Papuans are said to possess the most delicate and acute senses of sight and hearing.

PSYCHICAL CHARACTERISTICS.

As yet, the materials for a complete science of comparative human psychology hardly exist; yet from what we do know of the subject, the direct drift of its teaching is to strengthen the position of those who maintain the unity of mankind, the psychical differences between different races being clearly accounted for by the recorded

differences in the degrees of civilisation through which these races have passed within the historic period. We may admit that the mental endowments of the Negro are so far inferior to those of the European, that it would be impossible to say the former was capable of doing the strong intellectual work of the latter. But the two races are passing through different stages of civilisation, and cannot possibly be expected to have the same intellectual capacity. Then the intellectual capacity of a race denotes not the work it is capable of doing at a given time, but the best possible work it might be able to achieve if existing in the best possible circumstances. It has yet to be shewn that, if the lower races were placed in the same favourable circumstances as the European, and that, too, for the same length of time, they would manifest any inferior capacity for intellectual development. We not only find at different periods the greatest differences as regards the degree of intellectual development they have attained, but we find these differences characteristic of different races at the same period of history, and in no case do we find them greater or less than those that exist in the various 'races of men' now peopling the earth. It has been asserted, and the assertion has been denied, that there are no races so low as to have no vestige of religion amongst them. The controversy is chiefly a war of words. If it is meant that all races believe in a god or gods, the assertion is not absolutely true, and the natives of New Caledonia may be cited as one amongst many examples we might bring forward in support of the literal godlessness of savages. Yet even they have their magic and magicians; and the Dyaks of Borneo, who have neither priests, temples, nor images, believe in augurs and omens. Indeed, we find that the proof of the alleged want of traces of a religion gradually fades away as we get more information about the race of whom it was asserted. In every tribe, no matter how degraded, we find a belief, not in gods perhaps, but in the Supernatural—in viewless, mystic powers or spectres, capable of not only controlling the forces of nature, but making and marring the fate and fortunes of man.

In the lowest races, we find traces of the power of design, and crude ideas of beauty. The black intertropical races are not all equally low in the scale of civilisation and mental development, but they have a tendency to idleness, want of prudence, and energy, which renders them incapable of coping with the races that inhabit more temperate climates. The Negroid races are the lowest; the black aborigines of Australia being lowest of all, possessing in many cases but rudimentary notions of a social community. The American Indians, especially those of the north, are powerful and warlike, and often display moral and mental qualities of the highest kind. The Mongolians are higher still, and possess a literary culture, and powers of invention, together with capacity for persevering industry, which, were it not for their stationary character, might enable them to cope fairly with Europeans. Europeans have, in addition to their other high mental qualities, the desire and capacity for progress and improvement, which, with their greater moral and intellectual weight and energy, make them soon become masters of whatever part of the world they settle in.

GENERAL QUESTIONS.

The vast number of these makes it impossible that we should do more than glance at a few of the most prominent.

Migrations and Extinctions of Races.

Man has the power of adapting himself to all varieties of climate, and the human race being in its early stage of development nomadic and pastoral, we may easily understand how migrations of races from their original centres to more fertile places would soon occur, and how, when two races came thus into collision, the weaker would be displaced or absorbed by the stronger. Examples of migrations, from the Celtic migrations from Asia already mentioned, down to the modern emigrations of Europeans to America, must occur to every one. Early migrations of peoples with but the rude elements of culture, account for the fact that it is the most primitive arts that are most widely distributed all over the world. As the arts rise in the scale of perfection, their areas of distribution become more and more limited.

Some have thought it impossible to extinguish a race. That it is possible, is proved by the fact, that in 1872 the last of the Tasmanian race disappeared for ever from the face of the earth. If the races that come into collision are widely divergent, the weaker dies out. If not, intermixture takes place, and a new, and probably stronger, race is formed, both parent races disappearing. The most remarkable example of extinction of races, regarding which most contradictory views are abroad, is that of the American Indians. The aborigines of the West Indian Islands were swept away by the barbarity of European conquerors. Dr Robert Brown, the author of one of the ablest works on the *Races of Mankind* in our language, and one of the best authorities living on the anthropology of the North-west American Indians, holds that the extinction of these tribes is due to (1) frontier wars with white emigrants; (2) the greater fatality of inter-tribal wars, due to the introduction of firearms among them; (3) alcoholic excesses; (4) diseases, such as smallpox and syphilis, which the white man brings to them from Europe; (5) diseases the scantily clothed savage contracts after getting to wear the white man's heavy clothing, diseases such as consumption, which are due to his being less able, in consequence of accustoming himself to European clothing, to stand exposure to cold and wet; (6) diseases of the digestive system—for example, dysentery, introduced amongst them after they change their food, and use that used by the whites. To these causes, rather than to any proved inherent incapacity for civilisation, would this traveller attribute the decay of savage tribes that come into collision with the white man.

Miscegenation.

The mixture of different races gives rise to half-breeds, to which various names are given. Europeans and Negroes produce Mulattoes; Europeans and American Indians produce Mestizoes; Negroes and Indians produce Zamboes. The European and Mulatto produce the Terceron; the

Terceron and the European, the Quadroon; the Quadroon and the European, the Quinteron, who in slave countries used to rank as a white man. It is the favourite dogma of the modern school of French anthropologists that mixed races are not permanent. Opposed to this, we have the facts that our Anglo-Saxon race owes its strong vitality to its being a mixed race, whereas the purest race in Europe—the Danes—are on the decline. In Red River Settlement, a country peopled by a mixed or hybrid race of whites and red Indians, population has been increasing. The Mestizoes of Granada and Paraguay (mongrels of Spaniards and native Indians) shew no signs of decay or diminished vitality. The nearer the parent races are allied to each other, the less will be the diminution of vitality produced by miscegenation. In such cases, it is probable that miscegenation may produce a better race than in-breeding. The greater the difference between the parent races, the less persistent and permanent will be the mixed race they beget. It seems as though the European and the higher races of American Indians can produce not only a permanent but lusty and powerful mixed race, but that, when the European and the Negro intermarry, the divergence of the parent races is too great to admit of a stable race of hybrids being produced. The coloured population of the slave states increased so long as slavery was an institution, by constant intermixture of the original parent races, and not by the reproductive power of the hybrid races, which the 'peculiar domestic institution' of these states encouraged. Since the abolition of slavery, the Negroes and hybrid races have not been cultivated and bred as valuable chattels, but have been left to the mercy of the natural 'struggle for existence,' and it would appear that they are gradually dying out.

Acclimatisation.

Natives of temperate, who emigrate to tropical, climates, die soon. Even when they manage to live, their children die before reaching maturity. When a white man goes to a tropical climate, he and his descendants, if he have any, become darker in colour. The Negro and his descendants when transplanted to a cold climate become paler. It is doubtful whether the European has yet been thoroughly acclimatised even in the temperate regions of America. Recent statistical investigations go to shew that the native white population of the United States is not on the increase, and that any apparent increase is due to reinforcements from European emigration. There are some anthropologists who hold that the European races in America are being modified in physique in the direction of the Indian type. The general law seems to be, that the capacity of a race for acclimatisation is proportionate to its intellectuality.

ORIGIN AND DESCENT OF MAN.

Two hypotheses are advanced as to the origin and descent of man, neither of which admits of scientific demonstration—namely, (1) the hypothesis of special creation; (2) the derivative hypothesis of Mr Darwin. Scientifically speaking, the chief objections to the former are: that it is an assertion wanting the solid proofs on which scientific theories are usually based; that it explains very few of the facts capable of demonstrative proof; and that it is little more than a formulated assertion, that of the origin of man nothing is known save that nothing will ever be known—apart from traditions and the revelations of religion. The derivative hypothesis asserts that the origin of man is in harmony with that of all organised and living things, a process of evolution of the higher and very highest from the lower and very lowest forms of life. (See ZOOLOGY.) It rests mainly on (1) the existence in animals of useless rudimentary structures, which are found in man developed into usefulness, and of useless structures in man representing the survival of organs found well developed in lower forms, and of use there; (2) the resemblances between man and animals in embryonic development and homological structure; (3) the absence of any differences, bodily or mental, between the highest apes and the lowest savages, wide enough to make it impossible they should have had a common progenitor.

The derivative hypothesis is one which has the advantage, at present, of accounting for more otherwise inexplicable facts than any other; its advocates very plausibly shew that it is not inconsistent with the facts it does not account for, and that it is no more contrary to revealed religion than the now accepted doctrines regarding the antiquity of man and the geological development of the earth were once held to be. We may therefore expect that it will daily gain adherents, till a more adequate and perfect hypothesis is started. At present, it is adopted by scientific men as a convenient provisional theory, preferable to, because less inadequate than the alternative, special creation hypothesis, which seems a mere confession of ignorance of the subject. The great objection to the derivative hypothesis used to be the assumption it compelled us to make of longer periods of time having elapsed since the first appearance of man on the earth than recorded history could cover; periods during which it was possible for the Stone-age savage to develop into the nineteenth-century Christian. However, the

Antiquity of Man

is now, on all hands, admitted to be immensely greater than we were wont to consider it according to Archbishop Usher's chronology. Ages before history and even tradition began, it can be shewn man lived on the earth, and human remains are found associated with the fossil relics of animals now extinct, and belonging to a period of probably from 50,000 to 100,000 years back. Sir John Lubbock, our greatest authority on this subject, thinks man may have existed during the Miocene period; and the other day it was reported that bones taken from undisturbed caves in Miocene rocks on the Mediterranean coast, had carved on them figures of prehistoric animals.

Unity or Plurality of Human Species.

Those who hold the doctrine of *polygeny*, or that mankind do not form one, but many distinct species, sprung from stocks specifically distinct, and those who believe in *monogeny*, or the essential specific unity of the human species, have long warred with each other without satisfactory results.

The influence of the derivative hypothesis of

Mr Darwin has of late done much to strengthen the monogenists—indeed, the ablest naturalists are now monogenistic in their tendencies. Those who hold that the races of mankind are specifically distinct, rely chiefly on the assertion, that the present diversities in the various races cannot be accounted for in any other way, and that physical types in man are so permanent, that they cannot be changed to such an extent, by climatic and other external influences, as to account for existing diversities amongst different races. Any one who studies Mr Darwin's work on *Animals and Plants under Domestication*, will see at once how feeble this argument is, in the light of his discoveries of the almost incredible diversity in form and physique that can be produced within the limits of one single species—say, in dogs or pigeons (diversities far greater, it would seem, than any found within the limits of the human species)—merely by the operation of artificial selection, and hereditary transmission of parental peculiarities to offspring. The polygenists relied greatly on Dr W. F. Edwards's argument in favour of permanence of racial types, drawn from the resemblance of the pictures of Jews and Negroes on the old Egyptian monuments to the Jews and Negroes of the present day. In regard to the Jews, it would be very strange if a community, whose social and religious observances so carefully prevent any intermixture with alien races, exhibited any signs of departure from the original type. All these monuments prove is, that in the *same conditions*, the most striking race characters have not become altered in the course of 3000 years. They do not prove that the type would have remained unchanged if the race had been subjected to great diversity of climatic changes for 30,000 years. Dr Edwards's idea, that permanence of type was proved by the fact, that mixed races, such as those inhabiting France and Italy, revert to the original type, is worth little, for we have no anatomical proof of what the original types were in such cases; and we may ask, if a *mixed* race reverts to its original type, to which original type does it revert? The late Professor Agassiz held that the races of man sprung from eight provinces of creation, where they now exist. But opposed to this doctrine we have philological proof that the Indo-European race did not spring up in their present area, but came from Asia; and it is absurd to suppose the Eskimos sprung up in Professor Agassiz's arctic province, for they would have been frozen to death there long before they had learned to protect themselves from the cold. The cradle of primeval man must have been a warm region, and knowing, as we do, man's restless migratory tendencies, it is imprudent to uphold a theory which permanently fixes parent stocks to particular provinces, as though they were plants incapable of the desire for emigration, and devoid of the means of gratifying it. The polygenists have to place themselves in a curious logical dilemma, for doubting the vitality of hybrid races, they deny that the different races could be brought into permanent existence by intermixture of stocks so divergent from each other as were those that produced the various peoples of the earth; yet they attribute to intermixture the manifold diversities which they admit exist in the sub-types into which what they call the different human species are split up. They are in the same dilemma with regard to the influence of climate and external agents; for, in both cases, it seems that if the manifold differences they admit as occurring within the limits of one of their many species, could be produced by admixture and climate, the production of the differences in virtue of which they defend the specific distinctness of their primal types, might also be produced in the same way by the action of longer periods of time, such as those, in fact, that the recent researches on the antiquity of man make it probable have operated on the human race. Science as yet affords material for no *certain* conclusion whether mankind is derived from one pair of human beings or from several. But, whichever view be adopted, there can be little doubt that the balance of evidence does not favour the idea that the nations of the earth are specifically distinct, or, however many pairs they may be derived from, belong to different species. Zoologically speaking, the races of men are of one blood and one brotherhood.

The development and destiny of mankind are subjects of too vast importance to be discussed in a few lines. Science teaches us that primeval man was a savage; and the notion of Archbishop Whately and the Duke of Argyll, that man was aboriginally civilised, and became degraded, and that savage races are incapable of self-civilisation, is refuted by the researches of Tylor, Lubbock, Darwin, and others. Modern civilisation has developed gradually from prehistoric savagery. The history of humanity in the mass is substantially the history of moral and material progress. That some races have been, for the limited period over which human history extends, stationary, whilst others have even retrograded, is adduced as a proof that progress is not the law of humanity. But this is to mistake the eddies in the course of the river of life, that may for a time be washing backwards a few fragments of our race, for its broad strong current, which, flowing ever onwards, bears on its bosom the mass of humanity, with all its highest hopes and aspirations, towards the perfect ideal which lies beyond.

LANGUAGE.

LANGUAGE in its widest sense signifies any means by which one conscious being conveys what it thinks or feels to another. Thus we speak of the language of the eyes, the language of birds. But in ordinary usage we understand by language the system of sounds uttered by the human voice in the intercourse of society—articulate speech. The writing of language does not alter its character in this respect; it only introduces an intermediate set of signs or marks. The written characters do not convey the meaning directly, they only indicate certain sounds; and it is these sounds that are still the immediate vehicle of the thoughts. It is language in this sense—the communication of our thoughts by means of spoken signs*—that is the subject of the present paper.

Human speech is the result of a kind of tacit convention as to the meanings of the several signs, so that they are intelligible only to those who have learned them. Such signs are in this respect *artificial*. But distinct from this there is a kind of *natural* language which is universally understood without being learned, and which the lower animals to some extent possess. It is made up of the instinctive and untaught movements of the body that feelings, passions, and desires give rise to. These natural, outward signs of inward mental states consist of the tones of the voice, the play of the features, the movements of the limbs, and the gestures of the body. Every conspicuous passion or emotion gives a distinct expression to these various organs, by putting them into the state most in harmony with itself; and each different expression tends, by an instinctive operation of fellow-feeling, to call forth its proper emotion in those who witness it. The howlings and contortions of pain, the quakings of terror, the fixed gape of astonishment, the wailings and tears of wounded affection, the swellings of rage, the eagerness of pursuit, the cry of victory, the placid repose of contentment, the outburst of the ludicrous, the bending of reverential feeling, the urgent movements of entreaty—are all peculiar effects on the bodily organs, characteristic of the several feelings, and capable of communicating these feelings at once, and independently of all instruction, from one human being to another. But these signs are by far too limited to express the wide variety of thoughts and sentiments which the human mind can entertain, and which require to be communicated between man and man. Even in the most perfect development of this mode of expression, in the stage pantomime or dumb-show, it is very obscure when it attempts to convey anything beyond the most obvious ideas and feelings. So far as it goes, however, it is the most powerful means of impressing one man's feelings on another, or of inspiring a multitude with a common enthusiasm; hence it continues to be used along with artificial speech, as is seen in the gestures, grimaces, movements, and modulations of conversation and oratory. It is the resource of children, and of persons ignorant of one another's language; and is partially employed by the deaf and dumb. On this we need not dwell longer, but return to audible speech.

We may occupy ourselves with languages for two very different purposes. In most cases, the object in studying a language is to be able to understand it, and to speak and write it. When the knowledge of languages is spoken of, few, we apprehend, think of anything but knowledge of this directly useful kind. From the time we begin to lisp to the time we leave school or college, and even after, we are chiefly occupied in learning our mother-tongue, or other living or dead tongues; and until recently, the multitude of dictionaries, grammars, critical commentaries, and the like, that constitute so vast a bulk of the literature of the world, turned almost exclusively on the right understanding, and the correct or elegant use of the individual languages.

But there is another light in which the same subject-matter may be viewed. We may study two or more languages, in order to compare them with one another, and note in what they agree and in what they differ. When a considerable number of tongues are subjected to this kind of examination, it is found that some features are widely prevalent, and in some instances universal, or all but so; while others are confined to a narrower circle, or, it may be, are peculiar to a single tongue. It is the general facts thus arrived at by induction that form what are called the general principles or laws of language—universal grammar—as distinguished from the peculiarities of individual languages. Nor is this the only result of such comparison. It becomes at once evident that any particular tongue differs widely from one set, while it agrees extensively with another; and thus the known languages of the world can be *classified*, in much the same way as minerals, plants, and animals are.

In this process of comparison we do not take a language as it was spoken at any one date, and confine ourselves to that. Not only are different languages compared with one another, but the same language is compared with itself at different times throughout the period of its known existence. The historical method is thus conjoined with the comparative, and it is this conjunction that has shed the most light on the laws of language. All languages are found to be undergoing incessant change; waste and repair of parts are constantly going on, as in a living organism, the result being a gradual change in the aspect and character of the whole, so that, after the lapse of centuries, it shall seem to the superficial observer a new tongue. These changes do not happen by blind chance or caprice; they are found to take place on the whole

* This is the proper etymological meaning of Language, which is a French word formed from *langue*, the tongue. In classical Latin the word is *lingua*; but the old form was *dingua*, and with this the English *tongue* is evidently cognate.

according to discoverable laws, some of which are general, and others more or less special. Those laws by which languages become transformed, or developed, as it is called, are among the most important of the general principles of language.

In all this, there is an obvious analogy to the study of natural history. The zoologist, for example, investigates the structure and functions of the different animals, and assigns to each its place in the classification of the animal kingdom. But he has this advantage over the linguist: he can trace the organism he is investigating from the embryo, through every stage of its development and growth, to its death, and thus give a complete scheme of its life. The student of language, on the contrary, has his survey in the historical direction hemmed in by narrow limits. He has never seen, and can never hope to see, a language in embryo; the oldest relics of language that have come down to us are such as to imply centuries on centuries of previous existence; so that he is like the naturalist if reduced to study organisms exclusively in the adult state. He is not, however, precluded from all hope of arriving at some notion of the embryo condition of speech. By analysing languages as they exist, and finding the ultimate elements of which the words are built up; and by reasoning from the way in which words are seen to change, and new words to come into use, we may hope to arrive at some conclusions more or less probable as to what the beginnings of language must, or, at all events, may, have been. It is this speculation as to the *Origin of language* that forms the crowning of the philological edifice.

The learning of languages for use is treated of in the grammars and dictionaries of the several languages. The only part of this vast field that at all falls in with the scheme of this work is the grammar of the English language, which is briefly sketched in a special paper. It is the natural-history aspect of speech, above described, its physiology, as it were, and the classification of the different forms it assumes, that is the subject of the present number. This study, as a distinct branch, is of recent growth, and has not yet settled down into a fixed name. It is variously spoken of as Comparative Grammar, Comparative Philology, Linguistic, the Science of Language. The last name seems the most appropriate, but has the disadvantage of being rather cumbrous.

Although investigations of the kind described may not promise any directly useful result, they are not without interest of an absorbing kind. Speech is at once the sign and the means of man's superiority over the rest of the animal kingdom; and he who can find no interest in learning the nature and workings of this precious faculty unless it promise to make him richer, can hardly be called a man. Besides its own inherent attractions, the comparative study of tongues is one of the chief instruments in another inquiry of universal interest, that, namely, of the affinities of nations; Comparative Philology is the handmaid of Ethnology. See ANTHROPOLOGY, No. 53.

The science of language, as already remarked, is of recent origin. It is not to be understood by this that it never occurred to anybody, until recently, to seek for affinities between the words of different tongues, and to speculate as to the nature and origin of language in general. On the contrary, inquiring minds have at all times been fond of exercising their ingenuity in this field. The exercise, however, was long little better than beating the air; it consisted mostly in blind gropings, wild guesses, and fanciful theories that died with their projectors. The cause of this fruitlessness lay in the reasoning being founded on too few facts. The ancient Greeks speculated largely on language, but, as a rule, they knew no tongue but their own, and considered all others barbarous jargons, and unworthy of study. The scholars of modern times for a long period confined their attention to Greek and Latin, including, it might be, Hebrew, with a contemptuous glance at their mother-tongue; hence their theories were nearly as baseless as those of the Greeks. They were mere *a-priori* speculations, akin to the 'Theory of the Earth,' written by the learned Thomas Burnet in 1689, before the strata of the earth's crust had been at all explored.

One great obstruction to the true course of inquiry was the assumption, first made by the Church Fathers, and for a long time unquestioned, that Hebrew was the primitive language of man, and that, therefore, all languages must be derived from Hebrew. A prodigious amount of learning and labour was wasted, during the seventeenth and eighteenth centuries, in trying to trace this imaginary connection. Leibnitz was the first to set aside this notion, and to establish the principle, that the study of languages must be conducted in the same way as that of the exact sciences, by first collecting as many facts as possible, and then proceeding by inductive reasoning. It was owing to his appeals and exertions that missionaries, travellers, and others, now began making those collections of vocabularies and specimens of languages and dialects which form the *Herbarium*, as it were, of human speech. The truths deduced from these collections were at first fragmentary, and without any fixed principles of classification. The light that brought order into the chaos rose with the study of Sanscrit, first made accessible to European scholars by Sir William Jones, Colebrooke, and other members of the Asiatic Society, founded in Calcutta in 1784. The similarity of Sanscrit to Greek and Latin, especially in the grammatical forms, struck every one with surprise. Sir William Jones declared that 'no philologer could examine the Sanscrit, Greek, and Latin without believing them to have sprung from the same source, which perhaps no longer exists. There is a similar reason, though not quite so forcible, for supposing that both the Gothic and the Celtic had the same origin with the Sanscrit. The old Persian may be added to the same family.' German scholars now took up the subject, and have since been the chief workers in this field. Frederick Schlegel has the merit of first (in 1808) boldly embracing the languages of India, Persia, and Europe in one family group by the comprehensive name of the Indo-Germanic languages. When first advanced, this could be considered only as a more or less probable assumption; but its truth has since been demonstrated by an accumulation of evidence, and it is now received as an established fact. Among the contributors to this demonstration, the chief place is due to the eminent scholar, Franz Bopp, Professor in the University of Berlin. The first instalment of his labours appeared in 1816, and they culminated in

his great work (published 1833–52) on the Comparative Grammar of the Sanscrit, Zend, Greek, Latin, Lithuanian, Old Slavonian, Gothic, and German. In this work it is shewn that the grammatical forms—the endings of the declensions and conjugations, &c. and the methods by which words are built up from other words, are fundamentally the same in all; these tongues, therefore, must have been inherited by all from a common source. This formed the foundation of the science of language, and the edifice has since been rising steadily under the hands of quite an army of workers. The method of investigation, thus invented and perfected in the field of the Aryan tongues, has been applied to other languages, and considerable progress has been made in forming the principal varieties of human speech into groups, which, again, fall into subdivisions or branches, according to the different degrees of nearness in the relationship.

We will now proceed to give some account of the kind of facts and reasonings by which these results are arrived at.

THE VOICE.

A necessary preliminary to the study of speech itself is that of the organs that produce it. They consist of the same organs that serve for breathing, chewing, and swallowing, with certain additions and modifications. The sounds that compose speech are made out of emitted breath by means of mechanical modifications. As emitted breath proceeds from the lungs, that organ, together with the chest which compresses it, and the windpipe, may be considered as the fundamental organ of speech—the bellows. When the breath issues gently and without constraint, as in ordinary breathing, it is almost noiseless; by constricting the throat, and thus roughening the stream, we give it that kind of audibility known as a whisper. But in speaking aloud, the breath is chiefly *sonorous*. This quality it receives in the larynx, a kind of cartilaginous box between the windpipe, or trachea, and the throat. It is a complex structure; but the essential parts for our purpose are two membranous bands, called the *vocal chords*, running parallel from before, backwards, across the glottis or opening of the larynx into the throat. In a state of rest there is a considerable opening between the chords, and the air passes freely; but when we wish to speak or sing aloud, the chords become tightened, their edges approach, the stream of air makes them vibrate, and a sound is produced of the nature of a musical note or tone, on the same principle as in a *reed* instrument. The *pitch* of the sound depends mainly on the tension of the parts; and by varying this tension, a series of musical notes is produced. But it is not this kind of modification that produces articulate speech. For this purpose, the sounds produced in the larnyx, whether of high or low pitch, must be further modified by the throat, the tongue, the teeth, the lips, the nose, which constitute, therefore, the remaining organs of speech.

Although loud speech is mostly made up of vocalised breath or tones, yet the indistinct sounds, or rather noises called breathings, of which whispering is made up, enter largely into its texture. By careful attention to the movements of the organs we are sensible of when producing the several sounds, and by means of the laryngoscope, an instrument which lays bare what takes place in the larynx, much has been done to render the mechanism of the elementary sounds of speech plain. We can only give the results in outline.

When the mouth is sufficiently open to allow the breath to flow without obstruction or roughening, the air is moulded into the various qualities of *vowel*-sound. When the channel of the mouth is obstructed so as to stop the current of breath, or so narrowed at any part as to produce a rushing or hissing sound, *consonant*-sounds are produced.

Vowels.—The fundamental vowel may be considered as the open, Italian *a*, heard in *father;* it seems to issue full as it comes from the throat, without any special movement in the oral passage. This fundamental sound becomes modified into two divergent series, the one produced by the tongue, the other by the lips. By raising the convexity of the tongue a little towards the roof of the mouth, the breath column becomes flattened or thinned, and yields the vowel heard in *an;* still greater degrees of convexity yield the *e* of *ell*, and the *a* of *ale;* while the greatest degree possible, without actual contact or friction, yields the *ee* of *eel*. In all this the lips take no share; but in the other series they are the active modifiers, and the tongue is passive. When the aperture of the lips is gradually contracted, the open *ah* is converted successively into *aw*, the *o* of *ore*, the *o* of *no*, and the *oo* of *ooze*. A third series of vowels is formed by combining elevated positions of the tongue and contracted positions of the lips, or retracted positions of the tongue and expanded positions of the lips. Of this labio-lingual series, the German *ü* is the most contracted, and the English sound heard in the word *err* the most open.

The following table shews the principal vowels of each class:

	Lingual.	Labio-lingual.	Labial.
Close.....	*ee(l)*	*ü*	*oo(ze)*
Medial.....	*ai(l)* / *e(re)*	*eu* / *ö*	*o(ld)* / *o(re)*
Open.....	*ah*	*e(rr)*	*a(ll)*

The possible modifications of the oral channel are endless, and untraceably minute, as are the shades of vowel-quality heard in dialects, and among individual speakers. In English, there are altogether *thirteen* established varieties, as heard in the words *eel, ill, ale, ell, an, ask, ah, err, up, all, ore, old, ooze*. Besides these, which a perfect alphabet must represent, we have the diphthongal sounds heard in the words *isle, owl, oil*, and the asperated compound *yoo*—the sound of the letter *u* in *use*—which is often, but erroneously, supposed to be a diphthongal vowel.

The Aspirate H.—The letter *h* represents an expulsive breathing, modified by the form of the vocal element which follows it—as in *he, hay, high, hoe*, &c. in which the H will be observed to have the quality of *ē, ā, ī, ō*, &c. but without the laryngeal contraction, and consequent asperation of the breath, which forms a whispered vowel.

Consonants.—The most characteristic of the consonants are those that altogether stop the emission of breath. When the tongue is raised convexly against the back of the palate so as to stop the breath, the separation of the parts is accompanied by a percussive effect, represented

in the English alphabet by *c*, *k*, and *q*. When the stoppage is made by the fore-part of the tongue against the front of the palate, the effect of separation is the sound *t*. Similarly, the separation of the closed lips gives rise to *p*. Intimately connected with *k*, *t*, *p*, are the series *g* (gun), *d*, *b*. The same contact that produces *p* produces *b*; but the latter is attended with a kind of muffled sound, which cannot, however, be prolonged. Similar is the relation of the other pairs *t-d*, *k-g*. The nature of the difference seems to be this: It is ascertained that in pronouncing *k*, *t*, *p*, the vocal chords are wide apart; but for *g*, *d*, *b*, they approach so as to moderate the rush of air, and also to be able to yield a tone during the brief time that air continues to escape from the larynx into the mouth after the latter is closed. That there is such an escape, any one may satisfy himself by trying to prolong the sound of *b*, when he will find his mouth become distended. The difference between the two series is marked by contrasting them, as *surd* and *sonant*, or, better, perhaps, as *sharp* and *flat*.

The six consonants now described completely arrest the issue of breath from the mouth, and are therefore called *checks*. The term *mutes*, often applied to them, is hardly appropriate in the case of the flat series, seeing there is a momentary tone. In all the other consonants, the breath is not stopped, but only constrained or squeezed more or less, so that the sound can be prolonged. On this account, these consonants are called *continuous*. The distinction of flat and sharp pervades the continuous consonants as well as the percussive. In the sharps, the glottis is wide open, and the prolonged sound is that of a stream of breath roughened by narrowing of the passages in the mouth (*if*); in the flats, the continuous mouth-sounds are accompanied by a muffled sound from the narrowed glottis (*iv*). The chief continuous consonants are thus formed:

If, while the organs are in the several positions that produce the checks *g*, *d*, *b*, the vocalised breath is allowed to pass through the nose, the sounds *ng*, *n*, and *m*, respectively will be heard.

The elevation of the base of the tongue so as to leave a narrow aperture between its centre and the back-part of the palate forms, with vocalised breath, the sound of initial *y* heard in *ye*. The same position, with voiceless breath, forms the German *ch* heard in *ich*, which is the same as *h* before *u* in English—for example, *hue*. The Scotch guttural in *loch* and the German *ach* differ from this only in the more retracted position of the tongue.

The elevation of the middle of the tongue towards the front of the palatal arch, with a narrow central passage for the breath, produces the element which, for lack of an alphabetic character, is represented by the digraph *sh*; and the same position forms, with vocalised breath, the common element heard in *pleasure*, *seizure*, &c. but which has no appropriate literal symbol in English.

The approximation of the flattened point of the tongue to the front of the mouth, so as to leave a narrow central passage between the tongue and the upper gum, forms the sound represented by *s*; and by *z* when the breath is vocalised.

The elevation of the tip of the tongue towards the rim of the palatal arch causes a degree of vibration of the edge of the tongue, and consequent asperation of the breath, proportioned to the degree of elevation, which is the English sound of the letter *r*.

The approximation of the lower to the upper lip, so as to leave a central aperture for the breath, produces, with vocalised breath, the sound of *w* initial, as in *woo*. The sound of *w* resembles that of the vowel *oo*, but with a more contracted aperture. The same position, with voiceless breath, forms the element represented, for lack of an alphabetic character, by the digraph *wh*.

The remaining varieties of English articulate sounds are formed by forcing the breath through *lateral* apertures, instead of one central aperture.

When the fore-part of the tongue is spread against the front of the palate, and vocalised breath passes laterally over the middle of the tongue, the sound of *l* is heard.

When the tip of the tongue is applied to the upper teeth (or the gum), and the breath is emitted laterally over the point of the tongue, the sound of the digraph *th* as in *thin* is heard; and, with vocalised breath, the sound of *th* in *then*,—neither of which is now represented in our alphabet.

When the middle of the lower lip is applied to the edge of the upper teeth, and the breath is emitted laterally between the teeth and the lip, the sound represented by *f* is produced; and, with vocalised breath, the sound of *v*.

Liquids.—The voice is so little intercepted in passing through the nostrils in forming *m*, *n*, or *ng*, and through the wide apertures of *l*, and also of *r* when not initial in a syllable, that the sound has almost the pure sonorousness of a vowel; and these elements have received the name of Liquids, to designate their property of syllabically combining with voiceless consonants—seeming to flow into and to be absorbed by them, and losing much of their natural quality as vocal sounds.

Consonants form, as it were, the bare and bony skeleton of speech; vowels give definite shape and individuality to words. Thus the consonants *sprt* constitute the common skeleton of such diverse words as *sport—spirt*, *sprat—sprite*, *spirit*, *support*, *separate*, *aspirate—asperate*, which receive their distinct configuration and filling up from the vowel-sounds, which cover the consonant skeleton with moulded elegance and variety. Consonants are thus the more stable elements of words, and their interchanges in the corresponding words of allied tongues are found to follow certain general laws dependent on the relations and affinities of letters. These relations are exhibited in the following table:

	SHUT.		OPEN.		NASAL.	
	Sharp.	Flat.	Sharp.	Flat.	Sharp.	Flat.
1. Labials.....	*p*	*b*	*f*, *wh*	*v*, *w*	†	*m*
2. Linguals....	*t*	*d*	*th*, *s*, *sh*, *	*dh*, *z*, *zh*, *r*		*n*
			ll (Welsh)	*l*		
3. Gutturals...	*k*	*g*	*ch* (loch), *ch* (ich)	*gh*, *y*		*ng*

* The 'sharp' or voiceless *r* is of frequent but unrecognised occurrence. It is heard in French, as the sound of *r* final after a consonant, as in *theatre*; and in Scotch, as a substitute for *thr*, as in *three*, pronounced *hree*.

† The 'sharp' forms of the nasals are in constant use as interjectional sounds, as in *humph l* (pronounced *'hm l*), *'hn l* (expressive of sneering), and *'mhm l* (used as an affirmative in Scotland).

In pronouncing the letters of the first class, the lips are chiefly concerned; in the second, the principal organ is the tongue, or the tongue and the teeth (whence they are also called *dentals*); and in the third, the back-parts of the tongue and palate are employed.

The branch of the science of language which treats of the elementary sounds of speech is called Phonetics (from Greek *phone*, sound); and, along with the sounds themselves, it considers their representation by visible signs or letters. How imperfectly the elementary sounds of English are represented by the letters that compose the English alphabet, is apparent from the analysis above given. That alphabet is imperfect both by redundancy and defect. (1.) The same sounds are represented by more than one letter; as *c*, *k*, and *q*; *c* and *s*; *g* and *j*. (2.) The same letter represents more than one sound; as *c*, which is sometimes *k*, and sometimes *s*; *g*, which is sometimes the vocalised form of *k*, and sometimes *j*; *n*, which is sometimes *n*, and sometimes *ng*; *s*, which is sometimes *s*, and sometimes *z*; and *y*, which is sometimes a consonant (when initial), and sometimes a vowel, sounded like the letter *i*. (3.) Single letters are used to represent articulate compounds; as *g* and *j*, which are sounded *dzh* [the voiceless form of *j* is represented by *ch*, as in *chair*]; *u*, which is sounded *yoo*; and *x*, which is sounded *ks*, and sometimes *gz*. (4.) The alphabet contains no characters for six of our undoubted consonant elements—namely, *wh*, *th*(in), *th*(en), *sh*, *zh*, *ng*. (5.) Each vowel-letter represents many sounds; and the lack of seven characters to denote the excess of our vowel-sounds over the number of our vowel-letters, is supplied by about sixty combinations of two or of three letters, so that the original phonetic character of the alphabet is almost entirely lost in the confusion of our orthography.

HOW LANGUAGE CHANGES.

Language passes from generation to generation by tradition; the rising generation naturally learn to speak as the adult generation speaks; and where there is any express teaching on the part of the old, it is to the effect of guarding the young against any deviation from existing use. But, notwithstanding this, language does change, has always changed, and will continue to change, like everything human. In proof of this, we have only to look back at English as it appears in any book written two or three hundred years ago. It already begins to have a strange aspect, and were it not that almost everybody still reads the Bible and Shakspeare, its strangeness would strike us still more. Chaucer, who wrote two centuries earlier, can be understood by ordinary English readers only with pains and the help of a glossary. When we go back five centuries further to King Alfred, the language of the royal author is as much foreign to us as Dutch. So much is this the case, that it has got a different name, and is spoken of as Anglo-Saxon. It is really, however, the same uninterrupted stream of English, only traced farther up towards its source.

Languages change in various ways. One change going on daily before our eyes consists in the introduction of new words. As a rule, we have an instinctive and salutary hostility to new words. They, in fact, defeat the very end of speech; to which it is essential that the meaning of the signs used be commonly known. But when we have a new thing or a new idea to speak about, we must either describe it in a roundabout way every time we mention it, or invent a special name for it. This is legitimate innovation. The progress of art and science has, within the last hundred years, enriched the English and other European tongues with many thousands of new technical terms. These terms have very various origins. Many of them are formed from Greek or Latin words; others from the names of persons; sometimes, in importing a new product or notion from a foreign country, we retain its native name: *e. g.* palæontology, megatherium, Galvanism, Faradisation, Darwinism, Macadamise, electro-magnetism, zincography, spectroscope, telegraph, telegram, Magenta, gutta-percha, trepang, tomahawk.

In the more generally current part of the vocabulary, new coinages are naturally less frequent; and when a new word does appear, it has to run the gantlet of criticism before admission. The right of *reliable*, which has only recently come into frequent use, to rank as a genuine English word, is still disputed. The Americans are less fastidious in this respect than we are, and not a few words of transatlantic manufacture are asserting a place in England, although still looked askance at by purists: *e. g. to progréss* as a verb from *prógress*; *to interview'* from *in'terview*.

The counterpart of this birth of new words is the decay and death of old ones. Many words current in England in the days of Shakspeare are no longer heard, unless, it may be, in provincial dialects: barn (child), eyne (eyes), wee (small), caliver (hand-gun), chare (a turn of work), fardel (burden), foison (plenty), geck (fool), stomach (courage), welkin (sky), yare (ready).

A more important change than the growth of new words and the death of old, is the transformation that words undergo while still continuing in use. This transformation is either in the meaning or the form, or in both. 1. *Changes in meaning.*—The Anglo-Saxon *sælig*, from which the modern English *silly* has been formed, means 'blessed,' 'happy.' But the best type of unalloyed happiness is that of a child, and as the happiness of a child is accompanied with innocence and simplicity, the word acquired the secondary meaning of 'innocent, simple,' and after a time, altogether lost its primary meaning. Milton uses 'silly'—into which form *sælig* had by degrees been transmuted—in the sense of 'simple,' without implying any disparagement. But simplicity borders on ignorance and feebleness of mind, and hence a second transition to the modern meaning of *silly*, in which nothing remains of the former stages. The same word *selig*, while continuing to be used in German in the sense of 'blessed,' has acquired the secondary sense of 'departed,' 'dead,' 'the late.' The association of ideas here is obvious, and the substitution of *selig* for a more obviously appropriate term is prompted by the desire to suggest a disagreeable idea in an indirect way. This instinct of politeness in speech—euphemism, as it is called—which seeks to hint at an unpleasant or an indelicate thing, rather than name it directly, has had much to do in making words acquire new meanings and

lose old ones: thus, 'plain' has usurped the sense of 'ugly;' 'fast,' of 'dissipated;' 'gallantry,' of 'licentiousness.' To trace such transitions in the meaning of words is one of the most interesting and instructive studies. It has been treated by numerous writers in regard to English; among others by Archbishop Trench on *The Study of Words*.

2. *Changes in form.*—One obvious change of this kind in English is the shifting of the accent a syllable forward. It is not long since everybody said reve'nue and balco'ny; now everybody says re'venue and ba'lcony. It is held incorrect to accent *ally* on the first syllable; yet many do so, being guided by the analogy of the language, which seldom has the accent on the final syllable; and there can be little doubt that a'lly will in the end triumph over ally'.

Since Anglo-Saxon times, and even since the days of Chaucer, the vowel sounds of English have been greatly altered. The investigations of Mr Ellis lead him to the conclusion that the vowel letters were pronounced by Chaucer's contemporaries pretty much as they continue to be pronounced in broad Scotch.

But a more striking change is the dropping of sounds altogether out of words. This change is very much disguised by the conservative effect of writing, which tends to preserve the spelling of words, although the pronunciation has altered. Johnson's Dictionary did much to stereotype the spelling of the English language, although it has not been completely successful recently: *e. g.* emperour,' 'arithmetick,' are now 'emperor,' 'arithmetic,' and 'honour' is on the inevitable road to 'honor.' The essential thing, however, are the spoken words, and they are constantly suffering curtailment whether the spelling alter or not. Thus, in *soften*, the *t* was originally pronounced, but it is now considered formal and old-fashioned to do so. Nearly all our silent letters, as they are called, were at one time heard, as in *psalm, wrought*. In words like *knee*, there was, in the primary forms, a vowel after the silent letter—k(e)nee—as we see in the corresponding Latin *genu*. This vowel vanishing, the *k* becomes difficult to pronounce, and is left silent in standard English, though still heard in Scotch and other dialects. Mistress, as a courtesy title, has dwindled into Misses for a married woman, with a kind of diminutive, Miss, for a young woman.

This curtailing of language has for its cause the natural tendency to economise exertion—laziness, in short. We instinctively seek to save our time and breath, and make as short work as possible with a word, provided it still conveys its meaning distinctly. Hence the vowel of an unaccented syllable becomes gradually shorter and more indistinct, until at last it is dropped altogether, and two syllables are pronounced as one, as in the instance just given of *knee; know* is a case of the same thing, as is seen from the old word *ken*, which is from the same root. But in this process the result is often not all gain in the way of ease; for the coalescence of syllables frequently causes combinations of consonants difficult of utterance. A great many of the existing clusters of consonants in the languages of civilised nations are distinctly traceable to this kind of coalescence (*debitum, debit, debt*), and it is believed that all of them orginated in that way, and that the primitive form of all tongues was what we still see among barbarous peoples (*e. g.* Kamehameha, the name of the late king of Hawaii), where every consonant is accompanied by a vowel.

This 'phonetic decay,' this wearing away and crumpling up of words for the sake of shortness, is strikingly seen in tracing the transition of Anglo-Saxon into modern English. Thus *dæg* becomes day; *fæger*, fair; *hlaford*, lord; *hlafdige*, lady: *wîf-man*, woman; *niht* (with the guttural *h* pronounced, as in Scotch), ni(gh)t; *wêorold*, world; *Eofor-wic*, York. One marked tendency or law may be observed in all this—namely, the tendency to drop or soften down the rough gutturals. Although it is generally by leaving out articulations that ease is sought, the same end is sometimes attained by inserting anomalous ones; thus, on borrowing the French *genre*, we have made it *gender*, because it is more easy in passing from *n* to *er* to take *d* by the way. In the same way *b* is brought in as a bridge of transition in *slumber*, from Anglo-Saxon *slumerian;* in *humble*, from Latin *humilis;* in *dissemble*, from *similis*. The Greek word *ambrosia* would have been *amrosia*, if the Greeks could have tolerated *r* after *m*, for the word is from *a*, negative, and the root that we see in Latin *mors*, death, and means 'undying.'

The Latin tongue, in being transformed into French, has suffered severe degradation. *Pater* became *père; frater, frère; presbyter*, first *prestre*, and then *prêtre; magister, maistre, maître*. The termination *-atus* dwindled away to *é*: *e. g. amatus* = *aimé*, *privatus* = *privé*. Before the inhabitants of Gaul began to learn the language of their conquerors, the Romans, they spoke Celtic. Now, such combinations as *sp, st*, are unknown in that language; and therefore, to make them pronounceable, the Gauls prefixed *e*, and turned *sperare* into *espérer*, *stabilire* into *establir* (English *establish*) and then into *établir*. This peculiar habit, together with the change of *-atus, -ata, -atum*, into *é*, or *ée*, shews at once how *épée*, a sword, grew out of Latin *spatha* or *spata*, a blade of any kind (English *spade*).

It is manifest at a glance, even from the few examples given, that the curtailments that words undergo do not take place by chance or caprice, but in a more or less regular and uniform way. These uniformities in phonetic change and decay are among the most important of the laws of the life of language, which it is the business of philology to study.

It may seem strange to speak of decay as life; yet it is just as much a part of the life of language as waste of the tissues is in the life of the animal body. But the important part it plays will be best understood by considering it along with the counter-process—namely, the building up of new words from old material.

WORD-BUILDING.

When we have to speak frequently about a thing that has no single name, as 'the top of the house,' 'a road provided with rails,' 'a ring for the ear,' 'a boat moved by steam,' we put the two words together without the connectives, and say 'house-top,' 'rail-road,' 'ear-ring,' 'steam-boat.' What constitutes a perfect compound in such a case is the sinking of the accent of one of the parts. We can bring together the two words *ocean*

steamer, but they remain two words, each with its own accent; the combination is not required sufficiently often to have formed them into a unity. There are a great many black′ birds′, but only one black′bird. When a compound has been long in use, the hyphen is dropped, and phonetic corruption sets in, if not in the spelling, in the pronunciation. In *forehead* and *shepherd*, it is only on consideration that we feel the two parts of the word as distinct. The sailor, familiar only with *bōs'n*, never thought of a *boat* or a *swain* in connection with the officer so called, and would not know what was meant by *boat-swain* if he saw it, or heard it for the first time. In *nostril*, we readily recognise the first syllable, but for the second we must go back to Anglo-Saxon *nas-thyrel;* and even then, it requires some etymological expertness to connect this with 'to drill,' 'to bore,' and to see that the full etymological meaning is 'nose-bore.' In *bōs'n* and *nostril* the fusion is felt to be complete, and two words have been welded into a single integral word; and, what it is of consequence to observe, this does not take place until we cease to perceive the meanings of the separate component parts, or at least of one of them. The necessary obscuration is brought about unintentionally, by slurring over the sounds; and thus the corruption of two old words results in the birth of a new one.

Affixes and other formative Particles.—The important part played by phonetic degradation and fusion is best seen in classes of words like god-ly, friend-ly; king-dom, heathen-dom; good-ness, hard-ness; plen-ty, pover-ty; bishop-ric; hard-ship, wor-ship; plente-ous, graci-ous; god-less, aim-less. The affixes or derivative terminations in such compounds were, there is little doubt, originally distinct words; it is demonstrable in the case of many of them, and may be confidently inferred in the case of all. That 'godly,' 'friendly,' are merely degraded forms of 'god-like,' 'friend-like,' is made certain by a reference to the Anglo-Saxon *god-lic*, *freond-lic*, and to the corresponding forms in other Teutonic tongues. We have shortened the Anglo-Saxon adverbial form *-lice* also into *-ly*, and now add it to all manner of adjectives to form adverbs: *e. g. privately;* we can even say *godlily*, in which the word 'like' occurs twice. The affix *-dom* is doom, judgment, jurisdiction; *ric*, in Anglo-Saxon, means kingdom, rule, and is from the same root as *rex; -ship* is nothing else than *shape*, condition, dignity; and 'god-less' is Ang.-Sax. *god-leas*, in which *leas* is the adjective *leas*, loose, free from, without. The affix *-ty* belongs, apparently, to an earlier stage than the other elements we have been considering; it is through the French (*pauvrete*), from Lat. *-tas*, *-tat*(is), (*pauper-tas*, *-tatis*), in which, owing to the wear and tear of long ages, it is difficult to say what may have been the original form.

The earlier and primitive affixes seem to have been built up of monosyllables of the nature of demonstrative adverbs or pronouns, indicating primarily position in space—'here,' 'there,' 'up,' 'down,' 'towards,' 'away from,' &c. Two of these pronominal roots, *ma*, 'here' (pointing towards the speaker), and *sa*, or *ta*, 'there,' can be traced in all the Indo-European languages; they enter into the personal and other pronouns, and into the cases of nouns and the terminations of verbs. In the earliest form known, the three persons of the present singular of the verb ended in *mi*, *si*, *ti*. These are evidently connected with the personal pronouns, so that *dada-mi*, *dada-si*, *dada-ti*, are compound words, equivalent to 'give-I, give-thou, give-he;' or rather, 'giving-of-me, giving-of-thee, giving-of-him.' The plural terminations *mas*, *tas*, *nti*, contain the same elements with an indication of the plural number. The pronominal element *sa* entered into the nominative singular of masculine and feminine nouns, as in Lat. *equu-s*, Gr. *hippo-s*. A bare stem or root, with a general predicative meaning, was not considered a word without an addition to limit and fix it down. Thus *voc* in Latin has the sense of calling or sounding; *voc*-sa or *voc*-s (*vox*) is 'sound'—that, or that which, sounds—'the voice.' The plural *voc*-es is believed to be a corruption of *voc-sa-sa*, 'sound that and that,' the doubling of the pronoun expressing symbolically a plurality of the same thing.

In many of the tense-endings it is possible to recognise auxiliary verbs. Thus Lat. *ama-vi* is for *ama-fui*, and *fui* is part of the verb *fu*, to be; so that *ama-vi* is literally, 'love-was I,' or, 'I was in the act of loving.' The future tense in French is known to have been formed within historical times by affixing the present tense of the auxiliary *avoir*, 'to have,' to the infinitive of the verb—for example, *finir-ai* is, 'to-finish-have-I,' or, 'I have to finish.'

The formation of the English past tense in *d* or *ed* is a most instructive instance of this kind of composition. One of the earliest expedients for expressing past time seems to have been the repetition of the root; thus, from the root *dā*, 'give,' the Sanscrit formed *dadāu*, the Greek *dedōka*, and the Latin *dedi*, in which the reduplication of the word symbolises thorough, complete action—'have given'—thereby implying that the action is over and past. Similarly, the root *dha*, 'put' or 'make,' furnished Gr. *tetheika*, Old High German *teta*, Ang.-Sax. *dide* or *did*. In nearly all simple Greek verbs, the perfect was formed by reduplication. Many of the oldest Latin verbs retained it, as *cado*, *cecidi*, to fall; *pello*, *pepuli*, to drive; and its previous existence may be inferred in *tŭli* for *tetuli*, *fēci* contracted for *fefici*. How readily the first syllable, being without the accent, would fall off is seen in its uniform absence in compound verbs: *e. g. compello*, *compŭli*. In modern Teutonic languages, the only remaining instance of the reduplicated past is *did* (Ger. *that*); but in Mœso-Gothic, the oldest form of Teutonic known, there were a considerable number of reduplicated past tenses—for example, *haldan*, to hold, perfect *haihald;* in Ang.-Sax. *heold*, for *hehold;* Goth. *haita*, to command, perfect *haihait*, in Ang.-Sax. *héht* for *hehet;* Old. Eng. *hight; letan*, to permit, *lailôt*. The reduplication, it is to be observed, is usually accompanied by a change of the root-vowel. This seems not to have been an essential part of the process, or, at most, only an accessory. The vowel-change was probably not intended to signify anything, but arose from the lengthening of the word. The addition of a syllable to a word has frequently this effect: *e. g. revīse*, *revīsion; proclāim*, *proclāmation; nātion*, *nātional*. But when the reduplication fell away, the altered radical vowel came to be looked upon as in itself the mark of past time. The vowel-changes, however, were irregular, and seemingly capricious, so that no rule could be

deduced from them for forming the past tense of a new verb. Besides, reduplication is only suited to simple verbs—root or stem verbs. Accordingly, in the case of compound and derivative verbs, the expedient was adopted of affixing an auxiliary verb. In Latin, as already observed, a common form was *vi* or *ui* (*ama-vi*, *par-ui*), corrupted from *fui*, which is a contraction of the reduplicated past *fufui*, of *fu*, to be. In perfects like *scrip-si*, we may recognise the relics of an obsolete reduplicate perfect of *es-*, to be. The Teutonic languages employed the reduplicated preterit of the verb 'do.' That the modern signs of past time in English (*d* or *ed*), and in German (*te*), are relics of Ang.-Sax. *dide*, and Old German *teta*, is rendered certain by the occurrence of such forms in Mœso-Gothic as *salbo-dêd-um*, *tame-ded-um*, which are as explicit as 'anoint-did-we,' 'tame-did-we.' The preterits formed in this way soon came to outnumber the older reduplicated forms, and we now speak of them as 'regular,' and of the others as 'irregular.' Many verbs that in Old English formed the past tense by a change of vowel, now follow the prevailing fashion, and take *d*—as *leap*, which had at one time *lap* in the past tense, and has so still in some provincial dialects.

Assimilation.—When the composition of words brings incompatible letters together, one of the two is assimilated to the other. The same takes place when the falling-out of a vowel allows two incompatible articulations to come together. The operation of this law is conspicuously seen in words from Latin and Greek, compounded with prepositions and other prefixes; as *af*-firm for *ad*-firm, *ar*-rogate for *ad*-rogate, *il*-licit for *in*-licit, *sup*-port for *sub*-port, *sym*-metry for *syn*-metry. In these cases, the assimilation is complete; but the same end, namely, ease of pronunciation, is often attained by approximation merely, as *im*-pute for *in*-pute, in which the transition to the labial *p* is easier from the labial nasal *m*, than it would have been from the lingual nasal *n*. The case of prefixes, however, is of less importance in comparative philology than other parts of the process of word-building. Whenever we form a new compound, although we may retain the spelling, we instinctively accommodate the pronunciation of one part to that of the other. Thus, handkerchief is pronounced hang-kerchief. Here *d* is altogether dropped, and the lingual *n* is changed to the guttural *ng*, in order to make the transition to *k* more easy.

In the earlier and more fluent stages of language, this process of accommodation was more rapid and complete, being without the drag put upon it by writing and printing. Of complete assimilation of the preceding consonant to the following, we have examples in the Latin words *sum-mus* for *sup-mus*, *sel-la* for *sed-la* (*sed-*, to sit), *puel-la* for *puer-la*, *gram-ma* for *graph-ma*. In *longis-simus* for *longis-timus*, *facil-limus* for *facil-timus*, the latter is assimilated to the former. Approximation is seen in scri*p*-tus for scri*b*-tus, a*c*-tus for a*g*-tus (*ag-*, to do or drive), so*m*-nus for so*p*-nus (compare *sop*orific), Sa*m*-nium for Sa*b*-nium. Instead of assimilation, one of the consonants is frequently dropped, in which case the vowel is usually lengthened by way of compensation. For example, the Latin for foot was originally *ped-s*, which first, probably, became *pess*, and was then written *pēs*; *lū-na* is for *luc-na* (*luc-*, to shine), *lu-men* for *luc-men*.

Sometimes ease of pronunciation is sought in *dissimilation:* as in eque*s*-ter for eque*t*-ter, claus-trum for clau*d*-trum. A great many adjectives in Latin were formed by the affix *-alis*, as *mortalis*, *regalis*; but when the stem contained *l* in the last syllable, *-aris* was substituted: *e.g. popul-aris*, *vulg-aris*. In cæ*r*u-leus for cæ*l*u-leus (compare *cælum*, heaven), it is the stem that is changed.

In making these accommodations each language has peculiarities of its own. The Latins, for example, found such a combination as *genesis* (the original form of the genitive of *genus*) inconvenient, and changed the first *s* into *r*—*generis*; the Greeks threw it out altogether, and made *genesos* into *geneos*, and then into *genous*. The ancient Celtic inhabitants of Spain disliked initial *sp*, *st*, as their neighbours of Gaul did (see p. 22), and changed Latin *spata* into *espada*, *stabilis* into *estable*. Modern Italian tolerates *sp*, *st*, but not *fl*, *pl*, and turns Latin *flor* into *fiore*, *planus* into *piano*. French and Spanish retain these combinations, having *fleur*, *flor*, and *plain*, *plano*. Spanish has the peculiarity of turning Latin initial *f*, in many cases, into *h*, so that, *e.g. facere*, *filius*, *fames*, *formosus*, appear disguised as *hacer*, *hijo*, *hambre*, *hermoso*.

These examples will suffice to shew how, what were originally the same words, may, in the mouths of people living apart, and with different idiosyncrasies, after a lapse of years, become so different as to form a new language. This leads us to the subject of

DIALECTS.

In speaking of a people having essentially all one language, but living extended over a wide territory, the name of *dialects* is given to those varieties or peculiar forms which that language assumes among the various tribes or other local divisions of the people. It is clear that the wider the separation comes to be between the several tribes, and the more they differ in mode of life and other circumstances, the more marked will the differences of dialect become. When, again, a particular tribe of this people increases in numbers, and also extends its territory, the same process is repeated, and its dialect becomes broken into a number of sub-dialects. The principal check to this tendency to seemingly endless subdivision of language, is furnished by an increasing degree of common culture and civilisation. Where this is wanting, as in Africa and among the native populations of America, the subdivision is practically endless.

A further check to divergence is usually found in one dialect of a country acquiring a dominance over the others. Various circumstances may give rise to this. The tribe that succeeds in establishing political supremacy is likely to make its dialect also prevail. A popular poet also may give his local dialect a general currency. Accidental circumstances have, in many cases, decided the rivalry. The Bible happened to be translated by a High-German, Luther, into his native dialect; other works on the then all-engrossing subject of religion followed in the same dialect; happily, too, the art of printing had just attained the perfection necessary to give these productions general

circulation. It was this concurrence of circumstances that decided that High-German should in future be the spiritual bond among the widespread German people. For there were other dialects whose claims to the distinction were at that time equal, if not higher.

When a dialect has thus become the vehicle of written communication, and of the higher kinds of oral address, its character and position become changed; and it stands henceforth in a sort of antagonism to the other dialects, and even to that out of which itself sprung. After a time these dialects become the exclusive possession of the uneducated classes, in which position they preserve many relics of old grammatical forms long after these have disappeared in the language of literature. It is thus to take an erroneous view of dialects, to treat them as corruptions of the standard language; they had an independent origin, and they and the written standard continue to act and react on one another. The genius of a national language cannot be fully understood without taking into account its provincial varieties.

It is obvious that dialect is entirely a *relative* term, and that what we call by that name in one connection, we may call a language in another connection. Thus, the most casual observer must be struck with the family likeness of Italian, French, and Spanish; indeed we know, as an historical fact, that all three were formed out of the same material, namely, the language of the ancient Romans. We might therefore speak of these languages as sister dialects, sprung from one common mother. But in ordinary usage, however nearly related the speech of two peoples may be, we do not apply the term dialects, unless the peoples are mutually intelligible, and have a common literary standard. Intelligibility does not go for much, but political relations enter more or less into the notion. Thus, Scotch is sometimes spoken of as a distinct language from English; and yet in no part of Scotland is the common speech so unintelligible to an Englishman as is that of Somerset, which is always a 'dialect.' This arises from Scotland being thought of as a separate country, which it once was; and its speech as the vehicle of a peculiar literature.

FAMILIES OF LANGUAGES.

The idea of groups or families of allied languages is thus an extension of the idea of dialects or varieties of one language; the differences are perhaps more numerous and profound in the one case than in the other, but they are of the same kind. The relation is the same in both cases—namely, that of sisters sprung from a common mother. The most important of the groups as yet established is that already named, the Indo-European. This great family embraces seven stocks, each with its ramifications.

1. The ancient *Sanscrit*, with its modern descendants, the Hindu dialects spoken all over Northern Hindustan.

2. *Persian*, ancient and modern, along with Armenian, Kurdish, and Afghan.

3. *Greek*, ancient and modern. Notwithstanding the important part played by the Greek people in the intellectual history of mankind, their language now occupies but a small area, being mostly confined to Greece itself, and to the islands of the Ægean. Modern Greek is much less changed from classic Greek than Italian is from Latin.

4. *Latin.*—The modern representatives of Latin form a sub-family called the Romanic languages, consisting of Italian, French, Spanish, Portuguese, Rhæto-Romanic—spoken in several dialects in the valleys of the Rhætian Alps—and Walachian.

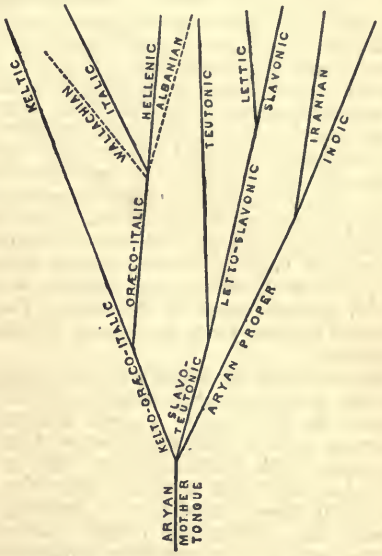

Fig. 1.—Outline Genealogical Tree of the Aryan Tongues.
From Farrar's *Families of Speech.*

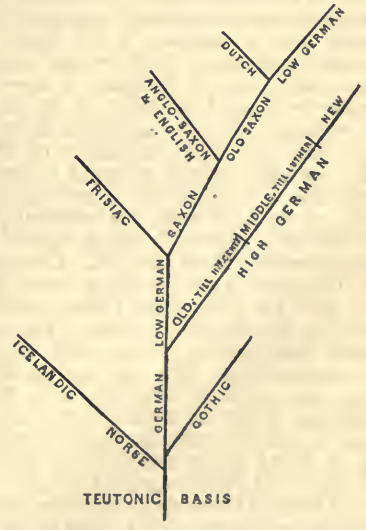

Fig. 2.—Ramifications of the Teutonic Stock.
From Farrar's *Families of Speech.*

5. The *Teutonic* stock, divided into two branches, the Germanic and the Scandinavian. The Germanic branch embraces the various dialects, High and Low, spoken in Germany proper, together with the Dutch or Netherlandish of

Holland and Belgium, and English, the last two being varieties of Low-German. The Scandinavian branch occupies Denmark, Sweden, Norway, and Iceland.

6. The *Slavic* or *Slavonic* stock, covering Russia, Poland, portions of Austria, and the north of Turkey. The chief languages are Russian, Polish, Bohemian, Servian, Bulgarian.

7. *Celtic.*—At the dawn of history, tongues of this stock were spoken over a great part of Europe—Gaul or France, the British Islands, part of the Spanish peninsula, many parts of South Germany, and the north of Italy; and judging from the names of mountains, rivers, &c. the Celtic area must at one time have been still more extensive. It is now confined to Ireland, the Scottish Highlands, Wales, the Isle of Man, and some parts of Brittany. The remnants of the Celtic tongues present two types, forming two branches. The Irish, the Gaelic of Scotland, and the Manx, belong to the northern or Gadhelic branch (Gaelic is merely a short form of Gadhelic); the southern or Cymric branch is represented by the Welsh, Cornish of Cornwall (extinct since 1778), and the Breton of Brittany.

The evidence on which all these tongues are believed to be sprung from one original tongue, consists in their having a great many words in common, and in their grammatical forms being the same. This latter kind of evidence is considered a surer test of affinity than the former. For when those elements of a language which express the relations of things—case, number, tense—have once become mere terminations, and lost their original form and independent meaning, they can only be transmitted by tradition; and when the same grammatical forms are found possessed in common by two or more tongues, they must be an inheritance from a common ancestor. It is difficult, without entering into minute details, to exhibit even a specimen of the identity of the inflectional endings of the Germanic tongues, for instance, with those of Sanscrit; it is more easy to make the radical sameness of the individual words apparent. In judging of this sameness, we are no longer guided by mere similarity of sound; on the contrary, identity of sound is generally a presumption that a proposed etymology is wrong. Words, as we have seen, are constantly undergoing change, and each language follows its own fashion in making those changes. Corresponding words, therefore, in allied tongues must, as a rule, differ, and the differences follow certain laws which it is possible to ascertain; and unless a proposed identification accord with those laws, it is inadmissible. We are not at liberty to suppose any arbitrary omission of a letter, or substitution of one letter for another, as was the fashion in the old guessing school of etymology. Thus, it would be inadmissible to assume Old Irish *athir* to be identical with Latin *pater*, unless it be the habit of the Irish to drop the initial *p* of the original word; but this is seen to be the case by such additional instances as *iasg*, Old Irish *isc* = Latin *piscis*, a fish; *lan* = Latin *plenus*, full.

GRIMM'S LAW.

Of the laws of interchange of sounds in the Indo-European family, the most important is that known as Grimm's Law, so called after the famous German philologist who investigated it. It is of extensive application, affecting the whole consonantal structure of the Aryan tongues, and in its whole extent is rather intricate. The following table exhibits the more important interchanges between the ancient classic languages and the Germanic:

	Labials.			Dentals.			Gutturals.		
Greek (Latin, Sanscrit)....	p	b	f	t	d	th	k	g	ch
Gothic.....	f	p	b	th	t	d		k	g
Old High German.....	b (v)	f	p	d	z	t	g	ch	k

Examples.

Sans. pad-as, Gr. pod-os, Lat. ped-is, Goth. fot-us, Eng. foot, O. H. Ger. vuoz, Ger. fuss.

Sans. pitri, Gr. and Lat. pater, Goth. fadrs, Eng. father, O. H. Ger. vatar.

Sans. bharami, Gr. phero, Lat. fero, Goth. baira, Eng. bear.

Sans. bhrag, Gr. phlego, Lat. flagro, Goth. bairht, Eng. bright, O. H. Ger. percht, Ger. pracht.

Sans. tola, Gr. talan, Lat. tolerare, Goth. thulan, Scot. thole, Ger. dulden.

Sans. damja, Gr. daman, Lat. domare, Goth. tamjan, Eng. tame, Ger. zähmen.

Sans. uda, Gr. hydor, Lat. u(n)da, Goth. vato, Eng. water, Ger. wasser.

Sans. hrid (krid), Gr. kardia, Lat. cord-is, Goth. hearto, Eng. heart, Ger. herz.

Sans. kas, Gr. kos and pos, Lat. quis, Goth. hvas, Eng. hwo, hwat (who, what), Ger. was.

Sans. ganaka, Gr. gennetor, Lat. genitor, Goth. kyning, Eng. king, O. H. Ger. chunine, Ger. könig. 'King' thus meant originally 'father.'

Sans. gani (mother), Gr. gyne (woman), Lat. gene-trix, Goth. qino or qens, A. S. cuen, Eng. queen.

Sans. hansa, Gr. chen, Lat. (h)anser, A. S. gos, Eng. goose, Ger. gans.

There are, of course, many exceptions to the law, arising from the influence of adjoining letters and other incidental causes. It holds good oftenest at the beginning of words. It will be observed that the English differs more from the High-German than it does from the Gothic, which belongs, like English itself, to the 'low' Teutonic group. By observing the relations between the German and the English exhibited in the following table, the beginner of German may easily recognise the English equivalent of many German words:

Ger. *d* = Eng. *th.*			Ger. *z* = Eng. *t.*			Ger. *th* or *t* = Eng. *d.*		
dies	=	this.	zahlen	=	tell.	thau	=	dew.
das	=	that.	zehe	=	toe.	theuer	=	dear.
denn	=	then.	zinn	=	tin.	theil	=	deal.
denken	=	think.	zoll	=	toll.	tanz	=	dance.
dick	=	thick.	zu	=	to.	tag	=	day.
dein	=	thine.	zwei	=	two.	taube	=	dove.

It is difficult to account for such dialectic diversifications, as the greater part of them cannot be ascribed to the tendency to seek ease of utterance. Max Müller thinks it necessary to go back to a time when many of the articulations were not yet sharply defined; and he appeals, in illustration, to the confusion children make between such sounds as *tat* and *cat;* and, what is still more in point, to the analogy presented by languages like the Polynesian. In the language of the Sandwich Islands, the two consonants, *k* and *t*, run into one another, 'and it seems impossible for a foreigner to say whether what he hears is

a guttural or a dental. The same word is written by Protestant missionaries with *k*, by French with *t*. It takes months of patient labour to teach a Hawaian youth the difference between *k* and *t*, *g* and *d*, *l* and *r*. . . . If colonies started to-morrow from the Hawaian islands, the same which took place thousands of years ago, when the Hindus, the Greeks, and Romans left their common home, would take place again. One colony would elaborate the indistinct, half-guttural, half-dental contact into a pure guttural; another, into a pure dental; a third, into a labial.' Much light is thrown on this question by those phonetic peculiarities—those deficiencies and predilections of articulation which characterise whole tribes and nations, as they often do individuals. They may have originated, perhaps, in the idiosyncrasies of individual ancestors (a lisping patriarch might produce a tribe of lispers, without their inheriting the physical defect which caused the lisp in him), or in a common habit of the organs of speech produced by external circumstances; but once established, they are very persistent and influential. The Mohawks, and several other American tribes, have no *p*, *b*, *m*, *f*, *v*, or *w*; they never articulate with their lips. In Chinese, there is no *d*; *r* is also wanting; and as the habit of the language requires a vowel after every consonant, the nearest approach they can make to the sound of *Christ* is *Ki-li-se-tu*. An analogous habit of articulation transforms the English word *gold* in the mouth of a Kafir into *i-go-li-de*.*

By observing the laws which we have above illustrated as regulating the interchange of sounds among the Indo-European languages, we can often identify words where there is little or no internal resemblance. Take Eng. *feather*. If there is a corresponding word in Greek or Latin, the root-consonants must, by Grimm's law, be *p-t*; which leads us to the root *pet*, signifying in both languages, to fly. From this the Greeks formed *pet-eron* (contracted into *pteron*), a wing, which there is no difficulty in admitting to be the same word as feather. It is hard to believe the same of the Lat. *penna*, until we learn that it once had the forms *pet-na* and *pes-na*, *penna* being the result of assimilation. Again, we undertake to identify French *larme* with Eng. *tear*. No one will dispute that *larme* is a corruption of Lat. *lacrima*; in fact, it can be followed through the successive stages of change. Now, we know that the Romans had a peculiarity of letting *d* in some positions degenerate into *l*. Nor is this unaccountable, when we consider that the contact of organs which produces *d*, differs from that which produces *l* chiefly in being more energetic; a slovenly *d* slides into *l*. Thus, the Greek name, Odysseus, became, in the mouths of the Romans, Ulysses; they said *odor* (a smell), but *oleo* (I smell); and, instead of *impedimentum*, *dedicare*, we sometimes find *impelimentum*, *delicare*. These and other instances would warrant us to conclude that *lacrima* was a corruption of *dacri-ma* (corresponding to Gr. *dakru*), even if we had not the express statement of Festus that *dacrima* was the older form. After this, there is no difficulty in recognising *dacri*, or *dakru*, as identical with Gothic *tagr*, Eng. *tear*.

The words which are most palpably and unmistakably the same throughout the Indo-European tongues are the numerals, the pronouns, and those expressive of family relations. The following table, taken from Professor Whitney's excellent volume on *Language and the Study of Language*, exhibits in a clear way some of these correspondences. Under each word is added its equivalent in two other languages, Arabic and Turkish, which, though existing in proximity to the Aryan languages, will be seen to have no affinity with them or with one another.

English.....	two.	three.	seven.	thou.	me.	mother.	brother.	daughter.
Germanic:								
Dutch.....	twee.	drie.	zeven.	....	mij.	moeder.	broeder.	dochter.
Icelandic.....	tvð.	thriu.	sið.	thu.	mik.	modhir.	brodhir.	dottir.
High-German..	zwei.	drei.	sieben.	du.	mich.	mutter.	bruder.	tochter.
Mœso-Gothic..	twa.	thri.	sibun.	thu.	mik.	....	brothar.	dauhtar.
Lithuanic.....	du.	tri.	septyni.	tu.	manen.	moter.	brolis.	dukter.
Slavonic.....	dwa.	tri.	sedmi.	tũ.	man.	mater.	brat.	dochy.
Celtic.....	dau.	tri.	secht.	tu.	me.	mathair.	brathair.	dear (??)
Latin.....	duo.	trẽs.	septem.	tu.	me.	mater.	frater.	....
Greek.....	dũo.	treis.	hepta.	sũ.	me.	meter.	phrater.	thugater.
Persian.....	dwa.	thri.	hapta.	tum.	me.	matar.	....	....
Sanscrit.....	dwa.	tri.	sapta.	twam.	me.	matar.	bhratar.	duhitar.
Arabic	ithn.	thalath.	sab.	anta.	ana.	umm.	akh.	bint.
Turkish.....	iki.	ũch.	yedi.	sen.	ben.	ana.	kardash.	kiz.

Such are a few specimens of the mass of evidence which goes to prove that the Indo-European languages are only later dialectic varieties of a single original tongue. No one of these languages—not even the Sanscrit, old as we know it to have been—can claim to be the parent of the others. The relation among them is that of sisters, daughters of one mother, which perished, as it were, in giving them birth. If we ask where the tribe or nation lived that spoke this parent tongue, we get little beyond conjectures for answer. Most of the speculations on this topic point to Central Asia, somewhere east of the Caspian, and north of the Hindu Kush. And, from the legendary traditions of the sacred books of the ancient Persians, there seem good grounds for believing that in that region—the ancient Bactria—the Indo-Persian branch of the family once lived together; that they there quarrelled, owing to religious

* These predilections and idiosyncrasies of articulation are strikingly exhibited in a New Zealand newspaper printed in parallel columns of English and Maori. The Maori version exhibits European proper names and words borrowed from English, transliterated as the natives pronounce them. The Maoris seem incapable of articulating *d*, *b*, *f*, *v*, *l*, or *s*, or of pronouncing any consonant without a vowel after it; so that in their mouths Donald Fraser becomes Tonore Pereiha; Stephen = Tepene; Martha = Maata; Locke = Raka; Jerusalem = Hiruharama; October = Oketopa; September = Hepetema; school = kura; horses = hoiho; bay = pei; courts = cooti.

differences, and that one section made their way across the Indus, to become the Sanscrit-speaking Hindus, while the other moved southwards, and settled in Persia.* But that the Indo-Persians had always lived in that northern region, or that the western members of the family migrated from thence, there is no direct evidence. One distinguished ethnologist, Dr Latham, believes the seat of the mother Aryan nation to have been Central Europe; but the probability seems to be in favour of the East.

The time of these migrations is equally unknown with the point of departure; they had taken place ages before the dawn of history.

But although left in darkness as to the when and where of the primitive Aryans, we are able, strange as it may seem, to speak with some confidence as to their state of civilisation. Where the same name for an object or notion is found used by the widely spread members of the family, it is justly inferred that that object or notion must have been familiar to them while yet resident together in the paternal home. It is in this way established, that among the primitive Aryans not only were the natural and primary family relations of father, mother, son, daughter, hallowed, but even the more conventional affinities of father-in-law, mother-in-law, sister-in-law; that to the organised family life there was superadded a state organisation with rulers or kings; that the ox and the cow constituted the chief riches and means of subsistence; and that houses and towns were built. In this mainly pastoral life, the more important of the primitive arts were known and exercised; fields were tilled; grain was raised and ground into meal; food was cooked and baked; cloth was woven and sewed into garments; and the use of the metals, even of iron, was known. The numbers as far as a hundred had been named, the decimal principle being followed. The name for a thousand had not come into requisition until after the dispersion, for it differs in the different Aryan tongues.

THE SEMITIC FAMILY.

The only other group of tongues among which a family relation has yet been satisfactorily made out, is the Semitic or Shemitic, so called from Shem, the son of Noah, who is represented in Genesis as the ancestor of the chief tribes that spoke those tongues. The Semitic tongues are divided into three classes: 1. The northern or Aramaic, spoken at one time over the region lying to the north of Palestine and Arabia as far as the Taurus range in Asia Minor, and extending in longitude from the Mediterranean to the Tigris. Eastern Aramaic, comprising the dialects of Assyria and Babylon, is sometimes called Chaldee; the western is known as Syriac. Aramaic was the common language of Palestine in the time of Christ, the Hebrew being then the sacred language. 2. The southern class, comprising Arabic, and the Amharic of Abyssinia, which has superseded the older allied Ethiopic. 3. The middle class, consisting of Hebrew, and the dialects spoken by the other inhabitants of Palestine, the chief of which was the Phœnician. This Semitic dialect had at one time an extensive area by means of the settlements of the Phœnicians at Carthage, and other places on the islands and coasts of the Mediterranean. With the exception of some remnants of Syriac, spoken by a few scattered Christian communities in Asia, and the Amharic of Abyssinia, Arabic is the only living representative of the Semitic tongues. From Arabia proper it has spread into Egypt and the whole of North Africa, and the vocabularies of modern Persian and Turkish are largely composed of Arabic words.

The inflection of the Semitic tongues is of a type quite distinct from that of the Aryan family, nor can any correspondences be found between the words of the two families beyond chance resemblances in sound. The cases of similarity that have been adduced are those of words directly borrowed from the Semitic, as camel from *gamal*, sapphire from *sappir*, or of onomatopoetic words, formed in imitation of the sound of the action, as *charat* = grate, *parak* = break. The attempt, on which so much learned labour was once bestowed, to trace Latin, Greek, and other words to a Hebrew origin, is now acknowledged by all competent philologists to be futile.

TYPES OF LANGUAGE.

Besides the division of languages into families bearing traces of a common origin—the genealogical classification—there is a division into three orders, as they may be called, depending upon a radical difference of structure. Speech, as the expression of thought, contains two elements: ideas or conceptions, which constitute the substance or material part; and the relations of these ideas to one another, which constitute the formal part; and the nature of a language depends upon the particular way in which the vocal expression of these two elements is combined. At the foundation of all words lie roots, or simple sounds expressive of meaning. Now, some languages, as the Chinese, use these roots in their naked form as words, the same syllable, according to its position, serving as noun, adjective, verb, &c.—*e.g. ta* means 'great,' 'greatness,' 'to be or to make great,' 'greatly,' or 'very.' The relational part of the thought, for the most part, gets no vocal expression; it is only indicated by position, as when *min*, people, and *li*, power, are simply put together (*min li*) to signify the people's power. Relations not readily indicated by position are expressed in a round-about way, by using additional significant words: thus, *tschung* (mass or multitude) *jin* (man) = men; *niu* (woman) *tsè* (child) = daughter; *ŷ min li* (employ people power) = with the people's power. Even in such cases, each root preserves its independence, and is felt to express its own radical meaning. Languages like the Chinese, whose development has been arrested at this rudimentary stage, are called *Monosyllabic* or *Isolating*.

The next stage of development is that of the *Agglutinate* languages, which are by far the most numerous, including the Turanian and American

* The region that forms the water-shed between the basin of the Sea of Aral and the streams that run eastward and southward has been only recently explored. It is not so much a mountain chain as a vast table-land of great elevation fringed with towering sierras, and is called the Pamir Steppe or Plateau. In the upper valleys that slope down from this great mountain mass are found isolated tribes strikingly different from the Tatar races all around them, and shewing what are believed to be affinities, both in physique and language, with the Aryan races.

groups. In these, the relational part of thought obtains prominent vocal expression by separate roots, joined or *glued* on to the significant roots as terminations. These terminations were originally themselves significant roots, and many of them are still used as separate significant words, although the greater part have sunk down to mere signs of cases and other relations. The compound expression thus formed never, however, attains perfect unity; the significant root always remains rigid, unobscured in its sense, and unchanged in form, and the termination is felt as something distinct from the body of the word.

Thus, the Finnish declension exhibits a structure of the most mechanical and transparent kind —*e. g. karhu*, bear; *karhu-n*, of the bear; *karhutta*, without bear; *karhu-sta*, out of the bear; and so on through fifteen cases. The insertion of the plural suffix, *i*, gives *karhu-i-n*, of the bears; *karhu-i-ta*, without bears; *karhu-i-sta*, out of the bears; &c. But this composite mechanical structure reaches its climax—remaining all the while perfectly transparent—in the Turkish verb. Thus, the root *sev* has the indefinite meaning of loving, and the inf. is *sev-mek*, to love; which then, by the insertion of certain suffixes, can take on as many as forty forms or voices—*e. g. sev-me-mek*, not to love; *sev-e-me-mek*, not to be able to love; *sev-dir-mek*, to cause to love; *sev-dir-ish-mek*, to cause one another to love; *sev-il-mek*, to be loved; *sev-il-e-me-mek*, not to be able to be loved; &c. Each of these forms, then, runs through a large round of tenses and moods, with their persons and numbers.

The languages of the American Indians are all of this agglutinating type, although they have also got the name Incorporative, or Intercalative, because they run a whole phrase or sentence into one word—*e. g. hoponi*, to wash; *hopocuni*, to wash hands; *hopoaduni*, to wash feet; *ninacaqua*, I (*ni*) eat (*qua*) flesh (*naca*). The Basque language partakes of this character. In building these compounds, it mostly happens that only fragments of the single words are used. Thus, in Mexican, *alt*, 'water;' *chichiltic*, 'red;' *tlacatl*, 'man;' and *chorea*, 'weep,' are clipped and fused into *achichillachocan*, which means, 'the place where people weep because the water is red.' Similarly, the Basque language makes *ilhun*, 'twilight,' out of *hill*, 'dead,' and *egun*, 'day;' and *belhaun*, 'the knee,' from *belhar*, 'front,' and *oin*, 'leg.'

It is only in the third or *Inflectional* stage that perfect unity of the two elements is attained. In the Aryan and Semitic tongues, which alone have reached this highest state of development, the significant root and the termination have become blended into one both in effect and form, and phonetic changes have for the most part obliterated the traces of composition. Yet no doubt is felt by philologists that the most highly organised of the inflecting or amalgamating languages began with the radical stage, and passed through the agglutinate. The analytic powers of comparative grammar have succeeded in tracing back the formal elements of the Aryan tongues to original independent words, agglutinated to other words to modify them. Of this we have given numerous examples when speaking of word-building. Against this theory it has been urged, that there is no historical instance of a language so changing its type, and passing from one stage to another. But a sufficient account of this phenomenon may be found in the different mental habits and political positions of the peoples (see Max Müller, *Lectures on the Science of Language*, First Series, page 316). Besides, the languages of the lower types do shew a tendency, under favourable circumstances, to produce grammatical forms of the higher kind. Even in Chinese, in some of its modern dialects, something like cases is to be seen; and Finnish and Turkish, in contact with the inflected languages of Europe, are making approaches to the inflectional type.

On the other hand, the inflectional languages had, before the earliest times of which we have any written monuments, entered on the reverse phase —the *analytic*. By the process of phonetic change and decay, the grammatical forms have been gradually becoming obliterated and losing their power, and their place has been supplied by separate words, in the shape of prepositions and auxiliary verbs.

No satisfactory classification of the monosyllabic and agglutinate languages has yet been made. This is owing partly to the nature of their structure, and partly to the circumstance that they have been less thoroughly studied. They may be arranged in groups having more or fewer points of similarity; but it has not been conclusively shewn with regard to any group that the members of it are genealogically related—that the features of resemblance are owing to a common parentage. The more cautious school of philologists object to the term 'Turanian Family,' which has been much used to comprise 'all languages spoken in Asia and Europe (including Oceania), and not included under the Aryan and Semitic families, with the exception of Chinese and its cognate dialects.' They would restrict the term Family to the two genealogical groups, the Aryan and the Semitic. Only in one other case, that of five of the so-called 'Turanian Family,' the Finnic, Samoiedic, Turkic, Mongolic, and Tungusic, would the evidence of family affinity seem to be strong; and even that is spoken of with hesitation. This group has been called the Alatyan group or family, from the name applied by the Tatars of Siberia to themselves. As a convenient way of designating the languages which are not Aryan and not Semitic, it has been proposed to call them Sporadic, *i.e.* scattered, or Allophylian, *i.e.* spoken by other different tribes (see Farrar's *Families of Speech*).

On the principles of classification above sketched, the chief languages of the earth may be thus arranged:

I. *Monosyllabic or Isolating.*—1. Chinese, the typical language of this order. 2. Tibetan, which shews some beginnings of grammatical forms. 3. The languages of the Eastern Peninsula—Siamese, Anamese, Burman. Japanese and the language of Corea are doubtful.

II. *Agglutinate.*—1. The Alatyan group above described. 2. The Dravidian languages spoken in the south of Hindustan (Canarese, Tamul, Telugu, &c.). 3. North Asiatic (Kamtchatdales, Kuriles, &c.). 4. Malayo-Polynesian group. 5. African Languages. Some of the languages of Africa are allied to the Semitic family, and were introduced by immigration, such as the dialect of Tigré in Abyssinia and the Arabic dialects spoken by the

Mohammedan population of the coasts, and which have even penetrated deep into the interior. How far the Berber dialects are of Semitic character, is a disputed question; and the same is the case with the language of the Gallas in Abyssinia. Little has as yet been done in investigating and classifying the native Agglutinate languages of Africa, which have been designated by the common name of Hamitic. The ancient Egyptian, from which the modern Coptic is derived, would seem never to have got beyond the isolating stage. Some of the languages adjoining Egypt are thought to be allied to the Coptic. The Negro languages, properly so called, of the Sudan, and of the west coast from the Senegal to the Niger, are exceedingly numerous and widely diverse. The languages to the south of the equator are markedly different from those to the north. They fall, according to some, into two great families, the Congo family on the west, and the Kafir family on the east. The Hottentot language is distinct from both. A valuable contribution to the study of part of the field is to be found in Bleek's *Comparative Grammar of the South African Languages* (1862). 6. The Languages of the American Indians. The native languages of the New World are numbered by many hundreds, all differing totally in their vocabulary, but still agreeing in the peculiar grammatical structure which has given the name of Incorporative. Their area is fast contracting, and they seem destined to disappear. 7. The Basque or Euscara.

III. *Inflectional.*—This order consists of two families, the Aryan and the Semitic, so distinct in their grammatical framework that it is impossible to imagine a language of the one family derived from one of the other. It is the peoples speaking these languages that have been the leaders of civilisation within the historic period (see pp. 25–28).

ARE ALL LANGUAGES SPRUNG FROM ONE?

Connected with these radical differences of type, is one of the higher and more speculative problems of the science—the question as to the common origin of all languages. The inherent and apparently ineffaceable difference of structure in the three orders above described, as well as the absence of all sure marks of genealogical affinity even between the two families of the inflectional type, the Aryan and the Semitic, are considered by some as insuperable objections to the theory of a common origin. But although it may be fruitless to look for extensive identifications of the roots and grammatical forms of the Aryan tongues, even in the oldest forms to which we can trace them, with those of the Semitic, still more with Chinese or Turkish elements; it seems rash and unscientific to affirm that, going back to the radical stage, the development of all could not have begun from a common stock of monosyllabic roots. The wonderful transformations exhibited by language in the course of its known history, seem sufficient ground for maintaining the *possibility* of a common origin. On the other hand, the nature of the case forbids all hope of ever being able to *prove* it; for the coincidences that occur (*e. g.* Chinese *fu*, Tibetan *pha*, Lat. and Gr. *pa*-ter, Eng. *fa*-ther; Chin. *mu*, Egyp. *mu*, Lat. and Gr. *ma*-ter, Eng. *mo*-ther), even though they were much more numerous than they are, might well arise from the mind and vocal organs of man being everywhere essentially the same.

MIXTURES OF LANGUAGES AND RACES.

On counting the words in one of our larger English dictionaries, it is stated that about 13,000 are of Teutonic origin, while 29,000 can be traced either mediately or immediately to Latin.* It might seem from this that English ought to be classed along with French, Italian, and Spanish, as one of the Neo-Latin or Romanic tongues. But if we take a page of an English book and count the words as they occur, an overwhelming majority will be found to be Teutonic. Thus there are only three Latin words in the Lord's Prayer. All the words of most frequent occurrence—the articles, pronouns, prepositions, and auxiliary verbs, together with the names of the most familiar and essential conceptions, without which there could be no communication—are all, or nearly all, from the Anglo-Saxon. Its grammatical apparatus, too, is purely of the same origin. From whatever source they may have come, when once adopted into English, a noun forms its plural in *s*, and its possessive in *'s*; a verb has its past tense and past participle in *d*; and an adjective is compared by *er* and *est*. The life-blood of English is thus Teutonic, and this determines its relationship. There is no such thing as a mixed idiom. Whenever two languages come in conflict, by the peoples speaking them being mixed, they may exist distinct side by side for a time, but they always end by one giving way to the other, being either altogether extruded, or in part absorbed and assimilated by the other.

It is not always the tongue of the more numerous people that carries the day. The Roman armies and officials that conquered and ruled Gaul, were few compared with the native inhabitants; yet the subject Celts had in a few generations entirely given up their own tongue, and taken to speaking Latin as they best could. They felt the superiority of the Romans in culture, and adopted their language as the most direct expression and vehicle of that culture. It was the same with the handful of Sanscrit-speaking Aryans, who, unknown centuries before the Christian era, migrated from Bactria into northern Hindustan, and imbued the millions of its previous inhabitants with their language and religion. On the other hand, the Franks and other Germanic tribes who subdued Gaul in the 5th century A.D. were at least as numerous as the Roman conquerors had been; but this time, the language of the subject people, the Romanised Gauls, was the cultured language; it was, too, the language of the new religion, to which the heathen Germans soon submitted; and thus the dominant people dropped their own language, and adopted that of their subjects, infusing into it, however, a good many Teutonic words, still recognisable in modern French (*e. g. guerre* = Eng. war, *marche* = Goth. *mark*, a boundary). The disappearance of

* Other enumerations make the proportion of the Teutonic element greater than that stated in the text. In fact, if we set aside the more strictly technical terms that occur only in books of science and art, and look at the vocabulary of general literature, the Teutonic words are even more numerous than those of Latin origin.

the Scandinavian tongue of the Northmen who settled in the north of France in the beginning of the tenth century, was still more rapid and signal. When the descendants of those Northmen conquered England, only a century and a half afterwards, they were thorough Frenchmen in tongue. This conquest gave rise to another struggle between a Teutonic tongue and the Neo-Latin. In this case, the two were in some respects on an equal footing. The Anglo-Saxon was a cultivated literary language as well as the Norman-French; and both peoples were Christian, so that neither had to adopt the religion of the other. The struggle was therefore long, and the result doubtful. The French had the advantage of being the language of the ruling class and of the courts of law; and if, in addition, the subject people had been heathens, and had received their religion from their conquerors, the inhabitants of Britain would, in all probability, have now been speaking a French dialect. As it was, the Norman-French had to yield to the weight of numbers, and be absorbed and assimilated by the Anglo-Saxon. It had to content itself with furnishing about half the vocabulary of the common language now spoken by the united peoples, while its rival furnished the rest, and the mould in which the whole was cast, the grammar. In the effort of assimilation, however, the Anglo-Saxon grammatical forms were dislocated and shattered, and now exist only in a mutilated form, as compared with the German dialects, which have not come through a like crisis.

ROOTS.

Root, in Philology, is that part which is common to a group of allied words—the germ out of which they have all sprung. It is arrived at by taking away the formative parts—the suffixes and affixes, and reversing any change that their presence may have caused. Thus, in co-in-*cid*-ence, the root-syllable is *cid*, the primary form of which in Latin is *cad*, to fall. It is seldom that this analysis can be successfully performed with only one language; in order to get at the true root, the corresponding words in all the languages of the same family must be compared. Thus, in the Eng. words *story*, *history*, *historical*, *historically*, *histor* would seem to be the root; but by comparing the Greek with the Latin and Sanscrit, we arrive at a syllable *vid*, meaning to see or know, of which the Eng. (to) *wit* (wist) is only another form. And even then we are not sure that we have arrived at the original and most simple form. Thus, Eng. *yoke*, Lat. *jugum*, come from the syllable *jug*, to join, seen in Lat. *ju(n)go*, Gr. *zeugo*; and this might be rested in as the root, were there not a simpler form, *ju*, preserved in Sanscrit, and having the meaning of mingling or being together; this, which may be taken as the primary root, gives rise to the two secondary roots or modifications, *jug*, to join, and *yudh*, to fight (*i. e.* to join battle).

The roots of the Aryan languages are always monosyllabic, as *i*, to go; *ga*, to go; *ad*, to eat; *vak*, to speak; *star*, to strew. They are divisible into two classes, the one expressing some action or general property, as in the instances now given; the other indicating relative position, as *ma*, here or me; *ta*, there or that. The one class are called *predicative* roots; the other, *pronominal*. They all expressed primarily some physical notion or relation palpable to the senses; but from these the transition to the impalpable conceptions of the mind is natural and obvious; thus, *vid*, 'to see,' served also for 'to know.' The notion expressed by a root-word is always of a very general kind; but by a variety of expedients, such as lengthening the vowel, reduplication of the syllable, prefixing and affixing letters and syllables (many of which at least are evidently pronominal roots), and composition with other predicative roots, one germ gives rise to a whole group of words expressive of the specific applications of the generic idea; *e. g.* from the root *spac* or *spec* (in Gr. *skep*), to look, have sprung a numerous family of words in the English and other kindred tongues; *spy*, *despise* (to look down upon), *spite* (through old Fr. *despit*), *respite*, *respectable*, *suspicion*, *prospect*, *inspect*, *auspices*, *speculum*, *species* (*i. e.* the appearance or individual form, as opposed to the kind or genus), *spices*, &c. From the root (Sans) *vid*, (Gr.) *id* or *eid*, (Lat.) *vid*, (Teut.) *wit* or *wis*, there are upwards of a hundred derivatives in the English language alone.

It requires but a few germs to produce, by the processes above described, the most copious vocabulary. The 50,000 words of the Chinese dictionary are formed from 450 roots; those of Hebrew and of Sanscrit are reckoned at about 500; and there are probably not many more in English.

ORIGIN OF LANGUAGE.

Having seen how words grow or are built up, and traced them back to their roots, a still further question presents itself: how, namely, these roots, this raw material of language, came first into existence? Although this question is purely speculative, it is more attractive to most minds than the more matter-of-fact inquiries we have been considering. It was, in fact, the question with which all inquiries into the nature of language began; and in recent years a whole crop of treatises on it, by the most distinguished philologists of the day, have made their appearance. As was inevitable in a matter of the kind, diverse views are advocated; we can only afford to state, briefly, and with as little controversy as possible, the view that seems to us the most reasonable.

Man speaks because he thinks and feels, and, being a social animal, has a desire to communicate his thoughts and feelings to his fellows. The impulse to utterance of some kind, either of gesture or vocal sound, seems instinctive; and a sound uttered repeatedly in connection with a particular object or impression, would become by association a sign or symbol of that object or impression. Even the lower animals, some of them at least, seem able to go a little way in this direction. But man alone possesses the faculty of analysis and abstraction necessary to convert such marks of individual things into symbols of more generalised conceptions—to make them words instead of mere animal sounds.

The necessity of words to think in is much insisted on by speculators on this subject, as being the motive-power in the generation of language; and no doubt it is true that, without language, thought could advance but little, if at all, beyond what is manifested by the brutes. But when they argue as if this necessity of having his ideas objectively depicted, in order to exercise his own

reason, would impel an individual man to construct a language for his own use, they make the unwarranted assumption that, under any circumstances, even though he grew up from infancy in solitude, the thinking powers of a human being must of necessity develop themselves. The necessarily few facts that bear on the case look the other way. Kaspar Hauser, the mysterious German youth, who had been kept in seclusion from childhood to the age of seventeen, instead of elaborating a system of symbols of thought for himself, had forgotten what he had once possessed; his faculties of thought and of speech seem to have been simultaneously arrested. Observation rather favours the opinion, that man in solitude—if he could exist in solitude—would be as mute as the lower animals. The social nature of man helped to give birth to the germs of speech, no less than his rational nature. An instinctive desire to give a sensible sign of his impressions to his fellows, was perhaps the primary impulse; the aid thus given to his own thinking powers, a secondary result.

The main question in this speculation is—what determined particular vocal sounds to be first uttered in connection with particular objects and ideas? One view is, that the conscious nature of man responded to the impressions made upon it, as a solid body does when struck; and thus produced a number of 'phonetic types,' which formed the roots of language. This is known as the 'ding-dong' theory, and is unsupported by any facts or positive arguments. The analogy of the bell does not hold; unless we could find one that gave out a different note for every object it was struck with. Any mysterious inherent correspondence between any one conception of the mind and a particular articulate sound is out of the question. As little can we think of the choice of an audible mark being altogether arbitrary or fortuitous. The sound uttered must have been suggested by something connected with the object or action itself; and by what more naturally than by the inarticulate sound which the object or action emits?

Every language contains numerous words formed on this imitative principle, such as *cuckoo*, Lat. *cucu*(lus); *pee-wit*, Dutch *kie-wit; cock; clash; rap; tap; quack; rumble; whizz; clang*. Such words are called onomatopœian or onomatopoetic, from the Greek compound *onomatopoieia*, signifying, literally, the invention of names, and used by philologists to denote the formation of words in imitation of natural sounds. The opinion that all language began in this way, is known as the 'Onomatopoetic Theory.'

The chief objection to this theory is, that if the first words were merely reproductions of natural sounds, the same natural objects would have had the same names all the world over. To which it is answered, that the mind in its first efforts at naming did not seek an exact reproduction of the sound, but a suggestive imitation; primitive words were not echoes, but 'artistic representations.' Now, the sounds of nature are not simple, but composite. Like other concrete phenomena, they present a variety of aspects; and according as one or another aspect seemed the most prominent to the observer, a different vocal sound would suggest itself as the appropriate symbol. Thus, when Professor Max Müller argues (*Science of Language*, London, 1861), that if the 'bow-wow' theory, as he nicknames it, were true, men would have everywhere spoken of a *moo*, as is done in the nursery, and not of a *cow;* it seems a valid answer to say, that the Indian *gu*, the Teut. *kuh* (Eng. *cow*), and the Græco-Lat. *bou-*, are really as suggestive imitations of the animal's actual voice as *moo*. To take a more striking instance: few words differ more in sound and aspect than the Eng. *thunder* (Ger. *donner*, Lat. *tonitru*, Fr. *tonnère*) does from the Mexican name for the same thing, *tlatlatnitzel;* and yet it would be difficult to say which is the more suggestive of the natural sound.

It is no doubt true that the great bulk of names are derived from roots having a general predicative power; but this by no means excludes the principle of onomatopœia. Thus, to take one of those instances adduced by Professor Max Müller himself, that of *raven* or *crow* (Sans. *kârava*, Lat. *corvus*, Gr. *korônê*); this is derived from the root *ru* or *kru*, which means to cry or call, and the bird was called a kârava, or crow, not in imitation of his voice, but because he was 'a shouter, a caller, a crier. The name might have been applied to many birds, but it became the traditional and recognised name of the crow.' But how came the articulation *ru* or *kru* to be chosen to convey the general meaning of crying or calling? May we not suppose that it was suggested by the voice of birds of the crow kind, whose notes are most markedly cries or calls to their fellows, as distinguished from singing? Once adopted in this particular case, it would naturally be extended to any kind of cry or call, from the harshest to the softest.

In the case of ideas unconnected with any natural sound, names would readily be suggested in many cases by analogies, real or fancied, with things that were attended by sounds (*e. g.* a *loud* colour).

The imitative theory by no means excludes the view that words may grow out of those natural involuntary exclamations—those *ahs* and *ohs* and *poohs*—which seem produced by a reflex action of the emotions on the outward organs. It is highly probable that the natural organic expression of disgust, *ugh!* gave rise to Eng. *ugly*, Old Eng. *ugsome*. Eng. *woe*, is clearly cognate with the Latin and Greek interjections *vae* and *ouai*.

But although language may have had its first beginnings in this way, it is hopeless to look for traces of onomatopœia in the great bulk of the words of any modern tongue. We have seen how a general name for 'calling' might arise from an imitation of the crow's voice. The operation of this principle, and that of phonetic change, which makes it impossible to say what the very earliest form of a root may have been, are sufficient to account for the absence of such traces, except in comparatively rare instances.

CONSTITUTION OF SOCIETY—GOVERNMENT.

MAN is a gregarious, or, as Aristotle said, a political animal; that is, he loves to herd with his fellows—to live in society. There are, indeed, instances of men fleeing society, and spending existence in solitude, but these unhappily disposed individuals form rare exceptions to the general rule.

FAMILY RELATIONSHIP—MARRIAGE.

The origin of civilisation has recently been the object of earnest investigation by numerous inquirers, who seem to have made it clear that in the lowest stages of savage life the family relation does not exist. The same authorities hold that all branches of the human race have passed through this lowest stage. Be this as it may, the formation of the family is the first step toward the formation of the civilised community. A family consists of husband, wife, children. This is not an accidental or arbitrary arrangement. The family originates in the necessities of our nature, and springs up inevitably wherever that nature develops itself. Accordingly, all attempts to encroach on the obligations or the privileges of the family are simply attacks on civilisation. In antiquity, slaves were regarded by their masters, and regarded themselves, as members of the family, and it is a very poor account of Christianity if a less kindly and intimate relation prevails between masters and servants in modern times. The relation of master and servant, by whatever name we choose to call it, is necessary for the purposes of civilisation, and is founded on nature, just as much as the relation between parents and children, or husbands and wives. If God has bestowed a progressive nature on man, he must have intended that some men should, by the aid of others, be freed from domestic occupations which, by absorbing their time, would prevent them from devoting themselves to those pursuits on which progress depends. The relation between master and servant is one of mutual obligation. It imposes duties on the former as well as on the latter, and it is a very low view of it, particularly within the domestic circle, to regard it as a mere pecuniary arrangement.

The fundamental object of the family compact is a due provision for the affections, and for the nurture and education of rational beings, and free and orderly citizens. This is insured by the matrimonial engagement—a solemn covenant between a man and a woman to attach themselves to each other through all the contingencies of life, till the death of either dissolve the union. In every nation removed from barbarism, marriage is a recognised ordinance, guarded by law and custom. In some eastern countries, polygamy, or the marriage of a man with many wives, has long been tolerated; but that relations of this kind are unnatural, is testified by the fact, that polygamy is degrading to the female sex, unfavourable to the rearing of children, and that it is inconsistent with the numerical equality of the sexes. In all countries in which polygamy is tolerated, woman occupies a degraded position, and society is rude and unexpansive in its character. Nature has designed woman to be the equal of man as a moral and intellectual being; and when she confines herself to the exercise of her proper duties as a wife and mother, she is placed in a favourable position as regards her own happiness and the happiness of her husband. And all this can only be realised by monogamy—the marriage of a man with but one wife. We have deemed it necessary to state thus unequivocally at the outset what appear to be the primary principles of human relationship; for there are not wanting those who would endeavour to rear systems of society in which the family compact is to have no place, and parental care is to be absolved from its duties—a dream which the common-sense of mankind will ever reject as visionary.

Society, as has been shewn, is necessarily composed of distinct families. The manner, however, in which these families should associate with respect to each other, is a question which has been often agitated, and here deserves some degree of notice. The true explanation, we think, lies in an appeal to nature.

It would appear that from the beginning of the world every nation has consisted of a certain number of families, and that each family, in its general circumstances, has been independent of others. Families, in the patriarchal times, may have been less or more dependent on, or connected with the head of a tribe; but we nowhere read of families yielding up their individual identity, and living in private community with each other. In all the higher races of mankind, at anyrate, each family has always had its own house, its own joys, sorrows, hopes, fears, and historical traditions. Each father of a family, a sovereign within his own domain, has been left to govern his little realm, and to undertake the obligation of finding his wife, children, and domestics in the means of daily subsistence.

A practice so universal cannot be supposed to be a violation of either nature or convenience. It has sprung up from the wants and feelings of mankind, and may be said to be a spontaneous result of unalterable circumstances. Tracing it to its true source in the mental and physical constitution, we find that it affords the widest scope for personal enterprise, perseverance, and other useful emotions. It is an error to suppose that it is selfish in principle, because it is the form of existence which best ministers to the good of the whole state, and even the whole community of mankind, as well as to that of each separate household.

In opposition to the exclusiveness inseparable from the family relations, it is urged that, by leaving society to spontaneous arrangement, there comes a time when each nation is consumed by its internal disorders. The clever, the industrious,

and the persevering become wealthy; vast numbers, either from lack of capacity or opportunity, sink into a state of extreme indigence; and a number become criminals, and prey on the rest. There is truth in this severe statement of facts; for in every nation there are rich and poor, good and bad. Nevertheless, such a mingled tissue is an inevitable consequence, not of the structure of society, but of human nature, on which society is founded. We must seek a remedy in the improvement of man's moral and intellectual constitution, not in subverting the whole organisation of society, and attempting to reunite it on fantastic principles at variance with nature. Nor should any alarm be entertained respecting the lamentable evils which seem to be inseparable from society as it at present exists. These evils, and they are great, will never utterly disappear, because human perfection is unattainable, but they will in time be much modified. In every region, society goes through a period of barbarism, during which many cruelties are perpetrated and privations endured; after this, as men become enlightened, the worst kind of evils gradually disappear, and others of lesser severity remain. At present, society in Great Britain and most civilised nations is in a transition state from barbarism to enlightenment. Within even the recollection of men now living, the steps in advance have been considerable, and every year adds to the number of both physical and social meliorations. Whatever may be the fate of individuals or nations who, from sensuality, vanity, and other forms of selfishness, neglect their duties to others and to themselves, there can be no reasonable doubt that society, as an institution of God and nature, will continue to improve, and that much that is now matter for regret and reproach will be amended or removed.

UTOPIAN COMMUNITIES.

Ingenious men have at different times conceived to themselves the idea of a state of society, or republic, in which vice, sorrow, indolence, poverty, and other evils shall either be unknown, or at least reduced to a scarcely perceptible amount. None of these theories has gained so much celebrity as that announced by Sir Thomas More, under the name of Utopia (from a Greek word signifying *no place*). The author was Chancellor of England in the reign of Henry VIII. and was a man of the highest and most honourable character. His work was written in Latin, and the elegance with which he propounded his apparently benevolent but really satirical scheme, has made the name of his imaginary republic to be adopted in our language as a current expression to denote any plan of social economy which is founded on views of human nature too favourable to be practicable.

The work was written not long after the discovery of America, near which continent, south of the line, the island of Utopia is supposed to lie. The story of discovering this island is represented as being told by a venerable traveller, whom the author met at Antwerp.

The *Utopia* of Sir Thomas More was suggested to him, no doubt, by the reading of Plato's *Republic*, which has been the parent of all such proposals. In later times, schemes not very dissimilar have been seriously proposed by benevolent speculators, and partly carried into practice, though with no prospect of permanent continuance. At the head of this class of projectors may be mentioned Robert Owen and Fourier, the latter a religious enthusiast in France. Generally stated, these plans consist in causing fifty or a hundred families, as the case may be, to live in one community, in which all are to labour for the general behoof, and all to be supported on equal terms out of the common stock. Individual property is to be unknown; all personal feelings are to be sunk in that of the community. How it is proposed to meet differences as to the education of children, religious belief, and other important matters—how evil passions are to be extinguished, or what is to be the consequence of the idle preying on the industrious, has never been satisfactorily explained. According to Fourier, we believe, members seriously transgressing the rules are to be expelled the community; which amounts to a giving up of the whole principle. If the community cannot reclaim and retain its evil-disposed members, the scheme is confessedly worthless. Defective as ordinary society is allowed to be, it does not eject the most vicious or the most improvident of its members—for the criminal it finds prisons and penitentiaries, and to the poor and starving it offers workhouses; even the most dissolute can pick up an alms. The fundamental error of all such schemes consists in the notion that society is the result of human ingenuity, and admits of being reconstructed and remodelled at will; whereas it rests upon natural laws, and results from individual characteristics, which are as unchangeable in their action as those which govern growth and decay in the vegetable world. It is no more possible to make all men equally good, and wise, and happy, than to make all trees grow equally straight or equally tall. And out of the natural inequalities and diversities of gifts and endowments, spring the inequalities of means, and the diversities of position—in a word, the whole organic structure of society as it exists, and, with such improvements as advancing civilisation may bring along with it, always must exist. By observing its laws, we may improve the condition of its individual members, as we may improve the plants in our gardens by observing the character of the soil, and the effect of the means which we employ to enrich it. But we can no more change their individual characteristics, or obviate the consequences and relations which naturally result from their peculiarities, than we can convert onions into apples, or make plants grow with their roots in the air.

PATRIARCHAL SOCIETY—CLANSHIP.

The patriarchal condition of society has prevailed in Arabia and other eastern countries from the most remote periods of history. It is the most simple kind of social union. A patriarch, so called from a word signifying father or head of a family, is the head or governor of a tribe, who obey his orders, and depend in a great measure on his judgment. Generally, the office of patriarch is hereditary, but it is also sometimes elective, though very generally in the same family. The most distinguished of the ancient patriarchs was Abraham, the great progenitor of the Hebrew nation, who was originally a dweller in Arabia.

The leaders of tribes in these pastoral regions are now known by the title of *Sheiks*—the word sheik in Arabic signifying the elder or eldest.

In this rudimentary state of society, the tribe has usually no fixed residence, but wanders from place to place in company with its flocks and herds, in quest of pasture, or for the sake of hunting wild animals. In making their long and toilsome journeys through the wilderness, the families and tents are carried on the backs of camels. From leading this wandering life, the members of these tribes are called *Nomades;* or are said to be *nomadic* in their habits, from a Greek word signifying pastoral.

From the accounts given of the patriarchal ages in the Bible, a much more favourable idea is formed of nomadic life than a close inspection is found to warrant. Carried away with pleasing fancies respecting pastoral simplicity and freedom from the cares of civilisation, we are apt to forget that human passions are the same in all ages and countries, and that every condition of life has its own peculiar difficulties and vexations. The truth seems to be, that this roving, haphazard mode of existence is full of miseries, and that force is the only law. Mr Stephens, an American traveller, who journeyed through Arabia Petræa, under the hired protection of a number of Bedouins, headed by their sheik, thus destroys the gloss which had been thrown over the nomadic social system:

'One by one I had seen the many illusions of my waking dreams fade away; the gorgeous pictures of oriental scenes melt into nothing; but I had still clung to the primitive simplicity and purity of the children of the desert, their temperance and abstinence, their contented poverty and contempt for luxuries, as approaching the true nobility of man's nature, and sustaining the poetry of the "land of the East." But my last dream was broken; and I never saw among the wanderers of the desert any traits of character, or any habits of life, which did not make me prize and value more the privileges of civilisation. I had been more than a month alone with the Bedouins; and to say nothing of their manners—excluding women from all companionship; dipping their fingers up to the knuckles in the same dish; eating sheep's insides; and sleeping under tents crawling with vermin, engendered by their filthy habits—their temperance and frugality are from necessity, not from choice; for in their nature they are gluttonous, and will eat at any time till they are gorged of whatever they can get, and then lie down and sleep like brutes. I have sometimes amused myself with trying the variety of their appetites, and I never knew them refuse anything that could be eaten. Their stomach was literally their god, and the only chance of doing anything with them was by first making to it a grateful offering; instead of scorning luxuries, they would eat sugar as boys do sugar-candy; and I am very sure if they could have got pound-cake, they would never have eaten their own coarse bread.

'One might expect to find these children of nature free from the reproach of civilised life—the love of gold. But, fellow-citizens and fellow-worshippers of Mammon, hold up your heads! this reproach must not be confined to you. It would have been a pleasing thing to me to find among the Arabs of the desert a slight similarity of taste and pursuits with the denizens of my native city; and in the early developments of a thirst for acquisition, I would have hailed the embryo spirit which might one day lead to stock and exchange boards, and laying out city-lots around the base of Mount Sinai or the excavated city of Petra. But the savage was already far beyond the civilised man in his appetite for gold; and though brought up in a school of hungry and thirsty disciples, and knowing many in my native city who regard it as the one thing needful, I blush for myself, for my city, and for them, when I say that I never saw one among them who could be compared with the Bedouin; I never saw anything like the expression of face with which a Bedouin looks upon silver or gold. When he asks for bucksheesh, and receives the glittering metal, his eyes sparkle with wild delight, his fingers clutch it with eager rapacity, and he skulks away like the miser, to count it over alone, and conceal it from all other eyes.'

The same species of patriarchal society prevails, as is well known, among the tribes of North America; each tribe being governed by its chief, an arrangement which does not prevent it from being exposed to all the calamities of a state of untutored nature.

Out of the patriarchal condition of society in the East, sprung the system of clanship, long prevalent among Celtic nations after they had ceased to be nomadic. The word *clan* signifies family, and is applied to a tribe claiming to be descended from one head; the lineal descendant of which is the chief. All the members of the clan consider him as a common father and protector, to whom they owe an implicit obedience. This form of society was brought into Western Europe by the Celts in exceedingly early times, and disappeared slowly before the encroachments of the Teutonic races. The last of its strongholds were the Highlands of Scotland, where it was finally abolished by law in 1748, and where it is now only known as matter of tradition or private feeling. The error of the patriarchal system, in point of principle, consists in the fact, that it relies on the paternal element in the social relations, to the exclusion of the fraternal. It thus prevents the development of individual character, and the formation of separate households. In this respect it is the antithesis of the democratic system, which recognises the fraternal to the exclusion of the paternal element, and thus, whilst stimulating individuality, breaks up the family, annihilates authority, silences tradition, and finally tends to destroy the historical character of a people. The patriarchal system is unprogressive, but its relation to barbarism seems accidental; and it cannot be shewn, in principle, to be retrogressive, like the systems which, resting on the supremacy of numbers, subject the higher to the lower social influences. All civilised nations have arisen out of a modification of the paternal system, but history as yet affords no example of a nation which has been held together by means of what is called 'fraternity.' It is only in subordination to the paternal that the fraternal bond retains its coherence, and becomes operative as a social force. It is from the relations of the family that we learn our relations as citizens of the state, and the first and most important family relation is that of parent and child.

SLAVERY.

That every human being possesses, as against every other human being, a free and inalienable right of property in his own person, seems an undeniable proposition; and yet it is one which even till this day is by no means universally recognised. In certain countries, there are individuals—men, women, children—who are not proprietors of themselves; they are bought and sold—treated as chattels; and they possess no civil rights whatsoever. A person in such circumstances is called a *slave*—a word of modern origin, supposed to be derived from the Slavi or Slavonians, whom the Venetian merchant-state had the cruelty to sell into bondage.

Slavery, in one form or other, has existed in the world from the most remote period of history. It existed, as we know, among the patriarchs. Joseph was sold by his brethren to a party of Midianite merchants, who carried him to Egypt, and there sold him to Potiphar (Genesis xxxvii.). A grievous famine having occurred in Egypt, the people, after disposing of all their property in exchange for corn, came to Joseph and offered their own bodies and their lands for food. Joseph complied with their request. 'Behold, I have bought you this day and your land for Pharaoh' (Genesis xlvii. 23). These occurrences alone, mentioned without comment, shew that selling and buying human beings was customary in those early times. From other parts of the Scriptures, we learn that a state of bondage, which was nearly equivalent to modern slavery, was a recognised institution among the Jews. So also did slavery exist among the ancient pagan nations—the Phœnicians, the Greeks, the Romans.

Nothing is more certain than that, in all countries in ancient times, there was a mass of the population in a state of compulsory and perpetual servitude. Even in what are termed the freest states of antiquity, a large proportion of the people were slaves, and possessed no civil rights. At the very time when Athens is spoken of as the model republic of antiquity, it contained 400,000 slaves, and only 20,000 freemen. The practice of slavery arose out of the selfishness of barbarism, and did not appear to its perpetrators either sinful or unjust. Debtors were seized, and, in liquidation of petty claims, sold like ordinary property by their ruthless creditors. Gamblers, having lost everything, staked their persons as a last chance; and being unsuccessful, became the bondsmen of the winner. Men, for their crimes, are still deprived of liberty, but in ancient times they were publicly sold into bondage. In cases of famine, parents disposed of their children, to relieve their own wants. And lastly came war, the scourge of mankind, and the fruitful cause of slavery in all ancient nations. 'It was a law established from time immemorial among the states of antiquity,' says a Greek author, 'to oblige those to undergo the severities of servitude whom victory had thrown into their hands.' There was an exception, however, in the case of civil war, the prisoners taken in which, like all prisoners of war originally, were not made slaves, but generally massacred. Besides the regular wars between nation and nation, it sometimes happened that a vagrant population overran an adjoining country, and made the peaceful and dispossessed inhabitants their slaves. Thus, the Spartans were served by a race of hereditary bondsmen, the old inhabitants of the district, called Helots—a term afterwards used by the Romans to designate men in a servile condition. The unfortunate Helots of Sparta occasionally rose in rebellion against their masters, and attempted to gain their liberty; but these efforts were always suppressed with merciless slaughter.

As Christianity spread over Europe, its beneficent influences modified slavery; and during the middle ages, the institution took the form of *serfdom*. The children born on an estate remained the *thralls* or bondsmen of the proprietor of the soil, and were bought and sold along with it, but could not legally be removed. In England and Scotland, the greater portion of the peasantry were serfs, or, in strict law-phrase, *ascripti glebæ*—that is, attached to the soil. Their masters retained them in perpetual servitude, fed them and cared for them, punished them for faults, and in some instances put metal collars round their necks, inscribed with their names and the names of their owners. This species of slavery disappeared in the progress of civilisation without direct legislative interference; it being, in reality, a greater burden to the land-proprietors than to their servants. The institution prevailed in Prussia till the beneficent legislation of Stein, and in Russia till the imperial decree of 1861, which came into full operation in 1863.

As is well known, slavery, in its more rigorous forms, is banished from every European nation except Turkey. In some parts of Asia and Africa, it exists in its original force, and having, as regards Negroes, been transferred to America, it flourished even in many of the southern states of the union up to the period of the late war, of which its abolition, whether it was the object or not, was certainly the result. Whether the inferior races of mankind, if such there be, will succeed in availing themselves of the liberty which has almost everywhere been bestowed on them, is a problem which time and experience only can solve. But their right to make the experiment cannot be questioned.

INDIVIDUAL RESPONSIBILITY—CIVIL SOCIETY.

Civil society is constructed on a system of individual efforts and interests. Each person is expected, so far as he is able, to act an independent part, controlled only by law and usage. While every one is free, therefore, he is at the same time bound to contribute to the maintenance of the society of which he forms a part, to give obedience to all existing laws, and respect to all properly constituted authorities. In consequence of the general freedom which every one enjoys, and in contradistinction to so-called *socialist* communities, society is said to be founded on the *competitive* principle. No one being interfered with, all are left to compete with each other in industrial enterprise. This may, and does, have the effect of causing a great disparity of condition—men of commanding abilities, steadiness, and perseverance usually attaining distinction and wealth, while those of weaker capacity, or who are less fortunate, lapse into poverty. Such is the arrangement of nature, and however mysterious or sad it may appear to us in individual cases, it is not difficult to see that, all things considered, freedom

of individual enterprise is most advantageous on the whole, and must therefore be carefully preserved as the basis of civil society. By holding out a premium for diligence, it induces mental culture and exercise, and affords all an equal opportunity of distinguishing themselves. It likewise ought to point out the duty of establishing systems of universal education, by which we should be assured that every one at least possessed the elements of instruction and opportunities of self-advancement. With respect to those who, from absolute incapacity, and other unavoidable circumstances, become poor, it is now a generally settled principle that they have a claim in law, as well as on principles of humanity, for support from their more fortunate fellow-creatures.

The organisation of civil society, though possessing a general resemblance, differs in a few particulars in every country. The chief difference consists in the diffusion of privileges. To understand distinctions of this nature, it is necessary to peruse a course of history, ancient and modern. Little can be learned from looking at the present aspects of things; we require to search the records of human progress for the origin of almost every institution, as well as for the philosophy which may be drawn from it.

Throughout Europe, society has generally arisen from similar circumstances. The rudimental germ of every state was a handful of adventurers, who, by military prowess, made themselves masters of the country. The leading men in such enterprises were chiefs with retainers. The principal chief became king; the chiefs assumed the character of an aristocracy; and the retainers, with the inhabitants whom they helped to subdue, from being at first serfs, finally attained the rank of freemen. It was long, however, before this latter result was achieved. For many ages, the chiefs or nobles holding lands by a military tenure from the sovereign, formed a feudal aristocracy, by whom in reality the whole system of government was conducted. The idea of imparting privileges to the common people, though recognised by the oldest institutions of the Teutonic races, was long in attaining practical efficacy—not only because the nobles needed vassals to execute their will, but because the humbler classes had really no means of an independent existence. (See HISTORY OF THE MIDDLE AGES.)

The original source of the political franchises of this country is the Crown. From having been companions and assistants of the sovereign, the principal barons were constantly encroaching on his prerogatives. Sometimes the concessions of the crown, as those of Magna Charta, made by King John, were necessary and desirable; but more frequently the nobles were inclined to exact so much power in the state as would have rendered the king's authority a nonentity. The danger of these encroachments caused the monarch to seek aid from the commons. With the view, therefore, of raising up a means of protection in this quarter, he encouraged the building of cities, to whose inhabitants he gave certain important privileges. The civic corporations, therefore, which in the older European cities continued to represent the Roman *municipia*, must be viewed as the cradle of freedom. From them sprung much of the present constitution of society. Relying on their privileges, and surrounded by walls, these burgher communities defied the nobles, and sided with the king. Sometimes the barons sided with the burghers, and to no historical individual do the commons probably owe so much as to Simon de Montfort, Earl of Leicester, who, in the reign of Henry III. and in the year 1265, ordered writs to be issued for the return of two citizens or burgesses, to represent every city or borough in the kingdom in parliament. From this time, the feudal principle declined, serfs were gradually emancipated, and ultimately every man was declared to be equal in the eye of the law.

It is necessary to be thus particular, for a notion prevails among the humbler classes that they have been deprived of rights enjoyed by their ancestors. History most explicitly shews that, in early times, the peasantry and operative bodies possessed no privileges whatever. Magna Charta does not so much as mention them. Society, in fact, has been quite a progressive development. Little by little, privileges have been widened in behalf of the citizen class, though by no means always by their own efforts, and if they continue to deserve them, there can be no doubt that they will go on widening as circumstances render it desirable. Doubtless, it may be alleged that all men are equal, and deserve to possess equal privileges; but to this assertion, contradicted as it is by the most ordinary observation and the most elementary common-sense, there are, as to all other false principles, practical as well as theoretical objections, which will always defeat the objects of those by whom it is made. Its realisation as the basis of society, would demand, as we have seen, a reversal of the laws of nature, and may safely be pronounced to be impossible, however great may be the confusion produced by such attempts to realise it as those which we have so often witnessed in France. Equality before the law—that is, the equal right of every man to be valued at what he is worth, not in his own eyes, but in the eyes of his fellow-citizens—is the only form of equality that is either just or attainable. If a man is dissatisfied with his position, it is he himself that must improve it by his own industry, intelligence, and frugality. The law cannot make him better than he makes himself. These are assertions apart from all party creeds, which lie at the root of political philosophy, and which the simplest citizen may substantiate by his own experience and reflection. Meanwhile, we desire to fix attention on the vast impulse given to civilisation by the erection of cities.

CITIES.

It is to cities or large towns that mankind chiefly owe the blessings of civilisation and the valuable institutions which they now enjoy. With cities, everything that is great and glorious—arts, science, literature—began, and after beginning, was duly fostered. Through their means, civil society began to assume a more systematic character. The division of labour, the refinements of social intercourse, the development of laws caused by the conflicting interests of many people living closely together, the idea of equality before the law, the growth of patriotism, springing from the sense of advantages enjoyed, and the exertions necessary to maintain them, were the salutary consequences of the establishment of cities.

Under the mild sky of Asia, Africa, Greece, and Italy, cities were built first, and in the greatest number. The Phœnicians and Egyptians particularly distinguished themselves by the erection of cities, which soon attained a high degree of wealth, and consequently of civilisation. The Egyptians considered their city Diospolis (Thebes) older than any of the Greek cities; and Pliny says that Cecropia (erected in Attica by Cecrops 1582 B.C. and afterwards called Athens) was the oldest city of Greece. Several confederations of cities existed in the ancient world; for instance, the Phœnician, consisting of the cities of Tyre, Sidon, &c.; and the Achæan League, formed by the most important cities of Greece, in order to strengthen themselves against the power of Macedon. Under Augustus and his successors, the Romans began to establish colonial cities in Germany, having done the same long before in Gaul, Spain, Africa, &c. In Switzerland, they first erected cities about 70 A.D. which, however, were mostly laid waste by the Alemanni, and subsequently rebuilt under the government of the Franks (496 A.D.).

The Germans, accustomed to a wild, rambling life, did not shew any disposition to live in cities, until Charlemagne laboured to collect them together in settled abodes, from his desire to civilise them. Henry I. distinguished himself particularly in this way, and on this account has been called by some Henry the City-builder. He gave the cities great privileges, in order to induce his subjects to live in them, and thus laid the foundation of that power which at a future period contributed most to break down the feudal system. In many cities, imperial castles were erected to protect the inhabitants; and the insupportable oppressions and even cruelties exercised by the feudal lords upon their peasants, or by the wandering knights and robbers, drove many people into the cities. The attacks of the neighbouring lords gave firmness to their union, and compelled them to cultivate their resources. Commerce, and the various arts and trades, were soon cultivated within their walls, and their wealth and respectability increased.

One of the most important remnants of the great fabric of ancient civilisation was the cities of Italy. What the world would have become without them is not to be calculated. In spite of their bloody contests with each other, and the vices to which these gave rise, they must be considered as having lighted the torch of modern civilisation. It was not the monarchies, it was not the courts of the great princes, it was the cities of Northern Italy which opened the way for the progress of improvement; and the petty princes of Italy caught from them the spirit which prompted their efforts to promote it. Under the reign of Conrad III. (1138–52), the cities of Lombardy, and particularly Milan, which stood at their head, had acquired a high degree of wealth and power, and had formed themselves into a confederation. The struggles between the emperors and these cities form one of the most important portions of the history of the German Empire and of Italy. Frederick I. in vain demolished the powerful city of Milan. It was soon rebuilt; and the cities of Lombardy, in alliance with the pope, obliged the emperor to conclude with them a very disadvantageous peace at Constance. Two other confederations of cities, highly important, were formed during the interregnum of the German Empire, between 1256 and 1272. One of them was the powerful league of the Hanse towns; the other, the confederacy of the High-German and Rhenish cities from the foot of the Alps to the mouth of the Maine, established, by Walpode of Mentz, in 1255. A similar confederacy, and a very important one, was that of the Swabian cities, instituted in 1488, to repel the outrages of the feudal lords and knights. By degrees, great cities arose in the different countries; and wealth, industry, knowledge, and equal laws spread from them through Europe.

Much has been said and written on the immorality of large towns and cities, and the fact cannot be denied; but immorality is not confined to them. The petty vices of small places, though less glaring, are perhaps equally injurious, making up in constant repetition for their comparatively less degree of noxiousness. It is much more difficult, moreover, to preserve one of the most important possessions — independence of character — in a small place than in a large one. The cry against the immorality of large cities should not make us forget the many great and admirable things which mankind have been enabled to perform by means of the collected strength of talents and resources combined in large cities, and their influence in forming the character of great men, who could not have acquired elsewhere their variety of accomplishments, and the well-proportioned cultivation of their various faculties. But though such considerations may be advanced to palliate, if not to controvert the charge of immorality against great cities, it is impossible to deny their exceeding unhealthiness. In the supplement to the monthly and quarterly returns for 1872, the Registrar-general says (p. 9): 'The several town and rural districts of Scotland shewed the usual striking differences in their mortality during the year just closed. Thus, for every 10,000 persons in each of the five new groups of districts into which Scotland is divided, there occurred 276 deaths in the principal towns, 251 deaths in the large towns, 215 in the small towns, 172 deaths in the mainland rural districts, but only 157 deaths in the insular rural districts. These facts might be otherwise expressed by saying, that there occurred one death out of every 36 persons in the principal towns, one death in every 40 persons in the large towns, one death in every 46 persons in the small towns, one death in every 58 persons in the mainland rural districts, but only one death in every 64 persons in the insular rural districts.' It is true that the birth-rate compensates the death-rate, the result being the production of a more and more numerous population, which goes on continually degenerating in physical if not also in moral and intellectual qualities. Yet, notwithstanding these deplorable facts, which are continually published on the highest authority, the country populations continue to pour into the towns both in this and, though in a minor degree, in other countries. The only remedy seems to consist in attempting, as far as possible, to counteract the now established law, that *the death-rate rises with the density of the population*, by spreading the cities over the country. It is a remedy which admits of extensive application, and which, there seems reason to hope, is now

beginning to be understood. The last census exhibits a very marked tendency in the poor population of London to migrate from the centre to the circumference, and the same tendency is perceptible in Edinburgh and in many provincial towns.

Capitals, in the modern meaning of the word, can hardly be said to have existed in ancient times; at least they were then only the seat of the sovereign, but not the centre of all the national activity, Rome only perhaps excepted; but this city was for a very long time the state itself, and, at a later period, the tyrant of the whole empire, rather than the head of a well-organised body. In Asia, there existed, indeed, in ancient times, capitals of very large empires; but they are not to be compared to the capitals of large modern empires, since the channels of communication and intercourse had not then reached that degree of perfection which enables them in our days to bring into close connection all parts of a country. Each province was, therefore, left much more to itself. It would be difficult to determine whether the good or evil consequences of large capitals in modern times are greater, and such an examination would far exceed our limits; otherwise, it would be very easy to point out, in every department of civilisation, in science, social intercourse, arts, &c. both salutary and pernicious effects resulting from the influence of capitals. It seems to us a matter of little doubt that it must be regarded as disadvantageous to any country if the capital ceases to be the concentration of the skill, genius, and strength of a nation, for the benefit of the whole; but by a disproportionate superiority it destroys the importance of the rest of the country, as we find to be the case with Paris, which, as has been often observed, contains France. In Germany, the state of things is quite the reverse. A multitude of university towns are scattered all over the country, and there is no city which may boast of being the point of intellectual concentration or refinement. The consequences have been very advantageous to science and literature. In politics, this want of a central point, as regards Northern Germany, has been remedied by the adoption of Berlin as the seat of the empire. London never exercised that degree of influence over England which Paris has over France; one reason of which may be, that the institutions for the diffusion of knowledge are not seated in the metropolis. The system of concentration has, there is little doubt, been carried to an extreme in Europe—the best of everything having been collected in the capitals, and the provinces having been almost stripped of pictures, libraries, &c. In many countries, this fault is acknowledged, and a return to a more equitable system is perceptible. The injury done to the provincial towns in Britain by the concentration of institutions of various kinds in the capital, is likely soon to be greatly modified, by the establishment of railways and other improved means of communication, which will tend to give all parts of the kingdom an equality of advantages.

GOVERNMENT.

If all mankind were naturally virtuous, and disposed to act justly and kindly towards each other, there would be little use in establishing any kind of government. According to ancient poets, there was once a period called the Golden Age, in which there prevailed universal peace and loving-kindness, and vice had no existence. Never was there such a period. The farther back we go in history, we find that society was the more rude. Civilisation has been a plant of slow growth, often retarded, and in particular countries almost rooted out for a time by erroneous conceptions of its character, and the conditions of its existence, but always springing up afresh. The world never was better than it is at this moment. According to all experience, society cannot exist without some species of government. It must possess a power to enforce order, to prevent the strong from oppressing the weak, to chastise vice, and perform many other necessary functions. The government may be better or it may be worse, but a government of some kind there must be. There will always, in every society, be some who have a desire to rule over others—to make others work out their purposes—and some who are satisfied to submit to the domination of those who are more ambitious. There will always be among those who are ambitious of governing, some who unite to the desire the talents necessary to enable them to attain their ends, and others who do not; some who seek to found their power upon their own force, or upon the prejudices of others, or upon their power of persuading or convincing men that they know better what is good for them than they do themselves. The propensities and faculties which induce and enable some men to aspire to be leaders, others to contest the leadership with them, and others, again, contentedly to follow the lead, are implanted in them by nature; they cannot help having or exercising them. But it is with these elements of our nature as it is with our instinctive propensities to eat and drink, to love or hate; by the proper use of their knowing and reflecting powers, men may so control and direct them as to render them instruments for producing great good and happiness to the whole human race. Government exists not to annihilate the power of individuals, but to direct it; for though the strong may be the greatest enemies of mankind, it is they only who can be great public benefactors.

FORMS OF GOVERNMENT.

The patriarchal and clanship systems of government have been already adverted to. With these, mankind may be said to have made a beginning. The next step in progress seems to have been a government by kings, which is only a more developed form of the patriarchal system, the kingly being a centralisation of the patriarchal or feudal power. In some ancient nations, a government of priests superseded that of kings. This species of government was called a *theocracy*, from *Theos*, the Greek word for God; it being represented by the priests that they ruled according to the will of God directly revealed to them. Although to a great extent based on superstitious fears, priestly governments were an advance on governments of mere fighting-men.

Out of these early systems of government, in conjunction with the experience of ages, all existing governments have sprung. Although, however, there is nothing of which mankind has had

so extensive or so varied an experience, the only fact which can be said to have been ascertained is the impossibility of devising any one form of government which shall be of universal application. Much has been written on the subject of what is called a 'perfect government;' but the result of all inquiry seems to be, that nothing is permanent except general principles or natural laws. Those, therefore, who contend for any particular model of government, without a due regard to circumstances, only pursue a delusive fancy. No species of government that could be devised will apply universally. The only practical rule of any value is, that every nation should possess a government in harmony with its state of civilisation, and the tastes and habits of the more enlightened portions of the community, to which the tastes and habits of the less enlightened may be expected gradually to conform.

As there is no such thing as a universally suitable form of government, so the form of government of any particular country requires to vary, and alter its character in adaptation to the advance or retrogression of society. In proportion as the people are ignorant and turbulently disposed, the government requires to be strong and arbitrary; and according as the people are enlightened, and disposed to live peacefully, the government may be mild and liberal. The ambition of kings and emperors, no doubt, is observed to sustain an arbitrary rule in circumstances where greater freedom should be accorded; but, as a general principle, it is evident that arbitrary military governments can only exist where the people at large are incapable of guiding and enjoying free institutions; or, in other words, where they are required. Sooner or later, the government of every country must bring itself into harmony with the society it rules, otherwise it will be overthrown. The cause for this is evident. Every government acts upon its subjects by means of themselves; it employs its subjects to keep its subjects in obedience. The consequence of this is, that in every country, and in all ages, the most seemingly despotic government is kept in check by the opinions of its subjects. No doubt, means, in some cases, are adopted to restrain the operation of public opinion; but, on the whole, the feelings and prejudices of the parties governed must ultimately be consulted.

Government being thus compelled to a certain degree to make justice and the good of the community its aim, it is important that the community be so enlightened and organised in opinions and wishes that it will easily and unobtrusively act on the controlling authority. There is another object to be gained by thus enlightening and organising the people, besides that of making them an efficient check upon government when it goes wrong; it is only by enlightening and organising the people that they can be rendered capable of lending due force to the operations of government, when these are what they ought to be. An unenlightened people is quite as likely to entertain mistaken notions of what is for its good as correct ones; it is quite as likely to oppose government when it tries to do what is right, and to support it when it tries to do what is wrong, as the reverse. The British government was in the right when, about the year 1780, it repealed some of the worst enactments against the Catholics; but the people were so far from heartily approving of this act of justice, that Lord George Gordon's riots in London, and the burning of Catholic chapels in Edinburgh, had nearly frightened government out of its good intentions.

The first step, then, in making such arrangements as are necessary for keeping government in its just and useful line of action, is to enlighten the people. There goes more towards *enlightening* the people than merely giving them school instruction, however thorough and extensive that may be. The people require to take every opportunity of acquiring knowledge, of extending their stock of ideas, of elevating their tastes, and of cultivating a brotherly benevolence. The great retarding influence in every nation has been less the arbitrary will of government, than the mass of voluntary ignorance which has nestled in the bosom of society. Nor is ignorance the only retarding influence. Mutual jealousy between the various classes into which society, by the action of natural laws, inevitably divides itself, may render even a comparatively well-instructed people totally incapable of self-government. In point of intelligence, the French have certainly always held a good place amongst the nations of Europe. But the selfishness, vanity, and exclusiveness of the higher classes in France had this effect up to the period of the Revolution, and vices of a character closely analogous on the part of the lower orders, have had the same effect ever since. The whole nation seems now to have become incapable either of governing or obeying; and, as has been wittily said, 'everything is impossible in France.' A consideration of this circumstance ought to temper observations on the strictly monarchical and aristocratic forms of government, and on the characters of those by whom they are attempted to be administered.

Aristocracies.

An *aristocracy*, a class of privileged persons, has its origin in the circumstance that greater skill, enterprise, intelligence, and perseverance, at first threw a comparatively great amount of wealth and power into the hands of a few families. That the management of that wealth, and the exercise of the power and influence which it conferred, were occupations calculated to give a greater practical development to the faculties of their descendants, than the routine drudgery of those who earned their daily food by their daily labour, is obvious, and these inherited qualities, or qualities at any-rate which were strengthened by the advantages of inherited position, were further strengthened by direct education. We have no desire to palliate the evils of aristocratic government, which more, perhaps, than even democratic government, tends to degenerate into government for the benefit of a class. But we must not, therefore, be blind to the fact, that aristocratic government is one of the stages through which all societies must pass on their way to something better; or that it has roots in nature, and consequent uses, which will always preserve it as an element, even in the highest forms of government to which mankind can attain. Inequality of civilisation, which gave rise to aristocratic power and influence, exists in many different forms and modifications. Even in our own country, an uncivilised class is found—that unfortunate class which supplies the precarious demand

for the lowest kinds of unskilled labour, and which fills our police-offices and courts of justice with the greater number of the victims to the security of society. Nor is there reason to believe that any future elevation of this class will ever bring it up to the condition of virtue and intelligence to which the higher class will then have attained. It is not of the lowest class alone that progress may be hoped; and if all classes progress, which is the only hypothesis on which the progress of the community as a whole is possible, the fact will afford no guarantee even for the diminution of the distance which at present divides them. To check the progress of the highest class would be to check civilisation itself, and if all classes progress *equally*, their *relative* positions will remain unchanged. But as one element of this, progress itself must consist in a better understanding of their relations to each other—that is, their respective rights and duties; the distinctions between classes will cease to be felt either as a source of pride on the one hand, or of humiliation on the other. Distinctions which are hedged in by impassable barriers are real impediments to progress, and justly excite indignation on the part of those whom they restrain. But these are not classes, but castes, which have always been repudiated by the constitution of this country, and even socially have never received any consistent recognition. So long as the son of a peasant may marry the daughter of a peer, and end by being a peer himself, whose son may marry the daughter of a queen, there is nothing really to complain of; and such is, and always has been, the relation of classes in this country. It is only want of mutual consideration on the part of individuals that sets them against each other, and the remedy demands no revolution.

The object of what are called constitutional governments is not to abolish classes, but to secure equally the privileges of all classes, by a definite arrangement, in place of leaving them to assert themselves on each occasion as it occurs. But no constitution will ever supersede the necessity for the exercise of citizen virtues on the part of the governed. Unless those to whom the function of government is intrusted are selected on the ground of fitness to represent the interests of the community as a whole, and not simply the interests of a particular class; and unless those who lead are somewhat in advance of those whom they lead, there can be no social progress, and there is not likely long to be even social stability.

Despotisms.

Out of Europe, the greater proportion of the governments throughout the world are of the character of *despotisms*. Of the multifarious despotisms which exist among barbarous nations, it is here needless to say anything; for the question of form of government only becomes interesting when applied to a wholly or partially civilised people. There is scarcely any country in Europe which can now be said to be governed despotically, the reforms of the present emperor having removed even Russia from that category. But when violent democratic outbreaks occur, despotic government usually appears as a temporary remedy. Of this character were the despotisms of the two Napoleons in France.

Though technically protected by codes of law, the subjects of despotisms are, in a great measure, at the will of a supreme authority, which has no check but public opinion. To insure obedience, a large military force is maintained, the press is under a censorship, the police act as spies on private actions, and travelling is regulated by passports. A leading feature of such despotisms is, that the whole system of government is *centralised* in a ministry in the capital of the empire, whence orders issue to all inferior authorities. By this means, the people, who are kept in order like children, do not acquire habits of self-government, and, except when exposed to some peculiar pressure, remain tranquil under a variety of restrictions. Offensive as such a system may appear to be, it often possesses qualities which for the time being recommend it to support: peace is thoroughly maintained; life and property are protected; the people, as objects of solicitude, are provided with public gardens and promenades, and allowed may other indulgences at the cost of the country; probably they are educated in the only possible way for the discharge of citizen duties, which, for the present, they are incapable of performing. Moreover, by bearing down factious opposition, and exerting a control over selfish private interests, a despotism is able to execute great and beneficial public works which seem to be beyond the reach of constitutional legislation; and it therefore commands a degree of respect which persons beyond its sphere do not readily appreciate. When it appears as a substitute for anarchy, the name technically applied to conditions of society in which there is no established government at all, and where the people are the prey of rival despots, who have sprung from their own ranks, the value of a single absolute ruler is still more obvious.

Constitutional Monarchies.

Europe abounds in constitutional monarchies—governments, that is to say, in which the king, or other chief ruler, is restricted in his powers by estates composed of representatives of, or delegates from different orders of the people. We should consider it quite useless to present detailed explanations of these constitutions. Those of them which are of modern origin, like that of Belgium and Italy, are more or less imitations of our own, and though in several—the Germanic Empire, for example—the monarchical element is imperfectly defined, and the reigning monarch can occasionally neutralise the will of the estates, they all afford extensive and substantial guarantees for popular rights. From the earliest period known to history, the Germanic races have possessed popular along-side of aristocratic and monarchical institutions. Tacitus mentions their existence amongst the tribes by whom the Roman Empire was overthrown, and they extended even to the island of Iceland. It is in these institutions that we must look for the origin of our own constitution of king, lords, and commons. This arrangement, in its general conception, would seem to be inseparable from the genius of the Teutonic races; it has rarely been successfully imitated by the other races of mankind. In Norway and Sweden, in Denmark, and in most parts of Germany, these old constitutions, which varied greatly in details, but rested always on some sort of widely extended, though graduated suffrage, and were frequently

very complicated, have since 1848 been greatly modified in the democratic direction, and made considerably more to resemble that of Great Britain, in its later form.

British Constitution.—In the constitution of this country we possess the most perfect example of a developed constitution of the Teutonic or Germanic type. The legislature, as is well known, consists of an hereditary sovereign (king or queen, as the case may be), an hereditary House of Lords, and an elected House of Commons. Previous to the Revolution of 1688, the sovereigns had assumed the prerogative of ruling by a divine, or inherent and indestructible, right. This unfortunate innovation on the old Teutonic or Germanic order of ideas was carried to so great an extent by the Stuart kings as to produce a violent reaction. This tendency resulted in the temporary establishment of the Commonwealth, or Republic, which, like most other republics in great countries, speedily degenerated into a despotism, in the person of the so-called Protector, Oliver Cromwell. Another reaction, ending in the restoration of the exiled royal family, was the consequence; and as they were no wiser after their return than before their banishment, we seemed at this period of our history in great danger of falling into the unsettled state of political life from which France and Spain have suffered and still suffer so much. The ultimate revolution, however, accomplished by William III. a Dutchman by birth, but the nephew and son-in-law of the exiled monarch, James II. was completely successful; partly, in consequence of the wisdom and moderation of that prince; but mainly because, on the whole, the Settlement, as it was called, was a return to the ancient constitution of England. According to the Revolution Settlement, the sovereign rules by a kind of bargain with the people. At his accession and coronation, he takes an oath to rule in terms of certain constitutional obligations; and by employing a ministry on whom the sole responsibility rests, he is presumed to take no part in public affairs, and is not held answerable for consequences. This is not merely a device for limiting the royal prerogative, but a remnant of the old mythical belief in royal infallibility, embodied in the phrase, 'The king can do no wrong.' As the ministry are amenable to the votes of the Houses of Parliament, they require to act in harmony with the wishes of the nation.

A *Parliament* is the term used to express the collective body of King, Lords, and Commons. The king, however, appears only by his ministers, and usually appends his signature to bills separately from the parliamentary business. By being composed of hereditary legislators, who are removed beyond the influence of popular clamour, the House of Lords is understood to impart a certain stability to the constitution. Between 1688 and the present time, two constitutional changes of considerable importance have been made, the one in 1832, the other in 1867-8. By the first, the Reform Bill of 1832, the English county constituencies were increased from 52 to 82; but in Scotland and Ireland the county representation remained as before. In England, 56 boroughs, containing a population, in 1831, of less than 2000 each, and returning together 111 members, were totally disfranchised; while 30 other boroughs, containing a population of less than 4000 each, were reduced to sending one member to parliament, instead of two. These boroughs, for the most part, had fallen off either in relative or in absolute population. On the other hand, 22 new boroughs, containing 25,000 inhabitants, received the privilege of returning two members; and 20 other new boroughs, containing each 12,000 inhabitants and upwards, that of returning one member. In Scotland, the town members were increased from 15 to 23, so that the number of representatives became 8 more than the number assigned to Scotland at the Union. As regards electoral qualifications, which were greatly reduced, the following were the provisions: In counties, an elector must be possessed of property in perpetuity or liferent to the value of £10 yearly, or lands held at a yearly rent of £50. In cities or boroughs, he must be proprietor of a house or shop valued, along with the land attached to it, at £10 yearly and upwards; or must occupy premises for which he pays a rent of at least £10 per annum.

In 1867-8 the changes were scarcely less momentous, though the measure was not called for by the same amount of popular excitement, or hailed with the same enthusiasm as the act of 1832. The most important provisions of this act, as regards England, are the clauses which establish household suffrage in boroughs, and the occupation franchise in counties. Clause 3 enacts that 'every man shall be entitled to be registered as a voter; and, when registered, to vote for a member or members to serve in parliament for a borough, who is qualified as follows: 1. Is of full age, and not subject to any legal incapacity. 2. Is on the last day of July in any year, and has during the whole of the preceding twelve calendar months, been an inhabitant occupier, as owner or tenant, of any dwelling-house within the borough. 3. Has during the time of such occupation been rated as an ordinary occupier in respect of the premises so occupied by him within the borough of all rates made for the relief of the poor in respect of such premises. 4. Has before the 20th day of July in the same year *bonâ fide* paid an equal amount in the pound to that payable by other ordinary occupiers in respect of all poor-rates that have become payable by him in respect of the said premises up to the preceding 5th day of January, and which have been demanded of him in manner hereinafter mentioned; or as a lodger has occupied in the same borough separately, and as sole tenant for the twelve months preceding the last day of July in any year, the same lodgings, such lodgings being part of one and the same dwelling-house, and of a clear yearly value, if let unfurnished, of £10 or upwards; and has resided in such lodgings during the twelve months immediately preceding the last day of July, and claimed to be registered as a voter at the next ensuing registration of voters: provided that no man shall, under this section, be entitled to be registered as a voter by reason of his being a joint-occupier of any dwelling-house.' The county clause (4) is this: 'Every man shall be entitled to be registered as a voter, and when registered, to vote for a member or members to serve in parliament for a county, who is qualified as follows: 1. Is of full age, and not subject to any legal incapacity; and who shall be seised at law or in equity of any lands or tenements or copyhold or any other tenure whatever,

except freehold, for his own life, or for the life of another, or for any lives whatsoever, or for any larger estate of the clear yearly value of not less than £5, over and above all rents and charges payable out of or in respect of the same, or who shall be entitled either as lessee or assignee to any lands or tenements of freehold, or any other tenure whatever, for the unexpired residue, whatever it may be, of any term originally created for a period of not less than sixty years, of the clear yearly value of not less than five pounds, over and above all rents and charges out of, or in respect of, the same. 2. Is on the last day of July in any year, and has during the twelve months immediately preceding, been the occupier, as owner, or tenant, of lands or tenements within the county, of the rateable value of £12 or upwards. 3. Has during the time of such occupation been rated, in respect of the premises so occupied by him, to all rates made for the relief of the poor in respect of the said premises. 4. Has before the 20th day of July in the same year paid all poor-rates that have become payable by him in respect of the said premises up to the preceding 5th of January.

The Reform Acts for Scotland and Ireland, passed in the session of 1868, differ in some important respects from that of England. By the Scotch act, the borough franchise is conferred upon every male person of full age, and subject to no legal incapacity, who has been for twelve months an occupier, as owner or tenant, of any dwelling, unless at any time during that period he shall have been exempted from poor-rates, or shall have been in receipt of parochial relief within twelve months. The lodger franchise, in Scotland, permits any lodger to vote who has occupied in the same borough separately, and as sole tenant, for twelve months, a lodging of the clear annual value, if let unfurnished, of £10 or upwards, and has claimed registration. In Scotch counties, the ownership franchise is £5, clear of any deduction in the shape of burdens, with a residential qualification of not less than six months. The Reform Act for Ireland made no alteration in the county franchise, but reduced that of boroughs to a £4 rating occupation, qualified as in England. It is now (1874) proposed to assimilate the county to the borough qualification by adopting household suffrage. With reference to these enactments, it is worthy of remark that, whilst a property qualification is to a certain extent retained as the test of fitness for the exercise of the franchise, not only is there no distinction of less and more, but owners and tenants are actually put on the same footing. The provision is intended to gratify the poorer classes, but it really inflicts a very great injury on the more industrious portion of the poorer classes themselves, by leaving the man who, by his honest exertions and praiseworthy self-denial, has succeeded in saving as much as to purchase his house or tenement, in precisely the same position as his idle and drunken neighbour, who has continued to be a tenant. It thus holds out no encouragement to industry and frugality, and were it to cease to be counteracted by the historical influences which are still so powerful in this country, it might land us in a revolution similar to that which has proved so disastrous to continental nations. That the sovereignty rests ultimately with the people, has always been the principle of our own, as of every free constitution; but it is a novelty in English politics, and a very unhappy one, borrowed from other countries, which identifies the people with the mere numerical majority, irrespective of means, as a guarantee for industry and frugality, or of education, as a guarantee for intelligence.

No monarchy on the face of the earth interferes so little with private conduct as that of Great Britain. Under its administration, the following important conditions are secured: Liberty of speech within constitutional limits; a similar liberty of the press in all its departments; liberty of personal locomotion, no passports being required; liberty of carrying on almost every branch of trade without inquiry or license; liberty of meeting in masses to be instructed by lectures on political or other subjects; liberty of meeting to discuss any political topic, general or local; liberty of presenting petitions to parliament, and memorials to the crown; religious toleration, and liberty for the performance of all forms of worship; liberty of setting up schools to instruct pupils in any branch of learning; protection from the law to life and property, without respect of person; privilege of trial by jury, and of forcing on a trial for any alleged offence; privilege of being held as innocent till proved to be guilty; incorruptibility of judges, these being no way exposed to intimidation either from power or popular prejudice, an advantage which is lost the moment that they are made elective, as in America, where the taking of bribes has recently prevailed to so fearful an extent as to render the successful litigant too often the litigant who has the longest purse. To these great bulwarks of civil liberty may be added the absence of military conscription; the non-existence of fortified or walled towns; the promptitude with which riotous proceedings are quashed and the peace preserved; and the absence of any restriction to prevent the most humble individual from rising to the highest rank and consideration. The drawbacks on all these advantages may be comprised in the following circumstances: The existence of a set of laws so complex as to be unintelligible, and so expensive in administration, that legal redress, so far as private interests are concerned, is almost beyond the reach of the lower classes; the too prevailing treatment of all great questions in parliament with reference to classes instead of to the whole people; and, till recently, the absence of a thoroughly national system of education, which might in time elevate the minds and morals of the people, and altogether produce a more wholesome social condition. Fortunately, these circumstances are all of a nature which admit of amendment; and they will, as a matter of course, be amended, as public opinion, enlightened by knowledge, is brought to bear upon them.

Republics.

A republic or commonwealth is a form of government in which the people, or at least a large portion of them, are acknowledgedly the source of power, and have the direct appointment of the officers, not only of the legislature but of the executive. There are few of this class of governments in existence. The oldest republics in the world are those of the Swiss cantons; each of which is a territory of generally a few square miles in size, and inhabited

by a few thousands of people, chiefly engaged in husbandry. In these cantons there are no great properties, and though there are many ancient families which enjoy much consideration, and to whose members, in the smaller cantons, magisterial offices are generally intrusted by a sort of tradition, there are none which in wealth are equivalent to the richer English landed gentry. There are some wealthy and intelligent merchants in the large towns; but the bulk of the population are a hard-toiling race of small farmers, who, in means and education, are little above a condition of mediocrity. The legislative and executive functions are conducted in accordance with this state of things; and it is no doubt owing to the smallness of its territory, and the comparative equality in wealth and intelligence of its inhabitants, that Switzerland has so long preserved its republican institutions. The constitutions of the separate cantons are divided into two classes, *absolute* democracies and *representative* democracies. In the former, the chief power belongs to the assembly of the whole adult male population, which meets once a year to pass laws and regulate the revenue and expenditure of the canton. Seven of the cantons have constitutions of this purely democratic kind. In the others, the people elect a council, to which they delegate their powers. These republics, centring in a general diet or congress, are greatly under the influence of the greater nations which surround them, by which, indeed, they are in a great measure tolerated only from mutual jealousy, and because the country is in some places almost inaccessible to hostile invasion. Since 1848, the power of the central element has been increased, and from being a league of semi-independent states, Switzerland has become a United Confederacy. The present constitution vests the supreme legislative and executive authority in a parliament of two chambers, a State Council and a National Council. The first is composed of forty-four members, chosen by the twenty-two cantons, two for each. The National Council consists of about one hundred and thirty representatives of the Swiss people, chosen in direct election, at the rate of one deputy to every 20,000 souls. Both chambers united constitute the Federal Assembly, and represent the supreme government of the republic. The chief executive authority is deputed to a Federal Council, consisting of seven members, elected for three years by the Federal Assembly.

On the continent of America, various republics have been founded on the wreck of the colonial institutions of Europe. The principal is the United States of North America, dating from 1776. The legislature and executive bear traces of their English origin; the main difference being an elective President as chief magistrate, instead of an hereditary sovereign, and the appointment of judicial and other functionaries by the people, instead of by the crown. The country is not one, but an aggregation of republics; each state being independent of the others as respects internal management. The power of legislation for the States, in their united character, is vested in a House of Representatives and a Senate, jointly forming a Congress. The House of Representatives is composed of members chosen every second year by the vote of all male citizens over the age of twenty-one, of the several states of the Union. Representatives are apportioned among the several states of the Union according to their respective numbers, which are determined by the census taken every ten years. A law passed in April 1872, after the results of the ninth census of the United States, taken in June 1870, had been ascertained, provides that from and after March 3, 1873, the House of Representatives shall consist of two hundred and eighty-three members. When new states are admitted to the Union, it is provided that their representatives shall be additional to the number of two hundred and eighty-three, which otherwise shall be the limit till the tenth census. No person is eligible as representative who has not completed his twenty-fifth year, and been seven years a citizen of the United States, and who is not, when elected, resident in the state for which he is chosen. In addition to the representatives from the States, the House admits a 'delegate' from each organised territory, with right to debate on subjects in which his territory is interested, but not to vote. Delegates are chosen in the same way as representatives, except in the territory of Wyoming, where the franchise is accorded to women. The Senate of the United States is composed of two senators from each state, elected by the legislature thereof for six years. One-third of the Senate goes out, and is replaced by a new election every two years. A senator must be thirty years of age, nine years a citizen, and resident in the state for which he is elected. All members, both of the general and state legislatures, are paid for their services.

The President is elected by the whole people, for a term of four years: at the close of that period, he may be re-elected; and, with two or three exceptions, all the presidents of the United States have been re-elected for a second term. Each state appoints a number of electors, equal to the whole number of senators and representatives to which the state may be entitled in the Congress; but no senator or representative, or person holding an office of trust or profit under the United States, can be appointed an elector. These electors meet in their respective states, to vote for President and Vice-president, one of whom at least shall not be an inhabitant of the state. In Delaware, South Carolina, and Tennessee, the legislature chooses the electors; in Maine and Maryland, electors are chosen by the people voting for one or more in each district; in all the rest of the states, they are chosen by a 'general ticket,' upon which the whole of the electors vote. The electors transmit sealed lists of all the persons voted for as President, and all those voted for as Vice-president, to the President of the Senate, who opens the lists, and counts the votes, in the presence of the Senate and House of Representatives. If for the person having the greatest number of votes for President, a majority of the whole electors have voted, he is declared President; if fewer, the House of Representatives elects by ballot one of the three who stand highest on the list. If for the person having the most votes for Vice-president, a majority of all the electors have voted, he is declared Vice-president; if not, the Senate names one of the two who stand highest on the list. The President and Vice-president must be natural-born citizens, thirty-five years of age, and fourteen years resident within the United States. The principle of electing representatives to the state legislatures is

almost that of universal suffrage; in most instances, every male citizen above twenty-one years of age who has resided a year in the state is an elector.

With an immensely large unoccupied territory, and general thinness of population, it is impossible to draw any just inference as to the stability of this still comparatively new and untried republican government. It has exhibited many forms of corruption, and the most respectable citizens have, for the most part, entirely withdrawn from political life. For the present, however, it is perhaps as suitable as any other form of government to the condition of the country; but whether it will maintain this character after the population of the United States has become as dense as that of England, and great diversities of wealth and intelligence have arisen, is a question which time alone can determine.

Revolutions.

A revolution is the overthrow of a government by some kind of convulsion out of the usual course of law, generally followed by the more or less permanent establishment of a new one in its stead. Modern history contains several examples of revolutions. The deposition and execution of Charles I. and the establishment of a Commonwealth, with Cromwell as dictator, formed the greatest revolution which has occurred in England, though it is never spoken of under that definition. The change of dynasty in 1688, with the guarantee of a constitution, is referred to as *the Revolution*. This revolution had the singular merit of being effected with little or no violence, a fact which, like the stability of the form of government which it introduced, was probably owing to the circumstance of its being, in the main, a return to the ancient institutions of the country. The revolt of the American colonies, and their assumption of independence, was a distinctly marked revolution, effected by military force, and crowned with a degree of success which astonished Europe. It was shortly followed by the revolution in France in 1789, to the violence and consequences of which no parallel is found in history.

Revolutions are almost invariably a result of misgovernment. Tenaciously clinging to old usages, and opposing themselves to every species of equitable reform required by alterations in society, or ruthlessly invading ancient privileges, governments sometimes, as in the foregoing instances, become so repugnant to the feelings of the nation, that at length a rebellion ensues, and if successful, it becomes a revolution. The revolution which placed Cromwell at the head of affairs in England, originated in Charles I. levying taxes without the concurrence of parliament, contrary to the constitution. The revolution of 1688 was caused by James II. assuming arbitrary powers vexing to the nation, and equally at variance with established rights. The American revolution occurred in consequence of government imposing taxes on the colonists, while they were not represented in parliament, and therefore in violation of the constitutional maxim of—no taxation without representation. The cause of the French Revolution, in 1789, was an entire disorder in society; but it was precipitated by the refusal of the clergy and nobility to contribute to the national taxes. A timely concession on the part of these bodies to aid the declining finances, by giving up a portion of their unjust exemptions from taxation, might perhaps have averted the terrible calamity which ensued.

From every revolution which has occurred, all governments may learn the valuable lesson of acting with a prudent regard to national traditions on the one hand, and on the other to constantly changing circumstances and feelings. Without respecting every antiquated prejudice, or yielding to every clamour, it is their duty and interest to adapt themselves to and even to stimulate the progressive views of mankind; graciously advancing with the intelligence of the age, keeping, if possible, rather before it than behind it. Lessons equally useful may be learned by the people from revolutions. To step in the slightest degree beyond the limits of constitutional law, and assume an attitude hostile to government, is always dangerous in the extreme—treasonable if defeated, and perhaps productive of unspeakable horrors if successful. Judging from the Cromwellian and the French Revolution, besides some successful revolts of lesser note, it would appear that a revolution in general circumstances runs a certain specific course. First, the old government is overthrown, and one thought to be more liberal is established. Second, the new government, being composed of men who acted from a conscientious conviction of evils to be redressed, is soon found not to go far enough in its measures; it is accused of being too moderate, and is overthrown. Third, a violent set of men, animated by feelings of vengeance, and professing boundless liberality, construct a fresh government. Fourth, anarchy sooner or later ensues, the nation is in universal disorder, and life and property are no longer secure. Fifth, out of the convulsion arises an individual, who, by his military genius, conquers inferior demagogues, and brings back a degree of tranquillity at which every one rejoices. Sixth, this tranquillity is speedily found to be a military despotism: a Cromwell or a Napoleon is at the head of affairs. And, brought to this condition, a long course of suffering is endured before the nation returns to the constitutional point whence it set out. Varied according to circumstances, such is likely to be the progress of every revolution occurring from heedless, though well-intentioned, democratic invasion. An expectation that the original movers of a revolution will be suffered to conduct it to a conclusion, is pretty nearly hopeless. The agitation brings all sorts of wild schemers into play, and one party after another is remorselessly trampled down in the contest.

It is now a settled political principle, that for revolutions to be attended with the good results anticipated by their promoters, they must, independently of other favouring circumstances, refer to a people who are qualified not only for self-government, but possessed of the nerve to unite and defend themselves against the anarchic forces which are almost certain to spring up. A usual cause of failure in the revolutions of continental Europe has been the political incapacity of the people—an incapacity amounting in some instances to an ignorance even of the forms necessary for regulating public assemblages of citizens. The revolution which gave independence to the United States was successful, because, among other favourable circumstances, it was promoted by an

intelligent and order-loving people, accustomed to freedom by a preliminary training under a constitutional monarchy. It is often loudly maintained by continental politicians, and tacitly assumed by those at home, that, however frightful may have been the horrors of the French Revolution, its ultimate results were a vast stride in advance in the direction of liberty, not for Frenchmen alone, but for mankind. That France has suffered more than she has gained, is a conviction which has been gradually forced upon most people, as each fresh page in her troubled history unfolded itself. But the impression of the general value of the revolution remains, and many have been brought by reiterated assertion to regard it as marking the point at which mankind fell heir to liberties of which even our own forefathers never dreamed. Yet can we put our finger on a single point in which the creed of the Revolution was really an advance on that which had been held, and more or less perfectly realised, by Englishmen for ages? We are told, for example, that 'it transferred the ultimate sovereignty from the king to the people;' but the people was the ultimate sovereign in England, as Mr Freeman has proved to us, from Anglo-Saxon times downwards. Then 'it broke up exclusive and privileged classes;' but we never had any exclusive classes at all, or privileged classes either, except the peerage, and even their privileges did not exempt them from citizen duties. It declared 'all careers open to talent;' but all careers, the throne only excepted, always were open to talent in England. It made 'all men equal before the law;' but therein it only recognised one of our oldest constitutional maxims. The moment it went farther, it went wrong. It no doubt declared all men equal in a sense unknown to us: it declared them equal in rights, however unequal they were in merits; whereas we had always followed more or less consistently the Aristotelian rule of making merits the measure of rights. But did it thereby lay the foundation of a wider liberty and a fairer order than ours; or did it simply offer to mankind the option of anarchy or despotism? The latter, as yet, must be the response.

Concluding Remarks.

In considering the nature and supposed influence of different forms of government, of which the preceding notices afford examples, it is important to guard ourselves against the too common error of mistaking names for things. A despotism has been described as the government of an irresponsible individual; and a republic, as a government formed by the concurrence of the whole people. We should, however, be liable to commit an error did we at once rush to the conclusion, that a despotism was invariably tyrannical; and that a republic was certain to be in every instance tolerant. It may happen that a despotism is really the more liberal of the two. This will occur when the despot is an intelligent and benevolent man. Instead of tormenting his subjects, he will take a pleasure in seeing them happy and prosperous; while, by a sleepless and undistracted vigilance, he will conduct the government with a degree of firmness and efficiency not to be equalled by a miscellaneously composed body. Such a beneficent government as this, is said to be *paternal*; the sovereign acting as if he were the father and guardian of his people. Could it be possible to secure a continuance of sovereigns of this character, we might almost arrive at the conviction that despotisms were the best forms of government; but, unfortunately, there is no security on this score; an evil may follow a well-disposed ruler, and suddenly the nation may be thrown into confusion. On this account, it should be the object of despotisms of the paternal character to prepare the people for the degree of self-government incidental to a constitutional monarchy; and having done so, to grant a constitution which will insure good government on a permanent basis.

That republics may be liberal and tolerant only in name, we have too many examples in history. Not to go farther back than the French Revolution of 1789–1793, what despotism ever equalled, or came within many degrees of, the republican Convention, which for years oppressed and deluged France in blood! Not even the tyranny of Nero or Caligula could be compared to the disregard of all public and private rights manifested by that iniquitous and popularly constituted body. The only historical episode that approaches it in atrocity is the brief reign of the Commune in Paris in 1871. The weak point in all republics is, that the most noisy and forward, who are usually the most ignorant, gain the ascendency, and, under colour of constitutional privilege, tyrannise over the more quietly disposed and intelligent citizens, many of whom, shrinking from the turbulence of faction, retire altogether from public affairs; so that, finally, the much admired republican government is found to be a mere government by venal and presumptuous demagogues. The same danger, in kind, if not in degree, attends all states, whatever their form, in which the ultimate sovereignty rests with the numerical majority. All this we mention, in consequence of the value which we attach to liberty as a reality, and in order to put people on their guard against the illusions of a name. Let it be remembered that government is a complex machine, fulfilling a wide variety of purposes, and that it is to be judged of less from the precise nature of its construction, than the quality of the work it performs. Another conclusion we arrive at is—That good government, although it certainly promotes the civilisation of a country, is much more its consequence than its cause; and that attention to the conduct and constitution of government, although a duty of the citizen, is only one of many public duties not less important and necessary both to the general wellbeing of society and the happiness of the individual.

GOVERNMENT ADMINISTRATION.

Whatever be the form of government, it requires to be conducted by a set of functionaries capable of superintending the different branches of the public service. The chief officials at the head of affairs, and who act as the cabinet council of the sovereign, are usually styled *ministers*, a word signifying servants; and collectively they are called the *ministry*. In constitutional governments the ministry are appointed by the sovereign, and take on themselves the entire responsibility of all acts of the crown. The British ministry, which is constructed on no broad principle, but is merely a result of occasional additions

dictated by special circumstances, is as follows: 1. First Lord of the Treasury; 2. Lord High Chancellor; 3. Chancellor of the Exchequer; 4. Lord President of the Privy Council; 5. Lord Privy Seal; 6. Home Secretary; 7. Foreign Secretary; 8. Colonial Secretary; 9. War Secretary; 10. Indian Secretary; 11. First Lord of the Admiralty; 12. President of the Board of Trade; 13. Chief Secretary for Ireland; 14. President of Local Government Board; 15. Vice-president of the Committee of Council on Education; 16. Chancellor of the Duchy of Lancaster. Such usually compose the cabinet; but there are nearly twenty other ministers—as Lord Chamberlain, Postmaster-general; and occasionally several of these are included in the cabinet, while one or two of those above specified are excluded. There is, in short, no distinctly settled ministry in England. The whole affair is a matter of arrangement at each change of ministry.

The First Lord of the Treasury is in general Prime-minister, and sometimes, as at present, Chancellor of the Exchequer. The Secretary of State for the Home Department may be said to stand at the head of the executive as far as the internal affairs of the country are concerned. The appointment of judges, sheriffs, and other functionaries is in his hands. Military affairs come under the jurisdiction of the Secretary at War and Commander-in-chief. The royal navy is similarly regulated by the First Lord of the Admiralty, and other members composing his council. The finances come under the cognisance and responsibility of the Chancellor of the Exchequer.

For the sake of local administration, the country is divided into counties, divisions anciently under the charge of earls or counts, but now committed to sheriffs and other officers. The *sheriff*, however, is a functionary of old standing. The title is derived from *shire* and *reeve*—the reeve of the shire. Reeve is an old title for an officer of justice inferior in rank to an alderman, and is derived from the Anglo-Saxon term *gerefa*. In Scotland, the sheriff of a county is a judge ordinary of his bounds, besides being intrusted with the execution of writs issuing from the crown. Towns possessing burghal privileges are exempted from the administration of sheriffs, and are governed by town-councils, including a burgh magistracy—such councils being annually elected by the parliamentary voters or qualified inhabitants. The chief magistrate of a town in England is entitled *Mayor;* in Scotland, *Provost*. In the principal cities only, the prefix *Lord* is added. In towns, and also in the rural districts, there is a miscellaneous magistracy, styled *Justices of the Peace*, who are nominated by the crown, and who possess a limited jurisdiction in civil and criminal matters.

The British is the least centralised government in the world, and in no other country is so much unpaid labour performed for the public, or performed so well.

Diplomacy

Is in all countries a separate branch of administration, which relates to intercourse with foreign powers. The persons deputed to act as foreign ministers are of several classes. Those of the highest class, called *ambassadors*, are not merely the agents of their governments, but represent their sovereign personally, and receive honours and enjoy privileges accordingly. The second class are envoys extraordinary and ministers plenipotentiary. A third class are called residents and *chargés d'affaires*. Consuls, of whom there are various grades, are confined in their duties to commercial affairs, and conduct no correspondence in relation to state-policy; yet, along with the whole ambassadorial class, they are expected to succour all subjects of the power which they represent, and facilitate their journey as to passports, &c.

Ambassadors, and even ministers plenipotentiary, have young gentlemen with them called *attachés*, who have no particular charge, but merely this title, to connect them with the legation, and to give them admission into the highest society. Sometimes they are sons of noble families, who are preparing themselves for diplomatic offices, and to whom the lighter duties of the embassy are intrusted. The suite of ambassadors always includes more individuals than the business of the embassy requires, a certain degree of pomp being considered necessary. An ambassador has generally three, always two secretaries of legation; other ministers often but one. A foreign minister receives letters of credence from his court, of which he delivers an attested copy to the Secretary of State, and afterwards gives himself to the monarch, or head of the government—if he is an ambassador, in a public audience; if not, in a private audience. After the reception of the credentials, the minister is said to be acknowledged. In some countries, he puts the arms of his nation or sovereign on his mansion. After his credentials have been received, he makes formal visits to the other ambassadors, to be recognised by them as such. These arrangements have been to some extent modified in this country in recent times, and as the Foreign Office is now far more exacting than formerly, our embassies have become comparatively hard-working institutions. From the moment that a minister enters the territory of the sovereign to whom he is sent, his person is held sacred and inviolable, and he acquires important privileges. To these belongs, first of all, his freedom from territorial restrictions—that is, he is not regarded as an inhabitant of the country; but his person, suite, house, equipage, &c. are considered as never having left the country to which he belongs, and as being without the jurisdiction of that in which he actually resides. From this follows the freedom of foreign ministers from the civil and criminal law; and the same applies to their suite; and all property belonging to a minister is free from taxes, &c. No common police-officer, tax-gatherer, or other public servant, can enter his hotel and make inquisition, as in the house of a private citizen. One of the especial privileges of ambassadors is that of worshipping according to the forms of their own religion in countries where their religion is not tolerated. In general, an embassy is considered as ended from the moment when the minister shews his letters of recall, or receives his passports for his journey home. When these are furnished him, he must leave the country; but his person remains inviolable even in case of war, and he is allowed to retire unmolested. The same inviolability of person is enjoyed in time of peace, by couriers and

expresses, as also by persons who, without any public character as envoys, are intrusted by their governments with the transaction of affairs of importance, and requiring secrecy and despatch; but these are not allowed to assume the state of a minister, and, in their relations to other citizens, are regarded as private persons merely.

Forces.

Every government employs force in the execution of its orders, or in defence of its rights. This force is divided into two departments, civil and military. The civil force consists of constables and other functionaries usually employed in the execution of legal judgments, in the maintenance of public peace, and in the enforcement of municipal regulations. Military force is quite a different thing: it is an organisation of men armed with weapons capable of inflicting wounds and death. In forces of this latter kind are included an army and a navy (see MILITARY AND NAVAL ORGANISATION). In the present day, with all its enlightenment, every civilised community less or more feels itself obliged to maintain an army; although many look forward to a time when international law and arbitration will supersede war.

HERALDRY—RANKS—TITLES.

No characteristic distinguishes so strongly a civilised from a barbarous people as the preservation of historical memorials. Savages have no history, and even their traditions lose all distinctness when they extend beyond the generation immediately preceding. And as historical nations retrograde in civilisation, they forget their past, even whilst they retain many traces of the culture which they owe to it. The Kabyles, or Berbers of the northern coast of Africa, whom their long contact with Phœnicians, Carthaginians, and Romans had raised to a high degree of culture, and who had been the hearers of Augustine and Tertullian in their day, have continued in some parts of the country to produce a species of poetry which it was supposed might throw light on their own conceptions of their history. But when translated by the industry of European scholars, these effusions were found to have reference almost exclusively to quite recent events—chiefly to the French conquest of Algeria. It is the same with families as with nations. Cultivated and progressive families retain, ignorant and retrograde families lose, the memory of the generations that have passed away. It is as a means of preserving family history, and of marking the relationships in which the different branches of families stand to each other, that the curious science of heraldry has kept its place in modern life. Originally, it was used for a different purpose. It consisted of an ingenious system of emblems and marks, which were painted on the shields of knights and nobles, in order that they might be readily distinguishable in battle. After these emblems ceased to serve their original purpose, they were retained by the families to whose heads they originally belonged, and are still cherished by their descendants as precious memorials. In the first instance, it is probable that each warrior adopted whatever emblem he fancied. But such license, it is obvious, must very soon have led to endless confusion, and defeated the whole objects of the institution. With a view to obviating this inconvenience, the right of granting armorial ensigns suited to the rank and condition of the wearer, was, at an early period, assumed by the sovereigns of this and all other European countries, and penalties were imposed upon those who arrogated to themselves emblems which they had not derived from this source. As the duty thus undertaken could not, except in very rare instances, be performed by the sovereigns in person, they delegated their authority to their heralds, who, in general, had made a study of what had now become a very refined and complicated branch of knowledge. It was thus that the heralds, whose function had been to proclaim within the lists the armorial bearings which individual knights had assumed, came to be government officials intrusted with the duty of conferring them and adjusting them to the condition of the wearers in the community at large. Jurisdiction in questions of arms has long been, and is now, vested, in England, in the Heralds' College; in Scotland, in the Lyon Court; and in Ireland, in the College of Arms. No one is entitled to bear arms unless he can claim them either by hereditary male descent from a person who has obtained them, or has himself obtained them by grant from the competent authority. Penalties, in Scotland, of rather a severe kind, may be enforced against any one by whom arms are assumed. The unauthorised use even of a crest renders the assumer legally subject to these penalties, whilst it involves the payment of assessed taxes equally as if the crest were genuine. Penalties for the use of false arms are seldom enforced, except in the case of a formal complaint being made to the Lyon by some one whose rights have been invaded. The social ridicule attending an act which in kind is the same as if a commoner were to call himself a lord, is generally found a sufficient deterrent, and practically, false arms are assumed only by ignorant and vulgar persons.

HISTORY AND NATURE OF LAWS.

A LAW, in its strict and original sense, is a rule of action contained in a command of a sovereign, addressed to and enforced upon his subjects; or, in other words, it is a rule of action prescribed to and enforced upon inferiors by their acknowledged superior. As the only universal superior is the Creator and Governor of the universe, all laws, in their last analysis, are divine, or, what amounts to the same thing, are natural laws. The conditions of the commands of a superior being laws, appear from this definition to be, that he has a competent authority—such as his subjects must obey, from whatever cause—and superior power, so as to be able to enforce his commands. Power and law are thus coincident, first in the divine, and then in the human lawgiver. Human or positive laws are attempts, necessarily more or less imperfect, to discover divine or natural laws by means of human intelligence, and to bring them into operation in special circumstances by means of human power. Their discovery belongs to, or rather is, the science of jurisprudence; the discovery of the means by which they may be enforced is the science of politics, or legislation in the general, and of jurisdiction in the special instance; their ultimate enforcement being the function of the executive, which is, as it were, the weapon with which power vindicates reason. In all states, the power of enforcing laws springs from and depends on the *consensus* of the subjects, which maintains the sovereign's authority. A real despotism, in the sense of a state in which the sovereign is absolutely independent of his subjects, is thus an impossibility. Even in the case of a foreign conquest, the subject population, in ceasing to govern, cease to constitute the state, and a new state arises.

A system of laws—or the law of a country—consists of the whole body of rules by which a people are bound together in civil society. It must always include CONSTITUTIONAL LAWS, to determine and regulate the political system and the public service; CIVIL LAWS, determining the subjects' rights of person and property; and CRIMINAL LAWS, defining and prohibiting offences. Human nature is such that men cannot continue in society without adopting, or being constrained to observe, a system of laws; and we know from history, that not only is society itself a growth and development, but that the laws which secure the coherence of its members grow and are developed with it so long as it progresses.

The rudimentary form of law is *custom*, while as yet there is no governmental agency to enforce it. At this stage, the system of laws is composed of modes of dealing and rules of conduct established by usage, and observed by the people, to avoid trials of strength. When the perception of the advantages of association, and of subordination to leadership, to reap these advantages to the full, conspiring with other causes, brings about government, there arises a regular agency for giving effect to the rules of custom. The sovereign or his functionaries interfere to suppress disturbances arising from the non-observance of these rules; and to judge between disputants, in order to prevent such disturbances, and to settle amicably cases unprovided for by custom. The advance of civilisation gives the strict character of law to custom, by prescribing the penalties under which it must be observed; and enacts new laws to meet new cases, or amends old rules to suit them to new circumstances. In the progress of time, in most countries the mass of the law—its rules constantly multiplying with the variety of new experiences—becomes cumbrous, and the rules themselves become indistinct; when to restore them to distinctness and certainty, a legislator—a Solon or Lycurgus, a Justinian or Bonaparte—arises, and rears up a homogeneous and systematic body of law, a code, out of the mass of popular usages and legislative enactments. This body thereafter undergoes successive changes as popular habits change with new occupations and circumstances, till, in the round of time, the necessity for codification recurs. 'For law, as for language,' says Savigny, 'there is no moment of absolute cessation; it is subject to the same movement and development as every other popular tendency . . . . it grows with the growth, and strengthens with the strength of the people, and finally dies away as the nation loses its nationality.' All positive law, whether codified or not, is thus necessarily variable, dependent on every variation in the character of the subjects with which it deals, and of the circumstances in which they are placed, whether these variations arise from race, stage of development, local situation, or any other cause. And yet all these variations are called for only in order that in various circumstances the same fundamental principles, or natural laws, may be vindicated. We thus perceive the necessarily variable character of positive, and the necessarily invariable character of divine or natural law, however much our conceptions of it may vary. From these remarks it will be apparent that the progress of jurisprudence depends on two factors. The first is the progressive discovery and more accurate definition of principles; and second, the more careful investigation of the circumstances in which these principles are to be vindicated.

The principal objects of law are personal safety, marriage, property, government, corresponding to universal necessities of human nature; and with these objects, laws are to be found in every society. While every society has within itself the causes of the growth, and materials for the nourishment, of law, none has ever been so isolated as not to owe some of the principles of its system to the laws of other nations. The first mercantile nations first develop mercantile laws, which, if they are not entirely copied, are more or less imitated by nations which subsequently turn their attention to

commerce. Thus the world, so far as we know, may be said to owe the first hints for a mercantile code to the Phœnicians; and to the Rhodians the earliest regulations applicable to shipping. But the ancient system which more than all others has influenced the laws of modern Europe, is the Roman.

ROMAN LAW, AND THE SYSTEMS DERIVED FROM IT.

Most European nations having risen from the ruins of the Roman Empire, have obtained the basis of their laws from the Roman law, which is therefore, by the common consent of Europe, denominated the *Civil Law*. In Europe, there was but one other system, at an early period, to combine with it; this was that code of usages which had sprung up in European nations before they received the civil law, and latterly became known as the *Feudal Law*. It is, after all, only in some countries that the feudal law exists: in other cases, the civil law has established a proportionate, and in some a preponderating influence. In Holland and Germany, the principles of the civil law have largely influenced the municipal systems, and have been studied with such zealous care, that the writings of the lawyers of those countries are quoted as the highest authorities on the law of Rome. In Spain, the system has been grafted on the feudal law, and on some peculiar customs derived from the Moors. In France, previously to the Revolution, the civil and the feudal law were united, as in most other nations of Europe; and in the Code Napoleon, to which we shall hereafter more particularly advert, there are many regulations from the jurisprudence of Rome allowed to exist, or revived, while many of the feudal customs which were formerly so prominent are abolished. England distinguished herself from the other nations of Europe by rejecting the civil law as authority, but many of her institutions were derived from its spirit and practice. 'With all its imperfections,' says Sir William Jones, 'it is a most valuable mine of judicial knowledge; it gives law at this hour to the greatest part of Europe, and though few English lawyers dare make such an acknowledgment, it is the true source of nearly all our English laws that are not of a feudal origin.' In Scotland, the Roman law has always been a special subject of study; and though the number of native decisions, the extent of statute law, and the necessary adaptation of the system to a state of society very different from that in which Justinian promulgated his code, have rendered references to this source comparatively unfrequent, the civil law is still authority where the particular law of Scotland does not contradict it. To complete the general outline of the influence of this system in modern Europe, it must be mentioned as the source of the canon law, which was created into a system by the Church of Rome, and still exists, more or less, either separately or incorporated with other systems, in all countries where the papal authority was acknowledged.

Writers have divided the legislative sources from which the laws of Rome sprung into five. Among the first of these is generally classed the people, and the laws sanctioned by them are technically divided into the *Lex* or *Populiscitum*, and the *Plebiscitum:* the former including the acts of the whole people; the latter, those of the plebeians convened by their tribunes. It would appear that, in the earlier periods of the monarchy, the authority of all classes was in this description of legislation tolerably equal. Servius Tullius, however, the sixth king, introduced the well-known divisions into centuries and classes, by which ninety-eight votes were secured to the first class, while ninety-five only were allotted to the remaining five, of which the lowest and most numerous possessed only one. The tribunes, who were officers chosen for the ostensible purpose of protecting the people from the tyranny of the aristocracy, were, by the exclusive and important power they possessed, again the means of restoring popular election. They procured the assembling of the people by tribes, in which their votes were given individually, and without the necessity of a property qualification. All direct popular legislation, however, soon disappeared with the authority of the emperors. Augustus, except in one instance, found the popular assemblies profoundly obedient, and under his successor they ceased to exist; so that, long before the Roman laws had become the grand system of jurisprudence into which they were formed under the auspices of Justinian, the direct popular source of legislation had been dried up.

The decrees of the senate (*Senatus consulta*) are another source of the Roman law. The legislative power of this body seems to have grown out of its judicial, which was at first its proper province. By the original constitution, the people alone were understood to be the makers of the laws, and their authority seems to have been gradually engrossed by the senate, the interference of which, from having been confined to mere advice and paternal assistance in legislation, gradually extended itself to that of making laws. It was not till the days of Tiberius that these decrees were publicly promulgated as laws; but the senate had by that time lost its independent authority, and become merely an instrument in the hands of the emperor. The proceedings of the senate were generally suggested by some public officer, and a majority decided for passing or rejecting. In later times, it became the practice for the emperor to propose a new law, either by a message or letter laid before the senate, or by an oration delivered; and as there was no opposition intended or permitted, the legislative body became the mere registrars of the monarch's will.

Another source of the civil law is the constitutions and rescripts of the emperors. At what time they commenced the practice of making laws without the nominal concurrence either of the senate or the people, is not very distinctly known. A passage in the *Pandects*, the authenticity of which, long doubted, has been confirmed by late discoveries, states that the will of the emperor is law, and that, by a particular act, the people had conferred upon him all their own power, which was thenceforth absolutely to remain in his hands —one of those transactions under the guise of which rulers are so fond of concealing their lust of power, by representing as a free gift that which no one can venture to refuse. Hadrian is believed to be the first emperor who exercised the authority of a supreme legislator.

Edicts of the prætors are another, and not the least important source of Roman jurisprudence.

Of these high magistrates, there were different numbers at different times; but the supreme authority vested in two, one having jurisdiction over the city, the other over the provinces. The prætor held his office for a year; and as a provision against his adapting his judgments to his own personal views, the Cornelian law obliged him to issue a sort of proclamation at the commencement of his magistracy, embodying the general principles to which he should adhere in his judgments; and thus, at the moment when he was least acquainted with the duties of his office, he had to fix the plan on which he was to execute them. The prætor was not originally vested with legislative power—it arose in the exercise of his judicial authority. He was merely the interpreter of the laws; but when they seemed to him to be hard, or otherwise erroneous, he did not scruple to suspend or alter their execution. The prætorian law has been compared to the equity system in England—a distinct system of law, arising out of those instances in which it was necessary to give relief from the strict interpretation of the common law. The common law had fixed a particular rule; a case would arise in which its application would be very oppressive; the common-law judges, bound by their system, could give no relief; but the chancellor took upon him to modify the evil, not by altering or developing the common law, so as to meet such cases in future, but by giving an equitable decision in the particular case, which decision was followed in like cases. By an enactment of the Emperor Hadrian, called the 'Perpetual Edict,' this doubtful and fluctuating branch of the law—at least as much of it as the emperor chose to sanction—received what might be called the royal assent, and was incorporated with the other portions of the civil law, as a distinct branch of the system.

It is a peculiarity of the civil, as distinguished from the English jurisprudence, that, according to the former, a law may be tacitly abrogated by long disuse. This, like many other principles of the civil law, was adopted by the law of Scotland.

The last fountain of Roman jurisprudence is the *Responsa Prudentum*—literally, the answers of the wise men—the opinions of the sages of the law. Even in England, where interference with the doctrines of the common law is so jealously opposed, the early commentators are the only authority for its provisions; and there is no doubt that they gave the hue of their own opinions to the doctrines they laid down. In Scotland, still greater influence has been exercised by the Text writers. In Rome, however, where the profession of the law conferred a high rank in society, the opinions of leading counsel had a much more extensive range. At an early period, the relation of lawyer and client was that of patron and dependent. Patricians alone could act as lawyers, and the science was involved in riddles to which they only possessed the key. The poor client was dependent on the good-will of his patron for such protection from oppression, whether through the law or otherwise, as the influence of the latter might enable him to afford. When population and transactions increased, and the laws, instead of a mystery, became a serious study, which depended more on laborious application than simple initiation, the profession was opened to plebeians. It became not an unusual case, at a still more advanced period, for the patron and lawyer to be separated—the former being chosen for his influence; the latter, for his skill. The forms which regulated the intercourse between patron and client, however, still retained some relics of their origin; and it is a striking illustration of the influence which Roman jurisprudence has exercised over the human race, to find these still existing. To this day, it is against etiquette to bargain with a barrister for his work. The law gives him no claim for remuneration, which it views as unworthy the dignity of his profession; and it is usual to pay him beforehand for his legal assistance. On the other hand, though he has been paid beforehand, he cannot be compelled to perform any duty in return, for he is presumed to assist the client from his own free good-will.

Under the earlier emperors, the privilege of promulgating authoritative opinions was confined to a limited number of lawyers, of equestrian rank, licensed by the government; but the profession was again thrown open to the public by Hadrian. The most brilliant era of legal wisdom commences within a short period of the decline of the republic, and terminates with the reign of Alexander Severus. Mucius Scævola, the tutor of Cicero, was one of its earliest ornaments; and it included the celebrated jurisconsults, Paul, Ulpian, Papinian, Capito, and Labeo. The last two of these, who lived in the age of Augustus, were the founders of the two sects called after two of their disciples—the Proculians and Sabinians. The former advocated the doctrine that the laws should be amended at discretion, to meet circumstances as they occurred; the latter maintained the theory of their strict interpretation, be its inexpediency in the particular instance what it may. Capito, conforming his doctrines to the inroads which the emperors were gradually making in the freedom of the republic, was a supporter of this species of innovation, and his followers were enrolled among the ready tools of despotism. Labeo sought to support the ancient freedom of the republic by an adherence to the letter of the old laws, and his sect became the champions of what may be termed constitutional freedom.

Having now enumerated the principal sources of the Roman law, we may notice its remarkable epochs. The laws enacted during the reigns of the kings exercised too little influence on the civil law, as handed down to modern Europe, to be of much practical importance. During the administration of the decemvirs, the celebrated laws of the Twelve Tables were adopted. The traditionary history connected with this code is, that the Roman government, conscious of the want of a proper legal system, sent commissioners to Greece, who, after studying the laws of that comparatively civilised nation, produced the Twelve Tables for the acceptance of the Romans. The tradition, like many others connected with the Roman history of the period, has not sufficient historical evidence to support it. Like the first laws of other rude states, they are simple and brief in their enactments. The bankruptcy system—which has so sadly shocked several benevolent scholars, that they have endeavoured to explain it as a merely symbolical

provision—is certainly very severe. It enacts that the insolvent debtor shall be cut in pieces, and that his body shall be distributed among his creditors. When law became a science openly studied, the Twelve Tables became the subject of many commentaries. It was not, however, till the Romans had been for some time degenerating, that those great collections of legislative wisdom which have come down to modern times were commenced. The first attempt to construct a code seems to have been the Perpetual Edict of Hadrian already alluded to. Two private individuals, Gregorius and Hermogenes, appear to have collected the imperial constitutions into a system, or code, of which some fragments are still preserved. Nothing whatever is known of the biography of these compilers: it has not even been discovered in what reigns they respectively lived, though their labours received high commendation at the hands of Theodosius the Younger. Under this emperor, the celebrated Theodosian Code was promulgated, in the year 438. The compilation of this body of laws was committed to eight individuals, who were allowed considerable latitude in explaining and abridging, and even in supplying deficiencies. It contains the legislative acts of sixteen emperors, from the year 312 to 438. Fragments of this code have been rescued from oblivion inch by inch, by modern scholars, whose labours, it may safely be calculated, have amounted to some twenty or thirty times more than those of the original compilers. The celebrated Godefroy of Geneva spent thirty years in the task; and more recently, the discovery of some further fragments induced the celebrated Angelo Mai to study the Roman law for the purpose of editing them.

We may now notice those great collections to which the above may be considered only preparatory. In 529, ten commissioners, appointed by Justinian, prepared the *Code* or *Codex*, as it is termed, from the collections previously made and the intermediate enactments. Soon after its promulgation, the emperor issued several new constitutions, and the whole were consolidated and reissued in 534. This great task was superintended by the celebrated Tribonian, whose eminent learning and discrimination, allied with untiring industry, but stained by the vices of corruption and partiality, have afforded a fruitful theme of praise and obloquy. This was by no means Tribonian's only labour. In the year 530, he was appointed the chief of a commission of sixteen, whose duty it was to cull the choice and useful passages from the authors of comments and opinions. The various authorities which, we are told, would have made several camel-loads, were thus reduced within a compass which, if it do look somewhat formidable to the consulter, is still manageable. Such are the fifty books which constitute the celebrated *Pandects*, or *Digest* of the Roman law—a work without which modern Europe would have known but little of the subject. Along with Theophilus and Dorotheus, the indefatigable commissioner was able to prepare, in conjunction with this great digest of the law, an abridgment or manual of its leading principles, which bears the well-known name of *The Institute*. This condensed and elegant little work was sanctioned by the emperor in 533. It has become the subject of innumerable comments, and has afforded the model on which the legal writers of most modern nations have desired to prepare their treatises. Justinian continued, during the remainder of his life, to promulgate new laws; and these, collected together under the title of *Novellæ*, or 'Novels,' form the remaining department of the '*corpus juris*,' or body of the civil law.

With Justinian we reach the climax of the Roman law; and to trace its further progress in the Empire has been more a subject of curiosity to the antiquary than of importance to the lawyer. Some fragments by later commentators, chiefly in the Greek language, have been disentombed by zealous searchers. The Roman law was nominally respected by the northern conquerors of Rome. Alaric, king of the Visigoths, indeed, caused a compendium to be prepared for the use of his dominions, consisting chiefly of an abridgment of the codes of Gregorius, Hermogenes, and Theodosius. Towards the end of the ninth century, Basilius, emperor of the East, issued a new code, intended to supersede the labours of Tribonian, termed the *Basilica*.

In the dark ages, however much of the Roman law may have remained in practice, it had died away in literature, and was neither studied nor commented on. At the taking of Constantinople in the fifteenth century, only one copy of one of the Justinian labours, the *Novels*, seems to have been discovered. It was long believed, indeed, in the learned world, that from the period of the *Basilica* to the twelfth century, the very existence of the Roman law was among the things forgotten. The circumstances of its resuscitation were found in a traditional anecdote, that at the siege of Amalfi, in 1137, some Pisan peasants discovered a complete copy of the *Pandects* among the plunder, the comprehensive philosophy and clear definitions of which so charmed the readers of that barbarous age, that its contents were immediately devoured with avidity and propagated with zeal. In Florence, a manuscript is still preserved, said to be the identical book with which this anecdote is connected, taken at the siege of Pisa in 1406. The essence of the tradition has been disproved by late discoveries, which shew that the civil law was known previously to the siege of Amalfi.

The real revival of the civil law is to be traced in the history of the universities. Of these, Bologna, Paris, and Leyden took the lead in the department of jurisprudence. Contemporary with, or immediately after the siege of Amalfi, lectures were given on the *Pandects* in the university of Oxford, by a teacher of the name of Vacarius. For reasons which we shall have to state when we come to treat of the laws of England, the civil law, thus early commenced, never made much progress in England. In the seventeenth and eighteenth centuries, the study was pursued with zeal. A prodigious number of civil-law books issued from the press during that period; Holland especially produced many eminent civilians—Grotius, Matthæus, Schulting, Noodt, Voet, and Huber belonged to that country. To Germany belonged the philosophic jurist Puffendorf, and Heineccius, whose elementary works—as the clearest and most methodical of the commentaries—have been popular as class-books of civil law. Grotius, Puffendorf, and Heineccius, however, are still more celebrated for their labours in the law of nature and nations. In modern times, the

German lawyers have taken the lead, and the name of Savigny stands venerated in Europe.

To give a general outline of the Roman law, would be to describe the common principles of the majority of the codes of civilised mankind. Although the progress of commerce and manufactures has introduced a number of new transactions and forms of creating obligations—such, for instance, as insurance and bills of exchange—which the Roman lawgivers could never have contemplated, yet their system is the foundation of all the commercial laws of Europe—a circumstance which has probably facilitated the uniformity so necessary in transactions which involve inhabitants of different countries. From the same source, Scotland and the greater part of continental Europe have derived a marriage law so different from the ceremonious system that prevails in England. Its leading principle is, that the consent of the parties alone is necessary to a valid marriage, and that when that is proved, nothing more is necessary; and that a child born between parties who are subsequently married, becomes legitimate by that act. The law of trusts and of the mutual rights and obligations of guardian and ward, have found their way more or less into every modern system, and even into the statute law of England. Prescription, or the principle that claims are limited by the lapse of time, has come down to us from the Romans. The law of testaments and the descent of movable property, is mainly derived from the same quarter. It is in the case of the tenure and transmission of land, indeed, that the person versed in modern systems will find himself least at home in the Roman, from the effect which the feudal institutions of the various nations of Europe have produced on that branch of the law. The subjection in which children were placed to their parents is apt to create surprise, even when compared with the strict filial etiquette of our own ancestors. A revolting feature of the *corpus juris* is the portion of legislation devoted to the subject of slavery and the property in slaves.

The Roman law may be mentioned as one of the sources of the law of nations, or, as it is more justly called, *international law*, in modern Europe. This law of nations, or law of the relations of separate communities, has been investigated by many ingenious men, and has, since the time of Grotius, taken rank as an independent branch of jurisprudence, though it can scarcely yet be said to have attained to the character of positive law. Great practical difficulties stand in the way of the establishment of an international legislature, tribunal, and executive; but till it is furnished with these, which are the organs of all true positive law, the opinion of each individual state must be the measure of the law of nations, and war the method of its enforcement. It is not to be supposed, however, that there are absolutely no courts where what professes to be the law of nations is enforced. Each country in Europe has generally a court where its own views on the subject are laid down. England has, for instance, the prize jurisdiction of the Court of Admiralty, which, by a misnomer, arising out of the fact that its judges and advocates were civilians, is called a civil-law court.

THE CANON LAW.

The Canon (Greek, from *kanon*, a rule) Law is, properly speaking, the ecclesiastical law of the Roman Catholic Church. In its more limited acceptation, it may be called the laws of the church as a separate corporation; but its field widened with the influence of the hierarchy. It embraced many subjects of pure civil and municipal law, such as the distribution of property between married persons, succession, &c. by linking them with ecclesiastical matters; and thus the clerical tribunals came to rival, if not to excel in importance, those of the state. The canons of the Greek Church, a portion of which were said to be the work of the apostles, added to and explained by general councils, were sanctioned by the *Novels* of Justinian, and have so been viewed as a portion of the body of civil law. A collection of canons was made in the year 520; and this work, with the papal decrees, and the privileges conceded to the church by Charlemagne, formed the chief subject-matter of the canon law down to the twelfth century. It was then that this law ceased to be the mere regulations of a peculiar body, and became a general system of jurisprudence. About the year 1114, a collection of the decrees of popes and cardinals was commenced by Ivo, bishop of Chartres, and was revised and completed in 1149 by Gratian, a Benedictine monk. Another element in the system consisted of the Decretals, which were rescripts or epistles by the pope, or by the pope and cardinals, deciding how the law of the church stood concerning disputed matters referred to them. These were first collected and edited in 1234 by Raimond de Renafort, chaplain to Gregory IX. This work was divided into five books, to which a sixth was added under the auspices of Boniface VIII. in 1298. These two great works, with some additions made to them by succeeding popes, formed what, in imitation of the collected works in the law of Rome, was called the *Corpus Juris Canonici*, or Body of the Canon Law. Besides these general statutes, there were local canon laws passed by the clergy of various countries, at national or provincial assemblies, held under the auspices of papal legates or archbishops. In the reign of Henry III. there were assemblies of the former kind; and under the respective archbishops of England there were frequent provincial synods. In Scotland, two provincial synods, held at Perth in 1242 and 1269, passed some important laws regarding tithes.

A great rivalry existed between the civil and the canon law; but it was in the main a friendly rivalry. In the north of Europe the clergy were the repositaries of both systems, and they had to decide how much should be assigned to the one, and how much to the other. The canon law borrowed largely from the civil, of which it is sometimes considered a mere branch; it was naturally, indeed, the object of the clergy not so much to change the law itself, as to take the administration of it into their own hands. To be *juris utriusque doctor*, or doctor of either law, civil and canon, was a common distinction; and hence has come down to us, though entirely diverted from its original meaning, our modern degree of LL.D. During Henry VIII.'s reign, lectures on the canon

law were abolished in England, and with them the corresponding degree. Jealous as the English were of the encroachments of the civil law, they still more determinedly opposed that of the canon. What the powerful court of Rome had set its heart upon, could not be wholly resisted; but it was always a principle, that though the civil authorities of England might take laws from the ecclesiastical system, the canon law was not to be obeyed within the realm.

THE FEUDAL LAW.

The feudal system and the Roman law—the one representing the Teutonic, the other the Romanic element in the organisation of modern states—may be said to have struggled for supremacy through nearly the whole of modern Europe. Of the influence of the latter, we have already taken a cursory view. The former was an ingredient in the constitution of the continental and British monarchies. It was the source of those popular or aristocratic assemblies which shared more or less, according to circumstances, the government of the various states in which they existed; and it was thus the ostensible origin of the British parliament. The constitution of the German Empire was essentially feudal; and the customs, or peculiar local laws of the various provinces of France, previously to the Revolution, were models from which the system was studied. The English law, especially that of real or landed property, is full of feudal usages, though their operation has often been checked. In Scotland, very many forms of the feudal system still exist, though, as we shall hereafter see, they have been adapted, perhaps as far as they are capable of being so, to the wants of civilised times.

The essential elements of the feudal system were land, and military service given for the use of it, by the vassal who held it, to the superior of whom it was held. It would be wrong to speak of either of these two parties as the absolute proprietor of the lands; for in the more perfect stage of the system, each had his own peculiar privileges, with which the other had no right to interfere, except where the law permitted him. The vassal was not the slave of the superior. The duties and services he had to perform were regulated by compact or custom. On the other hand, however, he was not the independent proprietor of the lands he held. He could not convey them to a purchaser, nor could he pledge or bequeath them, without obtaining the sanction of the superior to the person to be substituted for him. Land was thus completely removed from the unrestricted operation of commerce; and in those countries where the feudal system continued to exist, it was only by fictions and connivances—by bribing the superior, or getting the courts of law to compel him to give his consent—that sales and pledges could be effected. The lands held in this manner were termed *fiefs*. When they became hereditary, as they did apparently by custom, arising from the tacit consent of the parties interested, the superior was still presumed to give an assent to the change from father to son; and before he acknowledged the latter as his vassal, he exacted from him a fine. When the successor was a minor, and on that account unable to fulfil the military duties of the fief, the superior in some cases became his guardian, drawing the rents of the estate, and compelling him to marry whom he should point out, under a penalty. In some countries, females could not succeed. In others, where their right was acknowledged, the superior claimed the privilege of assigning husbands to them; and exacted a fine, sometimes for admitting the husband as a new vassal, sometimes as the price for permitting him to marry his ward.

The proper return of the vassal for his lands and the protection of his lord was, as already stated, military service. Where this system was established as a fixed law, the quantity of service to be so given was regulated. The church enjoyed lands which were not exempt from the ordinary feudal services. In the earlier ages, churchmen in many cases assumed the spear and buckler. When it was considered inconsistent for churchmen to fight, it was held as by no means unsuitable for the church to employ soldiers. A clerical establishment would sometimes appoint a patron, or chivalrous assistant, in the person of a neighbouring baron, who would be called the 'advocate' of the establishment It is not unfrequent to find in old tenures that a particular monastery is to supply so many archers and spearmen for so many days.

Borough communities were another class to whom military service seems inapplicable, but who, nevertheless, almost universally held by that tenure. They obtained certain privileges, and in return they had generally to keep watch and ward in their respective towns—a service in which their own safety might not be less interested than the ambition of their lord. As the privileges conceded to these communities were large and important, they did not, in general, escape taxation along with their military duties; and in later times, these exactions became generally commuted for a money payment. The privileges usually conceded to these commercial communities consisted of an exemption from the more vexatious of the feudal exactions, to be shortly noticed. These were generally conceded to them by the monarchs, as a counterpoise to the growing power of the feudal aristocracy; and within these sanctuaries commerce and civilisation created a power by which both kings and nobility were effectually held in check.

Among those who were placed in the position of feudal vassals to the seignior, or lord, were his own domestic servants, whose power and influence would be, to a certain extent, measured by that of their master. To perform the menial duties of his household, a Roman emperor employed a slave, just as a senator or a pro-consul might do. The barbarian conquerors, however, gave lands to those who performed these functions; and the person who performed for Charlemagne the office of butler, valet, huntsman, or groom, got for his services the commodity most readily at his master's hands—portions of conquered territory. It is important to observe, however, that the personal relation preceded the feudal one, and that it was the latter which grew out of the former. This point has been much insisted on by Mr Freeman, in its political bearings, in his *History of the Growth of the English Constitution*. 'Among the Teutonic nations,' he says (page 46), 'the personal relation coloured everything. . . . We are now accustomed to see this kind of service

paid in the case of royal personages only; a few centuries back, men of any rank deemed themselves honoured by paying the like service to men of the rank next above their own, or even to men of their own rank who had the start of them in age or reputation. The knight was served by his esquire, and the master by his scholar.' Apart from its more special political effects altogether, may it not be owing to this principle, or the spirit which engendered it, that we and the other nations whose blood is in a preponderating measure Teutonic, have escaped the allurements of a false equality which has been so ruinous to the Romanic races? The esquire might become a knight, the scholar a master, but the one was not ashamed of acknowledging that he was an esquire, or the other a scholar, so long as such was the fact. The right which he claimed was the right to rise, not the right to be treated as if he had risen, which is that for which the Romanic races so keenly contend, and which the French Revolution is supposed to have vindicated. Ultimately, no doubt, services were performed as the consideration for feudal benefices, which would not otherwise have been rendered. The menial servant of the monarch might have tenants and retainers under him; and from this relation to the crown which pervaded the whole system, the wages ennobled the functions, and were ennobled by them. Hence we have had in modern Europe masters of the robes, grooms of the stole, masters of the horse, &c. held by the highest nobility of the realm. The *graf*, or land-steward of a district, was an important personage. Instead of attending to the letting of paddocks and the rotation of crops, he was intrusted with the power of life and death over the inhabitants. The humble grieve, who has the management of a small landed estate in Scotland, and the shire-reeve, or sheriff, who performs judicial functions in the same part of the empire, have divided, as it were, between them the original duties of the feudal officer from whom their names are derived.

To the necessity of having acts regarding the fiefs of a superior witnessed by his vassals, can be traced two of the most important institutions of modern times. The great vassals of a king, met together in public assembly to discuss what aids they might afford for their fiefs, how they were to defend them, &c. merged into a great council or legislature; and it is to such a body that the British parliament partly owes its origin. Vassals of the lower grade were often summoned to attend at the hall of their lord as assessors, or assizers, to give, partly opinion, partly evidence, concerning some matter connected with the fief, or the conduct or rights of a fellow-vassal. With this institution, the system of trial by jury is intimately connected. A jury of perambulation, for the purpose of ascertaining boundaries—a sort of body lineally descended from the assemblage of co-vassals who were present at the investiture, and witnessed the extent of the gift—has been known in modern times. It was with a view to the preservation of evidence to be produced before such juries, or, according to the older custom, to have witnesses who should form part of them, that the singular practice, still observed in some places in England, of 'beating the bounds' by a band of schoolboys with white wands, was instituted; and the still quainter practice of beating the boys themselves, in order to fix the transaction in their memories.

It is probable that if the feudal system had only established a relation between the monarch and his immediate vassals, the influence it would have exercised over the state of Europe would have been comparatively slight. The distribution of land as the reward of services, is frequently exemplified in history; but that which chiefly distinguished the feudal system, is the numerous grades of dependence, and the manner in which all parts of society, from the emperor to the lowest serf, were bound together in one system of lord and vassal. The highest feudal noble was the Heretoch or Herzog, the leader of the Heer, or army, who, from the Latin *dux*, a leader, received amongst the Romanic nations the designation of duke: this class was intrusted with the administration of large provinces. The graf, who had a smaller charge, was called *comes*, or count; and one class of graf, who was intrusted with the marches, was called the *mark-graf*, *mar-grave*, or marquis. These nobles generally held lands of their sovereign, while they were authorised to represent his person over the districts to which they were assigned, administering justice in his name, levying his feudal exactions on his vassals, and receiving their homage.

From these high personages, vassalage went through many gradations, till it reached a condition not greatly superior to slavery. There were the *vavassors* and *châtelains*, dependents on the higher nobility, but who themselves had large estates and fortified their houses. There were the burghers of free towns, whose privileges have been already mentioned. Of rank corresponding in the rural districts, were the *socage-holders*, and the class so well known in England by the designation *yeomen*. The lowest grade were the *villains* or *serfs*, to whom was committed the task of tilling the lands which the soldier gained or protected.

THE LAW OF ENGLAND.

England has already been mentioned as an exception to the general prevalence in Europe of the civil and canon laws. So in the parliament held at Merton in 1236, the barons of England refused to admit the canon law legitimation by subsequent marriage, giving as their sole reason, 'Nolumus mutari leges Angliæ.' This resistance was due to the existence of a different and hostile system, called the common law, and the large power exercised by parliament of making new laws or statutes. The three great elements of the jurisprudence of England have for many centuries been the common law, equity law, and the statute law.

Common Law.

Speaking of the common law, Sir Matthew Hale, its historian, says: 'This is that law by which proceedings and determinations in the king's ordinary courts of justice are directed and guided. This directs the course of descents of lands, and the kinds, the natures, and the extents and qualifications of estates; therein, also, the manner, forms, ceremonies, and solemnities of transferring estates from one to another; the rules of settling, acquiring, and transferring of properties;

the forms, solemnities, and obligations of contracts; the rules and directions for the exposition of wills, deeds, and acts of parliament; the process, proceedings, judgments, and executions of the king's ordinary courts of justice; the limits, bounds, and extent of courts, and their jurisdictions; the several kind of temporal offences and punishments at common law, and the manner of the application of the several kinds of punishments; and infinite more particulars, which extend themselves as large as the many exigences in the distribution of the king's ordinary justice require.'

The origin of this system is involved in obscurity. Its progress subsequently to the reign of Edward I. called the English Justinian, is well known; but when we read those portions of English law-books which attempt to carry the history to an earlier period, we cannot help feeling disappointed at the result. The more marked features of the system were, doubtless, the customs of the Anglo-Saxons. A collection of the laws of England during the heptarchy, or laws of the Anglo-Saxons, was published by an eminent antiquary, David Wilkins, in 1731, but they may be best studied in the translation of Mr B. Thorpe, or, so far as they relate to constitutional history, in the extracts given by Professor Stubbs of Oxford in his *Select Charters and other Illustrations of English Constitutional History*. The fragments of Anglo-Saxon legislation which they contain refer chiefly to: (1) Criminal law, which included a variety of practices then common to all Teutonic races, but now unknown, such as 'wergeld,' or compensation in money or kind paid for murder or assault; ordeals by fire, iron, or water, supposed to be infallible tests for the detection of the guilty; compurgation, or the oath of a certain number of persons, according to the rank of the accused, in his favour, which was held conclusive proof of his innocence; (2) Ecclesiastical law, which included such subjects as the immunity of the persons and estates of the clergy from the ordinary courts, and the sanctity of holy places, persons, and things; and (3) Constitutional law, relating to the public assemblies and courts of the *witan*, or wise men, for the whole kingdom, and of the shire, hundred, or township for smaller districts, to the rank of persons, and to taxation. Concerning private rights, there is scarcely anything, except what relates to the tenure of land. The reason of this is partly, that much was regulated by unwritten customs, and still more, that private rights were less complex than in modern times. Several of the Anglo-Saxon kings, as Ethelbert, Ina, Edward the Elder, Athelstane, and Edgar, did no more than modify existing customs; Alfred, Canute, and Edward the Confessor, aimed at framing codes. The laws of the last are the most famous, but we have them only as written down in the reign of William the Conqueror.

The Conquest first firmly settled the feudal system, and the connection between vassal and superior became one of the most important features of the common law. The Saxons could not escape the influence of a system which had deeply rooted itself among the kindred nations of the continent; and many feudal institutions are to be found existing under the Saxon kings. The increase of the spirit of feudalism under William the Conqueror was, however, so great, that many authors have attributed its origin in England to this era. The Conqueror brought with him the system of his own province, for which he was a vassal to the king of France, and could not admit the possession of landed property in England, except as held from himself in the capacity of lord-paramount. The greater nobles naturally held the lands he liberally bestowed on them of him as superior, and they compelled all who lived upon their lands, or even in their neighbourhood, to acknowledge them as liege lords. Several of the Norman monarchs cleared large tracts of country of inhabitants, that they might enjoy the regal pleasures of the chase in undisturbed tranquillity. The Saxons had their own county courts, but the greater part of the causes were, after the Conquest, removed from them, to be pleaded in the court of the monarch, which attended on his own person. Legal proceedings were conducted in the Norman dialect of the French, which was afterwards changed into Latin. The use of a tongue unknown to the people at large continued down to the days of Oliver Cromwell, and at the Restoration was restored. It was finally abolished in 1731, by 10 Geo. IV. c. 26.

The charters that were so often granted by the earlier kings to the importunity of their subjects, were restrictions of the tyranny of the feudal law, and promises to adhere to the old Saxon customs—promises which would not have been so often exacted if they had not been continually broken. The most celebrated of these is that conceded by King John, called Magna Charta, or the Great Charter. Its privileges are in a great measure constitutional, and it has often been said that it was procured for the advantage of the aristocracy, and not of the people; but it is not without stipulations in favour of the latter, protecting them both from the crown and from the nobility. It restricts the tyrannical forest laws, and the arbitrary exactions by feudal lords from their vassals. The clause which has attracted chief interest is that which says that no freeman shall be affected in his person or property save by the legal judgment of his peers, or by the law of the land. The judgment by peers refers to jury trial, and the whole clause strikes against arbitrary imprisonment, and involves the principle of the *habeas corpus*—a form of procedure first introduced under that name in the reign of Charles II. —by which every man, whose liberty is restricted, may demand to be brought before some competent court, in order that he may be either convicted or liberated.

The progress of civil liberty in England has been in a great measure attributed to the division of interests in the country. The crown had an interest in checking the power of the great nobility, and the nobility that of the crown. That the exercise of this power was essential to the liberty that has existed in England, must be apparent to those who contemplate the state of France and Germany, where the aristocracy made themselves either quite or nearly independent of the crown, and often acted as tyrants to the people. A very important blow to the power of the aristocracy was accomplished by Edward I. in 1290, by the abolition of the system of sub-feuing. From that date, no vassal of the English crown could grant lands to be held of himself, as

he may to this day in Scotland—he could only put a new vassal in his own place, as an immediate dependent of the crown. There is a similar law in the Scotch statutes of Robert the Bruce, but it is doubtful whether it was ever enforced. The disputes with the church were also not without service. The attempts of the ecclesiastics to urge the claims of the civil and canon law, caused the common lawyers to resist their encroachment with true professional hatred. It was in the universities that the clergy had their chief influence; and the students of the common law formed themselves into rival institutions—the Inns of Court. Then there was in the boroughs a separate interest, possessed of an influence always increasing. The tendency of all these circumstances seems to have been to lead to a gradual return to Saxon freedom, and a fixing of the common law in conformity with the long-cherished feelings of the English people.

The repositories of the common law are the treatises of eminent lawyers and the reports of decisions. Of the former, there are several of the thirteenth and fourteenth centuries—Glanvil, Bracton, Hengham, and the book called *Fleta*, by an unknown author, Thornton, and Britton. Lyttleton's treatise on Tenures, the work of the more matured system of the close of the fifteenth century, was long the text-book in the practice of the feudal law. It was in the form of a comment on this work that Chief-justice Coke issued in 1628 the vast treasury of legal learning known as 'Coke upon Lyttleton.' The next great name is Blackstone, a man who wrote a book remarkable for perspicuity, but with several defects, of which the chief are unphilosophical arrangement, and eulogy of bad as well as good parts of English law; nor is his reasoning always accurate, as was shewn by Bentham in his essay on Government. With all its defects, Blackstone's work has not been superseded by any better book, unless it be the Commentaries of the American lawyer Kent, which, of course, contain much that is only applicable to the United States. The respect of English lawyers for whatever is ancient in the common law, is singularly apparent in the majority of law-books. If any great authority, such as Coke or Blackstone, has treated of a particular subject, whoever afterwards writes upon it seems to be held bound to incorporate all that he has said, not only in spirit but in words. Of the reports of cases, there is now a vast collection. From the time of Edward I. to that of Henry VIII. they were annually collected by officers appointed for the purpose, and were called year-books. They were latterly published by private reporters, and are now superintended by a council of lawyers chosen by the Inns of Court and the Society of Solicitors. As they are all precedents in succeeding cases, and therefore the source to which the public look for the interpretation of the laws they must obey, it may be questioned whether they should not be officially recorded by persons responsible for the accuracy of their reports, as is the case to a certain extent in America.

Equity Law.

This second great division of English law was originally a system by which relief was given in cases where a strict interpretation of the common law would have produced injustice. It could look to the influence of accident, error, and fraud when common law could not. A deed, for instance, was lost. The common-law courts could hear nothing about what might have been its contents, and as the deed could not be found, the party must suffer. Here the court of equity came to his relief, by compelling a 'discovery' of the terms of the agreement. When a trustee was put in possession, common law could not look at him in any other light but as holding for his own behoof; but equity compelled him to do his duty to his employers. Where an obligation was to pay, common law could exact performance; but if it was to perform any other act, the assistance of equity was generally necessary to enforce it. Again, the courts of law might give a remedy for a mischief, but they could not interfere to prevent it. This necessary branch of legal administration came likewise within the jurisdiction of the judge in equity, who, on cause shewn, could issue his 'injunction.'

The existence of equity, which in the technical sense attached to it is peculiar to England, though a similar distinction existed at an early stage of Roman law, is a singular monument of the imperfection of common law. The origin of this system is as obscure as that of the common law, though of more modern date. The earlier law-books do not mention it, and it was probably long in operation as a sort of exception to the ordinary course of law, before lawyers would acknowledge it as a system. It originated in persons who had suffered manifest injustice, which the ordinary courts could not remedy, applying for redress to the sovereign in person. The king's conscience-keeper, or chaplain, became referee on these occasions, and what he did he sealed, by way of testimony of the royal authority, with the king's seal. Hence the origin of the lord chancellor with his great seal, whose office, in some form, has been traced so far back as the days of Edward the Confessor. In early times, the chancellors were ecclesiastics, and they thus were in the habit of adjusting their equity, and the form in which they administered it, to the civil and canon law. Whatever may have been the origin of equity, it became at last a fixed system of law. It is a popular mistake that a judge in equity gives his decision according to what is called 'the general principles of equity and justice,' without reference to strict rules. He is bound down by precedents, and there are many acts of parliament which regulate his proceedings; so that in reality equity has become a department of the general system of law. It is a department, however, in which recent legislative effort has been steadily, though not as yet very successfully, directed to the amalgamation of the two systems; the law of Scotland, in which they never were separated, being in this, as in other instances, the real, though seldom the acknowledged model of imitation.

Statute Law.

The third branch of the law consists of statutes, or acts of parliament. The constitution of the legislature by which they are passed does not belong to the present subject; it need only be observed, that to be law, every word of an act requires to have the consent of the three branches of the legislature—Sovereign, Lords, and Commons. In very early times, acts seem to have been petitions by the parliament acceded to by the sovereign. The

parliament was convened to supply the king with money, and while it kept him in suspense, it sometimes prepared a petition against grievances, to which a needy monarch found it prudent to accede. It became a practice for the judges, at the end of a session of parliament, to convert the substance of the 'petitions,' or 'bills,' which had been acceded to by the king, into acts. This practice was dangerous, the judges having the power, when parliament had ceased to sit, of altering the intended provisions. To remedy this, the plan now followed was adopted, of making the bill contain the exact words which it was intended should constitute the act. Singularly enough, the bill is still in the form of a petition, and when made an act, the only alteration is, that the words 'May it therefore please your Majesty' are struck out.

A bill may be introduced either in the House of Commons or in the House of Lords. It is a rule that all bills affecting personal status—such as bills of attainder for treason, bills for naturalising foreigners, bills for divorce, until the establishment of a Divorce Court by 20 and 21 Vict. c. 85, &c.—make their first appearance in the House of Lords. The Commons possess the more substantial privilege of originating all bills of supply, or for the levying and appropriation of taxes. The privilege is jealously guarded, and it is usual, should the House of Lords amend such a measure, for the House of Commons to refuse to take it into consideration again, and to authorise their Speaker to throw it over the table. All measures involving taxation originate in what is called 'a committee of supply,' in which the house is presumed to be sitting, not to debate great questions, but simply to transact pecuniary business. In the case of the introduction of any ordinary bill, amending the law, into the House of Commons, the first stage is, to obtain leave from the house to 'bring it in.' In the House of Lords, a member may move a bill without previously obtaining leave. On a bill being brought in, the next step is the first reading. A member moves that it be read a first time. If there be a party in the house strenuously opposed to the principle of the measure, it may be opposed in this stage, and a debate and division will of course ensue. Objections to the details are reserved for a future opportunity.

The next and principal ordeal is the second reading, after which the bill is referred to a committee of the whole house. In this committee, as in a committee of supply, the body is the same in every respect as that which constitutes the House of Commons, but the members are considered as having assembled, not to debate general questions, but to enter on a business-like examination of the various clauses of the measure. When the committee have examined all the clauses, they report to the house. It is then moved that the bill be read a third time. This stage is, in disputed measures, generally the last trial of party strength. If the third reading is carried, there is still another motion, to the effect 'that the bill do pass,' but this motion is seldom opposed. On the bill passing one house, it is conveyed to the other, where it has to pass through the same succession of readings. When amendments are made on a bill after it has passed through one of the houses, in that to which it is then sent, it must be re-transmitted to the house where it first passed. That house may accede to the amendments, and so let the bill pass; or it may reject the whole measure in consequence of them; or it may, adhering to its first opinions, hold a conference with the other house, with a view to a settlement of differences. When a bill has passed both houses, its next step is the royal assent, which may be given either by the sovereign personally or by commission.

A bill that has received the royal assent becomes a law, the operation of which commences when the consent is adhibited, unless another point of time be stated in the act. All the statutes of a session are ranked in order, according to the date at which they have received the royal assent; and the whole set are distinguished from others by the year of the reign in which they have been passed. Technically, the whole legislation of a session is called one act, and each statute or act, according to the common acceptation of the term, a chapter of it. In the printed edition of the statutes, each chapter is divided into sections, but in the original copy of the act there is no such division—the whole is a continuous manuscript without break. Nor is the division into chapters even authoritative. The consequence is, that when a new act is passed, making alteration on some part of a previous one, instead of specifying the chapter and section that is altered, it describes the act vaguely, as an act passed in such a session, for such a purpose. Thus, in 1839, an act was passed to alter a section of the Patents Act, passed in 1837. For any ordinary purpose, this would have been called an act to amend the seventh section of the act 5 and 6 William IV. chapter 83; but as there are no such things as chapters and sections known in law, the legislature could only give a roundabout description, thus—'An act to amend an act of the fifth and sixth years of the reign of his late Majesty William IV. intituled an act to amend the law touching letters-patent for inventions.' Sometimes there is a series of acts, the latter ones amending those that have preceded them, so that the titles are involved in confusion. Even where the acts are divided into sections, as they are by the printers, it is found difficult for lawyers to unravel their meaning, and to unprofessional people they are often a sealed book. A section generally consists of but one sentence; and as it has often to give a long narrative of things that must be done, independently of circumstances, and others that must be done in particular cases, and others that may be done, but are not imperative, and others that must not be done, &c. the comprehension of the full meaning of the sentence requires a strong mental effort.

There are some acts which are passed every session in the same terms, such as the Mutiny Act, the indemnity for neglecting to take the oaths, &c. Independently of these, the statutes now passed in a single year are often over 100 in number, and generally fill a quarto volume of about 500 pages, very closely printed. Besides these acts, which generally either apply to the whole empire, or to some one of the great national divisions of it, there are annually passed several folio volumes of statutes called 'Public Local Acts,' consisting of the police acts of the various towns, and acts for the construction and management of harbours, turnpike roads, bridges, gas-works,

water-works, railways, &c.; and Private Acts, which relate to private and personal interests, such as naturalisation, restitution of honours, change of family name and arms, exchange or sale of entailed property, and the like.

The necessity of arranging and consolidating the statutes has from time to time been felt and expressed by statesmen. Lord Bacon, in whose days the statute law did not occupy a twentieth part of its present bulk, spoke with alarm of its overgrown size, and recommended that the whole be abridged, in order to its being made manageable. Something at last has been done to this end, and the existing statute law has been revised and compressed, down to the 10th of George III. or the year 1770, into two octavo volumes. The whole is expected to be completed in four volumes.

The necessity for the reform of the whole system of law, the introduction of one comprehensive code, and for the revision of judicial procedure, has now become very apparent. Although we must still wait for some time longer for a code of the whole law, a step of the greatest importance towards it has been taken by the passing of an act (afterwards explained) during the session of 1873, which amalgamates the jurisdiction of the common law and equity courts, and must before long result in removing all distinction between the two systems, the existence of which was the greatest defect in English law. This act was carried through parliament by Lord Chancellor Selborne, formerly Sir R. Palmer.

English Law-courts.

We have now to notice the various courts of law in England. The House of Lords might be considered, until the passing of the Judicature Act of Lord Selborne, just mentioned, as the general court of appeal from the whole kingdom. There is only one set of superior judicatures from which a reference may not come before it in some form or other—the criminal court of Scotland. The origin of parliament is connected with the great council of the feudal kings, which gave them advice both in legislative and judicial matters. When parliament was separated into two houses, the judicial business was kept by the upper, and, probably at the instigation of the bishops, the Lords adopted the power of administering oaths, not possessed by the Commons—a circumstance which more distinctly marked their judicial character. But though the appeal is nominally taken to the House of Lords, it is heard and decided on by one or more of the eminent lawyers, of whom there are always several in the house, and generally by the Lord Chancellor. Until the case of O'Connell in 1844, the lay or non-legal lords occasionally exercised their privilege of judging in appeals. Independently of their powers as judges of appeal, the Peers act as a criminal court in all cases where a peer of the realm is tried for a capital crime, presided over by a judge, called the Lord High Steward. This official is properly the judge, the peers acting as a jury, and giving their verdict on the question of guilt. The directly feudal origin of this rule of ancient practice will be at once recognised.

The principal courts were divided into courts of common law and courts of equity. The former were three in number: the King's or Queen's Bench, the Common Pleas, and the Exchequer. Each had a chief, and four assistant judges, called puisne or junior judges. These courts date their origin from the Conquest. On feudal principles, the Norman kings called all the principal causes which had, under the Saxons, proceeded before the county courts, to be decided in their own hall, or court, by their own great council, which was presided over by an officer called the Justiciar. This court, called the *Aula* or *Curia Regis*, the King's Court, at first followed the king's person—a great inconvenience, removed by Magna Charta, which fixed it permanently in Westminster. Under Edward I. the system was adopted of sending deputations from the court twice a year to try cases in various parts of the country—the origin of the present assize or circuit courts. Under the same monarch, the jurisdiction of the court was split into three parts. To the justiciar, afterwards called Chief-justice, were assigned the pleas of the crown, as they were termed, involving all the graver offences; and as he was the highest judicial officer in point of rank, his court was appointed to have cognisance over the two others. The matters connected with the exchequer—the regulation of the royal domains, the collection of duties and other taxes—were committed to judges called Barons, presided over by a Chief-baron. All questions about the possession of land, and other litigations between one citizen and another regarding matters of property, were called 'common pleas,' and were committed to certain justices, presided over by a Chief-justice.

The King's or Queen's Bench was thus the chief criminal court, and the Exchequer the principal tribunal for revenue matters; but these courts were by no means restricted to the departments to which they were so assigned—possessing, concurrently with the common pleas, a jurisdiction in all ordinary questions of common law.

An appeal lay from any one of the courts to the judges of the other two, who, when met to decide on such appeals, constitute a court called the Exchequer Chamber. Fourteen of the fifteen judges who form these common-law courts hold assizes in the various county towns—in some of them twice, and in others thrice a year. Here they act both as civil and criminal judges. Offences committed in London and its vicinity are tried by a tribunal lately created, called the Central Criminal Court. From the assizes, an appeal is competent to the court in London by a motion for a new trial on the ground that the judge misdirected the jury, or that the verdict was contrary to the evidence.

The principal equity tribunal in England was that of the Chancery. It had in it three distinct courts, and three judges—the chancellor, the vice-chancellor, and the master of the rolls; latterly, the number of vice-chancellors was increased to three. At one time, all proceedings in bankruptcy centred in the lord chancellor, but the increasing importance of this class of business rendered it necessary to appropriate a separate court to the purpose. This was accomplished in 1832 by Lord Brougham; and since then, the utility and importance of the Insolvent Debtors' Court have been materially enlarged. Another court is called the Judicial Committee of the Privy-council. It consists of selected judges of the other courts, and retired

Indian or colonial judges. Its principal jurisdiction is in appeals from the colonial courts and the Court of Admiralty. The Court of Admiralty has jurisdiction in maritime contracts and crimes committed on the high seas. It professes to follow, not the special law of England, but the general commercial law of modern Europe, founded on the principles borrowed from the Roman law, but modified by the practice of merchants and the decisions given in the principal Admiralty courts of Europe and America, particularly in that of England when presided over by Lord Stowell, the brother of Lord Chancellor Eldon. In time of war, the court receives a commission to adjudicate regarding prizes taken from enemies, or from neutrals committing breaches of neutrality. The Judicial Committee also determines appeals from the ecclesiastical courts.

Besides the tribunals mentioned, there are ecclesiastical courts in the two archiepiscopal provinces of Canterbury and York. In the former, there are the Court of Arches, the Prerogative or Testamentary Court, and the Court of Peculiars; in the latter, the Prerogative Court and the Chancery Court. There are also many inferior ecclesiastical courts. If we were to complete the list of English tribunals, it would be necessary to include the justices of peace, who, besides many special powers in revenue and other matters conferred by act of parliament, sit, at the general and quarter sessions, as judges in minor cases. In addition to all these, there are various courts, of greater or lesser jurisdiction, connected with cities and boroughs.

An important tribunal, called the County Court, was instituted by an act of Lord Brougham, 9 and 10 Vict. c. 95, for cases of minor value. Its jurisdiction was originally confined to common-law cases, but has since been extended to certain equity and bankruptcy suits.

Changes effected by the Judicature Act, 1873.

Such was, and still is, the system of the administration of law in England; but by the act before referred to, passed in 1873, called the Judicature Act, the following changes will come into operation on 2d November 1874. By this statute: (1.) The whole superior courts both of common law and equity, the Courts of Admiralty, Probate, and Divorce, the London Court of Bankruptcy, two peculiar courts of common pleas which formerly existed at Lancaster and Durham, are united into one supreme court. (2.) This court is to be divided into two branches—the High Court of Justice, for the exercise of original jurisdiction; and the Court of Appeal, with an appellate jurisdiction from the High Court. (3.) The appellate jurisdiction of the House of Lords in all English appeals is transferred to this new appeal court, as well as the appellate jurisdiction of the Committee of Privy-council in all Admiralty causes. Power is also given to the sovereign by orders in council to transfer to it the jurisdiction of the Privy-Council in ecclesiastical and colonial causes. It was proposed by the bill to transfer to the new appeal court the jurisdiction in Scotch and Irish appeals, but this was thrown out by the Conservative leaders in the House of Lords, and that jurisdiction will still, probably for a short time only, remain vested in the House of Lords. (4.) The new High Court is to recognise all rights, whether legal or equitable, which were recognised by any of the courts to whose jurisdiction it succeeds, and may give all remedies which it was in the power of any of them to afford to a suitor. (5.) A uniform procedure is to be followed in all the branches of this new High Court, which is intended to combine and adapt the best parts of the procedure in the equity and common-law courts. The pleadings under the new system will nearly resemble those of the English Admiralty Court and the Scotch Court of Session, in which the suitor or plaintiff has to give a short statement of the facts on which his claim is founded, and the defendant an answer thereto, with a similar statement of any defence independent of a mere denial of the claim. Jury trial is still retained, but provision is made for trying before a judge, or remitting to referees, cases more suited for that form of tribunal. (6.) The substance of the English law is in several important particulars expressly altered in favour of equity, and it is generally provided, that wherever the rules of law—*i. e.* the common law and equity—come into conflict, the rules of equity shall be preferred. (7.) The High Court is to be divided into five divisions—called the Chancery Division; the Queen's Bench Division; the Common Pleas Division; the Exchequer Division; and the Probate, Divorce, and Admiralty Division. These divisions are in the first instance to receive the business which belonged to the old courts from which they take their names, but provision is made for the transference of business from one division to another whenever necessary for its due despatch. (8.) The judges in the High Court are to be the existing judges in the supreme courts, but their number is to be reduced by vacancies to twenty-one. The judges in the Court of Appeal are to be five—the Lord Chancellor, the Lord Chief-justice of England, the Master of the Rolls, the Lord Chief-justice of the Common Pleas, and the Lord Chief-baron of the Exchequer; there is also provision made for the appointment, as additional judges, of certain retired judges, but no provision is made for any salary to be paid to these additional judges. (9.) Finally, it is provided that a council of the judges of the High Court is to meet at least once a year, under the presidency of the chancellor, to consider the operation of the act, and what changes may be necessary in it; and if such changes require the authority of parliament, they are to report their opinion on them to one of the principal secretaries of state. It is evident that, though the act directly deals with the constitution of courts and forms of procedure, it really introduces a complete change in the substance of English law. No measure of equal magnitude relating to the law has ever before been passed by the parliament of Britain, and we may entertain a hope that persons wise enough to devise, and skilful enough to carry so valuable a change, may proceed still farther, and produce a code of British law. If they do not attempt or succeed in this, they will at least leave an example to encourage those who come after them, and a proof that, though difficult, it is not altogether impossible to reform the law by the agency of the English parliament, most of whose members are ignorant in regard to it. To attain this desirable

object, efforts should be made to educate all citizens, and specially those who aspire to become members of parliament, in the laws of their country.

English Legal Usages.

Two English legal usages have played so important a part in preserving the liberties of the people, as to deserve separate notice.

1. *Trial by Jury*, in criminal cases, is of great antiquity, having its foundation in certain Anglo-Saxon forms favourable to individual liberty, and specially in the practice of compurgation, formerly referred to, for the compurgators, who were originally witnesses, became afterwards judges of the matters of fact in criminal trials. It was sanctioned by Magna Charta, and has ever since continued a marked characteristic of the law of England. During the present century, it has been adopted in criminal cases by most of the states of the continent. A jury originally consisted of persons in a rank as nearly as possible analogous to that of the party charged with an offence. Practically, it is composed of individuals miscellaneous in rank, so as to insure impartiality in decision. In England, the jury, in criminal cases, is of two kinds, the grand and the petty jury. The *grand jury* consists of twenty-four persons summoned by the sheriff, to attend the court and present all offences committed within the county; that is, determine whether the cases of criminal accusation shall go before the petty jury. The jury so called examine witnesses on oath, and receive other evidence; if satisfied that there are grounds for trial, they *find a true bill*, as it is called, and the trial proceeds. The object of this institution is to prevent the oppression or damage of innocent persons; but, in practice, it is a clumsy method of investigation and deliberation, and liable to error, from the vast quantity of business to be hurried through, as well as burdensome to the lieges. The time seems to have arrived when it will require to be superseded by the more efficient institution of a responsible public prosecutor.

The *petty jury*, for the trial of those against whom a true bill is found, consists of twelve men, drawn by lot from a larger number summoned. This jury is the sole judge of the fact or facts charged, and its decisions require to be unanimous. In many instances, a jury cannot conscientiously arrive at a unanimous conviction, in which case either one or more must yield to the majority; or the whole, after experiencing the pangs of hunger for one or two days, require to be discharged, when a new trial must ensue.

Trial by jury is usually considered to be the palladium of our rights and liberties; but this favourable view of its character needs modification. It is principally useful as a safeguard against vindictive attempts at oppression on the part of the crown or other powerful accusers; yet even in this respect it has on various occasions proved faulty. In Ireland, for example, where the English forms of grand and petty jury have been introduced, it is observable that there is scarcely a possibility of procuring a conviction where the state is the complaining and injured party, although the facts charged be proved beyond the possibility of cavil. It can command respect only where there is a deep sense of rectitude, and a disregard of public clamour.

2. *Habeas Corpus.*—Only the law, not the sovereign or any functionary of government, can imprison the person of a subject, who can reclaim against wrongful or unconstitutional seizure and incarceration by an action of *habeas corpus*, introduced in the reign of Charles II.; that is, an action before a competent court to be released, or have the custody of his own person, unless a legal warrant can be shewn for imprisonment. In periods of civil commotion, the habeas corpus is occasionally suspended by an act of the legislature; by which means the state can imprison without challenge, and dismiss without trial. As may be supposed, this serious infringement of the constitution is resorted to only in extreme cases. In Scotland, a law with a similar object was passed in 1701.

After this brief sketch of English law, it is unnecessary to describe that of Ireland, which is in most respects copied from it.

LAW OF SCOTLAND.

In its earliest form the law of Scotland bears a close analogy to that of England, and of the other Teutonic nations of Northern Europe. Amongst the external causes which modified it at a more recent date, two are the most important: the intimate connection which subsisted for several centuries between this country and the continent of Europe, more particularly France; and the union with England. First—to the French connection, we trace a large infusion of the principles of the Roman civil law into the Scottish law of marriage, of guardianship, of contracts; and the adoption of judicial arrangements peculiarly French, such as the constitution of the College of Justice on the model of the parliament of Paris, and the institution of a public prosecutor. Much of the legal and official terminology of the law of Scotland, which seems mysterious to English lawyers, is to be ascribed to the same cause. The *ouverture* of the French Estates still lives in the overture of the ecclesiastical courts; the English mayor and alderman, both familiar to our earlier statute law, became a provost (prévôt) and bailie respectively; the barrister is an advocate (avocat), and the attorney a procurator (procureur), and the like. Second—to the union with England is due the assimilation which has already taken place, and which is daily going on, between the laws of Scotland and England.

As in England, the law first became a matured system under the influence of feudalism. Little is known of the Anglo-Saxon, and still less of the Celtic customs, which undoubtedly existed, but have now almost entirely disappeared. The origin and progress of feudalism in Scotland are very obscure. The chroniclers attribute the foundation of the system to Malcolm II. in the eleventh century. It is more likely that, with the resort of foreigners, Saxon and Norman, to the court of the Scottish king Malcolm Canmore and his sons, the system was gradually introduced. The monarchs, who were ambitious of presiding over a distinguished court, gave encouragement to the Normans, to whom they granted large fiefs or lordships; and it was natural that they should retain the same usages to which they were accustomed in the country of their origin. The whole of the Lowlands and part of the Highlands became nearly as thickly adorned with Norman

names as England. There appear to have been many points on which the earlier laws of the two divisions of the island were identical. In England, however, the feudal system received many checks, while in Scotland it was allowed to grow rank, and the deference paid to the civil law in all matters not directly governed by the feudal law, served to widen the distinction between the legal institutions of the two countries.

Little information has yet been collected concerning the practice of the law in Scotland previous to the sixteenth century. Edward I. probably destroyed some vestiges, through which its history might have been traced; but he seems to have been charged by antiquaries with the destruction of more than ever existed. The earliest collection of the laws, the *Regiam Majestatem*, bears so near a resemblance to the English work of Glanvil, noticed above, that it is evidently copied from that work; for the view of some Scotch lawyers, that Glanvil copied the *Regiam*, is now abandoned. There is also an old collection of burgh laws, probably of the reign of David I. The first Scottish legal writer whose works are quoted is Balfour, who prepared, about the latter end of the sixteenth century, a compendium, chiefly derived from the *Regiam Majestatem*, the acts of parliament, and the decisions of the court. In the reign of James VI. a commission was appointed to make inquiry into the laws, of which Sir John Skene was a member. The commissioners collected and published many acts of parliament, the *Regiam Majestatem* and other consuetudinary laws, such as the customs of the royal burghs; and Skene wrote an interesting treatise on the meaning of technical legal expressions. Much labour has been bestowed on these subjects in quite recent times, and more accurate editions of them have been published.

The first scientific writer on the law of Scotland, however, was Sir Thomas Craig, whose book on the Feudal Law was published in 1655. It is a work of learning, in which the reader is somewhat surprised to find that, though the work professes to be a Scottish law-book, it should derive so much from the practice of continental nations. The next great authority is Lord Stair, the statesman of the reigns of Charles II. James VII. and the first years of William III. whose *Institute* is remarkable for the depth of its legal principles, and the acuteness with which they are applied. Sir George Mackenzie, called 'the bloody Mackenzie,' from his prosecution of the Covenanters as Lord Advocate of James VII. wrote treatises both on the civil and criminal law, but these are not of much value. Soon after the middle of the eighteenth century, a second *Institute* was prepared by Mr Erskine, Professor of Scottish Law in the university of Edinburgh, on the model of Stair's work, and better adapted to modern times. Sir Walter Scott has justly denominated Erskine's *Institute* the Scottish 'Coke upon Lyttleton.' There were formerly few opportunities of acquiring a legal education in Scotland, and it was the practice for Scotch students to repair to one of the continental universities, of which Paris and some of the other French universities in the sixteenth and seventeenth centuries, Leyden and Utrecht in the seventeenth and eighteenth centuries, were preferred. On the occasion of the appointment to a chair of law in Aberdeen, in the seventeenth century, Spalding the Chronicler says, it was 'strange to see ane man admitted to teach the lawes who was never out of the countrie studieing and learning the lawes;' thus expressing his astonishment that any man could be presumed to become acquainted with the system of law on the spot where it is administered. The first law-chair in the university of Edinburgh, that of Public Law, was instituted in 1707; five others have since been added; and the legal school of Edinburgh, though still far inferior to those of the German universities, is the most complete in this country. The German universities are still, however, resorted to by Scotch students for the study of Roman law. The civil law is still studied in Scotland, but its ancient influence has sunk, from the progress of commerce and the increase of statutory regulations.

Scotland has a considerable quantity of early statute law, but not nearly so much as England. Down to the Revolution, the general principles only of the acts had the assent of the assembled parliament—the details were prepared by a committee called the Lords of the Articles. The older acts are remarkable for their brevity and precision, which was commended by Lord Bacon. It must be confessed, however, that in some cases the brevity of the Scotch statutes has produced obscurity, which it has required many litigations to remove. According to a usage derived from the civil law, acts of parliament become repealed by disuse in Scotland, a principle unknown in English law.

The earliest tribunals in Scotland were either the parliament, as the great council of the realm, or committees of it, acting with the delegated powers of the whole body, and the king's privy-council. There was likewise, as in England, a king's justiciar, whose authority was large, and before the institution of the Court of Session, extended to civil as well as criminal matters, although the limits of his jurisdiction in the former were not well defined. Committees of parliament were, in the fifteenth and the beginning of the sixteenth century, sometimes formed into regular courts of justice. In 1532, the present Court of Session was constituted, on the model of the parliament of Paris. The chancellor, whose principal duties disappeared at the Union, was chairman of this body. It consisted of fifteen judges, including a president, who was chairman in absence of the chancellor. In 1830, the judges were reduced to thirteen, which is the present number of the court. It consists of two divisions, which are separate tribunals of equal authority. Five of the judges also act as individual judges in courts of their own, in which capacity they are termed 'lords ordinary.' An ordinary case, on coming into court, is discussed before a lord ordinary, from whom there is an appeal to one of the divisions of the 'Inner House,' as it is termed, where the remaining judges sit collectively; and from the Inner House there is an appeal to the House of Lords. There is no such conventional distinction as that between law and equity known in Scotland, and hence the Court of Session is sometimes called a court 'both of law and equity.' There are two very useful descriptions of action peculiar to this court: the one is called an action of 'declarator,' which a person may bring, to have the law as to his rights

declared; another is called a 'multiplepoinding,' which may be raised by a man having money in his hands which more than one person is claiming, that he may know to whom he can legally pay it: by a fiction analogous to those we have seen in the law of England, this action may also be raised, in the name of the holder of the money, by any of the claimants. Trial by jury was not, until lately, added to the jurisdiction of this court. It is limited to certain descriptions of cases, and has never become popular. The functions of the Court of Exchequer for revenue cases, and of the Court of Plantation of Kirks and the allocation of Teinds, have now been practically united with the Court of Session, though the Court of Teinds is still nominally a separate tribunal.

The principal criminal court is the Court of Justiciary, consisting of seven judges of the Court of Session, who sit in Edinburgh, and hold circuits in the country. The most remarkable peculiarity in Scottish legal usages is the practice of criminal prosecution, which is clear, simple, and effective. All crimes of a high class are prosecuted at the instance of the *Lord Advocate*, or chief public prosecutor, at the expense of the country. Lesser crimes are prosecuted by *procurators-fiscal*, of whom one is attached to each sheriffdom. In no case is the party injured put to any trouble or expense. The Lord Advocate, appointed by the crown, along with crown-counsel, judges of the propriety of prosecuting for crimes, there being no grand jury. The right of private parties to prosecute still exists, but is scarcely ever exercised. The jury before whom cases for trial are brought consists of fifteen persons selected by lot from forty-five summoned jurors, and the decision or verdict is by a majority. The Scottish criminal law is partly statute, partly founded on long usage. There are many offences punishable with death, if the prosecutor do not restrict the extent of punishment to be awarded, which he now does in almost every case except murder. The sheriffs, or local judges of counties, have important judicial powers, both civil and criminal. The former extends to every description of dispute regarding property, except such as depend on the title to land. The powers of these judges have lately received extensive additions, especially in matters of insolvency and bankruptcy. They do not employ a jury, except in criminal cases, in which their power of inflicting punishment does not exceed imprisonment. The *sheriffs*, called *sheriffs-principal*, or sometimes *sheriffs-depute*, because they were originally deputes of the hereditary sheriffs of the Scottish counties, are advocates, practising before the supreme courts, not honorary functionaries, as in England. In each county there are, besides, one or more resident sheriffs, or *sheriffs-substitute*, who issue warrants and hold civil and criminal courts. An appeal lies from the decision in civil cases to the sheriff-depute, and from him to the Court of Session.

THE FRENCH CODES.

The ancient laws of France were a mixture of the civil, canon, and feudal law, but there was a great distinction between the law of the northern and southern provinces: in the former, called *pays coutumier*, the customs, as in England, formed the basis of the law, and the civil law of Rome was only applied where these were silent or doubtful; in the latter, called *pays du droit écrit*, the Roman, which for long was the only written law, was the basis, though modified by particular usages and the feudal law. Partly they were the doctrines of the authorities on the civil law, and partly they were the ordinances issued by the various monarchs. By far the greatest portion, however, in bulk, consisted of the peculiar feudal customs of the various provinces. In these the feudal system was sometimes retained in so high a state of purity, that the collections of provincial customs are esteemed excellent authorities on the subject. But it was not merely in each province that there was a local custom. The power of the crown, or any other paramount legislature, was so feeble, that wherever an assembly of men were held together by one common tie, as where they were co-vassals of one lord, or members of the same civic community, they had in some measure a code of laws of their own. The royal codes were estimated at about 300, but of the number of inferior local customs it would be impossible to make an estimate. Voltaire observes, that a man travelling through his country has to change laws as often as horses, and that the most learned barrister in one village will be a complete ignoramus a few miles off. The principal courts of law were the parliaments of the respective provinces. Seats in them were generally held by purchase, or were in the hereditary succession of great families, who thus constituted a species of professional nobility. The decrees of these bodies were often baffled or reversed by the royal authority. These alterations of the decisions of the courts, however, were performed, not as a judicial revision, but by the simple authority of the king; and thus the parliaments, being subject to no judicial control or responsibility, adhered but slightly to fixed rules of law, and often acted according to their own will and discretion. The jury, even so much of it as may have existed under the old feudal form, had entirely disappeared, and proceedings were conducted in secret. Criminal investigations, instead of terminating in a conclusive trial, as in England, were greatly protracted; the torture was extensively employed, but in the general case, only when there was as much circumstantial evidence as would justify a conviction in this country.

The whole of this system was swept suddenly away by the Revolution. In 1800, Napoleon appointed a commission to draw up a project of a civil code. The project, when prepared, was circulated for comment and suggestion, and was afterwards, along with the observations made on it by the different courts of law, discussed in the council of state and the tribunate. Thus was formed the *Code Civil*, or civil code of France, more generally known by the term *Code Napoleon*, which was applied to it under the Empire. Nearly at the same time, and in the same manner, was framed the *Code de Procédure Civile*, or code for regulating the form of process in civil actions, and specifying the jurisdictions of the various courts. Being a subject more connected with technical detail, and involving less of general principle than the civil code, its provisions were left almost entirely to the arrangement of the lawyers. Besides the technical directions, there are in this manual many which concern the ordinary

proceedings of citizens at large, such as directions for the order to be taken regarding the effects of a deceased person, &c. This code is generally accompanied by a table of fees in law proceedings. In 1807, another code was promulgated, called the *Code de Commerce*, regulating partnership, bills and notes, banking, shipping, bankruptcy, &c. By this code, provision is made for merchants choosing boards or courts from among their own number, called *Tribunaux de Commerce*. The jurisdiction of these courts, which are very numerous, extends to questions between merchants, and disputes arising out of commercial transactions. In criminal legislation, a different order was pursued from that adopted in the civil; the procedure code was prepared and adopted before the crimes to which it was to apply, and the punishments it was to enforce, were defined. The *Code d'Instruction Criminelle* was promulgated in 1808, and the *Code Pénal* in 1810.

Such were the laws issued under the government of Napoleon, commonly called *Les Cinq Codes*, or the Five Codes. There are other collections of regulations, which should be added to make up a complete body of French laws—a military code, issued by Napoleon; regulations concerning woods and forests, issued under Charles X.; various laws as to the press and theatrical exhibitions, and alterations of the penal code, issued under the government of Louis-Philippe; and, lastly, the enactments under the Republic of 1848 and the Empire of Napoleon III. It is in the Five Codes, however, passed under Napoleon, and confirmed at the Restoration, that the modern laws of France are known to Europe at large. They are distinguished by the conciseness, clearness, and elegance of their language, and their intrinsic merits. Independently of the division into books and sections, the paragraphs in each code are numbered from the commencement—an arrangement which gives facilities for reference. Thus, there are in the civil code 2281 consecutively numbered paragraphs. In a country where the material of the law is so gigantic as it is in England, it is of the highest interest to mark the practical working of this. To an unlearned person in this country, it is a much easier thing to know the law of France on any particular point, than the law he is living under.

The French codes adopt the phraseology of the Roman law, and many of its principles. The most striking deviation from the previous law of France and the present system of other countries, is perhaps in the rules respecting succession. The children succeed to equal shares of the parents' property, whether it consist of land or movables; and if there be no legitimate children, illegitimate children may succeed. The parent is limited in the disposal of his property by will. He can only bequeath the half, if he have one legitimate child; and the third, if he have two. Restrictions somewhat similar are to be found in other countries with respect to movable property, but not as to land. The effect which the extensive partition, naturally occasioned by this law, has effected, and may effect in France, is a subject of great interest to political economists. In the mercantile law, there are several provisions unknown in this country, such as registers for hypothecs or securities held over movable goods or merchandise; and societies *en commandite*, or partnerships in which certain managing members are responsible for the obligations of the company to the extent of their whole property, while the sleeping partners who advance money are not responsible beyond the amount of their shares. The chief improvement in the criminal law effected during the Revolution, and sanctioned by the code of instruction, was jury trial, to which Napoleon was much opposed: the system, as finally settled, bore more resemblance to the Scottish than to the English form, prosecutions being conducted by public prosecutors, there being no grand jury, and the jury of final trial deciding by a majority. In other respects, the criminal law is more remarkable for its austerity than for its subserviency to the general good of the public. With Napoleon, though that object was not neglected, it was made secondary to the consolidation of his own power; and offences are measured less by their pernicious effects on society at large, than by the trouble or danger they might occasion to rulers. Hence was adopted in many cases the stern and simple method of putting arbitrary power over criminals into the hands of the administrators of the law, while punishments of the highest kind were reserved for offences against the authorities.

HISTORY OF ANCIENT NATIONS.

AS the memory of a man extends back only to some point in his early boyhood, so the memory of our race extends back only to from 3000 to 4000 years from the present date, leaving an indefinite space before that, during which the infancy of the species must have been transacted. The researches of the geologist, indeed, lead to the conclusion that the appearance of man upon our earth is comparatively a recent event in its history; but cannot assign even an approximate date in years or other measurable periods. Nor does the Scriptural account of the creation settle this point. As many as two hundred different calculations as to the age of our species have been founded, by different divines, on the statements of the sacred records—the discrepancy arising from the uncertainty of those texts of the Old Testament in which *numbers* occur. The longest of these calculations dates the creation of man at about 8800 years from the present time, or about 7000 years before the birth of Christ; the shortest at about 5300 years from the present time, or 3500 years before the birth of Christ: the system usually adopted by historians is that of Archbishop Usher, which fixes the event at 4004 B.C. or 5874 years from the present date.

At the earliest period to which authentic history reaches back, the greater part of the known world was more or less densely peopled by human beings, who were divided into races or varieties differing in physical conformation and in language pretty much as at the present day. Nevertheless, it is the prevalent opinion among ethnologists, who make these physical peculiarities and varieties of language a special study, that, altogether independently of Scripture, the great probability is that the race sprung from a single pair, and that from one primitive centre the most distant parts of the earth have been colonised. In the classification adopted in the article ANTHROPOLOGY the human race is divided into three primary groups, viz.—(1) The Mongolidæ, including Chinese, Japanese, Tibetans, Oceanic races, &c.; (2) The Atlantidæ, including the African races and Semitic races; and (3) The Japetidæ, including the Indo-European and Celtic races. Whilst we have said that there is no proof that any race is cursed with an inherent incapacity for improvement, we must also admit that it is only the Indo-European variety of the Japetidæ, and the Semitic variety of the Atlantidæ, who have had planted in them the germ of mighty progress, or made history on a large and lofty scale. From this and other causes they were long grouped together ethnologically as the Caucasian race, and this grouping is still convenient for historical purposes. The Mongolidæ have had at best but a material influence on the history of the world, and their highest civilisation is almost fixed and stationary. The Negro and Mongolian nations have been for the most part the hewers of wood and drawers of water to the pioneers of civilisation, which has been carried on chiefly by the Semitic and Indo-European races. Let us therefore glance first at the history of these humbler varieties of the human race.

ETHIOPIAN OR NEGRO HISTORY.

A German historian thus sums up all that is known of Ethiopian history—that is, of the part which the great Negro race, inhabiting all Africa with the exception of the north-eastern coasts, performed in the general affairs of mankind in the early ages of the world: 'On the history of this division of the species, two remarks may be made: the one, that a now entirely extinct knowledge of the extension and power of this branch of the human family must have been forced upon even the Greeks by their early poets and historians; the other, that the Ethiopian history is interwoven throughout with that of Egypt. As regards the first remark, it is clear that in the earliest ages this branch of the race must have played an important part, since Meroë—in the present Nubia—is mentioned both by Herodotus (408 B.C.) and

Strabo (20 A.D.); by the one as a still existing, by the other as a formerly existing seat of royalty, and centre of the Ethiopian religion and civilisation. To this Strabo adds, that the race spread from the boundaries of Egypt over the mountains of Atlas, as far as the Gaditanian Straits. Ephorus, too (405 B.C.), seems to have had a very great impression of the power of the Ethiopians, since he names in the east, the Indians—in the south, the Ethiopians—in the west, the Celts—in the north, the Scythians, as the most mighty and numerous peoples of the known earth. Already, in Strabo's time, however, their ancient power had been gone for an indefinite period, and the Negro states found themselves, after Meroë had ceased to be a religious capital, almost in the same situation as that in which they still continue. The second remark on the Negro branch of the human race and its history, can only be fully elucidated when the interpretation of the inscriptions on Egyptian monuments shall have been further advanced. The latest travels into Abyssinia shew this much—that at one time the Egyptian religion and civilisation extended over the principal seat of the northern Negroes. Single mummies and monumental figures corroborate what Herodotus expressly says, that a great portion of the Egyptians of his time had black skins and woolly hair; hence we infer that the Negro race had combined itself intimately with the Caucasian part of the population.'*

MONGOLIAN HISTORY—THE CHINESE.

Overspreading the great plains of Asia, from the Himalaya to the Sea of Okhotsk, the Mongolian variety may be supposed to have occupied the area known as China, to have crossed into Japan, and to have reached the other islands of the Pacific, and either through these, or by the access at Behring Strait, to have poured themselves through the great American continent; their peculiarities shading off in their long journey, till the Mongolian was converted into the American Indian.

We find this variety broken up into subdivisions (see ANTHROPOLOGY), of which subdivisions circumstances have given a higher degree of development to the Chinese and the Japanese than to the others, which are chiefly nomadic hordes, some under Chinese rule, others independent, roaming over the great pasture-lands of Asia, and employed in rearing cattle.

There is every reason to believe that the vast population inhabiting that portion of Eastern Asia called China can boast of a longer antiquity of civilisation than almost any other nation of the world; a civilisation, however, differing essentially in its character from those which have appeared and disappeared among the Japetidæ. This, in fact, is to be observed as the grand difference between the history of the Mongolian and that of the Japetic variety of the human species, that whereas the former presents us with the best product of Mongolian humanity, in the form of one great permanent civilisation, the Chinese, extending from century to century, one, the same, and solitary, through a period of 3000 or 4000 years; the latter exhibits a succession of civilisations—the Chaldæan, the Persian, the Grecian, the Roman, the modern European (subdivided into French, English, German, Italian, &c.), and the Anglo-American; these civilisations, from the remotest oriental to the most recent occidental, being a series of waves falling into each other, and driven onward by the same general force. A brief sketch of Chinese history, with a glance at Japan, will therefore discharge all that we owe to the Mongolian race.

The Chinese imagination has provided itself with a mythological history extending many ages back into the unknown past. Unlike the mythology of the Greeks, but like that of the Indians, the Chinese legends deal in large chronological intervals. First of all, in the beginning of time, was the great Puan-koo, the founder of the Chinese nation, and whose dress was green leaves. After him came Ty-en-hoang, Ti-hoang, Gin-hoang, and several other euphonious potentates, each of whom did something great towards the building up of the Chinese nation, and each of whom reigned, as was the custom in these grand old times, thousands of years. At length, at a time corresponding to that assigned in Scripture to the life of Noah, came the divine-born Fohi, a man of transcendent faculties, who reigned 115 years, teaching music and the system of symbols, instituting marriage, building walls round cities, creating mandarins, and, in short, establishing the Chinese nation on a basis that could never be shaken. After him came Shin-ning, Whang-ti, &c. until in due time came the good emperors Yao and Shun, in the reign of the latter of whom happened a great flood. By means of canals and drains, the assiduous Yu saved the country, and became the successor of Shun. Yu was the first emperor of the Hia dynasty, which began about 2200 B.C. and may be said to commence the purely historical period of Chinese development. Even in the story of his reign there is more fiction than fact. After this dynasty came that of *Shang*, the last of whose emperors, a great tyrant, was deposed by Wu-wong, the founder of the Tchow dynasty, which began in 1100 B.C. from which period many date the beginning of real Chinese history.

In this Tchow dynasty, which lasted upwards of 800 years, authentic Chinese history commences. It was during the reign of Ling-wang (571–544 B.C.), one of this dynasty, and most probably about 550 B.C. that the great Con-fu-tse, or Confucius, the founder of the Chinese religion, philosophy, and literature, was born. His name was Kong, but his disciples called him Kong-fu-tse; that is, 'Kong the Master or Teacher.' In the year 248 B.C. the Tchow dynasty was superseded by that of Tsin, the first of whose kings built the Great Wall of China, to defend the country against the Tatar nomades. By rooting out all the petty dynasties, and bringing the whole under one dominion, he may be considered the real founder of the Chinese monarchy; the very name China, or Tsina, is derived from him. When the Tsin dynasty had overpowered all rivals, one of its kings, for the first time in Chinese history, assumed the title of Hoang, or Emperor. The Tsin dynasty was a short one: it was succeeded in 206 B.C. by the Han dynasty, which lasted till 238 A.D. Then followed a rapid series of dynastic revolutions, by which the nation was frequently broken into parts;

* F. C. Schlosser's *Universalhistorische Uebersicht der Geschichte der Alten Welt und ihrer Cultur.*

and during which the population was considerably changed in character by the irruptions of the nomad hordes of Asia who intermingled with it. Early in the seventh century, a dynasty, called that of Tang, acceded to power, which ended in 897. After half a century of anarchy, order was restored under the Song dynasty, at the commencement of which, or about the year 950, the art of printing was discovered, five centuries before it was known in Europe. 'The Song dynasty,' says Schlosser, 'maintained an intimate connection with Japan, contrary to all Chinese maxims; the emperors of this dynasty imposed no limits to knowledge, the arts, life, luxury, and commerce with other nations. Their unhappy fate, therefore—on being extinguished, in circumstances of special horror, by the Mongol conqueror, Kublai Khan (1279 A.D.)—is held forth as a warning against departing a hairbreadth from the old customs of the empire. From the time of the destruction of the Song dynasty by the Mongol monarchy, the intercourse between China and Japan was broken, until again the Ming, a native Chinese dynasty (1368 A.D.), restored it.' Under this dynasty, Peking became the capital of the empire (1408), as a post of defence against the eastern Tatars, who, under the name of Mantchus, established (1644) the Ta-tsing dynasty, which yet occupies the throne. The Tae-ping rebellion is the most extraordinary event in recent Chinese history. Their leader, Hung-sew-tseuen, was a rejected candidate for a post in the civil service. He came across some Christian tracts, which impressed him so much, that he renounced idolatry, founded a society of Deists, and in 1850 revolted against imperial rule. Hung held that he had a divine mission to uproot idolatry, expel the Tatar intruders and existing dynasty, and establish a new dynasty, that of Tae-ping, or universal peace. After a wonderful career of success, he was finally put down by a native army under the 'ever-victorious Gordon,' a colonel in the Indian army.

We may therefore say that China, a country more extensive than all Europe, and inhabited by a population of more than 300,000,000, is an aggregation of matured Mongolian humanity, surrounded by Mongolian barbarism. Chinese history does not exhibit a progress of the Mongolian man through a series of stages: it exhibits only a uniform duration of one great civilised Mongolian empire, sometimes expanding so as to extend itself into the surrounding Mongolian barbarism, sometimes contracted by the pressure of that barbarism, sometimes disturbed by infusions of the barbaric element, and sometimes shattered within itself by the operation of individual Chinese ambition, but always retaining its essential character. In this region Mongolian humanity has been able to cast itself but into one civilised type.

The more salient features of Chinese civilisation may be thus described: China is governed as a despotism, with an emperor as head of the state. Subordinate authority is conducted by mandarins. The laws are exact, and administered with great severity. The bamboo is an instrument of punishment in universal use. The citizen is liable to be stripped and whipped by the orders of the mandarin; and the mandarin himself is liable to the same punishment by the orders of his superiors. Corporal punishment does not involve the same ideas of disgrace as in European countries; and every day in every province of China, thousands of grown-up men are flogged. The full number of strokes mentioned in the sentence is, however, rarely inflicted, part being usually commuted into a fine. Besides corporal punishment, the penalties most common in Chinese criminal procedure are imprisonment, banishment to Tatary, or death in one of the three forms of strangulation, decapitation, or slow torture. Of all offences, treason is the most severely punished; the relatives of the guilty party, and sometimes the neighbourhood to which he belongs, being condemned to share his fate. We may be assured that a people who submit to this species of injustice, and do not murmur under the degrading infliction of blows, are at a low stage of moral and intellectual development.

Properly speaking, the Chinese have no national religion; that which they profess as such is, more strictly, a system of ethical philosophy. They possess a code of morals, which, while it does not deny the existence of God and of a spiritual world, concerns itself chiefly with the business of the present life. The founder of this philosophy, and the most illustrious hero of the Chinese nation, was Confucius, who is supposed to have lived about the year 550 B.C. He appears to have been a man of the highest intellect and virtue; and the doctrines which he taught while alive, and which are also inculcated in numerous writings attributed to him and to his disciples, form at the present day the religious creed of most of the Chinese.

In the religion, or proverbial wisdom, of Confucius, filial mildness and courtesy of demeanour towards all, veracity, upright dealing, and forgiveness of injuries, are sedulously recommended; but from the general deceitfulness and roguery of the Chinese, as experienced by strangers, it would appear that this formal morality exercises but a feeble influence on the conduct. The most remarkable feature in the religion of Confucius is, that it prescribes a code of manners and etiquette to be observed in the general intercourse of society. Hence, in no country are politeness and attention to form and ceremony carried to such an extent as in China. There are, it is said, 3000 rules of manner which an educated Chinese is expected to observe; including rules for saluting a friend in the street, rules for sending gifts, and so forth. Respect for these rules characterises all ranks in China, though in their intercourse with foreigners they are frequently rude and inhospitable.

Cold and nearly atheistic as the philosophy of Confucius is, it recognises the practice of worship; or at least this practice has been ingrafted on it. Deities of three classes—the highest, to whom are offered the *Ta-sze*, or great sacrifices; the middle, to whom are offered the *Choong-sze*, or middle sacrifices; and the inferior, to whom are offered the *Seaoo-sze*, or least sacrifices—have temples in Chinese cities. This worship is in many cases only a profession of reverence for departed human worth. Among the highest objects of worship, besides the heavens and the earth, are the deceased Chinese emperors; among the medium gods are the sun, the moon, and the greater Chinese sages; among the inferior gods are the striking phenomena of nature—such as rain and thunder, as well as eminent Chinese

statesmen and scholars. Confucius is an object of special veneration. In every important town there is a temple to his honour, where sacrifices are regularly offered and sticks of incense are burned. The posterity of Confucius, who are very numerous, are highly revered. Religious homage is also paid to the reigning monarch, who is the supreme pontiff, as well as the civil despot of China; and, on the whole, the ecclesiastical routine of China is but a part of the system of secular government.

Dissatisfied with so ungenial a system, many of the Chinese have sought consolation in the religions of *Buddha* and *Taou*—two rival systems of faith which are tolerated, though not encouraged, by the Chinese government. Buddhism (see MOHAMMEDANISM, &c.) made great progress in China during the earlier part of the Christian era; and at present, thousands of lofty pagodas in honour of the Indian deliverer are scattered over the empire, many of which have extensive monastic establishments attached to them. The sect of Taou was founded by Laou-tsze, who was born in 604 B.C. 54 years before Confucius, and died in 523 B.C.—a Chinese philosopher who seems to have taught doctrines having a far higher scope than those of Confucius. He aimed at making man immortal by constant contemplation of God and repression of the passions. His moral code was good, but it has of late degenerated into all sorts of quackery, and has no hold on the educated people. Although neither sect receives any endowment from the state, she exercises control over both, and directs prayers to be offered at her pleasure in their temples. Nor is the profession either of Buddhism or of Taou inconsistent with orthodox Confucianism, which is more a system of morals than a theological creed.

Where women are treated with indelicacy or harshness, or not allowed to be the companions of men in ordinary affairs, society is in an abject condition. Such is the case in China. The practice of female infanticide is tolerated, and women are exposed to many indignities; the most degrading of which consists in deforming their feet, and rendering them lame by bandaging. Like the women of other Asiatic nations, they are shut up in domestic privacy; and though education is not denied them, they exercise no direct social influence, and are wholly dependent on the will of their husbands, fathers, or brothers.

At present, however, there seems little prospect of any reorganisation of the Chinese mind, except by means of a Caucasian stimulus applied to it. That Mongolian civilisation *is* capable of advancement, is, we think, proved by the recent progress of Japan, and a study of the history of that empire. Till lately, its organisation was purely military, war being, with the exception of the priesthood, the only occupation thought worthy of honour. Trade and agriculture were pursuits only fit for the lower classes. Since 1854, all that has been changed. Japan has opened itself to the influence of western ideas with wonderful rapidity, and is now organised on the type of the imperial system of France. The recorded history of Japan begins with the foundation of a dynasty of emperors by Zen Mou, in 600 B.C. A succession of rebellions under feeble sovereigns followed, till in 1192 A.D. the Tycoon (Chinese *Tai Koon*, or great lord), or chief of the army, usurped supreme authority on all temporal matters, leaving the Mikado, or emperor proper, only a shadow of suzerainty over him, and with possession of supreme authority in spiritual affairs only. Thus there was a double sovereignty—the Tycoon who governed, and the Mikado who reigned. The court of the former was at Yeddo; that of the latter at Miako. Up till 1854, Japan was, in other respects, very like England under the feudalism of the Plantagenets, Daimios, or feudal lords, ruling under the Tycoon with despotic authority the various provinces. In 1549, Francis Xavier introduced Christianity into the country, and the Portuguese opened up a trade with it; but in 1683, both Catholic missionaries and Portuguese traders were expelled, and a rigid policy of isolation adopted. In 1853, the Americans forcibly extorted a treaty from the Tycoon, and, much to the disgust of the Daimios, the country was opened up to foreign trade. Then it entered on a career of marvellous progress. The unification of the nation under the Mikado was first resolved upon, and the Tycoon abdicated after a *coup d'état* and short civil war in 1867–68. The Daimios, by a patriotic act of self-sacrifice, gave up their powers, and an imperial system was founded under the Mikado, who once more assumed supreme authority in temporal as well as spiritual matters. He has an executive ministry, a senate, a council of state; and the Daimios gave way to provincial prefects, who administer provincial affairs pretty much as they do in France. The army and navy were organised on European models. Railways, telegraphs, the arts, sciences, and inventions and industries of the West, were introduced; and it is even now in contemplation to institute an elective parliament; a national code on the mode of the *Code Napoleon* is being drawn up. The religions of Japan are Sintuism and Buddhism, the latter being a comparatively modern importation. The hierarchy of the former, or Sin-syu, consists of the Mikado—who, as descendant of the sun-goddess, unites in himself the attributes of the Deity—two ecclesiastical judges, monks and priests. The chief object of worship is *Ten-sio-dai-sin*, the great Sun-goddess; but there are hosts of demi-gods, for every patriot, warrior, or great man is made one after death. The chief tenets are purity of heart and abstinence from all that leads to impurity, diligent observance of holy days, and pilgrimages to holy places; according to some, mortification of the flesh. The worshippers first wash in a font, pray before the sacred mirror—which, as a symbol of purity, is placed on the altar—then drop a few cash in the money-box, and strike a bell to indicate that their devotions are finished. The social and political progress of Japan has progressed at such a wonderful rate since 1868, that some incline to think it has been too rapid—that, having been the result of forcing rather than growth, it wants the elements of enduring stability. The fact, however, that it *has* progressed under the stimulus of western ideas and influences, is a sufficient proof that a stationary condition is not the inseparable characteristic of Mongolian civilisation, and that the Mongol is not racially incapable of progress.

INDO-EUROPEAN AND SEMITIC HISTORY.

While the Negro race—if we except the ancient Ethiopians—seems never to have emerged out of

barbarism; while the Mongolian has, until quite recently, afforded the spectacle of a single permanent and pedantic civilisation retaining millions within its grasp for ages in the extreme east of Asia; the so-called Caucasian, as if the seeds of the world's progress had been implanted in it, has worked out for itself a splendid career on an ever-shifting theatre. Originating, according to the current view, in Asia, the Caucasian civilisation has shot itself westward, if we may so speak, in several successive throes, adding one country of Europe after another to the stage of history; and, lastly, in modern times, crossing the Atlantic, and meeting in America with a diffused and degenerate Mongolism.

Ancient India.

For the relation of the inhabitants of India to the so-called Caucasian family, we must refer to ANTHROPOLOGY. At what time the vast peninsula of Hindustan could first boast of a civilised population, it is impossible to say; all testimony, however, agrees in assigning to Indian civilisation a most remote antiquity. Another fact seems also to be tolerably well authenticated regarding ancient India—namely, that the northern portions of it, and especially the north-western portions, which would be nearest the original Caucasian seat, were the first civilised; and that the civilising influence spread thence southward to Cape Comorin.

Notwithstanding this general conviction that India was one of the first portions of the earth's surface that contained a civilised population, few facts in the ancient history of India are certainly known. The Hindus themselves, although they have abundance of early literature, have no history. What appears to be history, is a mass of fable, without the means of fixing a date, or extricating the possible facts from the fictions. Such accounts as we have from external sources, merely resolve themselves into the general information, that India, many centuries before Christ, was an important member in the family of Asiatic nations; supplying articles to their commerce, and involved in their agitations. Accordingly, if we wish to form an idea of the condition of India prior to that great epoch in its history—its invasion by Alexander the Great, 326 B.C.—we can only do so by reasoning back from what we know of its present condition, allowing for the modifying effects of the two thousand years which have intervened, and especially for the effects produced by the Mohammedan invasion, 1000 A.D. This, however, is the less difficult in the case of such a country as India, where the permanence of native institutions is so remarkable; and though we cannot hope to acquire a distinct notion of the territorial divisions, &c. of India in very ancient times, yet, by a study of the Hindus as they are at present, we may furnish ourselves with a tolerably accurate idea of the nature of that ancient civilisation which overspread Hindustan many centuries before the birth of Christ—and this all the more probably that the notices which remain of the state of India at the time of the invasion of Alexander, correspond in many points with what is to be seen in India at the present day.

The most remarkable feature in Hindu society is its division into castes, a system so intimately bound up with their religion, that we say no more on this head, referring to the article on HINDUISM &c. for further information.

A hundred millions of people professing this system, divided into castes as now, and carrying the Brahminical ritual into all the occupations of lazy life under the hot sun, and amid the exuberant vegetation of Hindustan—such was the people into which Alexander the Great carried his conquering arms; such, doubtless, they had been for ages before that period; and such did they remain, shut out from the view of the rest of the civilised world, and only communicating with it by means of spices, ivory, &c. which found their way through Arabia or the Red Sea to the Mediterranean, till Vasco da Gama rounded the Cape of Good Hope, and brought Europe and India into closer connection. Meanwhile, a Mohammedan invasion had taken place (1000 A.D.); Mohammedans from Persia had mingled themselves with the Hindus; and it was with this mixed population that British enterprise eventually came into collision.

History of the Eastern Nations till their Incorporation in the Persian Empire.

Leaving India, and proceeding westward, we find two large masses of the human species filling in the earliest times the countries lying between the Indus and the Mediterranean—namely, an Indo-Persian mass, filling the whole tract of country between the Indus and the Tigris; and a Semitic mass, filling the greater part of lesser Asia and the whole peninsula of Arabia, and extending itself into the parts of Africa adjoining the Red Sea. That, in the most remote ages, these lands were the theatres of a civilised activity, is certain, although no records have been transmitted from them to us, except a few fragments relative to the Semitic nations. The general facts, however, with regard to these antehistoric times, seem to be: *1st*, That the former of the two masses mentioned—namely, the population between the Indus and the Caspian—was essentially a prolongation of the great Indian nucleus, possessing a culture similar to the Indian in its main aspects, although varied, as was inevitable, by the operation of those physical causes which distinguish the climate of Persia and Cabool from that of Hindustan; *2d*, That the Semitic mass divided itself at a very early period into a number of separate peoples or nations—the Assyrians, the Babylonians, the Phœnicians, the Jews, the Arabians, &c.—and that each of these acquired a separate development, and worked out for itself a separate career; *3d*, That upwards of a thousand years before Christ, the spirit of conquest appeared among the Semitic nations, dashing them violently against each other; and that at length one Semitic fragment—that is, the Assyrians—attained the supremacy over the rest, and founded a great dominion, called the Assyrian empire, which stretched from Egypt to the borders of India (800 B.C.); and *4th*, That the pressure of this Semitic power against the Indo-Persic mass was followed by a reaction—one great section of the Indo-Persians rising into strength, supplanting the Assyrian empire, and founding one of their own, called the Persian empire (536 B.C.), which was destined in its turn to be supplanted by the confederacy of Grecian states in 326 B.C.

Beginning with Egypt, let us trace separately the career of each of the Eastern nations till that point of time at which we find them all embodied in the great Persian empire:

The Egyptians.

Egypt, whose position on the map of Africa is well known, is about 600 miles long from the Mediterranean to the First Cataract. Through its whole length flows the Nile, a fine large stream, rising in the equatorial regions of Africa, and, from certain periodic floods to which it is subject, of great use in irrigating and fertilising the country. A large portion of Egypt consists of an alluvial plain, similar to our meadow-grounds, formed by the deposits of the river, and bounded by ranges of hills on both sides. The upper part of the valley seldom exceeds ten miles in width, and in some places is barely two; the lower part spreads out into a delta about eighty miles at its greatest breadth.

A country so favourably situated, and possessing so many advantages, could not but be among the earliest peopled; and accordingly, as far back as the human memory can reach, we find a dense population of a very peculiar character inhabiting the whole valley of the Nile. These ancient Egyptians seem, as we have already said, to have been a mixture of the Semitic with the Ethiopic element, speaking a peculiar language, still surviving in a modified form in the Coptic of modern Egypt. In the ancient authors, however, the Egyptians are always distinguished from the Ethiopians, with whom they kept up so close an intercourse, that it has been made a question whether the Egyptian institutions came from the Ethiopian Meroë, or whether, as is more probable, civilisation was transmitted to Ethiopia from Egypt.

The whole country is naturally divided into three parts—Upper Egypt, bordering on what was anciently Ethiopia; Middle Egypt; and Lower Egypt, including the Delta of the Nile. In each, there were numerous cities in which the population was amassed: originally Thebes, a city of Upper Egypt, of the size of which surprising accounts are transmitted to us, and whose ruins still astonish the traveller, was the capital of the country; but latterly, as commerce increased, Memphis in Middle Egypt became the seat of power. After Thebes and Memphis, Ombi, Edfou, Esneh, Elephantine, and Philœ seem to have been the most important of the Egyptian cities.

Our accounts of the Egyptian civilisation are derived chiefly from the Greek historian Herodotus (408 B.C.), who visited Egypt and digested the information which he received from the priests as to its ancient history; and Manetho, a native Egyptian of later times, who wrote in Greek. From their accounts, it is inferred that the country was anciently divided into thirty-six sections or provinces, called *nomes*—ten in Upper, sixteen in Middle, and ten in Lower Egypt. Of this kingdom, the population, according to a rough estimate, may have been about seven millions. The government was a monarchy based on an all-powerful priesthood, similar to the Brahminical system of India; and, as in India, the most striking feature in the Egyptian society was the division of the people into hereditary castes. 'The population of Egypt,' says Mr Grote, in his *History of Greece*, 'was classified into certain castes or hereditary professions, of which the number is represented differently by different authors. The priests stand clearly marked out as the order richest, most powerful, and most venerated, distributed all over the country, and possessing exclusively the means of reading and writing,* besides a vast amount of narrative matter treasured up in the memory, the whole stock of medical and physical knowledge then attainable, and those rudiments of geometry—or rather land-measuring—which were so often called into use in a country annually inundated. To each god and to each temple throughout Egypt, lands and other properties belonged, whereby the numerous band of priests attached to him were maintained. Their ascendency, both direct and indirect, over the minds of the people was immense; they prescribed that minute ritual under which the life of every Egyptian, not excepting the king himself, was passed, and which was for themselves more full of harassing particularities than for any one else. Every day in the year belonged to some particular god, and the priests alone knew to which. There were different gods in every nome, though Isis and Osiris were common to all; and the priests of each god constituted a society apart, more or less important, according to the comparative celebrity of the temple. The property of each temple included troops of dependents and slaves, who were stamped with "holy marks," and who must have been numerous, in order to suffice for the service of the large buildings and their constant visitors.

'Next in importance to the sacerdotal caste were the military caste or order, amounting, when the population was at its maximum, to upwards of 400,000 men. To each man of this soldier-caste was assigned a portion of land, equal to about 6½ English acres, free from any tax. The lands of the priests and the soldiers were regarded as privileged property, and exempt from all burdens; while the remaining soil was considered as the property of the king, who, however, received from it a fixed proportion—one-fifth of the total produce—leaving the rest in the hands of the cultivators. The soldiers were interdicted from every description of art and trade.'

The other castes are differently given in different authors; the most probable account, however, is that which assigns them as three—the caste of the husbandmen, that of the artificers, and that of the herdsmen, which last caste included a variety of occupations held in contempt, the lowest and most degraded of all being that of swineherd. The artificers, constituting the vast town population of Egypt, were subdivided into a great variety of occupations, weavers, masons, sculptors, &c. who were compelled to these professions by hereditary obligation. It was by the labour of this vast town population, assisted by that of herds of slaves, that those huge works were accomplished, the remains of which still attest the greatness of ancient Egypt. These skilled artificers may be supposed to have acted as foremen and overseers of the great numbers of labourers who

* Mr Grote subjoins the following important note: 'The word *priest* conveys to a modern reader an idea very different from that of the Egyptian ἱερεῖς, who were not a profession, but an order *comprising many occupations and professions.*'

were employed in public works, such as the Pyramids. In the construction of these works, no degree of labour for any length of time seems to have intimidated the Egyptians. The huge blocks of stone, sometimes weighing 1000 tons each, were dragged for hundreds of miles on sledges, and their transport, perhaps, did not occupy less time than a year; in one case which is known, 2000 men were employed three years in bringing a single stone from a quarry to the building in which it was to be placed. Usually, the sledges were drawn by men yoked in rows to separate ropes, all pulling at a ring fixed to the block. See INLAND CONVEYANCE. Where it was possible, the blocks were brought from the quarries on flat-bottomed boats on the Nile. But the transport of these masses was much more easily accomplished than the placing of them in elevated situations in the buildings. They were raised by the power of levers and inclined planes at immense trouble and cost. The waste of human life in these gigantic works must have been enormous. About 120,000 men are said to have perished in the digging of a canal, which was left unfinished, between the Red Sea and an arm of the Nile; and according to Herodotus, the Egyptian priests of his day described the building of the Pyramids as a time of extreme exhaustion and hardship to the whole country.

The religion of the Egyptians seems to have been, in its popular form at least, a mere gross Fetichism, whose principal characteristic was a worship of teeming animal life—the bull, the cat, the ibis, the crocodile, &c.; different animals in different nomes. Whatever profounder meaning lay hid under this gross ceremonial the priest-caste reserved to themselves, as one of the mysteries the possession of which severed them from the rest of the population. Among these mysteries was the art of writing, which was practised both in the alphabetic and the hieroglyphic form; the latter being used for special purposes. Some vague notion of the immortality of the soul, resembling the Hindu tenet of transmigration, seems to have pervaded the Egyptian religion; and this belief appears to have lain at the foundation of the Egyptian practice of embalming the dead. The business of embalming was a very dignified one, and was aided by a host of inferior functionaries, who made and painted coffins and other articles which were required. The bodies of the poorer classes were merely dried with salt or natron, and wrapped up in coarse cloths, and deposited in the catacombs. The bodies of the rich and great underwent the most complicated operations, being wrapped in bandages dipped in balsam, and laboriously adorned with all kinds of ornaments. Thus prepared, they were placed in highly decorated cases or coffins, and then consigned to sarcophagi in the catacombs or pyramids. Bodies so prepared have been called mummies, either from the Arabian word *momia*, or the Coptic *mum*, signifying bitumen or gum-resin.

Although the 'manners and customs' of the early Egyptians have, in recent times, been disinterred, and set vividly before us in the sculptures, paintings, and embalmed monuments preserved in their tombs (see following wood-cut), we know little of the details of their history, properly so called, anterior to the time when the country was thrown open to the Greeks. Herodotus and Manetho, indeed, have given us retrospective lists of the Egyptian kings, extending back into the primitive gloom of the world; but portions of these lists are evidently constructed backwards on mythical principles. Thus Manetho, preserving, doubtless, the traditions of the sacerdotal Egyptian caste to which he is supposed to have belonged, carries back the imagination as far as 30,000 years before the birth of Christ. From this date, till 5702 B.C. great divine personages ruled in Egypt; then (5702 B.C. or, according to others, 3553 B.C.) it came into the possession of human kings, the first of whom was Menes. From the accession of Menes down to the incorporation of Egypt with the Persian empire (525

B.C.), Herodotus assigns 330 kings, or, as they are called in Scripture, Pharaohs, whose names, he informs us, were read to him out of a papyrus manuscript by the Egyptian priests, who pledged themselves to its accuracy; and Manetho reckons up twenty-six dynasties, some of them native and others foreign, which divided the long period into portions of different lengths. The earlier of these dynasties were for long looked upon as purely imaginary; but the names of many of the alleged Pharaohs from the fourth dynasty (3000 B.C.) downwards, have been recently identified with names actually existing, in hieroglyphics, on monuments believed to be as old as the times they refer to. Thus, Manetho ascribes the building of the greatest pyramid to Souphis (the Cheops of Herodotus), of the fourth dynasty; and in the interior has been found a royal name which scholars agree in reading *Shufu*. Between 2700 and 2000 B.C. occurred the invasion of the *Hyksos*, or 'Shepherd-kings,' a conquering people from the east, probably of Arabian or Phœnician lineage. It was in one of the three dynasties of these Shepherd-kings—the fifteenth in Manetho's list—that Abraham is supposed to have visited Egypt (1920 B.C.), and they were still reigning when Jacob and his sons settled in the country (1706). At length they were expelled by a native dynasty of Thebans, which ranks as the eighteenth, and the head of which is supposed to have been the Pharaoh 'who knew not Joseph.' The exodus of the Israelites from Egypt is believed to have taken place 1491 B.C. under the reign of the Pharaoh of the eighteenth dynasty, named Thothmes III.—the Pharaoh whose heart was hardened, and who was drowned in the Red Sea. This Theban dynasty produced many able sovereigns; and of almost all of them records have been discovered on existing monuments. One of them,

Rameses II. was a great conqueror, and extended the Egyptian dominion far into Asia. The twenty-sixth dynasty was from Sais. The first of its kings was Psammetichus I. whose reign (650 B.C.) constitutes an epoch in Egyptian history. Having attained to the throne by the aid of Greek mercenaries, he broke down the barriers which Egyptian exclusiveness had hitherto kept up against foreigners, greatly to the disgust of many of his subjects, especially of the priestly caste, whose trammels in other respects he threw off, and of the military caste, who found their places occupied by Ionian and Carian colonists. The successors of Psammetichus involved themselves in war with the Chaldæans or Assyrians of Babylon. The fourth of them, named Amasis (570–526 B.C.), rivalled Psammetichus in liberality of policy. He allowed the Greek merchants who visited the port of Naucratis to establish a privileged emporium, called the *Hellênion*. Under Amasis, Egypt attained to a great degree of prosperity, which was remembered the more that immediately after his death the country was subjugated by Cambyses, and annexed to the Persian empire (525 B.C.).

Arabia.

The great peninsula of Arabia was in the earliest times inhabited by a population of the Semitic stock, in all essential respects similar to that which inhabits it now, partly concentrated in cities, partly wandering in tribes through the extensive deserts which mark the surface of the country. The inhabitants of the towns subsist by agriculture and commerce; the wandering tribes by cattle-rearing and pillage. In ancient times, as now, the Arabs were celebrated for their expert horsemanship, their hospitality, their eloquence, and their free, indomitable spirit. In religion, however, the modern Arabs, who are Mohammedans, differ from the ancient Arabs, who were idolaters, chiefly worshippers of the celestial luminaries, nowhere so beautiful as in the sky of an Arabian desert. The Arabs themselves trace their history back, the older tribes to Kahtan (the Joktan of the tenth chapter of Genesis); the later, to Adnan, a descendant of Ishmael, the offspring of Abraham. It is unnecessary, however, to enter into this history, as Arabia was not incorporated with the Persian empire, and only assumed historical importance in later times, when it sent forth the religion of Mohammed over the East. See HISTORY OF THE MIDDLE AGES.

Syria.

The Semitic or Aramaic population overspreading Syria—which name is generally applied to the country lying between the Euphrates and Arabian desert on the east, and the Mediterranean on the west—had early divided itself into various independent states or kingdoms, which ultimately resolved themselves, it would appear, into three. These were *Phœnicia*, a narrow strip of coast-land, extending from Mount Carmel to the river Eleutherus; *Palestine*, or the *Holy Land*, including the country south of Phœnicia, between the Arabian desert and the Mediterranean, as well as the inland district lying between Mount Carmel and Mount Hermon; and *Syria Proper*, whose capital was Damascus, and which, when the power of the Damascan kings was at its highest, included all the country except Palestine and Phœnicia. Syrian history possesses no independent importance; we pass, therefore, to the history of the Phœnician and Jewish nations.

The Phœnicians.

Phœnicia was an exceedingly small country, its length being only about 120 miles, and its breadth nowhere greater than 20 miles. Indeed, it may be described as a mere slip of coast-land sufficiently large to accommodate a range of port-towns, such as a merchant-people required. The most northern of these Phœnician cities was Aradus, situated on a small island; the most southern was the famous Tyre; and between the two were situated many others, of which the chief were Sidon, Berytus, Tripolis, and Byblus. The greater part of the population was contained in these cities, the rural population being small in proportion.

Originally, Phœnicia was divided into a number of little states or communities, each having a town for its metropolis, with an hereditary king of its own; and ere the country was restricted by the formation of the Jewish nation, the number of these Phœnician or Canaanitish principalities must have been considerable. The Phœnicians were a fragment of the Canaanites of Scripture; and doubtless in the annals of the separate Phœnician towns, such as Tyre, Sidon, and Aradus, were preserved records, from the Phœnician point of view, of many of those ancient transactions which are related in the Scriptural account of the settlement of the Jews in Canaan.

The Phœnicians were the great trading nation of antiquity. Situated at so convenient a point on the Mediterranean, it devolved on them to transport to the sea-shore the commodities of the East, in which they employed Arabian caravans, and from the sea-shore to distribute them among the expecting nations of the West. Nor were they without valuable products of their own. The sand of their coasts was particularly suitable for the manufacture of glass; their bays abounded in a species of fish which produced a fine purple dye—the celebrated Tyrian purple of antiquity; and in various parts of the country there were excellent mines of iron and copper. It was, in fact, essential for the general interests of the race that the people inhabiting that portion of the Mediterranean coasts should devote themselves to commerce. In anticipation of this, as it might seem, the mountains of Libanus, which separated the narrow Phœnician territory from Syria, were stocked with the best timber, which, transported over the short distance which intervened between these mountains and the sea, abundantly supplied the demands of the Phœnician dockyards. There was something in the Phœnician character, also, which suited the requirements of their geographical position. Skilful, enterprising, griping in their desire for wealth, and in other respects resembling much their neighbours the Jews, to whom they were allied in race, and whose language was radically identical with their own—theirs was essentially the merchant type of character.

Standing, as the Phœnicians did, as the people by whom the exchange between the East and the West was managed, a complete view of their life and manner of activity should embrace *first*, their relations with the East—that is, their overland

trade with Assyria, Arabia, Egypt, Persia, and India; *secondly*, their relations with the West—that is, their maritime trade with the various nations of the Mediterranean and Atlantic coasts; and *thirdly*, the peculiar character of mind which either accompanied or resulted from the consciousness of such a position in the great family of mankind.

With regard to the overland trade of the Phœnicians with the eastern countries, it is probable that the Phœnicians managed this commerce not in their own persons, but as wealthy speculative merchants, dealing in a skilful manner with the native Egyptian, Assyrian, or Arabian caravan proprietors, with whom they maintained an understood connection. It was in their maritime trade with the West, however, that the Phœnicians chiefly exhibited the resources of their own character. Shipping the oriental commodities, as well as their native products, at Tyre or Sidon, they carried them to all the coasts of the Mediterranean as far as Spain, selling them there at immense profit, and returning with freights of Western goods. With some of the nations of the Mediterranean, their intercourse would be that of one civilised nation with another; with others, and especially with those of the West, it must have been an intercourse similar to that of a British ship with those rude islanders who exchange their valuable products for nails, bits of looking-glass, and other trifles. Whether their customers were civilised or savage, however, the Phœnicians reaped profits from them. Their aim was to monopolise the commerce of the Mediterranean. 'If at any time,' it is said, 'their ships bound on a voyage observed that a stranger kept them company, or followed them in their track, they were sure to get rid of him, or deceive him if they could; and in this they went so far as to venture the loss of their ships, and even of their lives, so that they could but destroy or disappoint him; so jealous were they of foreigners, and so bent on keeping all to themselves. And to add to the dangers of the sea, and discourage other nations from trading, they practised piracy, or pretended to be at war with such as they met when they thought themselves strongest.' This policy succeeded so far, that hardly a merchant-ship was to be seen in the Mediterranean not manned by Phœnicians.

From this extension of the Phœnician commerce throughout the Mediterranean, resulted, by necessity, an extensive system of colonisation. In process of time, Phœnician colonies were established at all available points of the Mediterranean—on the coasts of Africa, Sicily, Sardinia, and Spain, and in the Balearic Islands; the rising maritime spirit of the Greeks excluding the Phœnicians from the Ægæan and the coasts of Asia Minor. Among the most ancient of the colonies from Tyre were Carthage and Utica on the African coast, and Gades (Cadiz) in Spain; all of which were founded before the first of the Greek Olympiads (884 B.C.). From these afterwards arose smaller settlements, which diffused the Phœnician agency still more extensively among the uncivilised nations of Africa and Western Europe. Gades, in Spain, situated, according to the ancient mode of navigation, at a distance of seventy-five days' sail from Tyre or Sidon—a distance larger than that which now divides Liverpool from Bombay—was a colony of special importance; first, as commanding the inland Spanish trade, particularly valuable at that time, inasmuch as the gold and silver mines of Spain caused it to be regarded as the Mexico or Peru of the ancient world; and, secondly, as forming a point from which the Phœnician commerce could be still further extended along the extra-Mediterranean shores. From this point, we are told, the Phœnician ships extended their voyages southward for thirty days' sail along the western coast of Africa, and northward as far as Britain, where they took in tin from the mines of Cornwall, and even as far as the Baltic, where they collected amber.

As might be expected, this great merchant-people were among the most cultured of antiquity, and especially skilled in all the arts of luxurious living. The 27th chapter of the book of Ezekiel presents a most striking picture of the pride and magnificence of the Tyrians, and embodies many minute particulars relative to Phœnician customs and mode of life. Indeed, it has justly been pronounced the most early and most authentic record extant relative to the commerce of the ancients.

Among the contributions made by the Phœnicians to the West, were alphabetical writing, the Greek alphabet being a derivative from the Phœnician; scale of weight; and coined money. Phœnicia began about 700 B.C. to decline in importance; the Ionian Greeks, and latterly the Egyptians, becoming its commercial rivals on the Mediterranean; and the invasions of the Assyrians from the east depriving it of independence. Subdued by the Assyrians and Babylonians, Phœnicia was transferred with them to the Persians. Among the last of the Phœnician achievements was the circumnavigation of Africa, 600 B.C.—a feat undertaken by Phœnician sailors at the command of the Egyptian king Neco, one of the immediate successors of Psammetichus, and, as is now believed, really performed; the course pursued being from the Red Sea round Africa to Spain—the reverse, therefore, of that followed by Vasco da Gama 2000 years later. About the time that Phœnicia began to wane, her colony, Carthage, assumed her place in the affairs of the world. Carthaginian civilisation was essentially a mere repetition of the Phœnician, although under a different form of government: its history interweaves itself with that of the Romans (see HISTORY OF ROME).

Palestine—the Jews.

Palestine extends from north to south a length of about 200 miles, its breadth being 50; and is therefore, in point of size, of nearly the same extent as Scotland. The general character of the country is that of a hilly region, interspersed with moderately fertile vales; and, being thus irregular in surface, it possesses a number of brooks or streams, which for the most part are swollen considerably after rains, but are almost dry in the hot seasons of the year. The present condition of Palestine scarcely corresponds with its ancient fertility. This is chiefly attributable to the devastating effects of perpetual wars; and some physical changes have also contributed to the destruction of agricultural industry. Yet, after all, so excellent would the soil appear to be, and so ample its resources, that Canaan may still be characterised as a land flowing with milk and honey.

The history of the extraordinary nation which once inhabited this land, must be so much more familiar to our readers than that of any other ancient nation, that all that is necessary here is a brief sketch, such as will assist the imagination in tracing with due completeness the general career of the East till the establishment of the Persian empire. From the accounts given in Scripture, and from the *History* of Josephus, we learn that the Jews were descended from Abraham, the tenth in descent from Noah, through his second son Shem. According to Josephus, Abraham, who was born in the 292d year (according to other authorities, in the 352d year) after the Deluge, 'left the land of Chaldæa when he was seventy-five years old, and at the command of God, went into Canaan, and therein he dwelt himself, and left it to his posterity. He was a person of great sagacity, both for understanding of all things and persuading his hearers, and not mistaken in his opinions; for which reason he began to have higher notions of virtue than others had, and he determined to renew and to change the opinion all men happened then to have concerning God; for he was the first that ventured to publish this notion, that there was but ONE God, the Creator of the universe; and that as to other gods, if they contributed anything to the happiness of men, that each of them afforded it only according to His appointment, and not by their own power. For which doctrines, when the Chaldæans and other people of Mesopotamia raised a tumult against him, he thought fit to leave that country, and, at the command of God, he came and lived in the land of Canaan. And when he was there settled, he built an altar, and performed a sacrifice to God.' After the death of Abraham's son Isaac, *his* younger son, Jacob, remained for a number of years in Canaan, surrounded by a family of twelve sons, one of whom, Joseph, as related in Scripture, became the cause of the removal of his father and brethren, and all belonging to them, into Egypt. The Hebrew emigrants were seventy in number, and formed at the first a respectable colony among the Egyptians. Jacob died after having been seventeen years in Egypt, and his body was carried by Joseph to Hebron, and buried in the sepulchre of his father and grandfather. Joseph also died in Egypt at the age of 110, and at length his brethren died likewise. Each of the twelve sons of Jacob became the progenitor of a family or tribe, and the twelve tribes, personified by the term ISRAEL, continued to reside in Egypt, where they increased both in number and in wealth. Their rapid increase and prosperity soon excited the jealousy of the masters of the country; and from being in high favour, the different tribes gradually fell under the lash of power, and came to be treated as public slaves.

The entire body of Israelites, guided by Moses, fled from Egypt in the year 1490 before Christ, at a time when Thebes, Memphis, and the other magnificent cities of that country, were in all their glory. Proceeding in a north-easterly direction from Rameses (near the site of modern Cairo), they went through the level region of the land of Goshen (now a barren sandy plain) to the head of the Gulf of Suez, the western branch of the Red Sea. Here they crossed in a miraculous manner to the opposite shore, to a spot now called the Wells of Moses, where, according to the Scripture narrative, they sang their song of thanksgiving for their deliverance. The country in which they had now arrived was a portion of Arabia Petræa, consisting of a dismal barren wilderness, now called the Desert of Sinai, from the principal mountain which rises within it. From the point at which the Israelites had crossed the Red Sea from Egypt, they were conducted by a most circuitous and tedious route towards the Promised Land of Canaan. Their tiresome journey extended over a period of forty years, and was not completed till all the Hebrews who were above twenty years of age when they left the land of Egypt (excepting Caleb and Joshua) had died, and a new generation, possessing greater courage and confidence in the Almighty, had succeeded them. In the trackless wilderness through which they were led, their multitudes, as we learn from Scripture, could neither have traced their way nor procured subsistence without a continued miracle. The hand of God brought for them streams of water out of the flinty rock; rained manna or bread from heaven; and gave a pillar of cloud to direct their journeys through the day, and a pillar of fire by night. He delivered the tables of a moral law, comprehending the ten commandments, to Moses their leader; and promulgated a set of regulations for the ceremonies of worship, the establishment of a separate order devoted to religion and learning, and for the civil government of the nation. The Hebrews had thus a regular polity and written laws when most other nations knew only the law of the sword, or of savage animal superiority.

The country on the shore of the Mediterranean which was allotted as a settlement to this people, was at that time occupied by many warlike tribes, who had grown strong in its fertile plains and valleys; and the generation of the Hebrews who were conducted into it were compelled to fight for its possession. The struggle was not of long continuance. The whole land was conquered in the year 1450 B.C.

According to the account given in the 26th chapter of the Book of Numbers, the Hebrew nation thus brought out of the land of Egypt and settled in Canaan amounted to 601,730 souls, unto whom the land was divided for an inheritance, according to the number of individuals in the respective tribes. The tribe of Levi (to which belonged Moses, Aaron, and Eleazar the high-priest), amounting to 23,000 males from a month old and upwards, received no share of the land: being set apart for the priesthood, the tenth or tithe of the general produce was assigned them as their perpetual inheritance.

The political government of the various tribes, after their conquest and settlement of Canaan, appears to have been republican, with military leaders called Judges; but these acted by the direction of the priesthood, who were immediately counselled by the Deity within the sanctuary. This period of separate government in tribes, called the Period of the Judges, lasted 300 years (1427–1112 B.C.), and was one of daring actions and great deliverances—the heroic age of the Jews.

The epoch of kings succeeded that of judges. The reign of Saul, their first monarch, though the people were stronger by being united, was gloomy and troubled. David, who succeeded,

was a soldier and a conqueror. He left an empire peaceful, respected, and strong; and, what was of as much importance, he selected from among his sons a successor who was able to improve all these advantages. Under Solomon, the Hebrew government being able to protect its subjects in other countries, the people and their king began to employ themselves in commerce. Their trade was at first ingrafted on that of the Phœnicians of Tyre. A greater contrast cannot be imagined than between the troubles of the time of the Judges (only 100 years before), and the peace, security, and enjoyment of this reign.

After the death of Solomon, the country fell into the same divisions which had weakened it in the time of the Judges. Each of the districts of North and South Israel was under a separate king, and the people were exposed both to the attacks of their enemies and to quarrels with each other. Their history is a succession of agitating conflicts for independence, and of unexpected and remarkable deliverances, of a similar nature to those of the earlier period, and continuing for about the same length of time (380 years); but they are marked by fewer of those traits of heroic devotion which distinguished the epoch of the Judges. The backslidings, errors, and misgovernment of their kings are the chief and painful subject which is presented to us; and though these are relieved at times by the appearance of such monarchs as Josiah, Jehoshaphat, and Hezekiah, yet the whole history of this period is overcast with the gloominess of progressive decline. By far the most delightful parts of it are those which relate to the lives of the prophets, who were raised up at intervals to warn the nation and its rulers of the fate which they incurred by forsaking the religion of their fathers. These inspired men sometimes sprang up from among the humblest classes of the community: one (Isaiah) is, however, said to have been of royal lineage; but the works of all are marked with the same sacredness, and force of authoritative rebuke.

Of the two kingdoms into which Palestine had divided itself after the death of Solomon (975 B.C.), the northern, called the Kingdom of Israel, was conquered by the Assyrians of Nineveh (722 B.C.), who carried off many thousands of the people into captivity. What became of the ten tribes which were carried away captive by the Assyrians, is a question regarding which there has been much discussion. According to Scripture, they were first planted by Shalmaneser as colonists in certain cities of Media, which territory was then subject to Assyria; and recent investigations have proved the precise district to have been the neighbourhood of the Kezil-Ozan, a river in the north of modern Persia, near the Caspian Sea. Of the fact of the distribution of the ten tribes throughout Media, there is no doubt; but as Media not long after revolted from the Assyrians, the subsequent fate of these Jewish captives cannot be traced. The southern kingdom, called the Kingdom of Judah, retained its independence till 588 B.C. when it was invaded and subdued by Nebuchadnezzar, king of Babylon, who destroyed Jerusalem, and carried away a great number of the principal Jews into captivity at Babylon. On the subversion of the Babylonian dominion by Cyrus, seventy years afterwards, the captives, to the number of 42,360, were permitted to return to their own land, and rebuild Jerusalem. At this period, the whole of Palestine merged in the growing Persian empire.

Assyrians and Babylonians.

Assyria occupied the northern portion of the Mesopotamian plain, lying between and on the Euphrates, Tigris, and Kabour. It was bounded on the north by the Mons Niphates in Armenia, on the south by Susiana and Babylonia, on the east by the Zagros Mountains, and on the west by the watershed of the Euphrates. At a time far beyond the reach of history, there lived there a Semitic people under a well-defined organised government. The origin of Assyria, according to Genesis x. 10, 11, is simply that out of the land of Shinar, the kingdom of Nimrod, the son of Cush, who was the son of Ham, 'went forth Asshur, and builded Nineveh.' Be this as it may, it is almost certain that the Assyrians did originally come from the south, and had probably inhabited the flat alluvial plains at the mouths of the Tigris. Their architecture is founded on a style such as would originate in a region devoid of stones for building. Indeed, even after emigrating to their new quarters, where stone quarries were numerous enough, they persisted in retaining brick as their favourite building material. This migration northward of the people who founded the Assyrian empire, probably occurred anterior to the close of the old Chaldæan empire—that is, before the sixteenth century B.C. A broken tablet with inscriptions, giving a synchronous history of Babylonia and Assyria, preserves the names of the three earliest known Assyrian kings, and fixes the date of their reigns at 1650–1550 B.C. by connecting them with the time of Purna-puriyas, the early Chaldæan king. It must be noted, however, that the name of the first of these Assyrian kings—Asshur-bel-nisus—stands half-way down the column of this broken tablet. There may have been ten or twelve kings before him, which would put back the date of the Assyrian empire to, say, 1770 B.C. The northern migration of the founders of this empire was probably due to the spirit of enterprise that at that time seemed to have leavened the Semitic peoples of Southern Mesopotamia, who wandered much further even to push their fortunes. Says Mr Rawlinson in his *Five Ancient Monarchies*: 'Terah conducted one body from Ur to Harran; another removed itself from the shores of the Persian Gulf to those of the Mediterranean; while probably a third, larger than either of these two, ascended the course of the Tigris, occupied Adiabêne with the adjacent regions, and giving its own tribal name of Asshur to its chief city and territory, became known to its neighbours, first as a district, then as an independent power and people.'

From bricks of Babylonian type found at Killeh-sherghat, older than pure Assyrian remains, bearing the names and titles of Babylonian rulers, it seems probable that Assyria was at first governed by satraps from the parent country. When, however, we come to the time of the three earliest kings mentioned in the mutilated synchronistic tablet already referred to, it is clear the protectorate had been discarded. The first two kings whose names are mentioned—Asshur-bel-nisus

and Buzzur-Asshur—made treaties of peace with Babylonian contemporary monarchs; and the third, Asshur-vatila, had not only married one of his daughters to the Chaldæan king Purna-puriyas, but, on the death of that monarch, had even interfered with the domestic affairs of the parent country so far as to put down a usurper who tried to seize the throne, and restore to power the rightful heir. From his time, then, we may safely regard Assyria as an independent and pretty powerful state. Then a long dark break in the historical record occurs, regarding which nothing is known. A genealogical tablet gives us just a glimpse of the name of the next king—Bel-sumili-kapi—who reigned about 1450 B.C. and probably was founder of a new dynasty. Contemporary Assyrian record now aids us, and we come to a group of six kings, forming a line of direct descent from father to son between 1350 and 1230 B.C. The first is Bel-lush (1350–1330 B.C.); Pud-il (1330–1310 B.C.), and Iva-lush I. (1310–1290 B.C.), who come next, must have extended the city of Asshur greatly, for quantities of bricks bearing their names and titles have been recently found. The dates we give, it must be remembered, are only approximately true, and are based on calculations from well-ascertained fixed points; the average duration of an Assyrian king's reign being taken at twenty years. Iva-lush I. was succeeded by his son, Shalmaneser I. (1290–1270 B.C.). He founded Calah (Nimrud), long capital of the Assyrian empire, and pushed his frontier northwards, so as to secure possession of the region between the Tigris and the mountains, which afterwards became the metropolitan centre of Assyria. He seems to have been the first of the Assyrian conquering kings. Tiglathi-nin, his son (1270–1250 B.C.), may be reckoned as the first of the monarchs of what Herodotus understood as the great Assyrian empire. Inheriting the spirit of his father, he inaugurated the aggressively hostile policy towards Babylonia to which all his successors rigidly adhered. An inscription on his signet claims for him the titles of 'King of Assyria, and conqueror of *Kar-Dunis*,' or Babylonia—which may have remained thoroughly subject to Assyria for about a century after he attacked it. He was succeeded by his son, Iva-lush II. (1250–1230 B.C.), who still further extended by conquest his dominion.

A break of twenty or thirty years here occurs in the record, and then there appears another dynasty, consisting of six kings in consecutive series from father to son—their names being found inscribed on the cylinder of Tilgath-pileser I. (1130–1110 B.C.). The first of this dynasty was Nin-pala-zira (1210–1190 B.C.). His son, Asshur-dah-il (1190–1170 B.C.), was the second. He was succeeded by his son, Mutaggil-Nebo (1170–1150 B.C.), who was succeeded by Asshur-ris-ilim (1150–1130 B.C.), a warlike and aggressive monarch, who waged war not only with Babylon under the first Nebuchadnezzar, but is conjectured to have been the king of Mesopotamia mentioned in Judges iii. 8, by the name of Chusan-ris-athaim, who kept the Israelites in subjection for eight years. His son, Tilgath-pileser I. (1130–1110 B.C.), succeeded him, and of his reign there is a pretty full account, chiefly recorded on two duplicate cylinders now in the British Museum. He was a restless warrior, who subdued nearly all the tribes around him. He was as deeply imbued with a fanatical zeal for spreading the worship of Asshur, as for increasing the territory of Assyria, and his wars were to a great extent missionary wars. He greatly advanced the material prosperity of his people, and enriched Assyria by irrigation works, and by encouraging the importation of foreign products, both vegetable and animal. His son, Asshur-bil-Kala (1110–1090 B.C.), succeeded, and carried on the traditional war with Babylon. In his reign the Jewish monarchy under Saul must have sprung up.

Another long blank in the record comes, during which time Assyria rather declined in power. A new and more vigorous series of kings appears, beginning with the reign of Asshur-iddin-akhi (950–930 B.C.). He was succeeded by his son, Asshur-danin-il (930–910 B.C.); who was also succeeded by his son, Iva-lush III. (910–890 B.C.). His son, Tiglathi-nin II. succeeded, and reigned from 890 to 884 B.C.; and was followed by his son, Assur-idanni-pal (884–859 B.C.), the first Sardanapalus—one of the greatest of the Assyrian monarchs. Not unjustly, he styles himself 'the conqueror from the upper passage of the Tigris to Lebanon and the great sea, who reduced under his authority all countries from the rising of the sun to the going down of the same.' The glories of Assyria under his reign; her triumphs in the pursuits of war and peace; her conquests and wealth; her sumptuous luxury, the splendour of her palaces and temples; her exquisite skill in the fine arts and in inventions, are even now the cause of mingled admiration and wonder to European scholars, who can hardly believe that, nine centuries before the Christian era, a civilisation of such a lofty and dignified type could have so suddenly leaped into existence. The son of this great monarch, Shalmaneser II. (859–824 B.C.), succeeded him. He, too, was a warlike prince, and by his energy and valour, made Assyria the dominant power over the vast region extending from the Persian Gulf to Mons Niphates, and between the Zagros range and the Mediterranean. Phœnicia, Samaria, Damascus, all paid tribute to him, as did also the king of Israel, Jehu, 'son of Omri,' as the usurping son of Jehosaphat styled himself. In his later years, his eldest son rebelled, but was defeated and put to death; so his second son, Shamas-iva, succeeded him, and reigned from 824–810 B.C. residing, like his father, chiefly at Calah. He prosecuted the usual Assyrian war against Babylonia with such vigour, that in the reign of his son, Iva-lush IV. that state became thoroughly tributary to Assyria. Iva-lush IV. (810–781 B.C.) conquered Damascus, rendered part of Media tributary to him, and pushed the Assyrian frontier even to the very confines of Egypt. His queen was Sammuramit (Semiramis), regarding whom most written history is legendary. She was probably a Babylonian princess in no way very remarkable, whom he married in order to confirm his suzerainty of that country. From the fact that she thus occupied a more independent relation to her consort (holding joint sway over this very important fief) than was usual in eastern nations, and so comes into the historic record (which eastern women rarely do), the mythical and fabulous details, which made the figure of Semiramis stand out with such imperial grandeur on the canvas of the chroniclers of classical antiquity,

were gradually evolved and accumulated. After the death of Iva-lush IV. another blank occurs, regarding which we need only say that between 781 and 744 B.C. there reigned Shalmaneser III. Asshur-danin-il II. and Asshur-lush. This seems to have been a period of decadence. Assyria was getting corrupt and lazy with a surfeit of luxury, whilst surrounding nations were waxing in strength. It was most likely during this period that Jonah was sent forth to thrill them with the startling prophecy, 'Yet forty days, and Nineveh shall be overthrown.' In 744 B.C. the history of what Herodotus seems to mean by his later kingdom begins with the reign of Tilgath-pileser II. who was probably floated into power by the tide of a successful revolution. He was an able, energetic, and warlike prince, and he restored the pristine power and glory of Assyria. He rendered tributary again Damascus, Tyre, Judah, Moab, Ascalon, &c. In 726, he was succeeded by Shalmaneser IV. (thought to be his son), who warred with his rebellious vassal, Hoshea, king of Israel, and with the maritime states of Tyre and Sidon. Sargon, a clever and successful warlike usurper, reigned from 721–704 B.C. His career was one of incessant warfare. Under him, for the first time, Asia and Africa met in battle, for he attacked Gaza, an Egyptian province, and defeated the Egyptian army at Rapikh (Raphia of the Greeks, and *Refah* of moderns). He also brought some of the Arabian tribes under Assyrian rule, ravaged Babylon, and finally established the supremacy of Assyria over the whole of Chaldæa. From his magnificent palace at Khorsabad came the fine series of monuments now in the Louvre. To him succeeded Sennacherib, who reigned 704 to 680 B.C. He made Nineveh the capital, and repaired a palace there by forced labour of 300,000 men. He afterwards built a far grander one, which was excavated by our countryman, Mr Layard, and estimated to cover eight acres of ground. His annals extend only to the eighth year of his reign. He made a successful raid on Babylonia, and invaded Judæa, conquering King Hezekiah, and leading into captivity 200,000 Jews. In his second campaign, he met with a terrible disaster, when about to attack the Egyptians at Pelusium. As recorded in 2 Kings xix. 35, the morning of the battle, 185,000 of his men were found lying dead in their tents, having been smitten during the night, says the sacred narrative, by the angel of the Lord, in answer to the prayers of Hezekiah, on whom he was about to swoop down 'like a wolf on the fold.' Undaunted by this calamity, Sennacherib carried on several wars after this against Tyre and Sidon, Babylon and Susiana. He was the first to make Assyria formidable as a naval power. He was murdered by two of his sons, 'hungry for his empty chair,' neither of whom succeeded him. His successor was his third son, Esar-haddon, who seems to have ruled his empire sometimes from Nineveh and sometimes from Babylon—hence it was to the latter city Manasseh was brought to him when conquered by his troops. He warred with Phœnicia, Armenia, Edom, and even with the inhabitants of what is known as the modern Arabian kingdom of Hira, and subdued Egypt as far as Thebes. He was succeeded by Asshur-bani-pal—or, as the Greek writers call him, Sardanapalus—in 667 B.C. who completed and consolidated, with matchless ability, the splendid conquests his father had begun. He was the only one of the Assyrian kings who cared for literature, and encouraged scholarship. Under him Assyrian power and civilisation reached its culminating point, and it was not till after his death it declined. The stories of effeminate luxury and vicious imbecility told of a Sardanapalus are misapplied to him. They really refer, if to any one, to his son, Asshur-kinat, who succeeded him, probably in 647 B.C. and who may have ended his reign in 625. He is the Saracus of the Greek chroniclers. In his weak hands, the great Assyrian empire grew demoralised. The wave of Scythian invasion which at this time swept over all Syria, weakened it so much, that even after these northern hordes had retired, they left it so feeble that it fell a prey to the Medes, who had unsuccessfully attempted to conquer it in the beginning of Saracus's reign; but who, aided by the treachery of Nabopolassar, the Assyrian viceroy of Babylon, and under the leadership of Cyaxares, gave the final blow to Assyrian dominion. Saracus, when despairing of success, set fire to his palace at Nineveh, and perished in the conflagration that destroyed that imperial city. The northern portion of the empire was seized by the Medes. The southern portion, including Susiana, Syria, and Palestine, was given to Nabopolassar, as the reward of his treachery. Of this, Babylon became the chief city; and from this point Babylon, which had always hitherto, since the reign of Tiglathi-nin I. been a vassal of Assyria, sprung up into a new and entirely independent empire.

The sculptures and other objects brought to light by explorers, from among the ruins of the ancient

Assyrian cities, and now deposited in the museums of Paris and London, give us a high idea of the state of social advancement at which the nation had arrived. The grandeur of their architecture, the elegant forms of their furniture, the produce of their looms, their works in metal, stone, glass, and ivory, still excite admiration; while agriculture, by means of irrigation, seems to have been carried to the highest degree of perfection.

The Babylonian Empire.

Up to the period of the dismemberment of Assyria, the history of Babylonia is, as might be inferred from what we have said above, that of the relations of a mutinous disaffected vassal towards a stern, cruel, oppressive suzerain. As often as its viceroys asserted their independence of Assyria, they were crushed by the overwhelming force of that great empire. It was only when Assyria fell that Babylon rose upon her ruins into permanent independent existence.

Nabopolassar, the first monarch of independent Babylon, reigned from 625 to 604 B.C. The year before his death, he sent his son Nebuchadnezzar to recover Gaza, which Neco the Egyptian monarch had wrested from him, in which undertaking he was successful. Nebuchadnezzar, on succeeding to the throne in 605 B.C. found himself lord of all the dominions that had ever pertained to the monarchs of Assyria, with the exception of the nations which acknowledged the sway of Media. The long reign of this prince (605–561 B.C.) was the epoch of Babylonian splendour. Besides his important acts as a conqueror—the chief of which was his conquest of Judæa, Phœnicia, and Egypt, all of which countries he invaded several times—Nebuchadnezzar was celebrated for the magnificence of his designs as a ruler. 'Is not this great Babylon that I have built for the house of the kingdom?' is the expression attributed to him in the Book of Daniel, in which so many interesting particulars concerning his reign are recorded; and the expression was justified by the fact. Babylon had already been a great city, but under Nebuchadnezzar it became the metropolis of the Asiatic world. Herodotus, who saw the city in its decline, describes it as surrounded with walls in thickness 75 feet, in height 300 feet, and in compass 480 stadia, or about 60 of our miles. These walls formed an exact square, each side of which was 120 stadia, or 15 miles in length; and were built of large bricks cemented together with bitumen, a glutinous slime which issues out of the earth in that country, and in a short time becomes harder than the very brick or stone which it cements. The city was encompassed without the walls by a vast ditch filled with water, and lined with bricks on both sides. In the whole compass of the walls there were a hundred gates —that is, twenty-five on each side, all made of solid brass. At intervals round the walls were 250 towers. From each of the twenty-five gates there was a straight street extending to the corresponding gate in the opposite wall; the whole number of streets was therefore fifty, crossing each other at right angles, and each fifteen miles long. The breadth of the streets was about 150 feet. By their intersection the city was divided into 676 squares, each about two miles and a quarter in compass, round which were the houses, three or four stories in height; the vacant spaces within being laid out in gardens, &c. Within the city, the two greatest edifices were the royal palace with its hanging gardens, and the temple of Belus, composed of eight towers built one above another, to the enormous height, it is said, of a furlong.

Nor was the execution of colossal works confined to the city. The whole of Southern Mesopotamia was intersected by canals, many of which ran quite across from the Euphrates to the Tigris, and served both for irrigation and transport; and marshes were converted into vast tanks or reservoirs, one of which was fifty miles in circumference, and faced all round with solid masonry. The commerce of Babylon, when at the height of its glory, not only for home consumption, but as the great emporium between the east and west, was immense.

Nebuchadnezzar was succeeded (561 B.C.) by his son, Evil-Merodach, who was dethroned (559 B.C.) by his brother-in-law, Neriglissar (559–556 B.C.), whose son and successor, Laborosoarchod, was dethroned, after a brief reign, by Nabonadius, the Belshazzar of Scripture (555 B.C.); in the eighteenth year of whose reign (538 B.C.) Babylon was taken by Cyrus, and passed into the hands of the Persians.

The Medes and Persians.

Extending, as we have said, from the Mediterranean to the Indus, the Assyrian empire had included not only the chief Semitic nations of Western Asia, but also that portion of the Indo-Germanic family which was contained between Mount Zagros and the river Indus. Essentially a prolongation of the great race which inhabited Hindustan, the nature of their country—a vast table-land, here and there rising into hills, or presenting spots of great fertility—had made them quite different in character and habits from the settled and stereotyped Hindus. All parts of this plateau of Iran, as it was called, including the present countries of Persia, Cabool, and Beloochistan, were not alike: in some portions, where the soil was fertile, there existed a dense agricultural population; in others, the inhabitants were nomadic horse-breeders, cattle-rearers, and shepherds. All the tribes, however, were bound together by affinities of language and by a common religion. This religion, a modification, probably, of some more ancient form, from which Hinduism may also have sprung, was taught by Zerdusht, or Zoroaster, a great native reformer and spiritual teacher, who lived at Bactra, now Balkh, six or seven centuries before Christ. The principal doctrine of his religion was that of the existence of two great emanations from the Supreme and perfect Deity—the one a good spirit (Ormuzd), who created man and fitted him for happiness; the other an evil spirit, named Ahriman, who has marred the beauty of creation by introducing evil into it. Between these two spirits and their adherents, there is an incessant struggle for the mastery; but ultimately Ormuzd will conquer, and Ahriman and evil will be banished from the bosom of creation into eternal darkness. The worship annexed to this doctrine was very simple, dispensing with temples or images, and consisting merely of certain solemn rites performed on mountain-tops, &c. Fire, and light, and the sun, were worshipped either as symbols or as inferior deities. A caste of priests called the Magi, answering in some respects to the Brahmins of India, or the Chaldæans of Babylon, superintended these ceremonies, and commented on the religion of Zoroaster.

Various of the tribes of Iran associating themselves together, constituted small nations. Thus, adjacent to Assyria, and separated from it by Mount Zagros, was an agglomeration of seven

tribes or villages, under the special name of the Medes, the country which they inhabited being thence called Media. South from Media, and nearer the sea, was another district of Iran, called Persis or Persia, inhabited also by an association of tribes calling themselves the Persians. Other nations of Iran were the Parthians, the Bactrians, &c.—all originally subject to the Assyrian empire.

Median history begins with Cyaxares (for the list of her kings, beginning with Deioces, given by classical historians, is a fabulous one), who consolidated into an empire a heterogeneous mass of tribes, and extended the Median dominion as far westward into Asia Minor as the river Halys. He was engaged in an attempt against Nineveh, when he was called away to defend his kingdom against a great roving population, called Scythians, by whom he was defeated, and who continued to hold him tributary and plunder Media for twenty-eight years. At length, having assassinated their chiefs by a stratagem, Cyaxares drove the invaders back into the north. He then renewed his attempt against Nineveh; took it, and shared the Assyrian dominions with the monarch of Babylon. The Median empire, thus formed, he bequeathed (593 B.C.) to his son Astyages, having reigned, according to Herodotus, 40 years.

The circumstances which led to the revolt of the Persians under Cyrus* against the Medes, and the dethronement by him of Astyages (560 B.C.), had been woven into a romance resembling the story of Romulus, even so early as the age of Herodotus (408 B.C.), so that that historian could not ascertain the actual facts of the case. 'The native Persians,' says Mr Grote, 'whom Cyrus conducted, were an aggregate of seven agricultural and four nomadic tribes, all of them rude, hardy, and brave, dwelling in a mountainous region, clothed in skins, ignorant of wine or fruit, or of any of the commonest luxuries of life, and despising the very idea of purchase or sale. Their tribes were very unequal in point of dignity; first in estimation among them stood the Pasargadæ; and the first clan among the Pasargadæ were the Achæmenidæ, to whom Cyrus belonged. Whether his relationship to the Median king whom he dethroned was a fact or a politic fiction, we cannot well determine; but Xenophon gives us to understand that the conquest of Media by the Persians was reported to him as having been an obstinate and protracted struggle.'

Master of Media, the Persian chief, in his turn, became a great oriental conqueror; indeed, all the oriental conquests bear the same character. A nomadic race, led by a chief of great abilities, invades the more organised states, and conquers them; the chief assumes the government, and founds a dynasty, which, after a rule of several generations, becomes enervated, and gives way before some new nomadic incursion. The first power against which Cyrus turned his arms, after having subdued the Medes, was the famous Lydian kingdom, which then subsisted in Asia Minor under the great Crœsus. And here, therefore, we must give some account of the ancient condition of Asia Minor and its principalities.

* The Persian form of the word is *Khosru*, meaning 'the Sun,' which was corrupted by the Greek writers into *Kuros* (lord), the Latin form of which is *Cyrus*.

States of Asia Minor—The Lydians.

The river Halys divided Asia Minor into two parts. East of the Halys, or near its source, were various nations of the Semitic stock, Cappadocians, Cilicians, Pamphylians, &c.—each organised apart, but all included under the Assyrian, and latterly, as we have seen, under the Median empire. West of the Halys, the inhabitants were apparently of the Indo-Germanic race, although separated by many removes from the Indo-Germans of Persia. They are considered as belonging to what has been called the Pelasgic stock of the Indo-Germanic or European family, of which the inhabitants of Italy and Greece are also members. Overspreading this part of Asia Minor, as well as Thrace and other parts of South-eastern Europe, this great race had been broken up into fragments distinguished by characteristic differences. To enumerate these various nations, assigning to each its exact geographical limits, is impossible; the chief, however, were the Bithynians, a sort of Asiatic Thracians on the southern coast of the Euxine; the Lydians and Carians in the south-west; and, intermediate between the two, geographically as well as in respect of race and language, the Mysians and Phrygians. These were the native states; but along the whole Ægæan shore was diffused a large Greek population, emigrants, it is believed, from European Greece, chiefly gathered into cities. These Greeks of Asia Minor were of three races—the Æolic Greeks in the north, and the Ionian and Dorian Greeks in the south; and perhaps the earliest manifestations of Greek genius, political or literary, were among these Greeks of Asia. The intercourse of these Greeks with the native Lydians, Phrygians, &c. gave rise to mixture of population as well as to interchange of habits; the native music especially of the Lydians and Phrygians became incorporated with that of the Greeks.

When Lydia, with its capital Sardis, first began to be a powerful state, is not known; it is remarkable, however, that the Lydians are not mentioned in Homer. According to Herodotus, the Lydians traced their history back through three dynasties. *1st*, The Atyadæ, from the earliest times to 1221 B.C.; *2d*, the Heracleidæ, from 1221 B.C. to 716 B.C.; and *3d*, the Mermnadæ. Only the last dynasty is historic.

The first king of the Mermnad dynasty was Gyges (716-678 B.C.); the second, Ardys (678-629 B.C.), in whose reign the Cimmerians, from Scythia, invaded Asia Minor; the third, Sadyattes (629-617 B.C.); the fourth, Alyattes (617-560 B.C.). Each of these Lydian kings was engaged in wars both with the Asiatic Greeks of the coast and the native states of the interior. The growth of the Lydian power was impeded by the Cimmerian invasion; but those savage nomads were at length expelled by Alyattes; and Crœsus, the son of Alyattes by an Ionian wife, having succeeded his father 560 B.C. soon raised himself to the position of a great potentate, ruling over nearly the whole country westward of the Halys, comprehending Æolian, Ionian, and Dorian Greeks; Phrygians; Mysians, Paphlagonians, Bithynians, Carians, Pamphylians, &c. At Sardis, the capital of this extensive dominion, was accumulated an immense treasure, composed of the tribute which

the Lydian monarch derived from the subject states; hence the proverb, 'as rich as Crœsus.'

Separated from the Median kingdom only by the river Halys, the Lydian dominion naturally became an object of desire to Cyrus, after he had acquired the sovereignty of Media. Accordingly (546 B.C.), provoked by an invasion of Crœsus, who had received from the Delphic oracle the equivocal assurance, that 'if he attacked the Persians he would subvert a mighty monarchy,' Cyrus crossed the Halys, advanced into Lydia, took Sardis, and made Crœsus prisoner. It was intended by the conqueror that the Lydian king should be burned alive—it is even said that the fire was kindled for the purpose; Cyrus, however, spared his life, and Crœsus became his friend and confidential adviser. On the subversion of the Lydian monarchy, its subjects, the Greeks of Asia Minor, were obliged to submit to the conqueror, after having in vain solicited the aid of their brethren the European Greeks. The Lacedæmonians, indeed, sent an embassy into Asia Minor; and one of their ambassadors had a conference with Cyrus at Sardis, where he warned him 'not to lay hands on any of the Greek towns, for the Lacedæmonians would not permit it.' 'Who are the Lacedæmonians?' said the astonished warrior. Having been informed that the Lacedæmonians were a Greek people, who had a capital called Sparta, where there was a regular market—'I have never yet,' said he, 'been afraid of this kind of men, who have a set place in the middle of their city where they meet to cheat one another and tell lies. If I live, they shall have troubles of their own to talk about.' To save themselves from the Persians, the Ionian portion of the Asiatic Greeks proposed a universal emigration to the island of Sardinia—a striking design, which, however, was not carried into execution. All Asia Minor ultimately yielded to Cyrus.

The Persian Empire.

Having subdued Asia Minor, Cyrus next turned his arms against the Assyrians of Babylon. His siege and capture of Babylon (538 B.C.), when he effected his entrance by diverting the course of the Euphrates, form one of the most romantic incidents in history; an incident connected with Scriptural narrative through its result—the emancipation of the Jews from their captivity. Along with Babylon, its dependencies, Phœnicia and Palestine, came under the Persians.

Cyrus, one of the most remarkable men of the ancient world, having perished in an invasion of Scythia (529 B.C.), was succeeded by his son Cambyses, who annexed Egypt to the Persian empire (525 B.C.), having defeated Psammenitus, the son of the Pharaoh Amasis. Foiled in his intention of penetrating Libya and Ethiopia, Cambyses was dethroned by a Magian impostor, who called himself Smerdis, pretending that he was the younger brother of Cambyses, although this brother had been put to death by the order of Cambyses during a fit of madness. A conspiracy of seven great nobles having been formed against the false Smerdis, he was put to death. He was succeeded by one of the conspiring chiefs, called Darius Hystaspes, who reigned over the immense Persian empire, extending from the Nile to the Indus, and beyond it, from 521 B.C. to 485 B.C. 'The reign of Darius,' says Mr Grote, 'was one of organisation, different from that of his predecessor—a difference which the Persians well understood and noted, calling Cyrus, "the father;" Cambyses, "the master;" and Darius, "the retail trader or huckster." In the mouth of the Persians, this last epithet must be construed as no insignificant compliment, since it intimates that he was the first to introduce some methodical order into the imperial administration and finances. Under the two former kings, there was no definite amount of tribute levied upon the subject provinces. But Darius probably felt it expedient to relieve the provinces from the burden of undefined exactions. He distributed the whole empire into twenty departments—called satrapies—imposing upon each a fixed annual tax. This, however, did not prevent each satrap—the Persian governor appointed by the king—in his own province from indefinite requisitions. The satrap was a little king, who acted nearly as he pleased in the internal administration of his province, subject only to the necessity of sending up the imperial tribute to the king at Susa, the capital of the Persian empire; of keeping off foreign enemies; and of furnishing an adequate military contingent for the foreign enterprises of the Great King. To every satrap was attached a royal secretary or comptroller of the revenue, who probably managed the imperial finances in the province, and to whom the court of Susa might perhaps look as a watch upon the satrap himself. The satrap or the secretary apportioned the sum payable by the satrapy in the aggregate among the various component districts, towns, or provinces, leaving to the local authorities in each of these latter the task of assessing it upon individual inhabitants. From necessity, therefore, as well as from indolence of temper and political incompetence, the Persians were compelled to respect the authorities which they found standing both in town and country, and to leave in their hands a large measure of genuine influence. Often even the petty kings who had governed separate districts during their state of independence, prior to the Persian conquest, retained their title and dignity as tributaries to the court of Susa. The empire of the Great King was thus an aggregate of heterogeneous elements, connected together by no tie except that of common fear and subjection—noway coherent nor self-supporting, nor pervaded by any common system or spirit of nationality.'

Continuation through Greek and Roman History.

The conquering spirit of Darius soon brought him into conflict with the Greeks of Europe (490 B.C.), and from that time the main interest of the world's history is bound up with the career of that remarkable people, and subsequently with that of the kindred nation of the Romans. The further progress of the race, then, will be continued in the two succeeding numbers, under the Histories of Greece and of Rome.

The Acropolis at Athens.

HISTORY OF GREECE.

THE name Græcia, or Greece, was unknown to the inhabitants themselves, who called their country Hellas, and themselves Hellenes.

Hellas, or ancient Greece, extended farther northward than the modern kingdom of that name, the limit being about the fortieth degree of north latitude; and is throughout mountainous. About the latitude above named, the Pindus sends a lateral branch, Mount Lingon, westward to the Adriatic, ending in the Acroceraunian Promontory; and another at right angles eastward, the Cambunian Mountains, which culminates in Mount Olympus (9700 feet high), near the coast of the Ægæan. About a degree farther to the south, the central range of Pindus sends another lateral branch eastward to the strait at the north end of the island of Eubœa. Between this range, called Othrys, the Cambunians on the north, and Pindus on the west, lies Thessaly, one of the few extensive plains of Greece. Its eastern coast is also skirted by the mountain-chain of Pelion, whose northern summit, Ossa, is separated from Olympus only by the narrow defile of Tempe, through which the river Peneus, that drains the whole plain, finds exit. The northern boundary of the modern kingdom of Greece runs from the Gulf of Volo along the ridge of Othrys to Pindus, and thence west to the Gulf of Ambracia on the Ionian Sea. It thus includes the whole of ancient Hellas, with the exception of Thessaly; for the inhabitants of Epeirus—now the southern part of Albania—were not considered as Hellenes.

A little south of Othrys, the range of Œta forms a third eastern offset from the central chain, and was considered as forming the northern barrier of Central Greece. Near the point of junction with Œta, Pindus divides into two branches: one runs south-east, under the names of Parnassus (8000 feet high), Helicon, Cithæron, and Hymettus, to Cape Sunium in the south of Attica; the other south-west, towards the narrowest part of the Corinthian Gulf. The mountains in Peloponnesus (island of Pelops), now Morea, may be considered as continuations of the two ranges last described. A ring of mountains incloses the central district, called Arcadia, and sends off branches in all directions; one of these, Mount Taÿgetus (7800 feet high), ends in Cape Tænarus, now Matapan.

These main ranges and their numerous offsets leave room for few plains of any considerable size. One remarkable feature of Greece is the number of shut valleys or basins, from which the water can issue only by finding a subterranean passage through the limestone rocks that bound them. The Lake Copais, in the plain of Bœotia, has no outlet but a number of such natural tunnels, and is caused by their insufficiency to let off all the water of the Cephissus. The remains of an artificial tunnel, four miles in length, are still discernible, which is believed to have been made by the ancient

inhabitants of Orchomenos to aid the natural outlets, and the bed of the lake had then been a rich plain. But this tunnel was choked up before history begins.

The only large river in Greece is the Achelous, now Aspropotamo, which, rising on the western declivities of Pindus, flows south-west into the Ionian Sea at the mouth of the Corinthian Gulf. Alpheius, the chief river of Peloponnesus, after disappearing more than once in subterranean passages among the limestone valleys of Arcadia, flows west into the Ionian Sea.

The cultivable portion of Greece is small, being considerably less than half the surface,* and confined to the valleys and strips of level land on the coasts. Yet the diluvial and alluvial soil collected in many of the valleys and troughs of the hills is of singular fertility. The richest tracts in modern, as in ancient times, are in the basins of the Peneus in Thessaly, of the Cephissus in Bœotia, of the Achelous in Ætolia, and the Alpheius in Elis. The greatest hinderance to the fertility of Greece is the deficiency of water. Abundance of rain falls in the autumn and winter months, but little or none during summer. The naked limestone rocks that chiefly compose the mountains retain little of the rain, and there are very few springs. This evil is greatly increased in modern times by the destruction of the forests that once clothed the mountains.

The climate of Greece is one of the most delightful in the world, having a bright sun and cloudless sky, without any very oppressive heat. The principal vegetable productions in ancient times were wheat, barley, flax, with the vine and olive; but the country was, and is, more pastoral than agricultural. It is not rich in metallic minerals, though the mines of Attica were wrought for silver, lead, and copper.

The chief political divisions of Greece during the historic period were the following: In Peloponnesus—Arcadia in the centre, surrounded by its mountain boundary; on the north, Achaia; east, Argolis; south, Laconia and Messenia; and west, Elis. The territories of Corinth and Megara occupied the isthmus; south-east lay Attica; north-west of Attica, Bœotia; next Phocis, chiefly occupied by the heights of Parnassus; Doris; Locris, on the channel of Eubœa; and Ozolian Locris, on the Gulf of Corinth. West of the central range lay Ætolia and Acarnania, separated by the river Achelous. The chief Hellenic state north of Mount Œta and Thermopylæ was Thessaly; Macedonia was not, till a late period, considered as belonging to Hellas. Intimately connected with Greece, and forming part of it, are a multitude of islands. The long, lofty, and naked backbone of Eubœa appears as a prolongation of the Ossa and Othrys mountains. Further south is the group which was called the Cyclades, and to the east of these the Sporades, near the coast of Asia. To the south of these groups lie two large islands—Crete and Rhodes; and off the southern coast of Laconia, the island of Cythera. Between Attica and Argolis was the Saronic Gulf, containing the celebrated island of Salamis, which was reckoned part of Attica: here, too, was Ægina, its hated rival. In the Ionian Sea were—Corcyra, opposite Epeirus; Ithaca and Cephallenia, opposite Acarnania; and Zacynthus, near the coast of Elis.

Such is a brief description of Hellas Proper. But the Greek race had planted numerous colonies on the coasts of Asia Minor, of Africa, Italy, Sicily, and other parts of the Mediterranean; and wherever the Hellenic tongue was spoken and Hellenic ideas and usages prevailed, that was considered as forming part of Hellas, no less than Athens or Sparta. The history of Greece, then, must embrace these colonies.

THE HELLENES, OR PEOPLE OF ANCIENT GREECE.

The configuration of Hellas, as described above, was peculiarly calculated to foster a large number of independent communities, separated from each other by mountain-chains, but open to foreign intercourse by the sea, which was accessible to almost every state of Greece. Accordingly, we find that each of the principal cities was founded in one of the small plains or valleys we have described, and grew up in solitary independence of all the world besides.

To a modern reader, accustomed to large political aggregations, it requires a certain mental effort to suppose a time when even the smallest town clung so tenaciously to its right of self-legislation; nevertheless, this multiplicity of self-governing cities was a phenomenon common to ancient Europe, and placed it in singular contrast with the extensive monarchies of Asia; but it appears more marked among the Greeks than anywhere else; and doubtless they owed it to the multitude of insulating boundaries which the configuration of their country presented.

Though politically disunited, the inhabitants of Greece had some intimate bonds of union. They were, according to their own belief, all of one blood, boasting their descent from one common ancestor, HELLEN, after whom they called themselves Hellenes, while they stigmatised every other people as barbarians. They all spoke the same language, though broken into numerous dialects; and, whatever might be the diversity of their manners or character, there were some important points in which they resembled each other, while they differed from the most celebrated of the surrounding nations. Polygamy, the selling of children into slavery, the deliberate mutilation of the person, and the immolation of human victims to the gods, generally prevailed among the contemporaneous Egyptians, Carthaginians, Persians, and Thracians; but such practices were utterly abhorrent to the Hellenic mind. On the other hand, the cultivation of gymnastic exercises by public contests was common to all the Hellenes, but unknown, so far as appears, to any of their neighbours.

This people were united, likewise, by a community of religion and literature. They worshipped the same gods, and held sacred the same localities. They had a common stock of legends, maxims, and metaphors, embodied in the works of Homer and other early poets, which were familiar to all, and acknowledged by all as the standards of literary language. So also the councils called Amphictyonies, and the games known to us as the Olympic, the Pythian, the Nemean, and the Isthmian, presented opportunities of mutual intercourse to brethren habitually isolated from each other.

* The surface of modern Greece is stated at 12 million English acres.

By what circumstances, or out of what elements, this Hellenic family was formed, we know not. There were indeed traditions of Pelasgi, Leleges, Curetes, and other peoples, as previous inhabitants of Greece, but the whole is without evidence, and belongs to legend rather than history.

As little do we know of the foreign influences which were brought to bear on them. The legends tell of colonies led from Egypt and Asia into Greece. One colony is said to have been founded at Thebes, in Bœotia, by Cadmus, a Phœnician, from whom the Greeks learned the art of writing. Doubtless, the use of letters was derived from the Phœnicians; but with this exception there is little trace of the impress of any of these nations in the earliest Greeks.

The religious and historic legends, or *myths*, as they are called, to which we have referred as the common property of all the Hellenes, and the festivals which drew so many of them together at certain seasons, exercised so great an influence on the character and history of this remarkable people, that they demand more special notice.

THE GODS OF GREECE.

The legendary history of Greece begins with a history of the gods, whom it represents as both pre-existent and superior to men; and it gradually descends first to heroes, then to the ordinary race of human beings.

The numerous gods of ancient Greece were conceived after the model of human nature, but not on the same scale. They had the same appetites, passions, and affections that disturb the soul of man, but were at the same time invested with immensely greater powers, and gifted with immortality. Beings thus imagined were peculiarly suitable subjects for adventure and narrative; and the inventive fancy of the Greeks had full play in the fabrication of legends illustrative of their respective characters and attributes.

Pluto and Proserpina, with the dog Cerberus.

Chronos.

Jupiter.

The earliest mythical events are the proceedings of certain gigantic agents—the collision of certain terrific forces, which were ultimately reduced under the more orderly government of Zeus or Jupiter, with whom begins a new dynasty, and a different order of beings.

Neptune.

Apollo.

Zeus divided the sovereignty of the universe with his two brothers—Poseidon (Neptune) and Hades (Pluto). He retained for himself the æther and the atmosphere, together with the general presiding function. Poseidon obtained the sea, while Hades ruled the world of shades. These deities, with their sisters and divine progeny, comprehended the gods worshipped by the early Greeks. Twelve were especially called the great Olympic gods, being supposed to dwell on the heights of Mount Olympus, and to form the divine agora, or council of the gods, which was held there.

(1.) Zeus or Jupiter, the chief of the gods, is said to have been the son of Chronos, one of the Titans, who sprang from Uranus and Ge (the

Heaven and the Earth). Chronos, foreboding destruction to himself from his own children, swallowed them as soon as they were born. However, his wife Rhea contrived to conceal the birth of Jupiter, who grew to manhood, when he by stratagem induced his father to disgorge the five previous children—Vesta, Ceres, Juno, Neptune, and Pluto. Jupiter now determined to wrest the power from Chronos, and his brothers, the Titans; and a long and desperate struggle took place, in which the thunderbolts of Jupiter at length prevailed; and Chronos, with the other Titans, were irrevocably imprisoned in Tartarus. Chronos, usually identified with the Italian god Saturn, was considered as the god of Time, and was represented under the figure of an old man, holding a scythe in one hand, and a serpent, with its tail in its mouth, in the other. Jupiter is always represented as seated on a throne, with thunderbolts in his right hand, and an eagle by his side.

(2.) Poseidon or Neptune, the Earth-shaker and Ruler of the Sea, was second only to Jupiter in power. He is represented as a half-nude man, drawn in a chariot over the sea by water-horses, having a crown on his head and a trident in his hand.

(3.) Apollo, son of Jupiter, the god of Prophecy, Music, and Song, is represented as a handsome young man, with a lyre and a bow, and is very generally identified with the Sun. In the idea of Apollo, his worship, and his oracles, the brightest characteristics of the Greek mind are reflected.

(4.) Hephæstus or Vulcan was the god of Fire, and a great artificer in metals. Volcanoes were his workshops.

(5.) Ares or Mars, the god of War, delighted in the din of battle, the slaughter of men, and the destruction of towns.

(6.) Hermes or Mercury, the god of Eloquence, the messenger of the gods, the inventor of the lyre, which he transferred to Apollo, and the patron of knavery, is characterised by sandals with wings, which carried him rapidly over sea

Mercury presenting a Soul to Pluto.

Juno.

and land; a wand called caduceus, which he bore as herald; and a travelling-cap, which in later times was furnished with two wings.

(7.) Hera or Juno, the wife of Jupiter, a beautiful but unamiable goddess, quarrelled much with her husband, and persecuted his children. Her characteristics are a diadem, veil, sceptre, and peacock.

Minerva.

Diana.

(8.) Athena, Pallas, or Minerva, the goddess of Wisdom and War, is the type of composed, majestic, and unrelenting force. She is said to have issued in full armour from the head of Jupiter, and to have been inaccessible to feminine sympathies. She was worshipped in all parts of Greece, but was especially the tutelar divinity of the city of Athens, and the soil of Attica.

(9.) Artemis or Diana, the twin-sister of Apollo, and goddess of Hunting, is, like him, armed with a bow and arrows. Unlike him, she was ever unmoved by love. As Apollo had charge of the sun, so had Diana of the moon.

(10.) Aphrodite or Venus, the goddess of Love and Beauty, is generally represented with her son Eros or Cupid. The principal seats of her worship were the islands of Cyprus and Cythera.

(11.) Hestia or Vesta, the goddess of the Hearth, or rather of the fire burning there, was a chaste and home-keeping maiden divinity, believed to dwell in the inner part of every house. It was on the hearth that refugees, entering a house, implored protection of the inhabitants; and every town had a sacred hearth, where the goddess had her especial sanctuary, and where she protected suppliants. When a colony was sent out, the emigrants took fire from their native town, to kindle that on the hearth of their new home.

(12.) Demeter or Ceres, the goddess of Agriculture, acquired much importance in Greece, and was worshipped with great splendour by the Athenians.

Besides these, called the twelve great gods of Olympus, there was an indefinite number of others, some of whom were little inferior in power and dignity. Such were Helios or Sol, Bacchus, the Muses, the Nereides, the Nymphs, &c. There were also monsters, the progeny of the gods—as the Harpies, the Gorgons, Cerberus, the Centaurs, the Dragon of the Hesperides, Xanthos and Balios, the immortal horses, &c.

Centaur.

Some deities performed special services for the greater gods—as Iris, a messenger of the gods; Hebe, who waited upon them, and filled their cups with nectar; and the Horæ, who guarded the doors of Olympus.

It was thus that all nature was imagined to be moving and working through a number of personal agents; all things in earth and heaven, as well as the earth itself and the solid heaven, were considered as endowed with appetite, feeling, sex, and other attributes of humanity.

The gods were propitiated by animal sacrifices, of which the bones only and the fat were presented to them; likewise by offerings of fruits, oils, and fragrant odours; and by the dedication of lands and treasures to their service. Every king was the priest of his subjects, and every father sacrificed for his family.

At the favourite shrines of each particular deity, periodical festivals were celebrated; and at these festivals, hymns were sung in honour of the god, giving an account of his birth, and of the exploits by which he had manifested his divinity. These legends were for the most part sufficiently silly and grotesque, and sometimes shocking; but they were in harmony with the religious feeling of the believing Greek in the early ages, and were received with unsuspecting reverence.

As a specimen of these religious legends, we give that connected with the goddess Demeter or Ceres and the Eleusinian mysteries. These mysteries were one of a series of innovations on the primitive Hellenic religion. The native religious worship and ceremonies of the Greeks were simple, open-hearted, calculated for publicity, and of a joyous character, the very opposite of ascetic. But about the sixth century B.C. various religious novelties were introduced into Greece from Egypt, Asia Minor, and Thrace, attaching themselves chiefly to the worship of Bacchus and Ceres. Such were the special mysteries and *orgies* in honour of some particular god, distinct both from the public and the family solemnities of primitive Greece, celebrated apart from the citizens generally, and approachable only through a certain course of initiation.

These rites, particularly those in honour of Bacchus, were in many cases furious and ecstatic, especially among the women, who had everywhere occasional meetings of their own, apart from the men. At a stated time every three years, crowds of females, dressed in fawn-skins, and bearing the consecrated thyrsus, flocked to the solitudes of Parnassus, Cithæron, or Taÿgetus, and passed the night in dancing by torchlight, clamorously invoking the god, and abandoning themselves to the most frantic excitement; while the men celebrated noisy revels in the streets, playing the cymbals and tambourine, and carrying the image of the god in procession. It was understood that those who resisted the inspiration became obnoxious to the displeasure of the god.

The legend connected with the Eleusinian mysteries was in substance the following: Proserpina, the daughter of Ceres, had been seized by Pluto while she was gathering flowers in a meadow, and was carried off to become his wife in the world of shades. The disconsolate mother wandered for nine days and nights by torchlight in search of the maiden; and at length Helios (Sol) revealed the truth to her, and, moreover, that Jove had permitted the abduction. Ceres, in anger and despair, renounced the society of Olympus, abstained from nectar and ambrosia, and wandered fasting upon earth. Thus she came to Eleusis, where she was found by the daughters of the prince sitting in the form of an old woman by a well. She said she wanted employment as a nurse, and the damsels effectually used their good offices to have her intrusted with the care of their only brother, a new-born infant. She gave the child no food, but anointed him with ambrosia, and he grew like a god; every night she plunged him in the fire, and took him out unhurt. She would have rendered him immortal, but for the interference of the mother, who one night stealthily witnessed the process. The goddess now revealed herself, and directed that a temple and altar should be erected to her on the neighbouring hill, where she was to be served with orgies of her own prescribing. Her injunctions were obeyed, and she took up her abode in the temple, still pining with grief. She withheld from mortals her beneficent aid; the barley which was sown that year never sprung up, and the human race was in danger of starvation. Jupiter sent various deputations of goddesses to implore her to relent; but she would be satisfied with nothing except the restoration of her daughter, which Jupiter was obliged at length to effect. Ceres was now reconciled both to the gods and to men; the buried seed came up in abundance, and she returned to Olympus. She was obliged, however, to allow Proserpina to spend three months of every year with Pluto, departing always at seed-time.

ORACLES.

A distinguishing characteristic that continually meets us in the history of the Greeks, is their anxiety to penetrate the future, and their unwillingness to commence any enterprise without ascertaining that the gods were propitious to it. The divine will was supposed to be announced by visions, dreams, and various omens—as thunder, lightning, eclipses, the flight or the notes of birds, the entrails of sacrificial victims, but especially by oracles. The most ancient of these oracles was that of Dodona, in Epeirus, where Jupiter announced his will by the whistling of the wind through lofty trees. This oracle was afterwards superseded to a great extent by the one at

Delphi, which was built round one of the openings of a deep cavern in the side of Mount Parnassus. An intoxicating vapour arose from this chasm, over which the priestess, called Pythia, sat on a tripod when the oracle was consulted. The words she uttered, after inhaling the vapour, were believed to be the revelations of Apollo, and were communicated in hexameter verse by the attending priests to the inquirers.

THE OLYMPIC AND OTHER GAMES.

Intimately connected with the worship of the gods were the celebrated games called the Olympic, the Pythian, the Nemean, and the Isthmian, which, in their origin, were religious festivals; for the gods gave their sanction to recreation, and there was the closest connection between common worship and common amusement. The habit of neighbouring tribes or villages joining in sacrifice at each other's festivals, was one of the earliest usages of Greece; and to partake of the recreations which followed the religious observances, was a matter of course. As Greece emerged from the turbulence of the heroic age, the village festivals became city festivals; and thus the once humble gatherings at Elis and Delphi swelled into the pomp and confluence of the Olympic and Pythian games.

The most ancient as well as famous of these festivals was that celebrated in the plain of Olympia, near an ancient temple of the Olympian Jove. It was celebrated every four years, which interval was called an Olympiad; and the first register of a victor's name, which occurs in 776 B.C. supplies the earliest historic record of Greece —that from which the dates of later historians were calculated. At first, the amusements lasted but a single day, and consisted only of foot-races in the stadium; but various trials of strength and skill—as wrestling, boxing, throwing, and chariot-racing—were afterwards introduced, and the time was prolonged. The only prize given to the victor was a garland of wild olive; but it was reward enough that his name was proclaimed before assembled Hellas—that his statue was erected in the sacred grove of Jupiter at Olympia. He returned to his home in triumphal procession, and was rewarded by his fellow-citizens always with distinguished honours—sometimes with substantial benefits.

The Pythian games, second only to the Olympic, were celebrated in the third year of each Olympiad, on the plain of Cirrha. The Nemean were held every two years, in honour of the Nemean Jove, and in the valley of the same name between Phlius and Cleonæ; the Isthmian, by the Corinthians, on their own isthmus, in honour of Neptune. In the Pythian, Nemean, and Isthmian games, contests in music and poetry were added to gymnastics and races.

AMPHICTYONIC COUNCIL.

An Amphictyony was a confederation of neighbouring tribes for the protection of a common sanctuary, at which they assembled to celebrate religious rites and games, and to transact business. There were many such associations in Greece; but the one, consisting of twelve tribes, that had the protection of the great oracle at Delphi, became of national importance, and was called the Amphictyonic league, by way of eminence. The delegates or council of this league took a leading part in the politics of Hellas generally.

HEROIC LEGENDS.

Having briefly noticed the principal gods of Greece, and some of the usages connected with their worship, we come to the genealogies that connect them with historical men.

In the retrospective faith of a Greek, the idea of worship was closely connected with that of ancestry; every association of men traced its union to some common progenitor, and that progenitor was either the god they worshipped in common, or some semi-divine being closely allied to him. Every Greek loved to boast a genealogy filled not only with the names, but the splendid adventures of those who were little removed from the divine. These genealogies constitute the supposed primitive history of Hellas.

The wickedness of the earth provoked Jupiter to send an unremitting and terrible rain, which laid the whole of Greece under water, except the highest mountain-tops, on which a few stragglers found refuge. Deucalion, the son of Prometheus, was saved, with his wife Pyrrha, in an ark which his father had forewarned him to construct; and after floating on the water for nine days, he settled on the summit of Mount Parnassus. He now prayed that companions might be sent to them; and, accordingly, Jupiter directed them to throw stones over their heads, when those cast by Pyrrha became women, and those by Deucalion men, over whom he reigned as king in Thessaly. One of the sons of this pair was Hellen, the great progenitor of the Hellenes. Hellen had three sons by a nymph—Dorus, Xuthus, and Æolus. Æolus inherited the dominion in Thessaly, but his descendants occupied a great part of Central Greece, and became widely diffused, especially on the coasts. Dorus and his descendants occupied the country on the northern side of the Corinthian Gulf. Xuthus received Peloponnesus, and had two sons, Achæus and Ion, the progenitors of the Achæans and Ionians. Thus the four great branches of the Hellenic race became masters of Greece, the previous Pelasgic inhabitants either disappearing before them, or being incorporated with them. The Dorians and Ionians became, in historical times, the two leading races, represented by the Spartans and Athenians respectively; but in the heroic ages, the Achæans were the most distinguished, as being the most warlike of the races.

The first few generations of the family thus established in Greece are called the Heroic race, and the period in which they lived, the Heroic age. Two of the heroes, Hercules and Theseus, we must notice, on account of their connection with subsequent history.

Hercules, the greatest of all the Grecian heroes, was the son of Jupiter by Alcmene, the wife of Amphitryon, king of Thebes, in Bœotia, who adopted him as his own son. By a stratagem of Juno, Hercules was deprived of the empire which Jove had designed for him as the descendant of Perseus, and it became the inheritance of Eurystheus, another grandson of Perseus. She likewise

sent two serpents to destroy him in his cradle, but the infant hero strangled them with his hands. As he grew up, he was sent to tend Amphitryon's cattle; a huge lion made great havoc among them, and Hercules, slaying him, wore the skin ever afterwards as his ordinary garment, and the mouth and head as his helmet. The gods made him presents of arms, and he usually carried an immense club. After various adventures, he was instructed by the oracle of Delphi to live at Tiryns, and serve Eurystheus for twelve years, after which he should become immortal. Hence the twelve labours, performed at the bidding of Eurystheus.

In these are realised the great objects of all ancient heroism—the destruction of monstrous evils, and the acquisition of wealth and power. Such was the overthrow of the Nemean lion and the Lernean hydra; the seizure of the girdle of Mars from Hippolyte, queen of the Amazons; and the bearing away of the golden apples of the Hesperides, guarded by a hundred-headed dragon. But in the case of Hercules, we perceive human faults which demanded expiation. Having slain his friend Iphitus, he was smitten with sickness, from which he obtained deliverance only on condition of another servitude; in which he became the slave of Omphale, queen of Lydia, and spun wool with a distaff. The time of this servitude having expired, he undertook various warlike adventures, and married Deianira, whose jealousy became the cause of his death. Fearing that she might be superseded in his affection by Iole, a maiden whom he had captured, Deianira steeped a tunic in a liquid which she believed would secure his regards to herself. This was, however, a deadly poison; and no sooner had the hero put it on, than he was seized with excruciating pains. In vain he strove to wrench it off; it stuck to his flesh, which tore away with it. Willing to hasten his end, Hercules ascended Mount Œta, raised a pile of wood, placed himself on it, and directed it to be set on fire. While it was burning, a cloud came from heaven, and carried him to Olympus, where he was made immortal, was reconciled to Juno, and received her daughter Hebe in marriage. He was consequently worshipped throughout Greece both as a god and a hero.

After the death and apotheosis of Hercules, his children were persecuted by Eurystheus; the Athenians offered them shelter, and Eurystheus invaded Attica, but perished in the enterprise. His sons fell with him, so that the Heracleids were now the only representatives of Perseus. They made an effort to recover their rightful possessions, but were met at the isthmus by the combined forces of the Ionians, Achæans, and Arcadians, then inhabiting Peloponnesus. Hyllus, the eldest of the sons of Hercules, proposed to determine the contest by single combat, the condition being, that if he were victorious, the Heracleids should be restored; but if vanquished, they should forego their claim for a hundred years. Echemus, the hero of Tegea, accepted the challenge, and Hyllus was slain, in consequence of which the Heracleids retired, and resided with the Dorians, under the protection of Ægimius, the son of Dorus, till the stipulated period of time had expired.

The great Attic hero was Theseus, a contemporary and relative of Hercules, whose exploits he imitated. The Amazons—a race of female warriors—had scarcely recovered from the aggressions of Hercules, when Theseus attacked and defeated them, carrying off their queen, Antiope, which injury they avenged by invading Attica. They crossed the Cimmerian Bosporus on the winter ice, and penetrated even into Athens, where, after a desperate struggle, they were finally overcome by Theseus. The sepulchral edifice called the Amazonian, the tomb or pillar of Antiope, and the sacrifices which were offered to the Amazons at the periodical festival of the Theseia, were all so many religious mementoes of the victory.

Another famous adventure of Theseus was connected with the Minotaur. Minos, the ruler of Cnossus, in Crete, and his brother Rhadamanthus, were sons of Jupiter by Europa, daughter of the Phœnix. Androgeos, the son of Minos, having vanquished all competitors at an Athenian festival, was induced to contend with the bull of Marathon, and perished. Minos made war upon Athens, to avenge his death, and Jupiter sent pestilence and famine into the city. The Athenians were at length obliged to accept peace on any terms; and Minos required that seven youths and seven maidens should be sent to Crete every ninth year, to be devoured by a monster, half-bull, half-man, in a labyrinth, out of which no one could find a passage. The third period for despatching victims had arrived, and Theseus, craving the aid of Neptune, and receiving assurance that Venus would extricate him, offered himself as one of the fourteen. On his arrival at Cnossus, he at once captivated the affections of Ariadne, the daughter of Minos, who furnished him with a sword, with which he killed the Minotaur, and a clue of thread, by which he retraced his way out of the labyrinth. This done, he set sail from Crete with his companions, carrying off Ariadne also. On his way home, he stopped at Delos, to offer a grateful sacrifice to Apollo for his escape. It had been agreed between him and his father, that if he returned in safety, he should hoist white sails, instead of the black ones usually carried on this mournful embassy; but Theseus forgot to make the change; and his father watching the returning ship, and concluding that his son had perished, threw himself into the sea. The ship was carefully preserved by the Athenians, being constantly repaired with new timbers down to the time of Phalereus Demetrius; and every year she was sent to Delos with special envoys and a solemn sacrifice. During her absence, the city was held to abstain from all acts of public impurity, so that no one might be put to death even under judicial sentence till its return.

Besides the legends of individual heroism, there were a number of collective exploits and expeditions, of which we can afford to notice only two—the Argonautic Expedition, and most famous of all, the siege and capture of Troy.

THE ARGONAUTIC EXPEDITION.

During the age of Hercules, Jason, a prince of Thessaly, undertook an enterprise, afterwards celebrated as the Argonautic Expedition. Æson, his uncle, had usurped his throne, and consented to restore it only on condition that Jason should bring from Æa (Colchis), a region on the east of the Black Sea, a golden fleece, which was there hanging on a tree in the grove of Mars, guarded

by a sleepless dragon. The most renowned heroes of the time, including Hercules and Theseus, united with Jason in the enterprise; and the adventurers were called Argonauts, after the vessel which was built for it. When they arrived, the king, Æetes, promised to give Jason the fleece if he would yoke two fire-breathing oxen, with brazen feet, plough with them a piece of land, sow in the furrows the teeth of the dragon slain by Cadmus, and vanquish the warriors that would spring from this seed. Medea, the daughter of Æetes, who was skilled in magical arts, when her father still delayed to surrender the fleece, put the dragon to sleep, seized the treasure, and set sail with the adventurers. Æetes pursued them in vain; and after much circuitous voyaging, they safely reached their home.

THE SIEGE OF TROY.

The sacred city of Ilium, or Troy, was built on a plain in Asia Minor, near the shores of the Hellespont. On one occasion, as Paris, the son of Priam the king, was tending the sheep on Mount Ida, the three goddesses, Juno, Minerva, and Venus, were brought thither, that he might decide a dispute that had occurred as to which was the most beautiful. He awarded the palm to Venus, who thereupon promised him the possession of Helen, wife of the Spartan Menelaus, the fairest of living women. Paris then visited Sparta, and during a temporary absence of Menelaus, Venus brought about an intrigue between Helen and the guest, and they eloped, taking with them a large sum of money. The king, hearing of this perfidious abuse of his hospitality, hastened home; the outrage was made known throughout Greece, and its princes were solicited to aid in avenging it. Ten years were spent in preparing an expedition, and ten more in besieging Troy. The goddesses Juno and Minerva took an active part on the side of the Greeks. Among their heroes were Ajax and Diomedes, and the sagacious Nestor; while Agamemnon, brother of Menelaus, and the commander-in-chief, had a high reputation for valour and prudence. But the most conspicuous of all were Achilles and Ulysses (Odysseus). Achilles was a beautiful youth, born of a goddess, swift of foot, fierce in temper, and irresistible in strength; Ulysses, no less efficient from his wisdom and eloquence, and the combination of daring courage with deep scheming. Among the Trojans, the most striking hero was Hector, a son of Priam, forming a well-marked contrast with his effeminate brother Paris.

Troy was to remain invincible so long as a certain statue of Minerva, called Palladium, remained in the citadel. The daring Ulysses found means to enter the city, and steal this away. Another stratagem secured the victory. The Greeks, by his direction, constructed a great hollow wooden horse, in which they placed a hundred of their best warriors, the rest sailing away, under pretence of abandoning the siege. The Trojans were sorely puzzled with the great horse, which they brought into the city, making a breach in the walls to admit it. During a night of riotous festivity, the signal was given for the return of the Greeks by one whom they had left for that purpose; the warriors rushing out of the horse, were joined by the rest, and the city was overpowered. Troy was utterly destroyed, and Helen resumed her union with Menelaus.

The return of the Grecian chiefs from Troy furnished poetical materials hardly less copious than the siege itself. Many suffered shipwreck in attempting to reach their homes; and those who succeeded, found their places occupied by usurpers, their lands overrun by enemies, or wasted by neglect, their families ruined by jealousy and discord, and their cities distracted by faction and sedition.

How these legends of gods and heroes were originated; whether they are to be understood as pure fictions, or as intended to convey certain truths, are questions that have occasioned endless discussion. As early at least as the age of the Homeric poems, they had come to be understood in their literal sense. It was only at a comparatively late period that the legends, in their literal sense, began to shock the moral feelings, and to appear incredible as narratives. Attempts were then made to soften down the offensive parts by allegorical interpretations, and to remove the inconsistencies of the narratives by a multitude of assumptions, as destitute of evidence as the legends themselves. The legends were thus *rationalised* and digested by later Greek writers into a species of history of the foretime of the Hellenic race, reaching back a thousand years before the date of any authentic record; and writers on Greek affairs, in modern times, long assumed the legends to be based at least on matter of fact. But the essentially fictitious or mythical character of these early products of the Greek mind has of late become generally recognised; and in the great work of Mr Grote on the History of Greece, all attempt to extract history from the legends is given up as hopeless. They are regarded by him as imagined histories of the past—spontaneous creations of the Greek mind, by which it sought to account to itself for the existing state of things.

Other scholars are not content with this account of their origin, and hold that they were intended by their original utterers to express a real meaning. Those respecting the gods were attempts to describe the great appearances of nature—chiefly of the sun. They took their rise at a time when every word was a metaphor, and were themselves metaphors, no other mode of expression being then possible; but when the original and etymological significance of the names came to be lost sight of, the original application was forgotten, and the whole seemed to be spoken of persons. Professor Max Müller gives as an illustration of the process, the myth of Hellen and Pyrrha, given above. Pyrrha was the most ancient name of Thessaly; to say, then, that Pyrrha was the mother of Hellen, was in that age the only natural way of saying that the Hellenes came originally from Thessaly; just as we still say that Italy is the mother of art. When the Greeks ceased to know Thessaly under the name of Pyrrha, the historical fact degenerated into a myth.

ANCIENT EPIC POETRY OF GREECE.

Long before the period of literature, the praises of the gods and the exploits of heroes were embodied in verse, and sung from generation to generation. The myths passed into the verses of the

poets, where they were multiplied and transformed in various ways; and in process of time, numbers of these, at first short and unconnected lays, were combined and arranged so as to form continuous narrative or epic poems. There was a large number of such poems extant in ancient Greece, but they are all lost except the *Iliad* and *Odyssey*, ascribed to Homer, celebrating the siege of Troy, and the subsequent adventures of Ulysses. The controversies of the learned concerning the person and the works of Homer are endless. At least seven cities of Asiatic Greece laid claim to his birth. No less disputed is the date to be assigned to these celebrated poems: about the middle of the ninth century before the Christian era, is probably near the mark.

The legends thus embodied in song were recited either in short fragments before private companies, or as continuous narratives at public festivals, and they constituted the whole intellectual stock of the people for several ages.

Besides the poetic charm attaching to these works, they are interesting to us as revealing the state of society among the Greeks at that early age; for Homer's pictures of life and manners were those of his own day. The *Iliad* and *Odyssey* represent a state of society in which there is no such thing as law. The king or chief defends and governs his people according to immemorial usage; and is responsible to none but Jove for the exercise of his authority. The condition and character of the heroic Greeks bear no inconsiderable resemblance to those of chivalrous Europe in the middle ages, or even the clans of the Scottish Highlands a century ago; making allowance for differences resulting from climate and religion.

Hesiod, supposed to have flourished a considerable time after Homer, probably about 700 B.C. is the great authority as to the genealogy and history of the gods. His work is an ancient and genuine attempt to furnish a consecutive history of the divine foretime, and therefore his theogony obtained an extensive circulation among the Hellenes, and was in a manner their Bible.

HISTORIC AGES.

The authentic history of Greece commences with the epoch known as the First Olympiad, corresponding to the year 776 B.C. about which time the Greeks began to employ writing as the means of perpetuating the memory of events.

It falls naturally into six periods:

I. From 776 to 500 B.C. or the period during which the various states and colonies of Greece pursued their separate career, without either alliance or collision with each other.

II. From 500 to 478 B.C. or the period of the struggles with Persia.

III. From 478 to 404 B.C. or the period of the Peloponnesian wars, in which the peninsular states were struggling against the supremacy of Athens.

IV. From 404 to 371 B.C. when the battle of Leuctra crowned the efforts of Thebes to attain to the headship of Greece.

V. From 371 to 338 B.C. when the battle of Chæronea rendered Philip the Macedonian master of Greece.

VI. From 338 to 300 B.C. or the period of the Macedonian supremacy.

FIRST PERIOD: 776-500 B.C.

We cannot afford even to enumerate the multiplicity of independent states, or rather, self-governing towns, which during this period made up the Hellenic world. A few remarks on their condition generally, with a brief indication of the course of events in one or two of the more important states, must suffice.

Government and Social Condition.—Before the era of authentic history, the primitive kingships of the heroic ages had in most cases been abolished, and the government vested in some kind of oligarchy—a council deciding by the majority of votes, and electing some individuals of their own body as a temporary and accountable executive. This government of the Few was the first form of republicanism in Greece. The age of democracy, or the government of the Many, was still distant, and the condition of the general mass of freemen appears to have been little affected by the change. The first check which the oligarchies received arose from usurpers called *tyrants*, or *despots*, who availed themselves of prevailing discontents to compass the ends of their own ambition. Sometimes it was a magistrate, who, at the expiration of his term of office, found himself able to retain it in spite of the electors. More frequently, it was a demagogue, who stood forward as the champion of the many in their grievances, and engaged their strength to put down the few, and exalt him in their stead. Sometimes a presumptuous rich man hired a body of retainers to seize the Acropolis, and place the government in his hands. The period between 650 and 500 B.C. witnessed the rise and fall of many such despots and despotic dynasties, of which the most celebrated were those of Corinth, Sicyon, and Megara. But there was in the Greek mind a deeply rooted antipathy to anything like permanent or hereditary power vested in an individual, and even those who exercised a sovereignty with moderation, could never retain their popularity; for a position which dispensed with the restraints and obligations involved in citizenship, was understood to forfeit all title to the common sympathy and protection. The man who assassinated a despot was considered worthy of public honour and reward. Hence few of the despots lived to old age, and still fewer transmitted their power to their sons.

Sparta was the only state that retained a kingly government during the brilliant period of Grecian history. The two co-ordinate lines of Spartan kings continued to represent in unbroken descent the divine right of the Heracleids to the soil of Sparta. The Spartans were always ready to lend their powerful assistance towards the overthrow of usurpers in other states, but they seldom succeeded in restoring the oligarchy. The sway of the despots had done much to lessen the distance between the Few and the Many; and when they were removed, it was found impossible in most cases to reinstate the nobles in their ancient privileges. The internal history of the Grecian states became henceforth a struggle between the democracy and the aristocracy.

In reference to the social condition of the people,

it may be observed that slavery prevailed universally, the bond being much more numerous than the free. Where a conquering race had subjugated the previous inhabitants, the country population were in a state of serfdom, cultivating the soil for the benefit of the citizens. Such were the helots of Laconia, whose servitude was rendered more galling by the feeling that they were fellow-Greeks with their masters.

Early Greek Colonies in Asia and the Islands of the Ægæan.

The legendary history places the settlement of these colonies about three centuries before the First Olympiad. With the opening of authentic history, the whole coast of Asia Minor, from the Propontis southward to Lycia, together with the islands in the Ægæan, was occupied by a succession of Greek cities greatly in advance of the mother-country, both in wealth and civilisation. The cities on the northern portion of the coast and the island of Lesbos were inhabited by Æolic Greeks; Dorians occupied the southern portion; and in the middle were the Ionic colonies, comprehending the islands of Chios, Samos, and the Cyclades. The Ionic colonies were called by the collective name of Ionia, and it was among them that Greek poetry, painting, philosophy, and history were first cultivated.

Between the years 700 and 530 B.C. the maritime activity of the colonial Greeks made immense progress; and the ships of Miletus, Phocæa, and Samos gradually spread over all those waters of the Levant that had once been exclusively occupied by the Phœnicians.

About the year 650 B.C. a band of Ionians and Carians were taken into the service of Psammetichus, and materially aided him in obtaining the throne. The consequence was that Egypt was thrown open to the Greeks for permanent and friendly intercourse. The Greek mind thus became enlarged by the wide field of observation presented; papyrus, the only writing material then known, came into general use, to aid the progress of literature; and the fine arts made immense advances, probably from the Greeks obtaining from their new friends the knowledge of various technical processes, for want of which their genius had been cramped.

At the time the Greek colonies first settled in Asia Minor, the native populations seem to have been too disunited and feeble to oppose or interfere with them; but when the neighbouring monarchy of Lydia had acquired strength, the want of confederation among the Greek cities made them an easy prey, and accordingly Crœsus, the last king of Lydia (560–546 B.C.), subdued them one by one, and rendered them tributary, without, however, interfering with their self-government. Their further history connects itself with the Persian invasion.

Sicilian Colonies.

The Greek colonies to the west of the mother-country were, with one exception, formed within the historic period. The exception was Cumæ, on the Italian coast, northward from Naples, said to have been planted more than 1000 B.C. by colonists from Æolia in Asia Minor, and from Chalcis in Eubœa. From 700 to 500 B.C. it was the first city of Italy, but was subdued by the Samnites in 420 B.C. The first Sicilian colony was formed at Naxos 735 B.C. and the afterwards mighty Syracuse in the following year. Of the other Greek cities, Gela and Agrigentum were the most important. Phalaris was *tyrant* of Agrigentum about 570 B.C. and has left a name infamous for cruelty. One of his punishments was to shut up his victims in a red-hot brazen bull, the inventor of the instrument being the first to suffer by it. Gelon, despot of Gela, having seized Syracuse (485 B.C.), raised it to an unwonted pitch of wealth and prosperity, and wielded a power such as no Greek had ever possessed. When Greece was menaced with invasion by Xerxes, the Athenians and Lacedæmonians sent to beg his assistance, which was refused. In the same year (480 B.C.) that Xerxes invaded Greece, the Carthaginians under Hamilcar invaded Sicily with an immense army, composed of various nations, and were defeated at Himera by Gelon; 150,000 of the invaders are said to have fallen. Gelon was succeeded (478 B.C.) by his brother Hieron, a munificent patron of poets and philosophers, but more despotic in his government than his brother had been. His aid being invoked by Cumæ against the Etruscans, he gained a great victory (474 B.C.) over the fleet of the latter, and effectually broke their naval power.

Contemporarily with the colonisation of Sicily, the coasts of Southern Italy from Pæstum to Tarentum became studded with flourishing Greek cities, so that this part of the peninsula was known as Magna Græcia. The native tribes, called Œnotrians, as well as their kindred, the Sikels of Sicily, seem to have all belonged to the great family of nations known as Pelasgian, of which the Greeks themselves were a branch, so that they readily amalgamated with the colonists, and became partially Hellenised.

The earliest as well as the most prosperous of these cities were Sybaris and Croton, both Achæan settlements (720 and 710 B.C.), and situated on the Gulf of Tarentum. The walls of Sybaris were fifty stadia, or nearly six miles in circumference; those of Croton were little less than twelve; and both enjoyed an extensive dominion from sea to sea across the peninsula, dividing between them the whole length of the Tarentine coast.

It was during the sixth century B.C. that these cities reached the maximum of their power. They even surpassed the prosperous cities of Sicily; while their luxury, organisation, industry, and political power formed a striking contrast with Hellas Proper, which had poverty for a foster-sister. A Sybarite has become a proverb for luxury and effeminacy. The habits of the Crotonians were more active, and they furnished numerous victors at the Olympic games. The celebrated philosopher Pythagoras made Croton his residence (540 B.C.), where he introduced a system of mystic and ascetic observances, and induced multitudes to abandon their luxurious mode of living, and practise purity and self-denial. A contest having arisen between Croton and Sybaris, it ended in the total defeat of the Sybarites, and the demolition of their city, 510 B.C. From this time, the Greek cities began to decline.

These have been noted as among the first and most important of the early colonies of Greece; but similar establishments studded all the shores of the Mediterranean, which thus became a kind

of Grecian lake; and Trapezus, on the furthest shores of the Black Sea, Cyrene, in Africa, and Massilia (founded 597 B.C. now Marseilles), in Gaul, were as essentially Greek states as Sparta or Athens.

Argos—Sparta.

In Greece Proper, the states that made the most important figure in the earliest ages were the Dorian states of Peloponnesus; and the first glimpses of history shew us Argos as the leading power. Pheidon, king of Argos (747 B.C.), aiming at the universal sovereignty of Peloponnesus, was opposed and defeated by the Spartans, who henceforth became the dominant power.

The ascendency of Sparta was mainly owing to her peculiar institutions, which tradition ascribed to the legislator Lycurgus, who probably existed somewhere about 900 or 800 B.C. and more clearly defined and fixed already existing usages and regulations; for the peculiar constitution of the Spartans arose necessarily out of the circumstances in which they lived. They were originally a handful of conquerors among a subject race. In other parts of the Peloponnesus the Dorian conquerors coalesced in time with the natives; but in Laconia the separation was maintained. Such of the Achæans as readily submitted were allowed to retain their personal freedom, but they had no political rights, were governed by Spartan magistrates, and paid a rent to the state for their land. The greater part, however, of the conquered population were reduced to a state of slavery, and belonged as property, along with the patches of land to which they were attached, to individual citizens. By these Helots, as they were called, all labour was performed, the free Spartan disdaining every kind of industrial occupation.

The citizens of Sparta were thus a small class of lords among a tenfold number of slaves and subjects; and consequently their whole organisation and training was military. Military discipline and military objects regulated every detail even of domestic life. Marriage itself was not a matter of affection, but of producing a vigorous and warlike offspring. Hence weakly children were exposed to perish. The whole time of the Spartans was spent in public. They took their frugal meals at public tables in messes or companies, to which each contributed so much from the produce of his land. The rest of the time was spent in gymnastic exercises and military drill; for the education of a Spartan, beginning with his seventh year, was not relaxed till his sixtieth. He was inured to hunger and thirst, to the extremes of heat and cold; was obliged to tread every kind of ground barefooted, and to wear the same garment summer and winter. The virtues of an accomplished Spartan included likewise the exhibition of a silent and motionless deportment in public when action was not called for; the suppression at all times of external manifestations of feeling, and even the power of enduring bodily torture without complaint. To habituate them to endure suffering, they were at certain seasons scourged at the altar of Diana, and sometimes expired under the suffering without having betrayed it by word or gesture. To teach them strategy and secrecy, there were licensed expeditions for thieving, and severe punishment for those who allowed themselves to be detected in it.

The Spartan females were placed under a scarcely less hardy system of discipline. The beauty and vigour of the Spartan women were famous throughout all Greece, and the influence of their patriotism in sustaining that of the men is matter of historic celebrity. 'Return either with your shield, or on it!' was the exhortation of a mother to her son on his departure for the field of battle.

Spartan education produced warriors, but nothing else. From the wanton oppression with which they systematically treated the Helots, they lived in constant dread of the revolt of that wretched class; and in their devices to keep them down, they hesitated at nothing, however flagrant or cowardly. There was a regular system of espionage or police, called *crypteia*, consisting of select bands of Spartan youths, who ranged the country, and secretly assassinated such as were considered formidable. On one occasion, on which the Helots had stood their masters good stead in battle, they were invited to choose out all the bravest of their numbers for the purpose of receiving their freedom; but the 2000 selected for this high reward were never again seen or heard of.

It was the constant sense of this internal source of danger that enabled the Spartans to submit to a rigour of discipline such as no people before or since has endured. Sparta was the only government in Greece which could trace an unbroken and peaceable descent from a high antiquity, and from its reputed founder; and this was one of the main causes of that astonishing ascendency which the Spartans acquired over the Hellenic mind, and which they appear not to have deserved through any superior ability in the management of political affairs.

The constitution of Sparta was mixed. There were two joint-kings, belonging to parallel lines, who were very much restricted in power by the senate and by the popular assembly. The delegates of this popular body, called *Ephors*, gradually came to usurp the greater part of the executive power. Strictly speaking, there was no popular element in the constitution; for with regard to the great body of the inhabitants, the qualified citizens were a small and exclusive aristocracy.

Originally, the territory of Sparta was confined to the basin of the Eurotas, in the south-east of the peninsula; but after a protracted struggle, extending, with an interval of forty years, from 743 to 668 B.C. and known as the First and Second Messenian Wars, the Spartans succeeded in reducing their brother Dorians of Messenia to subjection and slavery, and thus extended their dominion to the Ionian Sea.

Athens.

It was the Ionic race that manifested most signally the distinguishing characters of Greek civilisation; and of this portion of Hellas, Athens stands out most prominently. According to the legend, Codrus, the last of its line of heroic kings, had devoted himself to certain death to save his country; and the Athenians permitting no one after him to assume the name of king, his successors ruled for a time as archons for life. The dignity of archon was then restricted to the duration of ten years;

and finally it was made annual, and also distributed among nine persons, one being called the *Archon Eponymus*, because the year was distinguished by his name. It is with the first annual archon, Creon, 683 B.C. that the authentic history of Athens begins. These archons, together with the council of nobles afterwards called the court of Areopagus, exercised the whole power of the state, and administered justice, such as it was. The Athenian government was thus an oligarchy; but the changes introduced by the archon Solon, 594 B.C. laid the foundation of that democratic constitution which was afterwards perfected by Cleisthenes. The condition of the population at the time of Solon was one of extreme suffering and discord, arising chiefly from the oppressive execution of the law of debtor and creditor. This law was of old extremely harsh in Greece; it assigned the debtor that could not fulfil his contract as the slave of his creditor. The great part of the soil of Attica was in the hands of the rich, and the mass of the population, who tilled the lands as tenants, were either in hopeless arrears, or already, with their families, actual slaves. Driven to desperation, the populace were ready to rise in mutiny; and thus it was agreed to confer dictatorial power on Solon, well known for his wisdom, integrity, and sympathy with the people, and allow him to solve the problem. The disease being desperate, Solon applied the desperate remedy of abolishing existing contracts, liberating those that had been reduced to slavery, and forbidding for the future any one from pledging his own person or that of a member of his family. He next divided the freemen into four classes, according to the amount of their property. It was only the richer classes that paid taxes and were eligible to the offices of state; but all had votes in the assembly that elected the archons, and all sat in judgment on their past conduct on the expiry of their year of office. The government, though still oligarchical, was thus modified by popular control. Its free operation was for some time (560–510 B.C.) interrupted by the usurpation of Peisistratus and his sons, whose *tyranny*, however, was mild and enlightened.

On the banishment of the Peisistratidæ (510 B.C.), a further political reform was introduced by Cleisthenes, who extended the basis of the constitution, and rendered it essentially democratic. To Cleisthenes is ascribed the origin of the practice called *ostracism*, by which any person might be banished for ten years, without being accused of any crime, if the Athenians apprehended that he had acquired too much influence, or harboured designs against the public liberty. Ostracism was so called, because the citizens, in voting for its infliction, wrote the name of the obnoxious individual upon a shell (*ostreon*).

Literature.—This age was distinguished for the cultivation of lyric poetry. The most distinguished poets of this class were Archilochus of Paros (700 B.C.), Alcæus and Sappho of Lesbos, Anacreon, and Pindar.

At the commencement of the sixth century before Christ, there sprang up in different parts of Greece a number of men who obtained the appellation of the Seven Sages, on account of their practical sagacity. These were: Solon, Thales, Pittacus, Periander, Cleobulus, Chilon, and Bias. Out of the wisdom of the Seven Sages, as from a germ, sprang the philosophy for which Greece was afterwards so celebrated. The first beginnings of geometry and astronomy have been traced to Thales of Milesia (650 B.C.), the founder of the school called the Ionic.

SECOND PERIOD: 500–478 B.C.

War with Persia.

On the overthrow of the Lydian monarchy (546 B.C.; see ANCIENT HISTORY), the Greek cities of Asia Minor fell under the dominion of Persia. The Athenians had aided their Asiatic kindred, though but feebly, and now the Persian monarch resolved to chastise Athens, and to subjugate the whole of Greece. He accordingly sent heralds through the Greek cities to demand 'earth and water,' as tokens of submission. Many of them sent in their submission; but Athens and Sparta treated the demand as an insult, and put the heralds to death. In the meantime, an immense Persian fleet and army, accompanied by the exiled despot of Athens, Hippias, as guide, crossed the Ægæan, laying waste the islands as they passed; and at last the army landed in the Bay of Marathon, on the east coast of Attica. Tidings of the imminent danger of Athens were immediately despatched to Sparta; but superstitious custom forbade the Spartans to march till after the full moon, five days later. The Athenians resolved to hazard battle alone, and marched against the enemy to the plain of Marathon. Their army numbered about 10,000, and they were joined on the battlefield by 1000 men from the little state of Platæa. This small force, skilfully disposed by the Athenian general Miltiades, attacked with such impetuosity the tenfold more numerous Persians, that the latter were completely routed, and driven on board their ships, with which they sailed back to Asia Minor (490 B.C.). The Spartan army arrived in time to learn that all was over. The battle of Marathon is justly reckoned one of those that influence the fate of the world; had the issue been the reverse, the whole course of subsequent history might have been different.

The after-career of Miltiades is melancholy. Intoxicated by the admiration his conduct had excited, he abused the unlimited confidence of his countrymen, and employed a force that they had placed at his discretion in avenging a private quarrel. For this he was impeached as worthy of death; and his friends, finding it impossible to excuse or even palliate his recent conduct, appealed to his previous services. The jurors were moved to commute the punishment to a heavy fine, which, however, he did not live to pay, having died shortly after of an injury received before his trial.

The danger from Persia was not yet over. Darius had for several years been levying forces for renewing the contest, when he was succeeded (485 B.C.) by his son Xerxes, who continued the preparations on a yet vaster scale. From every part of his wide dominions he collected an armament such as had never been seen before. For its transport into Europe, he caused a bridge of boats to be built across the Hellespont, where it is a mile wide. The first bridge having been destroyed by a storm as soon as completed, the wrath of the monarch was beyond all bounds. The heads of the engineers were struck off; the audacity of the sea was chastised by 300 lashes,

and by heavy fetters thrown into it; and the work was recommenced. At the same time, to avoid the perilous promontory of Mount Athos, a ship-canal, a mile and a half long, was cut across the isthmus, of which traces are visible to this day. The armament of Xerxes marched from Sardis early in 480 B.C. and took seven days and nights to cross the bridge in two columns. Herodotus makes the fighting-men and ships' crews exceed 2,500,000, the camp-attendants being at least equal in number.

Xerxes met with little opposition till he came to the famous Pass of Thermopylæ, where the range of Mount Œta approaches close to the Eubœan Gulf. Here it had been decided to make a stand, and here the Spartan king, Leonidas, with a small army of 300 chosen Spartans, with their attendant Helots, and about 5000 soldiers from other states, was stationed to guard the 'Gates' (*pylæ*).

For two days the Persians kept up renewed assaults on the pass, but making no impression. At last a treacherous Greek conducted a Persian detachment by a circuitous path over the mountains, which could thus attack Leonidas in the rear, and now Thermopylæ was no longer defensible. Retreat for a Spartan was out of the question; but, with the exception of 700 Thespians, the other Greeks retired. Leonidas and his devoted band now advanced, driving the Persians before them, until Leonidas having fallen, and their spears being broken, they were overwhelmed with missiles, and slain to a man; 20,000 Persians are said to have fallen. During the struggle at Thermopylæ, the united Greek fleet had been keeping up a desultory warfare with the Persian fleet in the Eubœan channel; but on the pass being carried, retired to the island of Salamis, opposite to Athens.

Nothing now stood between that devoted city and the destructive storm of Persian vengeance. The leading man of Athens at that time was Themistocles, whose aim had been to foster the maritime spirit of the Athenians, and who had induced them greatly to increase their war-vessels. An oracle had declared the safety of Athens to be in her 'wooden wall,' and Themistocles now interpreted that to mean her fleet. The Athenians therefore hurriedly removed their families to Salamis, Ægina, and the Peloponnesus, and betook themselves to their ships. The hosts of Xerxes soon poured down over Attica, laid waste the deserted country, and plundered and burned the temples and whole city of Athens. At the same time, the Persian fleet arrived, and Xerxes resolved to attack the Greek ships which were posted in the Strait of Salamis; but from a lofty throne erected on a rocky height overlooking the scene, he beheld his fleet driven into confusion and flight.

The presumptuous confidence of the monarch now gave place to alarm for his personal safety, and leaving Mardonius with 300,000 select troops to complete the subjugation of Greece, he hurried home by the way he came, multitudes perishing of famine and disease on the march. The following spring, Mardonius sought to detach the Athenians by offering them tempting terms of alliance against the Peloponnesians; but the Athenians shewed a courage and devotion to the common cause of Hellas, which, under the same depressing circumstances, perhaps no other Greek state was capable of, and which the Peloponnesians repaid by selfish and ungenerous neglect. He then once more laid waste Attica, and retired into Bœotia. Here, near the town of Platæa, he was encountered by the united Greeks, 110,000 strong, under Pausanias, and defeated with prodigious slaughter, so that only a fraction of the army left by Xerxes reached Asia. On the same day the remains of the Persian fleet were captured and destroyed by the Greek fleet on the coast of Asia Minor. Thus was Greece finally saved from coming under the dominion of Persia (479 B.C.).

It is sad to think that Themistocles and Pausanias ended their career as traitors to Hellas. Pausanias, with insane ambition, entered into secret negotiations with Xerxes to bring Greece under the Persian dominion, as a satrapy for himself: being discovered, he was put to death by his countrymen. Themistocles, the ablest man in Greece, was involved in the same intrigues, but escaped to the Persian monarch, who received him with great favour, and gave him a government in Asia Minor, where he died.

THIRD PERIOD: 478–404 B.C.

Athens the Leading State of Maritime Greece.

To preserve the freedom of the now liberated Greek cities on the islands and coasts of the Ægæan, a confederation was formed, of which Athens, from her powerful fleet, naturally became the head. Each state was bound to furnish a fixed quota to the united fleet, and Athens, as head, enforced the regulation. A rivalry thus sprung up between Sparta and Athens; the land states still clung to Sparta as their head, while the maritime states drew towards Athens. This leadership on the part of Athens, became in the end a sort of dominion. Individual members of the confederacy, becoming weary of personal service, prevailed on the Athenians to provide ships and men for an equivalent in money; which the Athenians, having a decided genius for naval warfare, were willing enough to do. Thus, the allies, instead of equals, became gradually tribute-paying subjects of Athens; and when any member grew tired of paying the contribution, and had to be compelled, Athens came to be looked upon as a despot, and to be feared and hated accordingly. Jealousy of the rising power of Athens led Sparta to combine with the oligarchical party in Corinth and Bœotia for her humiliation; but after a struggle, the Athenians succeeded in establishing their influence on land also, from the borders of the Corinthian territory to the Pass of Thermopylæ, forcing their opponents into exile, and putting the governments on a democratic footing. Athens was now (about 456 B.C.) at the summit of its power.

Pericles.

For above forty years, beginning about 470 B.C. the destinies of Athens were guided by Pericles, the most remarkable man that Greece ever produced. His character combined the integrity of Aristides the Just with the comprehensive views of Themistocles; to which were superadded a command of temper never disturbed, sound discretion, literary and philosophical education, and an eloquence such as no one had heard or

imagined before. When he spoke, he 'thundered and lightened,' as it was expressed. He cordially embraced the democratic party, yet no one more scorned the arts of the demagogue; and it is generally agreed that he was guided in all his measures by sincere patriotism, singularly unsullied by personal motives. Under his sway, the power of the *demos* or people was made more direct and effective, and most offices became open alike to rich and poor. The judicial power was transferred from individual magistrates to *dicasteries*, or panels of jurors. Six thousand citizens were annually chosen by lot to act as *dicasts* or jurors; and were distributed into ten panels of 500 each, with a reserve of a thousand to supply vacancies; and before some one of these dicasteries, every case was brought by the magistrate for decision. The court of Areopagus, the stronghold of the oligarchical party, was left little jurisdiction, except in cases of murder.

The city of Athens, under the administration of Pericles, rose to extraordinary splendour. In the year 480 B.C. it had been utterly ruined by Xerxes; but ere the lapse of forty-eight years, her walls, docks, arsenals, temples, statues, paintings, had stamped her as the imperial city of Greece, her outward magnificence conferring on her a moral ascendency beyond her direct power. The harbour of Piræus, containing the arsenal and docks, was connected with the city by two parallel lines of wall, four and a half miles long, so that city and harbour formed one continuous fortification. Among the many decorative works, the greatest was the temple of Athena (Minerva), called the Parthenon, adorned with a colossal statue of the goddess, forty-seven feet high, of ivory and gold, and other master-pieces of sculpture. Phidias was the director of the ornamental part of these works, having under him a school of pupils, and subordinates. The religious processions and festivals, and the theatrical exhibitions connected with them, were now conducted at Athens in a style of magnificence unattained elsewhere; and the poorer citizens were furnished from the public treasury with the means of attending these public shows and amusements. Pericles has been blamed for introducing this custom, as well as for that of paying the dicasts for their attendance at trials. The Athenians became accustomed, it is said, to spend their time in idleness and amusement, and that at the expense of their allies, from whose contributions chiefly the cost of all these embellishments of Athens was defrayed.

The Peloponnesian War.

In 445 B.C. a truce, to last for thirty years, had been concluded between Sparta and her adherents on the one side and Athens on the other; but before fourteen years had elapsed, the mutual animosities had risen to such a height that hostilities could no longer be postponed. The immediate occasion of the outbreak was a quarrel between Corinth and her colony of Corcyra (Corfu). The Corcyræans appealed to the Athenians, who entered into alliance with them, and interfering in a naval engagement between the two, caused the Corinthians to retreat. The Peloponnesians considered this as an infringement of the thirty years' truce, and both parties prepared for the war.

This contest, known as the Peloponnesian War began 431 B.C. was protracted over twenty-seven years, and ended in the complete destruction of Athenian ascendency. The Athenians were all-powerful at sea, but were unable to meet the large armies of the Peloponnesian confederates by land. When, therefore, the Spartan king, Archidamus, invaded Attica, they followed the advice of Pericles, and gathered the country residents with their movable property within the walls, conveying their sheep and cattle to the adjacent islands. This devastation of Attica was annually renewed for a succession of years, the Athenians meanwhile sailing round and ravaging the coasts of Peloponnesus.

The Plague.—In the second year of this destructive and fruitless war, Athens was visited by a terrible pestilence. It is described as having been a species of infectious fever, accompanied with many painful symptoms, and followed, in those who survived the first stages of the disease, by ulcerations of the bowels and limbs. The mortality was dreadful, and was of course greatly increased by the overcrowded state of the city. The prayers of the devout and the skill of the physicians were found equally unavailing to stop the progress of the disease; and the Athenians, reduced to despair, believed themselves to be forgotten or hated by their gods. The sick were left unattended, and the bodies of the dead allowed to lie unburied, while those whom the plague had not yet reached, openly set at defiance all laws, human and divine, and rushed into every excess of criminal indulgence.

In the impatience produced by this complication of suffering, the political enemies of Pericles began to turn the irritation of the public mind against him as the cause of the war. They even brought against him a charge of pecuniary malversation, and the veteran statesman was fined and deposed from his office as general. A reaction, however, soon took place, and Pericles was speedily restored to office and public confidence. But he was now almost heart-broken by domestic calamity, the epidemic having carried off both his legitimate sons and other members of his family, as well as his best political friends; and in 429 B.C. he died of a wasting fever. It is related that, when he was lying at the point of death, and while those who surrounded him were recounting his great actions, he suddenly interrupted them by expressing his surprise that they should bestow so much praise on achievements in which he had been rivalled by many others, while they omitted to mention what he considered his highest and peculiar honour—namely, *that no act of his had ever caused any Athenian to put on mourning.*

Athens had to struggle not only with her powerful enemies, but with repeated revolts of her subjects. In the seventh year of the war, she gained a signal advantage, by the capture of a large body of Spartan citizens of high family, on the island of Sphacteria, in what is now the Bay of Navarino. The desire to obtain the release of these prisoners, induced the Lacedæmonians, four years later, when their victorious general, Brasidas, had inflicted severe humiliations on the Athenians, to come to terms of peace, each party agreeing to surrender what it had acquired in the war. This treaty was known as the Peace of Nicias, from the name of the leader of the peace-party at Athens.

The peace was but of short duration. The

Spartans having got back their citizens, shewed a wish to evade the conditions on their part, and the distrust thus inspired was fanned into a fresh rupture by the machinations of Alcibiades, who about this time began to take a lead in Athens. The result was that the Athenians entered into a new alliance (420 B.C.) with some of the Peloponnesian states, who were dissatisfied with the selfish conduct of Sparta.

Alcibiades, now at the head of the war-party in Athens, was a young man of high birth and great riches, gifted with eminent ability and versatility, and remarkable for the beauty of his person. He was at the same time filled with inordinate vanity, confidence in his own powers, and love of distinction; while he was utterly regardless of the means he took to attain his end. His brilliant qualities and liberality led the Athenian people to overlook his licentious manners and want of moral principle, and allow him a sway in their councils, which he wielded to their ruin.

While the struggle was going on in Greece with little success on either side, an appeal for aid was made (416 B.C.) to Athens from some cities in Sicily against the dominant Doric city of Syracuse; and the ambition of the Athenians, and especially of Alcibiades, firing at the idea of the conquest of Sicily, led them to resolve on the Sicilian expedition. It was in vain that Nicias opposed the measure; against his judgment and will, he was appointed, along with Alcibiades and Lamachus, to the command of the most splendid armament that had ever left a port of Greece. Shortly after the fleet arrived on the coast of Sicily, Alcibiades was recalled to stand his trial, having been accused of being concerned in mutilating the statues of Hermes in Athens—a mysterious piece of sacrilege which had occurred during the preparation of the expedition, and had left the city in a state of consternation. Instead of returning home, Alcibiades went to Sparta, and became for a time the most active enemy of his country. The expedition thus left to the control of the timid Nicias, effected nothing. Syracuse was long besieged in vain; and although repeated reinforcements were sent from Athens, the Syracusans got the upper hand, shut up their besiegers in the great harbour, and (413 B.C.) destroyed or took captive the whole armament.

Athens never recovered this terrible disaster, and her power was clearly broken. At last the struggle was brought to a close (405 B.C.) at Ægos-Potamos in the Hellespont, where the Spartan admiral, Lysander, surprised and captured the whole Athenian fleet. After stripping Athens of all her dependencies, putting them under oligarchies in the interest of Sparta, Lysander blockaded and soon reduced the city itself, on which he imposed the most humiliating conditions, causing its fortifications to be demolished, and establishing an oligarchy, known as the Thirty Tyrants.

Literature and Philosophy.—The literary history of the fifth century B.C. is characterised chiefly by the development of the drama; the greatest tragedians were Æschylus, Sophocles, and Euripides, while Aristophanes excelled in comedy. The instruction of Greek youth was conducted by a set of men who called themselves Sophists, or Wise Men, and who taught them rhetoric and other accomplishments then deemed to constitute a liberal education. In the midst of these Sophists arose Socrates, who turned his attention chiefly to the study of men and morals. His method of teaching consisted in familiar conversation and a species of catechising, by which he confounded the pretended wisdom of the Sophists. Out of the intellectual school formed by Socrates arose all the leaders of speculative thinking in Greece for the next half-century; they took the name of Philosophers, or Lovers of Wisdom, as more modest than that of Sophists. Socrates, by his plainness of speech, made many enemies, who, in his old age, accused him of introducing religious novelties, and corrupting the youth of the city. He took no pains to defend himself, and was sentenced to drink the cup of hemlock, which was the usual mode of executing distinguished criminals. This happened in 400 B.C. after the overthrow of the Thirty Tyrants, and the restoration of the democracy.

FOURTH PERIOD: 404–371 B.C.

Sparta was now dominant in Hellas, and her empire was exercised by Lysander with such selfish harshness, as soon to excite a deeper feeling of jealousy and hatred than ever had been felt towards Athens. The Thirty Tyrants in the latter city made their rule so intolerable, that a revolution in less than a year restored the old constitution, with the consent of the Spartans. The leading event of this period is the rise of Thebes into the ascendency. The refusal of the Thebans to obey the dictation of Sparta brought a Lacedæmonian army into Bœotia to compel submission. But the Theban training had by this time been brought to such perfection, that it was more than a match for that of Sparta; and with less than half the numbers, the Theban general, Epaminondas, inflicted a signal defeat on the Spartan army, on the memorable field of Leuctra (371 B.C.).

FIFTH PERIOD: 371–338 B.C.

This battle was fatal to the empire of Sparta. The victorious Thebans proceeded to re-establish Messenia as an independent state, recalling, after a lapse of three centuries, the scattered families of the original Messenians, residing in various parts of Hellas, and raising the Spartan serfs that tilled the lands into free citizens. Arcadia also was organised into a Pan-Arcadian state, with a new city, Megalopolis, for its capital. The chief efforts of the Thebans were then directed to the confirmation of this new state of things in Peloponnesus, and the maintenance of their influence against Alexander, 'tyrant' of Thessaly, now become a formidable power. In a battle fought with the Lacedæmonians, near Mantinea in Arcadia, the Theban general, Epaminondas, fell in the moment of victory (362 B.C.). He left a name second to none in Greece as a soldier, a statesman, and a disinterested patriot. With the sixteen years of his political life, the ascendency of Thebes both began and ended; for no one rose to take his place. During the period of Sparta's highest ascendency, as well as during her fall, her destinies were guided by her king Agesilaus (398–361 B.C.), who, as it has been expressed, 'was himself Sparta's most perfect citizen and most consummate general; in many ways, perhaps her greatest man.'

Philip of Macedon.

Greece was ill prepared for the storm of danger to her liberties that was gathering in the north. Philip, who became king of Macedon about 360, having established his power at home, next extended his influence over Thessaly. Greece was at this time distracted by the Sacred War, occasioned by the Phocians having seized on the temple of Delphi, and then laid hands on its sacred treasures. The miserable rivalries of the other Greek states prevented united action, and Philip interfered as the vindicator of the Delphian god. It was in vain that Demosthenes sought to arouse the Athenians to the necessity of vigorous measures: by means of their still powerful fleet they might have barred the Pass of Thermopylæ to the Macedonians; but the cunning diplomacy of Philip, and the bribes by which he corrupted their envoys, paralysed all action, and the way was left open (346 B.C.). From that moment, Philip was master of the situation. Some years later (338 B.C.), Demosthenes roused the Athenians, in conjunction with the Thebans, to make one more struggle for liberty; but Philip had rendered the Macedonian phalanx stronger than even the Theban, and on the fatal field of Chæronea, the freedom of Hellas was lost for ever.

SIXTH PERIOD: 338–300 B.C.

Alexander the Great.

Philip now announced his intention of leading the united Greeks against Persia, avenging the invasion of Xerxes, and liberating the Greeks of Asia. But in the midst of his preparations, he fell by the hand of an assassin (336 B.C.), and was succeeded by his son Alexander, now twenty years of age, and who had already held a high command in the battle of Chæronea. After suppressing with terrible severity some attempts at insurrection in Macedonia and Greece, Alexander began the long-meditated invasion of Asia by leading (334 B.C.) an army of 30,000 foot and 5000 horse across the Hellespont. Having overthrown the Persian satraps of Asia Minor in the battle of the Granicus, and liberated the Greek cities on the coast, he marched eastward, and encountering Darius at Issus, at the head of an army of 600,000, gained a complete victory (333 B.C.). Proceeding along the coast of Syria, he was received as a deliverer, except by the cities of Tyre and Gaza, the former of which resisted him for seven months, and was terribly punished. He was next welcomed as a liberator by Egypt, which he visited (331 B.C.), and where he laid the foundation of the city of Alexandria.

Darius had now collected a still more numerous army, and Alexander, marching across Syria and Mesopotamia, again defeated him near Arbela, a little east from the Tigris, and southward from the site of Nineveh (331 B.C.). Taking first possession of Babylon, he proceeded to Susa and Persepolis in Persia Proper, enriching his army with the enormous treasures accumulated in those cities. Continuing his progress eastward in pursuit of Darius, he overtook him, deserted and expiring, his attendants having stabbed him (330 B.C.). Three years were next spent in subduing the provinces of Ariana, Bactria, and Sogdiana (lying north-west from the Indus). Constant success had by this time deteriorated the character of Alexander; he had come to relish the most fulsome eastern adulation, and, like an eastern despot, he transfixed, in a moment of passion, the friend that had saved his life. He had not yet reached the bounds of his ambition; with an army raised to 120,000 foot and 15,000 horse, he now advanced to the conquest of India (327 B.C.). In the Punjab, he was met by a powerful Indian prince, Porus, whom he defeated and took prisoner; but his army refusing to cross the Hyphasis (Sutlej), he proceeded down the Indus, and then returned across the desert to Persepolis and Susa (325 B.C.).

Revolving vast schemes, not only of conquest in Italy, Carthage, and the west, but of improvements commercial and agricultural, he entered Babylon, intending to make it the centre of his empire; but in a short time he was seized with fever, and died at the age of thirty-two, after a reign of less than thirteen years.

On the death of Alexander, his vast empire fell asunder; the generals, assuming the different provinces as governments, carried on a bloody struggle for ascendency and independent power. This uninteresting and confusing contest ended in confirming Ptolemy in the possession of Egypt; Seleucus in Syria, and eastward to the Indus; Lysimachus in Asia Minor; and Cassander in Macedon and Greece; who then assumed the title of kings (301 B.C.).

Several attempts were made in Greece, before and after the death of Alexander, to shake off the Macedonian yoke, which ended in only riveting it more closely. The last ray of lustre was shed by the confederation known as the Achæan League, which, under the guidance of Aratus (245–213 B.C.), rose to considerable strength; but the jealous selfishness of Sparta once more led to discord and strife, and the Macedonian king, being called in as umpire, was once more master.

But the Macedonian power was itself about to be swallowed up by a yet greater power. The Romans, having broken the strength of Carthage, now turned their ambition eastward, and after a protracted war (200–168 B.C.), Perseus, the last king of Macedonia, adorned as a captive the triumph of a Roman general. After this event, the Greek republics were for a short time left independent; but quarrelling once more among themselves, they were finally reduced to a Roman province, under the name of Achaia (146 B.C.). The outlying cities of Hellas, in Sicily and elsewhere, whose separate career our space forbids us to trace, sooner or later all shared the same fate.

Though from this time politically one of the least important of all the provinces of the Roman Empire, Greece retained its pre-eminence in learning and literature. No Roman youth of rank and wealth was held to have perfected his education without a visit to Athens, and a course of study under its professors. The language of Greece served, in later ages and other climes, to communicate to mankind the civilising influences of poetry, philosophy, and the Christian religion.

Among the writers, thinkers, and artists produced by Greece during the later periods now sketched, may be mentioned the historians, Thucydides and Xenophon; the philosophers, Plato, Aristotle, Zeno, and Epicurus; the orators, Demosthenes and Æschines; the painters, Zeuxis and Apelles; and the sculptors, Praxiteles and Lysippus.

Colosseum.

HISTORY OF ROME.

THE history of ancient Rome is for the most part the history of ancient Italy. Whatever we know of the various races that peopled the peninsula is—if we except the Greeks—first revealed to us in connection with the conquering progress of that marvellous city, that began its career as a border fortress, and ended by becoming the mistress of the world. Before touching on the rise and development of the Roman power, we may briefly glance at the *geography* and *ethnology* of the country. The south of Europe, like the south of Asia, is marked by three great peninsulas, which stretch into the Mediterranean Sea. Of these, Italy forms the central one. It is divided physically into two regions—the peninsula proper, the outline of which bears a strong resemblance to a man's leg; and north of that a broad plain, drained by the river Po and its tributaries. Alpine ranges form a natural boundary on the north and north-west, while right through the long peninsular section, to the very tip of the toe, run the Apennines, filling up the centre of the country with rugged mountain land, and leaving on either side a stretch of flat coast, sometimes broad, and sometimes narrow. The Romans called that part of the Mediterranean which washed the western shores of Italy, *Mare Inferum* (the Lower Sea), and that which washed the eastern, *Mare Superum* (the Upper Sea). The extreme length of Italy, from the Alps to Sicily, is about 700 miles; the breadth of the northern plain about 350; and of the peninsula about 100 miles.

Ethnology.—In the earliest times we find in Italy *five* distinct races, three of which (IAPYGIANS, ETRUSCANS, and ITALIANS) may, in a restricted sense, be termed 'native,' inasmuch as we do not meet with them elsewhere; and two, GREEKS and GAULS, 'foreign;' inasmuch as their chief settlements were not in Italy, but in Greece and Gallia. But, ethnologically, this distinction is arbitrary. There is no reason for believing that the first three races were indigenous, and the last two immigrant; the analysis of their languages, or of such fragments of their languages as survive, leads strongly to the conclusion that all were alike immigrant, and that in this respect the only difference between them is one of *time.*—1. *The Iapygians:* This race, monuments of which in a peculiar language (as yet undeciphered), have been found in the south-east corner of Italy—the Messapian or Calabrian peninsula—is in all probability the oldest.—2. *Etruscans:* The origin of this mysterious people is certainly one of the most interesting, if also one of the most insoluble problems in history, but Niebuhr's opinion is pretty generally accepted, that they were a mixture of an eastern and a semi-Hellenic race, who for a time settled in the Tyrol, and thence descended, first on the plains of the Po, and afterwards spread southward over

the Apennines as far as the mouth of the Tiber.—3. *Italians:* At what period the earliest immigrations into Italy of the so-called 'Italian' races—the Latins and Umbro-Sabellians, took place, it is wholly impossible to tell; but it was undoubtedly long before the Etruscans had settled in Etruria. They were by far the most important of the various races that inhabited the peninsula; in fact, the entire historical significance of Italy depends upon them; and therefore it is fortunate that their ethnological origin and affinities are capable of the most certain demonstration. An investigation of their language, subdivided, indeed, into numerous dialects, often widely differing, but fundamentally the same, has resulted in the discovery, that they belong to the great Aryan or Indo-Germanic family, and are in particular closely allied to the Hellenes. There is ground for believing that the Latins were the first members of the Italian family to enter Italy, and that, having crossed the Apennines, they spread themselves to the south along the western coast, driving the Iapygians before them, and finally cooping them up in the Calabrian peninsula—the heel of the boot. But this conquest belongs to prehistoric ages, and the original Latins of Campania, Lucania, Bruttium, perhaps even Sicily (*i.e.* the races spoken of in classic legend, as the Itali, from whom the peninsula received its name, the Margetes, Ausones, Siculi, &c.), were themselves in the course of time so thoroughly Hellenised by the influence of the rich and powerful Greek colonies planted on their coasts, or so overwhelmed by the successive invasions of Samnite hordes, that nearly every trace of a primitive Latin nationality has disappeared. It was only in Latium Proper, where no Greek colonies were founded, and where the fortune of war was in its favour, that the Latin branch of the Italian race firmly rooted itself. The other branch of the 'Italian' stock—the Umbro-Sabellian—must have entered Italy at a later period than the Latin. Its advance along the central mountain-ridge—the Apennines—from north to south can still be traced; and its last phases—*i. e.* the conquest of Campania and the other southern districts of the peninsula by the Samnite highlanders—belong to purely historical times. The oldest members of this branch are probably the Sabines, who seem to have fixed themselves in the mountainous region to the north-east of Rome, and are regarded as the progenitors of that multitude of tribes which we find occupying the central portion of Italy—the Picentes, Peligni, Marsi, Æqui, Vestini, Marrucini, Frentani, Samnites—perhaps also the Volsci and Hernici.—4. *Gauls:* To a period considerably later and comparatively historical, belong the settlement of the Gauls in the north, and of the Greeks in the south of Italy. The former, a branch of the Celtic race, itself now ascertained to be also a member of the great Aryan family, and therefore allied, however distantly, to the other Italian races, had for ages before history begins fixed themselves in the region now known as France. The first Gallic tribe that made its appearance on the soil of the peninsula is said to have been the Insubres, whose capital was Mediolanum (Milan); then followed the Cenomani, whose headquarters were Brixia (Brescia) and Verona, and afterwards numerous kindred hordes, among the latest and most powerful of whom were the Boii and Senones, who forced their way across the Po, and effected a lodgment in the modern Romagna, occupying (besides an inland district) the coast of the Adriatic as far south as Ancona. Hence, in ancient times, the whole of Northern Italy was for a long period known as Gallia Cisalpina (Gaul on *this*, *i.e.* the Italian side of the Alps), to distinguish it from Gaul Proper, which was called Gallia Transalpina. Gallia Cisalpina was again subdivided into two parts by the river Padus (Po); the northern being named Gallia Transpadana, and the southern (the country of the Boii and the Senones), Gallia Cispadana.—5. *Greeks:* The other people which we have distinguished as 'foreign' was the Greek. There is, however, this distinction to be observed, that the Greeks were not (like the Gauls) barbarians; they did not swoop down upon the southern shores of Italy (like the Norse pirates on the coasts of England and France) to plunder and devastate; nor did they force their way into the interior and dispossess the native inhabitants; they merely colonised the coasts, built cities, and carried on commerce. Through them it is probable the Romans acquired their earliest notions of the Greek literature, philosophy, and cultus.

Primitive Social Condition of the Latins.—With this brief introductory sketch of the various races that inhabited Italy in historical or prehistorical times, we may now revert to the Latins, with whom we have at present more particularly to do. What was the extent of their civilisation, or how far their social organisation had proceeded when they finally settled in the 'broad plain' (*Lātium*, connected probably with *lātus*, broad; *lātus*, a side; Gr. *platus;* Eng. *flat*) that stretches westward from the Alban Hills to the sea, may be conjectured, but cannot be positively ascertained. We know, indeed, that long before they had set foot in Italy, before even they had branched off from their Hellenic brethren, they had ceased to be *mere* nomads, or wandering shepherds. The evidence of this fact lies in their language. Not only do the names of the oldest Latin nations, as the *siculi* ('the sickle-bearers' or 'reapers'), and the *osci*, or *opsci* ('field-labourers'), clearly prove the antiquity of Italian husbandry; but the oldest agricultural terms are actually common to both Latins and Greeks. Moreover, the form of the plough was the same among both peoples, as also their mode of cutting and preparing the grain; many of the usages of social life; the oldest methods of measuring the land; and the style of their national dress—the Latin *tunica* corresponding exactly with the Greek *chiton*, while the Latin *toga* is only a fuller *himation*. Their method of building was also the same. In fact, the evidence of language shews that, before the Latino-Italians entered Italy, they had been accustomed to till the ground, to make wine, to keep gardens, to build houses, and to decently clothe themselves. As to their social organisation, less can be said. It appears, however—judging from the general bearing of the most ancient traditions, as also from the features exhibited in historical times—that at a very early period, and from causes of which we are now absolutely ignorant, they had begun to develop the germs of what may be called 'state-life.' As among their Hellenic brethren, the original foundation of their social constitution was 'households' (Gr. *oikiai*, Lat. *vici* or *pagi*, from *pangere*,

to 'fix' or 'drive in;' hence 'to build'): these, either by ties of blood, or by nearness of locality, were aggregated into clans, and their dwellings formed clan-villages (thus *pagus*, which probably meant at first only a single 'household,' came, by a natural transition, to denote a collection of households—a hamlet, or a village). Such clan-villages were, however, not regarded as independent societies, but as parts of a political canton or community—the *civitas* or *populus*. Each canton or *civitas* possessed a local centre or place of assembly, where justice was administered at regular intervals, where markets and sports were held, and religious rites celebrated, and which was besides fortified, to serve as an asylum or place of refuge for the inhabitants of the open hamlets and their cattle in time of war. Such a centre was termed the *capitolium*, *i.e.* 'the height,' from being originally fixed on a height or hill-top, and corresponded to the *akra* of the Greeks. Round this stronghold of the canton, which formed the nucleus or beginning of the earliest Latin towns, houses gradually sprung up, which in their turn were surrounded by the *oppidum* ('work,' from *opus*), or the *urbs* ('ring-wall,' connected with *urvus*, *curvus*, *orbis*); hence, in later times, *oppidum* and *urbs* became, naturally enough, the recognised designations of town and city.

The sites of the oldest of these cantonal-centres or primitive towns in Latium are to be sought for on the slopes of the Alban Hills, where the springs are freshest, the air most wholesome, and the position most secure. Tradition (which makes Alba Longa the oldest seat of a Latin community) is here in accordance with natural probability. On the same slopes lay Lanuvium, Aricia, and Tusculum, to the great antiquity of which ancient tradition bears testimony in many ways; on the offshoots of the Sabine range, in the east of Latium, stood Tibur and Praeneste; in the plain between the Sabine and Alban ranges, Gabii, Labici, and Nomentum; on or near the coast, Laurentum and Lavinium; and on the isolated hills overlooking the Tiber (the boundary between Latium and Etruria), the frontier town of Rome. How many cantons were originally in Latium, it is neither possible nor important to know. Tradition mentions thirty sovereign or politically independent communities (with Alba Longa at their head), which formed the famous Latin league. The historical order of their constitution is a point regarding which we are equally ignorant, but there is reason to believe that the Roman canton, or at least its capital, the town of Rome, was among the latest political organisations of the Latins. The history and fortunes of this canton we now proceed briefly to trace.

HISTORY OF ROME DURING THE EARLIEST OR REGAL PERIOD.

According to the myth of Romulus, Rome was an offshoot from Alba Longa; but the most rational view of the city's origin is that which is suggested by a consideration of its site. It probably sprang into existence as a frontier-defence against the Etruscans, and as an emporium for the river-traffic of the country; but whether it was founded by a common resolve of the Latin confederacy, or by the enterprise of an individual chief, is beyond the reach even of conjecture. The date fixed upon in the Romuleian myth for the commencement of the city, by the formation of the *Pomœrium* (viz. 21st April 753 B.C.), is, of course, perfectly valueless in its precision. We know and can know nothing whatever on the point. The three 'tribes,' Ramnians, Tities, and Luceres, who appear in the same myth as the constituent parts of the primitive commonwealth, suggest the idea that Rome (like Athens) arose out of a *synoikismos* or amalgamation of three separate cantons; but Mommsen rejects as 'irrational' the common opinion that these cantons represent different races, and that the Romans were a 'mongrel people,' made up of Latins, Sabines, and Etruscans, with perhaps a dash of Hellenic and imaginary 'Pelasgic' blood in their veins! The existence of a Sabine element, represented by the Tities, is indeed admitted; but its introduction is thrown back to a period long anterior to the foundation of the city, when the Roman clans were still living in their open villages, and nothing of Rome existed but its 'stronghold' on the Palatine.

The motives which probably led to the building of Rome, also led to its rapid development, so that the great peculiarity of the Roman, as compared with the other Latin cantons, is the prominence which its urban life assumed in the earliest period. No doubt the Roman continued to manage his farm in the cantonal territory, but the insalubrity of the Campagna, as well as the advantages of river-traffic, and the necessity for watchfulness imposed upon all frontier towns in rude ages, must ever have acted as an inducement to him to take up his residence as much as possible in the city. So markedly is this the case, that the beginnings of Roman history—if the ancient legend may be so designated—are mainly records of its urban expansion and political growth. That the Palatine Hill was the oldest portion of the city, is attested by a variety of circumstances. Not only does it hold that rank in the Romuleian myth, but on it were situated the oldest civil and religious institutions. The story of the establishment of an asylum on the Capitoline for homicides and runaway slaves, with all its famous consequences—the *Rape of the Sabine Women*, the wars with the Latins of Cænina, Antemnæ, and Crustumerium, but especially with the Sabines of Cures under their king Titus Tatius, the tragic fate of Tarpeia, and the fine feminine valour of the ravished maidens, who had learned to love their captors—is historically worthless; except, perhaps, so far as it shews us how from the beginning the Roman burghers were engaged in constant feuds with their neighbours for the aggrandisement of their power. The entire history of the 'regal period,' in fact, has come down to us in so mythical and legendary a form, that we cannot feel absolutely certain of the reality of a single incident. That such personages as Numa Pompilius, Tullus Hostilius, Ancus Martius, Lucius Tarquinius Priscus, Servius Tullius, and Lucius Tarquinius Superbus, ever existed, or, if they did, that the circumstances of their lives, their institutions, their conquests, their reforms, were as the ancient narrative describes them, are things which no critical scholar can believe. The destruction of the city records by the Gauls, when they captured

and burned Rome in the fourth century B.C. deprived the subsequent chroniclers of authentic information in regard to the past, and forced them to rely upon treacherous reminiscences, on oral tradition, on ballads, and on all the multifarious fabrications of a patriotic fancy, that would naturally seek compensation for political disaster in the splendour with which it would invest its primeval history. The utmost reach, therefore, to which our knowledge can attain, is to form some general idea—mainly by inference from the institutions that we find existing in later times—of the course that social and political progress followed in the Roman commonwealth.

From the very beginning of the city—and probably long before—the inhabitants were divided into two orders (exclusive of 'slaves')—viz. householders and their dependents, better known perhaps as 'patricians' (from *pater*, a father) and 'clients' (*i.e.* 'listeners,' from *cluere*, 'to listen'). The former alone possessed political, *i.e.* burgess rights. It was they who exclusively constituted the *populus* ('the people'); while the clients had no political existence whatever. That the clients formed a body essentially different from the *plebs* is not true, and seems based merely on the mythical account of what followed the destruction of Alba Longa by Tullus Hostilius. The name plebs (*i.e.* 'the multitude,' from the same root as *pleo*, I fill, *plenus*, full; with which is perhaps connected the other Latin word *vulgus*, English *folk*) is doubtless, as its signification indicates, of later origin than *clientes;* but both are applicable to the same persons, who were called 'listeners,' in reference to their being dependents on the different burgess-households, and the 'multitude,' in reference to their want of political rights. The constitution of the state was simple. All the burgesses were politically on a footing of equality. From their own ranks was chosen the king or 'leader' (*rex*), who was therefore nothing more than an ordinary burgess—a husbandman, a trader, a warrior, set over his fellows. But it must at the same time be observed, that his authority was great, for the Roman state was based on the Roman household, and something of the absoluteness of the *patria potestas* appears in the uncircumscribed nature of the regal powers. The *rex* held his office for life; he consulted the national gods; he appointed the priests and priestesses; he called out the *populus* for war, and led the army in person; his command (*imperium*) was not to be gainsayed, on which account on all official occasions he was preceded by messengers, or summoners (*lictores*, from *ligo*, 'to bind'), bearing the 'fasces' (axes and rods 'bound' up together), the symbols of power and punishment; he had the keys of the public chest, and he was supreme judge in all civil and criminal suits. The Roman religion or *cultus* was from the first thoroughly subordinate to the authority of the state; and all that we can infer from the myth of Numa is, that Rome perhaps owed its colleges of augurs and pontiff to the wisdom of some enlightened sovereign who felt himself at times embarrassed in his decisions on matters of religious and public law, and recognised how valuable might be the aid afforded him by a body of sacred experts. We may rest certain that originally the sole power was the regal, and that the subordinate magistracies found at a later time arose from a delegation of regal authority, rendered necessary by the ceaseless increase of state-business. On the other hand, we may believe that the *senatus*, or Council of the Elders, from its very nature, was as old an institution as the monarchy itself. Among the very first things the 'citizen-king' would do, would be to choose out of the ranks of his fellow-burgesses a number of experienced men to assist him with their counsel; but it is to be observed that this body possessed no coercive or constraining powers. They gave their advice when the *rex* chose to ask it; that was all. Yet, as the tenure of their office was for life, they necessarily possessed great *moral* authority; and it was only when the king, the senate, and the community were at one in regard to any important matter—a war, for example—that it was held to be righteous, and likely to be favoured by the gods. The burgesses, or householders, were divided into *curiæ*—*i.e.* 'wardships,' connected probably with *cura* and *curare*, 'to care for,' rather than with *quiris*, and the Sabine *cures*, as Varro thinks. Ten households formed a *gens* (a 'clan' or 'family'); 10 clans, or 100 households, formed a *curia*, or wardship; and 10 wardships, or 100 clans, or 1000 households, formed the *populus*, *civitas*, or community. But as Rome was a *synoikismos* of three cantons, the actual number of wards was 30, of clans 300, and of households 3000. Every household had to furnish one foot-soldier, and every clan a horseman and a senator. Each ward was under the 'care' of a special warden (the *curio*), had a priest of its own (the *flamen curialis*), and celebrated its own festivals. None but burgesses could bear arms in defence of the state (hence their designation, *populus*, 'the warrior body,' connected with *populari*, 'to lay waste,' and *popa*, 'the priest, or priest's assistant, who felled the victim at the altar—the sacred butcher'). The original Roman army, or *legio* (*i.e.* 'the gathering'), was composed of three 'hundreds' (*centuriæ*) of horsemen (*celeres*—*i.e.* 'the swift,' or *flexuntes*, 'the wheelers'), under their divisional leaders (*tribuni celerum*); and three 'thousands' of footmen (*milites*), also under divisional leaders (*tribuni militum*); to whom were added a number of light-armed skirmishers (*velites*), especially 'archers' (*arquites*). The *rex*, as we have said, was usually the general, but as the cavalry force had a colonel of its own (*magister equitum*), it is probable that he placed himself at the head of the infantry.

The 'foreign policy' of Rome seems to have been aggressive from the first, and this character it retained as long as the aggrandisement of the state was possible. We have, it is true, no certain knowledge of the primitive struggles in which the enterprising and ambitious Roman burghers were engaged, but it appears from the legend that at a very early period the neighbouring Latin communities of Antemnæ, Crustumerium, Ficulnea, Medullia, Cænina, Corniculum, Cameria, Collatia, were subjugated. The crisis of the Latin War, however, was undoubtedly the contest with Alba Longa, in which that 'sacred metropolis' of Latium was destroyed, and its leadership passed to the conqueror. How deadly the struggle between the two was, may be inferred from the tragic details in which the legend abounds. As a rule, on the subjugation of a canton, the conquered inhabitants were allowed to remain in

their open hamlets, but their *capitolium* was razed, their weekly market, their justice-court, their gods —everything, in short, strictly national — were removed to Rome, while they themselves were enrolled among the clients or plebs. But sometimes the inhabitants themselves, in whole or part, were transferred to Rome, and individuals or clans were even received into the ranks of the Roman burgesses, as in the case of Alba Longa. Some of the famous Roman *gentes* claimed to be of Alban descent—the Julii, Servilii, Quinctilii, Cloelii, Curiatii, and Metilii. The wars with the Etruscans of Fidenæ and Veii—assigned, like the destruction of Alba Longa, to the reign of Tullus Hostilius—were apparently indecisive; those with the Rutuli and Volsci, however, were probably more fortunate; but uncertainty hangs like a thick mist over the ancient narrative. Even the story of the Tarquins, though it belongs to the later period of the monarchy, is in many of its details far from credible. Both Niebuhr and Mommsen consider 'Tarquin the Proud' a historical personage, and without accepting literally all the circumstances of the tradition, believe the general outline—his character, his exactions, his expulsion, and his desperate efforts for the recovery of the throne—to be trustworthy. The memory of such a monarch was likely to be preserved by the very strength of the hatred he excited, and an act so daring as his expulsion (which was at the same time the death-knell of a system of government that had prevailed for ages) could hardly be a mere invention, though it might be overlapped with fold upon fold of picturesque fiction. The aristocracy or *populus* had become so much more powerful than the individual *rex*, that they wished to possess *de jure* as well as *de facto* the supreme authority. The pride and tyranny of a Tarquin may very well have aided in furthering their designs.

Meanwhile a great internal change had taken place in Rome. This is usually designated the Servian 'Reform of the Constitution,' although the expression is calculated to mislead. There was nothing directly political in the 'reform.' It was only a reform in the burgess-levy—*i.e.* in the mode of raising the army. The new arrangement is known in Roman history as the formation of the *Comitia Centuriata*. When or with whom the change originated it is impossible to say. The legend assigns it to Servius Tullius, predecessor of Tarquin the Proud; and it was in all probability the work of some kingly ruler who saw the necessity of reorganising the national forces. Its details were briefly as follows: Every Roman freeholder from the age of 17 to 60, whether patrician or plebeian, was made liable to serve in the army; but he took his place according to the amount of his property. The freeholders were distributed into five *classes* (*i.e.* 'summonings,' from *calare*, to 'summon' or 'call out'), and these *classes*, all of whom were infantry, were again subdivided into *centuriæ* ('hundreds'). The *first* class, which required to possess property valued at 100,000 ases, or an entire hide of land, furnished 82 'hundreds;' the second, property valued at 75,000 ases, or ¾ths of a hide of land, furnished 20 'hundreds;' the third, property valued at 50,000 ases, or ½ hide of land, furnished 20 'hundreds;' the fourth, property valued at 25,000 ases, or ¼th hide of land, furnished 20 'hundreds;' and the fifth, property valued at 12,500 ases, or ⅛th hide of land, furnished 32 'hundreds.' A single 'hundred' was, moreover, added from the ranks of the non-freeholders, or *proletarii* (mere 'children-begetters'), although it is possible that from the same order came the two 'hundreds' of 'horn-blowers' (*cornicines*) and 'trumpeters' (*tibicines*), attached to the fifth class. Thus the infantry 'hundreds' amounted to 175, that is, 17,500 men, besides whom were 18 'hundreds' of *equites* ('horsemen'), chosen from the wealthiest burgesses and non-burgesses; so that the Roman army now numbered in all nearly 20,000 men. We have stated that the original design of this new arrangement was merely military, but it is easy to see that it would soon produce political results. Duties and rights are correlative. The former suggest the latter, and create a desire for their attainment. Hence the Servian military reform paved the way for the grand political struggle between the patricians and the plebeians, which commenced with the first year of the Republic, and only terminated with its dissolution.

THE ROMAN REPUBLIC FROM ITS INSTITUTION TO THE ABOLITION OF THE DECEMVIRATE.

1. *Internal History.*—According to the legend, the expulsion of the Tarquins was mainly the work of their cousins Junius Brutus and Tarquinius Collatinus, in revenge for the outrage on the honour of Lucretia, and was followed by the abolition of the monarchy. The date usually assigned to this event is 509 B.C. The story is intensely tragical, and if we must consider it poetry rather than fact, yet it may safely be taken as evidence that it was an unbridled lust of power and self-gratification that brought ruin on the Romano-Tuscan dynasty. Of course, we can make nothing definite out of the early years of the republic. Dates and names, and even events, must go for very little. Valerius Publicola or Poplicola, Sp. Lucretius, M. Horatius, Lars Porsenna of Clusium, Aulus Postumius, with the glorious stories of Horatius Cocles and the battle of Lake Regillus, will not bear to be scrutinised. We must content ourselves with the knowledge of historical tendencies and general results. The change from 'kings' to 'consuls' (*consules*, 'those who leap together'—more generally those who *act* together) was not intended to diminish the administrative power of the supreme rulers, but only to deprive them of the opportunity of doing harm—of becoming Tarquins; and this it effectually succeeded in doing, by limiting their tenure of office to a year, and by numerous other restrictions. It is believed to have been about this time, and in consequence of the new political changes, that the old assessors of the king, such as the *quæstores parricidii*, formally became standing magistrates instead of mere honorary counsellors, and also that the priesthood became a more self-governing and exclusive body. During the regal period, the priests were appointed by the king, but now the colleges of augurs and pontiffs began to fill up the vacancies in their ranks themselves, while the vestals and separate 'flamens' were nominated by the pontifical college, which chose a president (*pontifex maximus*) for the purpose. In the details given us of the 'Servian Reform,' we can easily discern a spirit of compromise, the concessions

made to the plebeians in the constitution and powers of the *Comitia Centuriata* being partially counterbalanced by the new powers conferred on the old burgess body, the *Comitia Curiata*—viz. the right of confirming or rejecting the measures passed in the Lower Assembly. Towards the new assembly, therefore, it stood somewhat in the relation in which the House of Lords stands to the House of Commons, but the analogy must not be pushed too far; it is only general. The character of the senate altered under the action of the same influences. Although it never had been formally a patrician body—although admission to it under the kings was obtainable simply by the exercise of the royal prerogative, yet, practically, 299 out of the 300 senators had always been patricians; but after the institution of the republic, we are told that the blanks in the senate were filled up *en masse* from the ranks of the plebeians, so that of the 300 members less than half were *patres* ('full burgesses'), while 164 were *conscripti* ('added to the roll'), hence the official designation of the senators, *patres et conscripti* ('full burgesses and enrolled').

As yet, however, it is to be observed the plebeians were rigorously excluded from the magistracies. They could vote—*i.e.* they could exercise legislative powers—but they had no share in the administration. None but patricians were eligible for the consulship, for the office of quæstor, or for any other executive function, while the priestly colleges rigidly closed their doors against the new burgesses. The struggle, therefore, between the two orders went on with ever-increasing violence. The abuse of the *Ager Publicus*—that is, such portion of the land of a conquered people as had been taken from them, annexed to the Roman state, and let out originally to the patricians at a fixed rent, together with the frightful severity of the law of debtor and creditor, the effect of which was all but to ruin the small plebeian 'farmers,' who constituted, perhaps, the most numerous section of the burgesses—finally led to a great revolt of the plebs, known as the 'Secession to the Sacred Hill,' the date assigned to which is 494 B.C. On that occasion the plebeian farmer-soldiers, who had just returned from a campaign against the Volscians, marched in military order out of Rome, under their plebeian officers, to a mount near the confluence of the Anio with the Tiber, and threatened to found there a new city, if the patricians did not grant them magistrates from their own order; the result was, the institution of the famous plebeian *tribunate*—a sort of rival power to the patrician *consulate*, by means of which the plebeians, at least, hoped to be shielded from the high-handed oppressions of the wealthy. To the same period belongs the institution of the *ædiles*. A little later, the *Comitia Tributa* emerged into political prominence. This was really the same body of burgesses as formed the *Comitia Centuriata*, but with the important difference, that the number of votes was not in proportion to a property classification. The poor plebeian was on a footing of equality with the rich patrician; each gave his vote, and nothing more. Hence the *Comitia Tributa* virtually became a plebeian assembly, and when the *plebiscita* ('resolutions of the plebs' carried at these *comitia*) acquired (as they did by the Valerian Laws passed after the abolition of the Decemvirate) a legally binding character, the victory of the 'multitude' in the sphere of legislation was complete. The semi-historical traditions of this period—for we are now (fifth century B.C.) beginning to emerge out of the mythical era—unmistakably shew that the institution of the tribunate led to something very like a civil war between the two orders. Such is the real significance of the legends of Caius Marcus, surnamed *Coriolanus*, the surprise of the Capitol by the Sabine marauder, Appius Herdonius, at the head of a motley force of political outlaws, refugees, and slaves; the migrations of numerous Roman burgesses with their families to more peaceful communities; the street-fights; the assassinations of plebeian magistrates; the annihilation by the Etruscans of the Fabian *gens*, who had left Rome to escape the vengeance of their order for having passed over to the side of the plebeians; and the atrocious judicial murder of Spurius Cassius, an eminent patrician, who had also incurred the deadly hatred of his order, by proposing an agrarian law that would have checked the pernicious prosperity of the capitalists and overgrown landholders. Finally, 462 B.C. a measure was brought forward by the tribune C. Terentillius Ursa, to appoint a commission of ten men to draw up a code of laws for the purpose of protecting the plebeians against the arbitrary decisions of the patrician magistrates. The result was the famous code known as the *Twelve Tables*—at first *Ten*, to which two were afterwards added—the appointment of the *Decemviri*, and the abolition of all the ordinary magistrates, both patrician and plebeian. The government by decemvirs, however, lasted only two years; according to tradition, the occasion of its overthrow was the attempt of the principal decemvir, Appius Claudius, to possess himself by violence of the beautiful daughter of Virginius, a Roman centurion; but the real cause was doubtless political, though the cruel lust of a Claudius may have afforded the occasion; the result of which was the restoration of the pre-decemviral state of things—the patrician consulate and the plebeian tribunate.

2. *External History.*—The external history of Rome, from the establishment of the republic to the abolition of the decemvirate, is, it need hardly be said, purely military. The Romans fought incessantly with their neighbours. Long before the close of the regal period they had acquired, as we have seen, the leadership of Latium, and in all the early wars of the republic they were assisted by their allies and kinsmen; sometimes also by other nations—as, for example, the Hernicans, between whom and the Romans and Latins a league was formed by Spurius Cassius in the beginning of the fifth century B.C. The most important of these wars were those with the southern Etruscans, especially the Veientines, in which, however, the Romans made no way, and even suffered terrible disasters, of which the legend concerning the destruction of the Fabian *gens* on the Cremera (477 B.C.) may be taken as a distorted representation; the contemporaneous wars with the Volscians, in which Coriolanus is the most distinguished figure; and those with the Æqui (458 B.C.), to which belongs the fine legend of Cincinnatus.

FROM THE ABOLITION OF THE DECEMVIRATE TO THE DEFEAT OF THE SAMNITES, AND THE SUBJUGATION OF ALL THE 'ITALIANS' (449–265 B.C.).

1. *Internal History.*—The leading political features of this period are the equalisation of the two orders, and the growth of the new aristocracy of capitalists. After the abolition of the decemvirate, it would seem—judging from the course of events—that the whole of the plebeian aristocracy, senators and capitalists (from motives of selfish aggrandisement), combined with the 'masses' of their order to make a series of grand attacks on the privileges of the old Roman *noblesse*. The struggle lasted for 100 years; and ended, as it could only end, by the removal of all the social and political disabilities under which the plebeians had laboured—though the stratagems and artifices to which the old aristocracy had recourse, proved the reluctance with which they succumbed to fate. First in 445 B.C. only four years after the fall of the decemvirs was carried, the *Lex Canuleia*, by which it was enacted that marriage between a patrician and plebeian should be legally valid. At the same time, a compromise was effected with respect to the consulship. Instead of two patrician consuls, it was agreed that the supreme power should be intrusted to new officers termed 'Military Tribunes with Consular Power,' who might be chosen equally from the patricians or plebeians. Ten years later (435 B.C.), the patricians tried to render the new office of less consequence by the transference of several of the functions hitherto exercised by consuls to two special patrician officers named *Censors*. In 421 B.C. the quæstorship was thrown open to the plebeians; in 368 B.C. the mastership of the horse; in 356 B.C. the dictatorship; in 351 B.C. the censorship; in 337 B.C. the prætorship; and in 300 B.C. the pontifical and augurial colleges. These victories were not all won without the shedding of blood. How great was the exasperation of the patricians may be estimated from the story of Spurius Maelius, the rich plebeian, who was murdered simply because in a season of famine he sold corn at a very low price to the poor.

The only effect, it is to be observed, of these political changes was to increase the power of the rich plebeians; and consequently, the social distress continued to shew itself as before. Efforts were repeatedly made by individuals to remedy the evil, but without success. Such were the attempts of the tribunes Spurius Maecilius and Spurius Metilius (417 B.C.) to revive the agrarian law of Spurius Cassius; and of the noble and patriotic patrician, Marcus Manlius, who, though he had saved the Capitol during the terrible Gallic siege, was hurled from the Tarpeian Rock (384 B.C.), on the customary charge, as groundless in his case as it was base, of aspiring to the monarchy; but at length (367 B.C.), after a furious struggle of eleven years, the famous Licinian Rogations were carried, by means of which it was hoped that an end had been put to the disastrous dissensions of the orders.

That these laws operated beneficially on the class in whose interest they were passed, namely, the plebeian-farmers or middle-class of the Roman state, is unquestionable. The 'general coffers' were also filled by the revenue drawn directly or indirectly from the subjugated lands, so that a *tributum* (a forced loan) seldom required to be enforced at home, and the numerous colonies which Rome now began to send forth to secure her new acquisitions, consisted entirely of the poorer plebeians, who always received a portion of the land in the district where they were settled. The long struggle between the two orders was thus virtually at an end; but the date usually assigned to the termination of the strife is 286 B.C. when the *Lex Hortensia* was passed which confirmed the Publilian Laws of 339 B.C. and definitely gave to the *Plebiscita* passed at the Comitia of the Tribes, the full power of laws binding on the whole nation. Gradually, however, by steps which we have not room to trace, the importance of the popular assemblies declined, and that of the senate rose. The senate, it will be remembered, originally possessed no administrative power at all, but now it commenced a series of vast usurpations, of which the best defence is that they excited no opposition among the community. Every matter of general importance—war, peace, alliances, the founding of colonies, the assignation of lands, building, the whole system of finance—came under its supervision and authority. Nor, on the whole, did it prove itself the unworthy arbiter of a nation's destinies. It was not a self-elected oligarchy, but was rather composed of the ablest representatives of both orders.

2. *External History.*—We have said that the military successes of Rome during this period of internal strife were great; but we can only briefly allude to them. The irruption of the Gauls into sub-Apennine Italy (391 B.C.), though accompanied by frightful devastations, was barren of results, and did not materially affect the progress of Roman conquest. No doubt the battle on the Allia, and the capture and burning of Rome (390 B.C.), were great disasters, but the injury was temporary. The vigilance of Manlius saved the Capitol, and the heroism of Camillus revived the courage and spirit of the citizens. Again and again in the course of the 4th c. B.C. the Gallic hordes repeated their incursions into Central Italy, but never again returned victorious. In 367 B.C. Camillus defeated them at Alba; in 360 B.C. they were routed at the Colline Gate; in 358 B.C. by the dictator, G. Sulpicius Peticus; and in 350 B.C. by Lucius Furius Camillus. Meanwhile, aided by their allies, the Latins and the Hernicans, the Romans carried on the long and desperate struggle with the Æquians, Volscians, and Etruscans. Finally, but not till after they had sustained repeated defeats, the Romans triumphed. The causes that led to the decline of the Etruscan power, which, at the close of the regal period in Rome, and during the infancy of the republic, had been enormous, both by sea and land, cannot be considered at length here. Suffice it to say, that the terrible irruption of the Gallic barbarians into Etruria, and the victories of the Samnites in Campania, where also the Etruscans had established themselves, as well as the miserable jealousies of the different cities, combined to paralyse the power of this people, and paved the way for the final triumph of Rome.

But even before the Gauls had crossed the Apennines, the fate of Etruria was virtually sealed. The fall of Veii, 396 B.C. was really the death-knell of Etruscan independence. Although the story has undoubtedly descended to us in a mythical dress, the siege of Veii is by no means to be placed in the same category with the siege of Troy. Falerii, Capena, and Volsinii—all sovereign cities of Etruria—hastened soon after to make peace, and by the middle of the 4th c. B.C. the whole of Southern Etruria had submitted to the supremacy of Rome, was kept in check by Roman garrisons, and denationalised by the influx of Roman colonists. In the land of the Volsci, likewise, a series of Roman fortresses were erected to overawe the native inhabitants; Velitrae, on the borders of Latium, as far back as 492 B.C. Suessa Pometia (442 B.C.), Circeii (393 B.C.), Satricum (385 B.C), and Setia (382 B.C.): besides the whole Volscian district, known as the Pontine Marshes, was distributed into farm-allotments among the plebeian soldiery. Becoming alarmed, however, at the increasing power of Rome, the Latins and Hernicans withdrew from the league, and a severe and protracted struggle took place between them and their former ally. Nearly thirty years elapsed before the Romans succeeded in crushing the malcontents, and restoring the league of Spurius Cassius. In the course of this war, the old Latin confederacy of the 'Thirty Cities' was broken up (384 B.C.), probably as being dangerous to the hegemony (now rapidly becoming a supremacy) of Rome. The terms of the treaty made by the Romans (348 B.C.) with the Carthaginians shew how very dependent was the position of the Latin cities. Meanwhile, the Romans had pushed their garrisons as far south as the Liris, the northern boundary of Campania. Here they came into contact with the Samnites, a people as heroic as themselves, their equals in everything but unity of political organisation; perhaps their superiors in magnanimity.

The Samnites had long been extending their conquests in the south of Italy, just as Rome had in the centre and in Etruria. Descending from their native mountains between the plains of Apulia and Campania, they had overrun the lower part of the peninsula, and under the name of Lucanians, Bruttians, &c. had firmly established themselves, threatening everywhere the prosperity of the Greek and Etruscan possessions in those regions. But it was the dwellers in the original mountain territory who properly bore the name of Samnites, and between them and the Romans now commenced a tremendous struggle; the former fighting heroically for the preservation of their national freedom—the latter warring with superb valour for dominion. The Samnite Wars, of which three are reckoned, extended over 53 years (343–290 B.C.). The second, generally known as the 'Great Samnite War,' lasted 22 years (326–304 B.C.). At first, the success was mainly on the side of the Samnites; and after the disaster at the *Caudine Forks*, it seemed as if Samnium and not Rome was destined to become the ruler of Italy, but the military genius of the Roman consul, Quintus Fabius Rullianus, triumphed over every danger, and rendered all the heroism of Caius Pontius, the Samnite leader, unavailing. In 304 B.C. Bovianum, the capital of Samnium, was stormed, and the hardy highlanders were compelled to acknowledge the supremacy of the republic. The third war (298–290 B.C.) was conducted with all the sanguinary energy of despair; but though the Etruscans and Umbrians now joined the Samnites against the Romans, their help came too late. The victory of Rullianus and of P. Decius Mus, at Sentinum (295 B.C.), virtually ended the struggle, and placed the whole of the Italian peninsula at the mercy of the victor. It only remains to be mentioned here that at the close of the first Samnite War, which was quite indecisive, an insurrection burst out among the Latins and Volscians, and spread over the whole territory of these two nations; but the defeat inflicted on the insurgents at Trifanum (340 B.C.) by the Roman consul, Titus Manlius Imperiosus Torquatus, almost instantly crushed it, and in two years the last spark of rebellion was extinguished. The famous Latin league was now dissolved; many of the towns lost their independence, and became Roman *municipia;* new colonies were planted both on the coast and in the interior of the Latino-Volscian region; and finally, so numerous were the farm-allotments to Roman burgesses, that two additional tribes had to be constituted.

FROM THE CLOSE OF THE SAMNITE TO THE COMMENCEMENT OF THE PUNIC WARS.

The war with Pyrrhus, king of Epeirus, which led to the complete subjugation of Peninsular Italy, is a sort of pendant to the great Samnite struggle. It was brought about in this way.

The Lucanians and Bruttians, who had aided the Romans in the Samnite Wars, considering themselves cheated of their portion of the spoil, entered into negotiations with the enemies of their former associate throughout the peninsula. A mighty coalition was immediately formed against Rome, consisting of Etruscans, Umbrians, and Gauls in the north, and of Lucanians, Bruttians, and Samnites in the south, with a sort of tacit understanding on the part of the Tarentines that they would render assistance by and by. The rapidity with which it took shape shews alike the fear and the hatred inspired by the Roman name. In the course of a single year, the whole north was in arms, and once more the power, and even the existence of Rome, were in deadly peril. An entire Roman army of 13,000 men was annihilated at Arretium (284 B.C.) by the Senonian Gauls; but that dauntless spirit which the republic never failed to display in the crisis of its fortunes, and which gives a sublime dignity to its worst ambition, now shone out in the fulness of its splendour. Publius Cornelius Dolabella marched into the country of the Senones at the head of a large force, and literally extirpated the whole nation, which henceforth disappears from history. Shortly afterwards, the bloody overthrow of the Etrusco-Boian horde at Lake Vadimo (283 B.C.) shattered to pieces the northern confederacy, and left the Romans free to deal with their adversaries in the south. The Lucanians were quickly overpowered (282 B.C.); Samnium, broken by its long and luckless struggle, and overawed by the proximity of a Roman army, could do nothing. A rash and unprovoked attack on a small Roman fleet now brought down on the Tarentines the vengeance of

Rome at the very moment Rome was free to exert all her terrible power. Awaking to a sense of their danger, the Tarentines invited Pyrrhus over from Epeirus, and appointed him commander of their mercenaries. It is not necessary to narrate here the varying fortunes of the struggle between Pyrrhus and the Romans, which lasted only six years, and ended in his being obliged to return to Epeirus without accomplishing anything.

After Pyrrhus, baffled in his attempts to check the progress of Rome, had withdrawn to Greece, the Lucanians and Samnites, whom his reputation and original successes had induced to rise once more against the dreaded foe, continued the unequal struggle, but 'even the bravery of despair,' as it has been said, 'comes to an end; the sword and the gibbet at length (269 B.C.) carried peace even into the mountains of Samnium.' Tarentum had surrendered three years earlier; and now from the Macra and the Rubicon to the Strait of Messana, there was not a nation in Italy that did not acknowledge the supremacy of Rome. Distant kingdoms began to feel that a new power had risen in the world, and when Ptolemy Philadelphus, sovereign of Egypt, heard of the overthrow of the famous Epeirote warrior, he sent an embassy to Rome (273 B.C.), and concluded a treaty with the republic. To secure their new acquisitions, the Romans established in the south military colonies at Pæstum and Cosa, in Lucania (273 B.C.); at Beneventum (268 B.C.), and at Æsernia (263 B.C.), to overawe the Samnites; and in the north, as outposts against the Gauls, Ariminum (268 B.C.), Firmum in Picenum (264 B.C.), and the burgess colony of Castrum Novum. Preparations were also made to carry the great Appian highway as far as Brundisium, on the Adriatic, and for the colonisation of the latter city as a rival emporium to Tarentum.

The political changes were almost as important as the military. The whole population of Peninsular Italy was divided into three classes—1. *Cives Romani*, or such as enjoyed the full burgess privileges of Roman citizens; 2. *Nomen Latinum*—that is, such as possessed the same privileges as had been enjoyed by the members of the quondam Latin league—viz. an equality with the Roman burgesses in matters of trade and inheritance, the privilege of self-government, but no participation in the Roman franchise, and consequently no power to modify the foreign policy of the state; 3. *Socii*, or 'Allies,' to some of whom were conceded most liberal privileges, while others were governed in an almost despotic fashion. The *Cives Romani* no longer embraced merely the inhabitants of the old Roman community, the well-known 'tribes' (of whom there were now thirty-three), but all the old burgess-colonies planted in Etruria and Campania, besides such Sabine, Volscian, and other communities as had been received into the burgess body on account of their proved fidelity in times of trial, together with individual Roman emigrants or families of such, scattered among the *municipia*, or living in villages by themselves. The cities possessing the *Latinum Nomen* included most of the 'colonies' sent out by Rome in later times, not only in Italy, but even beyond it; the members of which, if they had previously possessed the Roman franchise, voluntarily surrendered it in lieu of an allotment of land. But any 'Latin' burgess who had held a magistracy in his native town, might return to Rome, be enrolled in one of the tribes, and vote like any other citizen. The *Socii* comprised all the rest of Italy, as the Hernicans, the Lucanians, Bruttians, the Greek cities, &c.

THE PUNIC WARS.

The first foreign people with whom the Romans came into collision were the Carthaginians—a people of Phœnician lineage, who, settling in that part of Africa now called Tunis, and building a city there, about a century before the date assigned to the foundation of Rome, had in the interval become a great commercial nation, with ships sailing to all parts of the Mediterranean, and with colonies along the coasts of Algiers, in Sardinia and Corsica, and even in Spain. They had recently gained a footing in Sicily, and now shared it with the Greeks of Syracuse; and it was on this rich island as a battle-field that the Romans first came into conflict with the merchant-people of Africa. Between the Carthaginians and the Romans there had long existed a nominal alliance—the oldest treaty dating as far back as the sixth century B.C. But this alliance had never possessed any real significance, and latterly the two nations had come to regard each other with considerable distrust. The incident that occasioned the outbreak was quite trivial, and need not be recorded. Suffice it to say that in 264 B.C. war was formally declared between the two nations, and incomparably the most terrible contest in which Rome was ever engaged, began.

We do not propose to follow minutely the course of the famous Punic Wars, but we may briefly indicate their character and result. The wars with Carthage, like those with Samnium, were three in number. The *first* lasted 23 years (264–241 B.C.), and was waged mainly for the possession of Sicily. Its leading feature was the creation of a Roman navy, which, after repeated and tremendous misfortune, finally wrested from Carthage the sovereignty of the seas. So energetically did the senate set to work, that (we are told) in sixty days from the time the trees were felled, 120 ships were launched, and soon after the consul Caius Duilius gained a brilliant success (260 B.C.) over the Carthaginians off Mylæ, on the north-east coast of Sicily. The *Columna Rostrata* ('Beaked Column') in the Forum preserved for ages the memory of the 'glorious victory.' Subsequent events, however, were less favourable. An invasion of Africa by Regulus ended in disaster, and the war, which was henceforth confined to Sicily, miserably languished. Thrice was the Roman navy annihilated by storms at sea (255 B.C. 253 B.C. and 249 B.C.); and in spite of a series of unimportant successes by land, the Romans long found it impossible to make any impression on the great Carthaginian strongholds of Lilybæum and Drepanum, mainly on account of the brilliant strategy with which they were held in check by Hamilcar Barca, the father of Hannibal. At last, however, a great sea-fight took place off the Ægates isles (242 B.C.), in which a Roman fleet, commanded by the consul Lutatius Catulus, obtained a magnificent victory. The Carthaginian government, whose treasury was empty, and who had in vain tried to raise a

state-loan in Egypt, could—for the present—continue the struggle no longer; and the whole of Sicily, except the territory of Hiero of Syracuse, who had been a firm ally of the Romans, passed into the hands of the victors, who constituted it a Roman province, and placed it under the government of a prætor.—A lapse of 23 years occurred before the second Punic War began, but during that interval neither Romans nor Carthaginians had been idle. The former, with worse than 'Punic faith,' had bullied their weak and exhausted rival into surrendering Sardinia and Corsica, which, like Sicily, were transformed into a Roman province. In addition, they had carried on a series of Gallic wars in Northern Italy (231–222 B.C.), the result of which was the complete humiliation of the barbarian Boii, Insubres, &c. and the extension of Italy to its natural boundary—the Alps. Meanwhile, the descent of Hamilcar on the Spanish coast was followed by the establishment of a new Carthaginian empire, or at least a protectorate, in the west; and thus, almost before the Romans were aware of it, their hated rival had made good her losses again, and was even able to renew the struggle in a more daring fashion than before. How confident the bearing of the Carthaginians had now become, may be seen from the fearless spirit in which they accepted the Roman challenge, and entered on the *second* Punic—or (as the Romans called it) the *Hannibalic*—War, the grand events of which were the crossing of the Alps by Hannibal, the terrible disasters of the Romans at Lake Trasimene and Cannæ, and the final overthrow of Hannibal at Zama, 202 B.C. by Scipio, which once more compelled the Carthaginians to sue for peace. It was with Carthage as with Samnium. The *second* war virtually sealed her fate, and the *third* displayed only the frantic heroism of despair. Her Spanish possessions, like her Sicilian, passed to the Romans (who formed out of them the provinces of *Hispania Citerior* and *Hispania Ulterior*); so did her protectorate over the Numidian sheiks. She was forced to surrender her whole navy (excepting ten triremes), and all her elephants, and to solemnly swear never to make war either in Africa or abroad, except with the consent of her vanquisher. Her relations, indeed, to the conquered Italian nationalities became much harsher than they had formerly been, for, after the first victories of Hannibal, these had risen against her. The Picentes, Bruttii, Apulians, and Samnites were deprived either of the whole or the greater part of their lands—some communities were actually turned into serfs—the Greek cities in Lower Italy, most of which had also sided with Hannibal, became the seats of burgess-colonies. But the loss of life and of vital prosperity was frightful. 'Numbers of flourishing townships,' says Mommsen, '400 it was reckoned, were destroyed and ruined.' During 201–196 B.C. the Celts in the valley of the Po, who, with the fiery unwisdom of their race, had recommenced hostilities at the very moment Rome was freed from her embarrassments, were thoroughly subjugated; their territory was Latinised, but they themselves were declared incapable of ever acquiring Roman citizenship; and so rapidly did their nationality dissolve, that when Polybius, only 30 years later, visited the country, nearly all traces of Celtic characteristics had disappeared. The Boii were finally extirpated about 193 B.C.; the Ligurians were subdued 180–177 B.C.; and the interior of Corsica and Sardinia about the same time. The wars in Spain were troublesome and of longer duration, but they were not at all serious. The natives were indeed perpetually in arms, and the Romans suffered frequent defeats from their sudden and impetuous insurrections; but in the end the superior discipline of the legions always prevailed, and the fiery and chivalrous tribes had of course to make ignominious submission. So little reliance, however, could be placed on these forced submissions, that the Romans felt it necessary to hold Spain by military occupation, and hence arose the first Roman standing armies. Forty thousand troops were maintained in the Spanish peninsula year after year. The most distinguished successes were those achieved by the younger Scipio, by Quintus Minucius (197–196 B.C.), by Marcus Cato (195 B.C.), by Lucius Æmilius Paullus (189 B.C.), by Caius Calpurnius (185 B.C.), by Quintus Fulvius Flaccus (181 B.C.), and by Tiberius Gracchus (179–178 B.C.).

MACEDONIAN AND GREEK WARS.

The causes that led to the interference of Rome in the politics of the East are too complicated to be given here, but the *Macedonian Wars* were owing immediately to the alliance formed by Philip V. of Macedon with Hannibal after the battle of Cannæ. Like the Samnite and Punic, the Macedonian Wars were three in number. The *first* (214–205 B.C.) was barren of results, mainly because the whole energies of Rome were directed to Spain and Lower Italy; but the *second* (200–197 B.C.), though it lasted only a third of the time occupied by the first, taught Philip that another and not he must rule in Greece. The battle of *Cynoscephalæ* ('Dogs' Heads' Hills, a range in Thessaly) was followed by a treaty which compelled him to withdraw his garrisons from the Greek cities, to surrender his fleet, and to pay 1000 talents towards the expenses of the war. Philip was thoroughly quelled, and during the remaining 18 years of his life, he adhered (like old Hiero of Syracuse, though less sincerely) to his Roman alliance. But the Ætolians, who had formed an alliance with Rome against Philip, quarrelled with their powerful 'friends,' and persuaded Antiochus of Syria to come over seas to Thessaly and fight them. A similar fate befell him to what had befallen Philip. After a war of three years, he found himself obliged to surrender all his possessions in Europe and Asia Minor, all his elephants and ships, and to pay 15,000 Euboic talents (£3,660,000) within twelve years. Next year the Ætolians were crushed; and a little later, the quarrels between the Achaians and Spartans led to a general Roman protectorate over the whole of Greece.

Philip of Macedon dying (179 B.C.), was succeeded on the throne by his eldest son Perseus, who resolved once more to try the fortune of war with the Romans; and in 172 B.C. the *third* and *last* Macedonian War began, the result of which, after four years of fighting, was the utter destruction of the Macedonian army at Pydna (168 B.C.) by the Roman consul Lucius Æmilius Paullus, the capture of the king, who adorned the triumph of the conqueror, and the dismemberment of the

Macedonian empire, which was broken up into four oligarchic republics. Further, the imperial republic stopped Antiochus Epiphanes in his career of Egyptian conquest, ordered him instantly to abandon his acquisitions, and accepted the protectorate of Egypt, which the grateful and frightened monarch offered her (168 B.C.). We may here, for the sake of connection, anticipate the course of history, and mention the last *Greek* and *Punic* Wars. Both of these came to an end in the same year (146 B.C.). The former was caused by an expiring outburst of pseudo-patriotism in the Achaian League, consequent on the return of the exiles from Rome, and was virtually closed on the destruction of Corinth by the consul Mummius. The latter was not so much a war as a bloody sacrifice to the genius of Roman ambition. After Hannibal's death, his party in Carthage seems to have recovered the ascendency, and as coincident therewith, the commercial prosperity of the city began to revive, a bolder front was shewn in resisting the encroachments of Masinissa, the Numidian ruler, whom the Roman senate protected and encouraged in his aggressions. This was enough. Fierce old Cato only expressed the instinctive sentiment of the Roman burgesses, when he came to utter incessantly *Delenda est Carthago*, and in 149 B.C. the senate adopted his barbarous conviction. After a siege of three years, in which the inhabitants displayed superhuman energy and heroism, Carthage was stormed by the younger Scipio, and the Carthaginian empire vanished for ever from the earth.

POSITION OF ROME AT THE CLOSE OF THE PUNIC WARS, AND SKETCH OF ITS SUBSEQUENT SOCIAL CONDITION TO THE TERMINATION OF THE REPUBLIC.

'Polybius dates from the battle of Pydna the full establishment of the universal empire of Rome. It was in fact the last battle in which a civilised state confronted Rome in the field on a footing of equality with her as a great power; all subsequent struggles were rebellions or wars with peoples beyond the pale of the Romano-Greek civilisation—the barbarians, as they were called.' But contemporaneous with this enormous extension of power and authority in foreign lands, the national character underwent a complete and fatal alteration. The simplicity and stern integrity of life, the religious gravity of deportment, and the fidelity with which common civic and household duties were discharged—well expressed in the saying of Cato, that it was 'better to be a good husband than a great senator'—which in early times nobly distinguished the Roman burgess, had now all but disappeared. Those hardy virtues—frugality, temperance, justice, and rectitude—which, combined with courage and energy, had given the strength to the nation that made it great, required for their permanence the social conditions out of which they sprang. But the class of peasant proprietors who had laid the foundations of Roman greatness were either extinct or no longer what they once had been. The victories of Rome abroad furthered rather than retarded that degradation. The long and distant wars made it more and more impossible for the soldier to be a good citizen or a successful farmer. The freedom and licentiousness of camp-life, the sweets of pillage and rapine, ever grew more pleasant to the Italian burgess and colonist; thus indolence, inaptitude, and spendthrift habits aided the greedy designs of the capitalists, and in most cases the paternal acres gradually slipped into the possession of the great landlords, who found it more profitable to turn them into pasture or cultivate them by gangs of slaves. The rise of the slave-system, though an inevitable result of foreign conquest, was, indeed, the most horrible curse that ever fell on ancient Rome; and the atrocities inflicted on its unhappy victims are far beyond the possibility of description. If the Italian farmer honourably strove to retain his small farm, he was exposed to the competition of the capitalists who shipped immense quantities of corn from Egypt and other granaries, where slave-labour rendered its production cheap, and of course he failed in the unequal struggle. Not less pernicious was the change that passed over the character of the rich. We have already shewn how the old Roman patricians lost their exclusive privileges, how the plebeians gradually acquired a full equality with them, and how the germs of a new social aristocracy originated, based on wealth rather than pedigree, and comprising both plebeians and patricians. During the fourth and third centuries B.C. the political power of this order immensely increased. In fact, the whole government of the state passed into their hands. Regarding themselves as the Roman community *par excellence*, and the poor burgesses as a mere *canaille*, whose wishes and interests were unworthy of a moment's consideration, they virtually relapsed into the exclusiveness of the ancient *populus*, with this difference for the worse, that their wealth, influence, and pride were a thousandfold greater than those of Coriolanus or Camillus. But far worse than even the nepotism and selfishness of the nobles was their ever-increasing luxury and immorality. When Rome had conquered Greece, and Syria, and Asia Minor, the days of her true greatness were ended. The wealth that poured into the state coffers, thence to be (really if not formally) distributed among the clique of nobles, the treasures which victorious generals acquired, enabled them to gratify to the full the morbid appetites for pleasure engendered by exposure to the voluptuousness of the East. Such results were, it is true, not brought about in a day, nor without a resolute protest on the part of individual Romans. The attitude of Cato Major towards the Hellenising tendencies of his brother nobles was doubtless patriotic, and posterity has been generous in its laudation of his antique virtue; but Cato Major was nevertheless only a political fanatic and incarnate anachronism. So long as Rome chose to subdue foreign nations, and to hold them by the demoralising tenure of conquest—that is, as mere *provinces*, whose inhabitants, held in check by a fierce and unscrupulous soldiery (like the Kabyles of Algeria by the French, or, until recently, the Hindus by the British), neither possessed political privileges nor dared cherish the hope of them—it was morally impossible for the citizens, either at home or abroad, to resume the simple and frugal habits of their forefathers. After Cato's time, things grew worse instead of better, nor from this period down to the final dissolution of the empire was a single

radical reform ever permanently effected. The momentary success of Tiberius, and of his far abler brother Caius, Gracchus, in their desperate and revolutionary attempts to prevent the social ruin of the state, by breaking down the powers of the senate, redistributing the domain lands, reorganising the administration, and partially restoring the legislative authority of the popular assemblies, hardly survived their death; and the reaction that ensued proved that the senate, like the Bourbons, could learn nothing from adversity, and that the rabble of the city were incapable of elevation or generosity of political sentiment. Henceforth, the malversation of the public money by prætors and quæstors became chronic, and the moral debauchery of the mob of the capital by the largesses of ambitious politicians and the vile flattery of demagogues, complete. The old Roman faith, so deep, and strong, and stern, disappeared from the heart. The priests became Pharisees, the nobles 'philosophers' (*i.e.* unbelievers), their wives practisers of oriental abominations under the name of 'mysteries;' while the poor looked on with unmeaning, yet superstitious wonder at the hollow but pompous ceremonies of religion.

FROM THE DESTRUCTION OF CARTHAGE TO THE TERMINATION OF THE REPUBLIC.

We have already alluded to the wars waged in Spain during the first half of the second century B.C. The humane and conciliatory policy pursued towards the natives by Tiberius Sempronius Gracchus, father of the ill-fated tribunes, brought about a peace, 179 B.C. that lasted 25 years; but in 153 B.C. a general rising of the Celtiberians took place, followed by another on the part of the Lusitanians of Portugal. The struggle maintained by these gallant barbarians against their mighty oppressor lasted, with intervals of peace, for the space of 20 years, but ended, in spite of gleams of brilliant success, as such contests invariably do, in the final overthrow of the undisciplined and uncivilised combatant. All the valour of the shepherd-warrior, Viriathus, even if the assassin's steel had spared his life, would not have prevented the annexation of Lusitania to the Roman empire, nor did the unsurpassable heroism of the besieged Numantines avail to baffle the military skill of the younger Scipio.

Towards the conclusion of the Numantine War occurred the first of those horrible social outbreaks known as 'servile' or 'slave' wars, which marked the later ages of the republic. The scene of the revolt was Sicily (134 B.C.), where the system was seen at its worst. Its leader was one Eunus, a Syrian, who, mimicking his native monarch, took the title of King Antiochus. The suddenness and barbaric fury of the affair for a time rendered all opposition impossible. The slaves overran the island, like demoniacs let loose; and routed one Roman army after another. But a slave insurrection has no aim beyond immediate revenge, and when the first wild paroxysms of ferocity are over, it becomes powerless, more even from a moral than a physical exhaustion, and can be quelled with ease. In 132 B.C. the consul Publius Rupilius restored 'order' in the island. In the East, fortune continued to smile upon the Roman arms. Attalus III., Philometer, a villainous despot of the true oriental stamp, who massacred or poisoned every one that ventured to give him advice, dying 133 B.C. bequeathed his client-kingdom of Pergamus to its protector—Rome; and after a fierce struggle with an ambitious pretender called Aristonicus, the Romans obtained possession of the splendid bequest, and formed it into the province of Asia, 129 B.C.

We may here enumerate the different provinces into which the Roman senate divided its foreign conquests in the order of their organisation. 1. Sicily, 241 B.C.; 2. Sardinia and Corsica, 238 B.C.; 3. Hispania Citerior, and 4. Hispania Ulterior, 205 B.C.; 5. Gallia Cisalpina, 191 B.C.; 6. Macedonia, 146 B.C.; 7. Illyricum, *circa* 146 B.C.; 8. Achaia (or Southern Greece), *circa* 146 B.C.; 9. Africa, (*i.e.* the Carthaginian territory), 146 B.C.; 10. Asia (kingdom of Pergamus), 129 B.C. A few years later, 118 B.C. an 11th was added by the conquest of the southern part of Transalpine Gaul, and was commonly called, to distinguish it from the rest of the country, 'the Province;' hence the modern *Provence*.

In Africa, the overthrow of Jugurtha, 104 B.C. by the consul Marius, added yet further to the military renown and strength of the republic. Meanwhile, from a new quarter of the world, a gigantic and unforeseen danger threatened the Roman state. North of the Alps there had long been roaming in the region of the Middle Danube an unsettled people called the *Cimbri*, whose original home was probably the north-west of Germany. They first came into collision with the Romans in Noricum, 113 B.C.; after which they turned westward, and poured through the Helvetian valleys into Gaul, where they overwhelmed alike the native tribes and the Roman armies. At Arausio (Orange) on the Rhône, 105 B.C. a Roman army of 80,000 was annihilated; but instead of invading Italy, the barbarians blindly rushed through the passes of the Pyrenees, wasted precious months in contests with native tribes of Spain as valiant and hardy as themselves, and gave the Romans time to recover from the effects of their terrible defeat. Marius, who had just returned from his Numidian victories, was reappointed consul; and at Aqua-Sextiæ (Aix, in Dauphiné), he literally exterminated the dreaded foe, 102 B.C. Next year, near Milan, the same doom befell another northern horde—the Teutones, who had accompanied the Cimbri in their irruption into Spain; but on their withdrawal, had parted from their associates in Gaul, forced their way back through Switzerland, and descended into Italy by the Tyrolese valleys. In the same year a second insurrection of the slaves in Sicily, which had reached an alarming height, was suppressed by the consul Marcius Aquillius.

For the next ten years the internal history of Rome is a scene of wild confusion and discord. Marius, an admirable soldier, but otherwise a man of mediocre talents, and utterly unfit to play the part of a statesman, was the idol of the poor citizens, who urged him to save the state from the rapacious misgovernment of the rich. His attempts were pitiable failures; the brave honest soldier fell into the hands of unscrupulous demagogues like Glaucia and Saturninus, and sullied the laurels he had won in war by associating with men who did not hesitate to assassinate a political opponent. Not less fruitless was the wise and

patriotic effort of Livius Drusus—'the Gracchus of the aristocracy'—to effect a compromise between the privileges of the rich and the claims of the poor. The oligarchic party among the former, *i.e.* the senate, were enraged by his proposition to double their numbers by the introduction of 300 equites; the latter by his offer to the 'Latins' and 'Allied Italians' of the Roman franchise. Drusus fell, 91 B.C. by the steel of a hired bravo. Hardly a year elapsed before the whole of the subject 'Italians'—*i.e.* the Marsians, Pelignians, Marrucinians, Vestinians, Picentines, Samnites, Apulians, and Lucanians—were up in wild and furious revolt against Rome; and, though the rebellion was crushed in less than two years by the superior generalship of Marius, Sulla, and Pompeius Strabo (father of the 'great' Pompey), the insurgents virtually triumphed; for the promise which Drusus had held out to them of the 'Roman franchise,' was made good by the *Lex Plautia Papiria*, 89 B.C. Yet the cost was terrible. It is calculated that 300,000 men—the flower of Rome and Italy, perished in the struggle; nor was even this tremendous holocaust sufficient to appease the Fates. The jealousy that had long existed on the part of Marius towards his younger and more gifted rival, Sulla, kindled into a flame of hate when the latter was elected consul, 88 B.C. and received the command of the Mithridatic War—an honour which Marius coveted for himself. Then followed the fearful years of the 'civil wars' between the two chiefs, 88–82 B.C. when blood was spilt like water; and proscriptions and massacres were the order of the day. It was a 'Reign of Terror'—surpassing even the excesses of the French Revolutionists. Sulla, the leader of the aristocracy, which was nominally the party of order, triumphed, but the ferocious energy displayed by the revolutionists convinced him that the 'Roman franchise' could never again be safely withdrawn from the 'Italians;' and Roman citizens, therefore, they remained till the dissolution of the empire; but, on the other hand, his whole legislation was directed towards the destruction of the political power of the burgesses, and to the restoration to the senatorial aristocracy and priesthood of the authority and influence they had possessed in the times of the Punic Wars. That his design was to build up a strong and vigorous executive, cannot admit of doubt, but the rottenness of Roman society was beyond the reach of cure by any human policy.

Abroad, the Roman army continued as before to prove irresistible. About 13 years after the extermination of the northern barbarians, the Cimbri and Teutones, or in 88 B.C. broke out in the far East the first of the 'Mithridatic Wars,' which, like the Samnite, Punic, and Macedonian Wars, were three in number. Begun by Sulla, 88 B.C. they were brought to a successful close by Pompey, 65 B.C. although the general that had really broken the power of Mithridates was Lucullus. The result was the annexation of the sultanate of Pontus, as a new province of the Roman republic. Next year, Pompey marched southward with his army, deposed Antiochus Asiaticus, king of Syria, and transformed his kingdom also into a Roman province, while in the following year (63 B.C.) he reduced to a state of dependence Phœnicia, Cœle-Syria, and Palestine, storming Jerusalem, and, to the horror of the Jews, violating their Holy of Holies.

But what a terrible commentary it is upon these glittering triumphs to remember that during the same year there was hatched at Rome the Conspiracy of Catiline, which, if it had not been crushed by an extraordinary display of decision on the part of the consul Cicero, would have placed at least the city of Rome at the mercy of a crew of aristocratic desperadoes and cut-throats. One thing now becomes particularly noticeable, viz. the paralysis of the senate—that 'governing board' as Mommsen calls it, that had once been the mightiest power in the world. Henceforth the interest as well as the importance of Roman history attaches to individuals, and the senate sinks deeper and deeper into insignificance, until at last it becomes merely the obsequious council of the emperors. The famous coalition of Crassus, Pompey, and Cæsar (known as the *First Triumvirate*), which dates from the year 60 B.C. proves how weak the government and how powerful individuals had become; and the same fact is even more dismally brought out by the lawless and bloody tribunates of Clodius and Milo (58-57 B.C.), when Rome was for a while at the mercy of bravos and gladiators. The campaigns of Cæsar in Gaul (58–50 B.C.), by which the whole of that country was reduced to subjection; his rupture with Pompey; his defiance of the senate; the civil wars; his victory, dictatorship, and assassination; the restoration of the senatorial oligarchy; the Second Triumvirate, composed of Antony, Lepidus, and Octavian; the overthrow of the oligarchy at Philippi; the struggle between Antony and Octavian; the triumph of the latter, and his investment with absolute power for life (29 B.C.), which put an end at least to the civil dissensions that had raged so long (and was therefore so far a blessing to the state), are among the most familiar and picturesque passages in Roman history.

THE ROMAN EMPIRE.

When Augustus had gathered up into himself all the civil and military powers of the state, its political life was at an end; henceforth the voices of the citizens are dumb, and only the rude clamour of the legions or the Prætorians is heard, as emperors rise and fall. It is, indeed, amazing to consider how long brute-force managed to keep under the elements of anarchy and dissolution in the empire; but it must be remembered that it was the East that ruined Rome, and not Rome the East. Even in the worst days of the republic, the Roman administrators of the provinces were acknowledged to be less unjust, ravenous, tyrannical, and cruel than the native princes and sultans; and the servile myriads of Asia Minor and Syria witnessed the deposition of their dynasts without a shadow of regret—sometimes even with a cry of joy. The Romans had, therefore, comparatively little difficulty in retaining and even increasing their eastern conquests, while the superior discipline of their well-trained soldiery enabled them to repel and subdue even the intrepid barbarians of the North, though singly these were probably more gallant men than the rank and file of the imperial legions. But no military prowess, however great, will, beyond a certain time, serve to keep a nation alive that is otherwise moribund; and even Christianity, with all its antiseptic and revivifying influences,

came too late to reanimate the national life of the empire. When Augustus died (14 A.D.), the Roman empire was separated in the north from Germany by the Rhine, but it also included both Holland and Friesland; from about the lake of Constance it ran along the Danube to Lower Mœsia, though the imperial authority was far from being firmly established there. In the east, the boundary-line was, in general, the Euphrates; in the south, Egypt, Libya, and, in fact, the whole of Northern Africa, as far west as Morocco, and as far inland as Fezzan and the Sahara, acknowledged Roman authority. The Roman franchise was extended to transmarine communities, and in the western provinces especially it became quite common. To keep this enormous territory, containing so many different races, quiet, an army of 47 legions and as many cohorts was maintained, most of whom were levied among the newly admitted burgesses of the western provinces. The reigns of Tiberius, Caligula, Claudius, Nero, Galba, Otho, and Vitellius, present little of any moment in a general survey of the external history of the empire, though the chronicle of their lives—those of Galba and Otho, perhaps, excepted—has all the horrible and revolting interest that attaches to records of conspiracy, assassinations, poisonings, massacres, lust, debauchery, and delirious madness. The most notable incident of this period is probably the concentration of the Prætorian Guards in the vicinity of Rome during the reign of Tiberius, which Niebuhr even pronounces 'the most momentous event in the history of the emperors;' and not without reason, for, until their dissolution by Diocletian, they were the real sovereigns of the empire. In Nero's time, Armenia was wrested from the Parthians, and only restored to them on condition of their holding it as a 'fief' of the empire; the Roman authority in England was likewise extended as far north as the Trent; and a great rebellion in Gaul (not, however, against Rome, but only against Nero), headed by Julius Vindex, a noble Aquitanian and a Roman senator, was crushed by T. Virginius Rufus, the commander of the Germanic legions. During the profound peace that the empire had enjoyed everywhere, except on its frontiers—since the usurpation of the imperial authority—its material prosperity had greatly increased. The population was more than doubled; the towns became filled with inhabitants, and the wastes were peopled, wherever, at least, the Publicani, or farmers-general, had not got the land into their rapacious hands; but the immorality of the rich, especially among the females, became yet worse than before, and virtuous men actually preferred concubinage with a slave, to marriage with a free-born Roman lady.

With the accession of Vespasian, a better era commenced, which, if we except the reign of Domitian, continued uninterrupted for a space of 100 years, comprising the reigns, besides those mentioned, of Titus, Nerva, Trajan, Hadrian, Antoninus Pius, and Marcus Aurelius. These were all men of fine and honourable character—some, as, *e.g.* Trajan, Hadrian, and Marcus Aurelius, were really illustrious rulers, worthy of the best days of Rome. Under all of them, the provinces were better governed, the finances better administered, and public morals wonderfully improved. Nothing, indeed, is more clear than that, after the time of Vespasian—that *restaurator rei publicæ*, as he has been justly called—the worst days of Rome (in a moral point of view) were over. Never again did she give way to the horrible sensuality, gluttony, and profligacy of the first century. Bad emperors she had as well as good, but they did not again succeed in corrupting their age. Blood, indeed, was shed freely enough, hostilities on the frontiers were as frequent as ever, and the violence and selfishness of military ambition were things that paganism did not seek, and had not the power, to quell; but the wild abyss of anarchy into which the empire latterly fell is less dreadful than the saturnalia of vice that filled the soul of Juvenal with indignation in the days of Domitian. How far the change was due to the influence of the ever-extending Christian religion, it is impossible to tell; but that Christianity did send a reinvigorating breath of new life through the old decaying body of the state is beyond all dispute, and is written on the very face of the history of the first centuries. The chief military events, from the days of Vespasian to those of Marcus Aurelius, are the final conquest of Britain by Agricola; the final conquest of the Dacian monarchy, the victorious invasion of Parthia and of Northern Arabia, and the conquest of the valley of the Nile as far south as Upper Nubia, by Trajan; the chastisement of the Marcomanni, Quadi, Chatti, &c. by Marcus Aurelius. Hadrian's long rule of 21 years was peaceful, but is memorable as the most splendid era of Roman architecture. The reigns of Commodus, Pertinax, and Didius Julianus were insignificant, except in so far as they shew us the wretched confusion into which the administration of affairs inevitably fell when bad, or hated, or feeble rulers were invested with the purple. Able generals, respectable jurists, honourable senators are not wanting, but their influence is personal and local. The reign of Septimius Severus (193–211 A.D.) is memorable as marking the first real change in the attitude of the emperors towards Christianity. The new religion was beginning to make itself felt in the state; and Severus, who was a Carthaginian, while his wife was a Syrian, may have felt a special interest in a faith that, like themselves, was of Semitic origin. At all events, it was taken under the imperial protection, and began to make rapid way. Caracalla and Elagabalus are perhaps the worst of all the emperors in point of criminality; but the mad brutality of the one and the monstrous debauchery of the other were purely personal affairs, and were regarded with horror by the citizens of the empire. The reign of Alexander Severus is marked by the downfall of the Parthian dynasty of Persian kings, and the rise of the native Sassanidæ, which, as Niebuhr observes, 'was one of the unluckiest things that could have happened to the Roman empire,' for the latter proved far more formidable enemies than the Parthian rulers. After the assassination of Severus (235 A.D.) followed a period of confusion, bloodshed, and general mismanagement. The names of Maximin, Maximus, Balbinus, Gordianus, and Philip recall nothing but wretched quarrels, often ending in assassination. Then followed 'the beginning of the end.' The whole of Europe beyond the Roman frontier—the mysterious North—began to ferment. The Franks

shewed themselves on the Lower Rhine, the Swabians on the Maine; while the Goths burst through Dacia, routed the forces of Decius, and slew the emperor himself at Mount Haemus, crossed the Euxine, and ravaged the whole northern coast of Asia Minor. A little later—during the reigns of Valerian, Gallienus, and the so-called *Thirty Tyrants*—the empire is nothing but a wild distracted chaos, Franks, Alemanni, Goths, and Persians rushing in from their respective quarters, like vultures scenting prey. The Goths swept over the whole of Achaia, pillaging and burning the most famous cities—Athens, Corinth, Argos, &c.; while the Asiatic hordes of Sapor committed even greater havoc in Syria and Asia Minor; and but for the courage and skill of Odenathus, husband of Zenobia, who had built up a strong independent kingdom in the Syrian desert, with Palmyra for its capital, might have permanently possessed themselves of the regions which they merely devastated. With Claudius Gothicus (268–270 A.D.), the fortunes of the empire once more begin to brighten. By him, and his successors Aurelian, Probus, and Carus, the barbarians of the north and north-west, as well as the Persians in the east, were severely chastised. Nay, when Diocletian obtained the purple (284 A.D.), it seemed as if the worst were over, and the empire might still be rescued from destruction; but his division of the empire into East and West, with separate *Augusti* and assistant *Cæsars*—though it sprang from a clear perception of the impossibility of one man administering successfully the affairs of so vast a state—led to those labyrinthine confusions and civil wars, in which figure the names of Maximian, Constantius, Galerius, Maxentius, Maximin, Licinius, and Constantine, and which were only brought to a close by the surpassing genius of the last-mentioned. Under Constantine (324–337 A.D.), as all the world knows, occurred the greatest revolution in Roman history since the birth of Christ, namely, the establishment of Christianity as the religion of the state. He also transferred the seat of government from Rome to Byzantium on the Bosporus, where he founded a new city, and named it after himself. But no sooner was the great statesman dead than the mutinous discords that he had kept under by the vigour of his rule, broke loose; the empire underwent a triple division among his sons; and though Constantius, the youngest, ere long became sole ruler, he failed to display the genius of his father, and in his repeated campaigns against the Persians reaped nothing but disaster and disgrace. But the political fortunes of the empire now possess only a secondary interest; it is the struggles of the Christian sects and the rise of the Catholic Church that mainly attract the attention of the historian. There, at least, we behold the signs of new life—a zeal, enthusiasm, and inward strength of soul that no barbarism could destroy. Christianity came too late to save the ancient civilisation, but it enabled the Roman world to endure three centuries of utter barbarism, and afterwards to recover a portion of the inheritance of culture that it once seemed to have lost for ever. Julian's attempt to revive paganism was a lamentable anachronism, but his efforts, when governor of Gaul under his kinsman Constantius, to repel the incessant incursions of the Franks and Alemanni, displayed a fine valour and generalship, and were crowned with success. The judgment of the poet Prudentius on the Apostate is that of posterity: *Perfidus ille Deo, sed non et perfidus orbi.* But after the death of Julian, the signs of the approaching dissolution of the empire became more unmistakable. Yet the great state was, if we may so speak, loath to die; and again and again in her death-agony, she put forth a momentary strength that amazed her foes, and taught them that even the expiring struggles of a giant were to be feared. Valentinian, Gratian, and Theodosius were rulers worthy of better times. The last-mentioned is even known to history as the 'Great.' But they fought against destiny, and their labour was in vain. Already swarms of ferocious Huns from the east had driven the Goths out of Dacia, where they had long been settled, and forced them to cross the Danube into the Roman territory, where the cruelty and oppression of the imperial officers goaded the refugees into insurrection; and in their fury, they devastated the whole east from the Adriatic to the Euxine. Theodosius indeed subdued and even disarmed them; but he could not prevent them from drawing nearer to the heart of the empire, and already they are found scattered over all Mœsia, Servia, and Northern Illyricum. Hardly was Theodosius dead when they rose again, under their chief, Alaric, against Honorius, emperor of the West. Rome was saved (for the moment) only by the splendid bravery and skill of Stilicho, the imperial general; but after his assassination, the barbarians returned, sacked the city (410 A.D.), and ravaged the peninsula. Three years earlier, hordes of Suevi, Burgundians, Alemanni, Vandals, and Alans burst into Gaul (where the native Celts had long been largely Romanised in language and habits), overran the whole, and then penetrated into Spain, where a Vandal empire was rapidly set up. It is utterly impossible (within our limits) to explain the chaotic imbroglio that followed in the West—the struggles between Visigoths and Vandals in Spain, between Romans and both, between usurpers of the purple and loyal generals in Gaul—the fatal rivalries of those otherwise noble and gifted men—Boniface, governor (*comes*) of Africa, and Ætius, governor of Gaul—which led to the invasion of Africa by Genseric, and its devastation from the Strait of Gibraltar to Carthage (429 A.D.). While such was the state of affairs in the West, things were not a whit better in the East. There the Huns, from mere love of havoc, had reduced vast regions to an utter desert; for nearly 50 years, indeed, the little ferocious demons had rioted in destruction. At last, a trivial quarrel sent them into Gaul; but somewhere in Champagne, they were routed with great slaughter (451 A.D.) by a combined force of Visigoths, Burgundians, Franks, and Roman mercenaries, under Ætius and Theodoric, king of the Goths; and in spite of their successful invasion of Italy in the following year, their strength was permanently broken, and henceforth they play an insignificant part in history. But Ætius, the only man who could have decently propped up the wretched ruin called the Western Empire, was assassinated by his contemptible sovereign Valentinian, whose own outrages led to his murder too; while his widow, Eudoxia, to be revenged on his murderer

and successor, Petronius Maximus, invited Genseric, the 'scourge of God,' over from Africa, and exposed Rome to the horrors of pillage for 14 days. Ricimer, a Sueve, next figures as a sort of governor of the city, and what relics of empire it still possessed; for Gaul, Britain, Spain, Western Africa, and the islands in the Mediterranean, had all been wrested from it. While Majorian—the last able emperor—lived, Ricimer's position was a subordinate one, but, thenceforth, the western emperor merely was an emperor in name—a *roi fainéant*—while the real sovereignty was exercised by this Suevic *Maire au Palais*, who was succeeded in his functions by the Burgundian King Eunobald, and the latter, again, by Orestes, in whose time the final catastrophe happened, when Odoacer, placing himself at the head of the barbarian mercenaries of the empire, overthrew the last, and the most ridiculous, occupant of the throne of the Cæsars (476 A.D.), who, by a curious coincidence, bore the same name as the mythical founder of the city—Romulus.

ROMAN LANGUAGE AND LITERATURE.

The Latin language, as has been already noticed, is a member of the great family commonly called Indo-European, or Aryan (see LANGUAGE). It was primarily developed among the people who inhabited that part of Western Italy which lies between the rivers Tiber and Liris; and though the city of Rome stamped her name on the political institutions of the empire, yet the standard tongue of Italy still continued to be called the *Latin* language, *not* the Roman. As the Roman conquests extended, Latin spread with equal strides over the conquered countries, and was generally used by the educated classes in the greater part of Italy, in France, Spain, Portugal, Germany, and other Roman provinces. But even in Italy itself, and in Latium, there seem to have been two forms of the language, differing very considerably from each other—a polished dialect and a rustic one. It was in the last years of the Republic and the first of the Empire that the polished language reached its highest point of perfection in the writings of Cicero, Horace, Virgil, and others. But by the influx of strangers, by the gradual decline of Roman feelings and Roman spirit, and by the intermixture of the classic forms with the dialects of the provinces, it became corrupted. Thus were formed the modern French, Spanish, Italian, and Portuguese.

For the first five centuries of their existence as a people, the Romans possessed no literature. A kind of rude poetry was cultivated from the earliest times, and was employed in such compositions as the *Hymn of the Fratres Arvales* (dug up at Rome in 1778), in the sacred songs to particular deities, in triumphal poems and ballads, in the *Fescennine Carols*, and other rude attempts to amuse or dupe an illiterate and vulgar audience. But it was not till they came in contact with the Greeks that the Romans began to develop their faculties in genuine literary compositions; and then, as was natural, their first productions were translations from, or imitations of, Greek writers. Livius Andronicus and Cneius Nævius (240 B.C.), the earliest Roman poets, seem to have been copyists of the Greek; as were also Fabius Pictor and Cincius Alimentus, the first Roman annalists, and who lived during the second Punic War. Between the second Punic War, however (202 B.C.), and the dictatorship of Sulla (81 B.C.), there arose a number of writers of no ordinary power, in whose hands the Latin language acquired force and flexibility, and whose works illustrate the native character of the Romans. Among these should be mentioned Ennius, the father of Roman poetry; Plautus, his contemporary, a man of rich comic genius; the elder Cato, the first prose writer of note; and Terentius, or Terence, a comic poet of a less rude style than Plautus, and whose first play was acted in the year 165 B.C.

The period from the dictatorship of Sulla (81 B.C.) to the death of Augustus (14 A.D.) is the Golden Age of Roman literature. Then flourished Cicero, undoubtedly the greatest as well as the most voluminous of Roman prose authors; Cæsar, whose brief *Commentaries* on his own campaigns are among the simplest and most compact of historical writings; his friend Sallust (born 68 B.C.), who has left us spirited accounts of the Jugurthine War and the conspiracy of Catiline; the didactic poet, Lucretius; his contemporary, Catullus, whose lyrical effusions are among the sweetest and most truly poetic things in the Latin language; and, not to mention a host of others, Virgil and Horace, the two chief classic poets of the Augustan age—the former the author of the celebrated epic poem, the *Æneid*, and if not an original, at least a graceful and pathetic writer; and the latter a sagacious and good-humoured observer of mankind, and the author of many odes, satires, and epistles. Somewhat later were Livy, the great historian of Rome, in 142 books, only thirty-five of which, however, have reached us; and Ovid, who ranks second to none of the Roman poets for ease and elegance.

Under the emperors, the Latin authors became more and more numerous, springing up in all parts of the Empire, and cultivating all departments. Out of the long list of authors intervening between the reign of Tiberius and that of Commodus, we may mention the poets Lucan and Silius Italicus; Martial, the writer of epigrams; Seneca, the Stoic philosopher, put to death by Nero; Quintilian, the rhetorician; Pliny, the celebrated natural historian, who was killed 79 A.D. by the great eruption from Vesuvius which destroyed the city of Herculaneum; Tacitus, the historian of the declining age of Rome; and Juvenal, whose satires reveal too horribly the immorality of the society in the midst of which he lived.

The host of petty rhetoricians, poets, &c. both Greek and Roman, who lived in the various cities of the Empire in the second, third, and fourth centuries, may be passed over. During these centuries, Christianity was overspreading the Empire, and drinking up all the intellect and enthusiasm of the various nations; and nothing more strikingly marks the decrepitude of polytheism at that time, as compared with the freshness of the new religion, than the contrast between the miserable verse-making, which seemed to be the only literary occupation practised in polytheistic circles, and the earnest and powerful writings of the Christian Fathers on those great theological topics which concerned the Divine nature and the everlasting destinies of man.

HISTORY OF THE MIDDLE AGES.

INTRODUCTION.

DURING the fifth century of our era, a succession of irruptions of tribes from the north overthrew the western portion of the Roman Empire, and shattered to pieces the organisation of its society. The mingling of these barbarians, as they were called, with the Roman or Romanised inhabitants of the various countries, produced for a time a chaotic confusion ; but as the amalgamation proceeded, a reorganisation of society under new forms began to shew itself, and those nationalities gradually emerged which, with greater or less modification, have continued to the present day. It is this reconstruction of society out of the newly infused barbaric elements, together with the fragments of the old civilisation, that forms the transition from the ancient world to the modern ; and the period during which the transition took place is called the 'Middle Ages,' the earlier and more chaotic portion being known as the 'Dark Ages.' It may conveniently be considered as extending from the dethronement of Romulus Augustulus (476 A.D.) to the end of the fifteenth century—the period of the 'revival of learning,' as it is called.

Society is always in a state of transition ; England under Victoria is very different from England under George I. But in such cases as this, the change is one of continuous growth ; whereas, in the transition from ancient civilisation to modern, there was a violent disruption of the continuity ; there was a disintegration and then a reorganisation. To understand rightly the nature of this mighty change, we require to take a brief survey of the state of the world immediately preceding it.

On the death of the Emperor Theodosius (395 A.D.), the Roman Empire was finally divided into two parts—the Latin Empire, or Empire of the West, the capital of which was Rome ; and the Greek Empire, or Empire of the East, the capital of which was Constantinople. The Latin Empire consisted of six *dioceses*—Italy, Gaul, Britain, Spain, Western Illyricum, and Africa ; the Greek Empire consisted of seven dioceses—the East, Egypt, Asia, Pontus, Thrace, Macedonia, and Dacia. These dioceses were again divided into provinces, and the administration of government was carried on by a multitude of functionaries in various grades of subordination—Prefects, Vicars, Consulars, &c. Though subject to one plan of civil government, the two empires presented many points of contrast. In the West, the Latin genius and habits predominated ; in the East, Greek habits of thought and feeling were more apparent. The Latin language, indeed, was the legal or official language over both empires ; but in the East, the general medium of communication, and the sole literary language, was the Greek.

But however different in physiognomy, dress, manners, and language the inhabitants of the various dioceses and provinces might be, society was everywhere, throughout both empires, divided into four grades or classes—the senatorial class ; the curiales or municipals ; the common people ; and the slaves. The *senators* formed a sort of aristocracy or peerage, with titles denoting various grades of nobility (*Nobilissimi*, *Illustres*, &c.). The *curiales* or *municipals* comprised those inhabitants of towns possessing landed property of a certain amount ; on them devolved the functions of magistracy in the various towns. The *common people* was composed of all freemen ranking below the curiales ; the greater portion consisted of free artisans. The *slaves* were a numerous class, and were either domestic servants in the more wealthy households, or rural slaves employed in agriculture.

Towards the close of the fourth century, the society of the Roman world was universally tending to corruption and decrepitude. Among the causes of this decay, the two principal seem to have been, the systematic oppression of the curiales by bad laws, and the universal prevalence of slave-labour. The curiales were compelled to undertake municipal office, and all deficiencies of revenue had to be made good by the general body ; nor did the laws permit them to escape from their hated position. The consequence was, that this most important section in every community—the middle or moderately wealthy class—became almost extinct. From the operation of the two causes, agriculture had sunk into the most miserable condition ; whole districts became deserted ; and at the beginning of the fifth century, there were lying untilled in Campagna the Happy, the most fertile district of the Roman domain, as many as 330,000 acres.

Amid the universal decay, however, with which the fabric of Roman society was thus afflicted, there was one element of vigorous and energetic life : this was the element of Christian ecclesiastical rule, independent of the course of civil procedure, and yet powerfully influencing it. The introduction and spread of Christianity gave an entirely new character to the ancient communities within the Roman Empire. The old paganisms, with their cruel rites, disappeared ; and, coming in their place, the beneficent doctrines of the Gospel, besides morally improving, stimulated the intellectual energies of mankind. As the accompaniment of this change, there had sprung up a new system of social organisation—that of the Christian Church, which was extended over the empire under the special administration of bishops and of pastors or clergy.

Beyond the pale of the organised society of the Roman world lay a great barbaric society, divided into two parts—the German or Teutonic half, geographically adjoining the Western Empire ; and the Slavonic or Scythian half, adjoining the Eastern Empire. The German barbarians were divided into a number of nations—Goths, Burgundians, Alemanni, Vandals, Franks, Angles,

Saxons, &c. The Slavonians, the ancestors of the modern Russians, Poles, and others, had their seats further east, and took less share in the events of medieval history. In the destruction which preceded the resurrection of modern European society, it was chiefly the western or Latin half of the Roman Empire that was involved, and the destruction was effected by the irruption chiefly of German nations, among whom the Goths were most prominent. The Gothic tribes were located, at the period when the movement began, in the extensive tract between the Vistula, the Danube, the Black Sea, and the Don, and were divided into Visigoths or Western Goths, and Ostrogoths or Eastern Goths.

The determining cause of the precipitation of the German races on the Latin Empire was, it is well known, the sudden invasion of Europe (375 A.D.) by the Mongolian or Kalmuck nation of the Huns. Subduing the Slavonic region of Europe, and establishing there a Hunnish Empire, which superseded that of its previous conquerors the Goths, these fearful Asiatic invaders produced a violent agitation among the Germanic peoples, and pressed them westward, as it were, in a mass —Goths, Vandals, Burgundians, Suevi, Alemanni, Franks, Angles, and Saxons, all together. The detailed narration of these agitations produced in Europe by the Huns, and of the consequent irruptions, protracted over a whole century, of the Germanic nations, sometimes in confederacy, and sometimes singly, into the provinces of the Western Empire, belongs to Roman history. It will be sufficient here to mention generally that the diocese of Gaul was overrun chiefly by Visigoths, Burgundians, and Franks; Spain, by Vandals, Suevi, and Visigoths; Africa, by Vandals crossing over from Spain; in Italy, successive invasions had left a deposit among the feeble native Italians, of Visigoths, Vandals, Huns, &c.; Britain, abandoned by its Roman garrison as early as 410, had become a prey to the Angles and Saxons.

As soon as this intermixture of the two societies —the Roman or civilised, and the Germanic or barbarian—had taken place, they began to act upon each other. Modern society, in short, is the perfected result of the incorporation of Roman with barbaric society; and it derives ingredients from both. From the barbarians were derived the love of personal liberty, and the sense of individual independence. From the Romans, on the other hand, were derived the forms of a regular and long-established civilisation. But more efficient still, as a means of acting on the barbarian conquerors, was the great institute of the Christian Church. No sooner were the invasions over, than the Roman clergy — on whom, in the state of civil disorganisation then prevailing, the duty of conducting negotiations between the conquered and the conquerors almost wholly devolved—exerted themselves to the utmost to obtain influence over the rude minds of the new lords of the soil. Their efforts were very successful. The barbarians regarded the clergy of their vassals with superstitious awe, and soon became enthusiastic converts.

The history of the reconstruction of civil society in the West may be divided into three periods—the Frankish Period, the Feudal Period, and the Period of National Monarchies. Our space prevents anything beyond a bare outline of the leading events.

I. THE FRANKISH PERIOD: 410–888 A.D.

The Franks, the Lombards, the Arabs, and the Greeks.

The Franks, a confederation of Low-German tribes, originally inhabiting the countries between the Lower Rhine and the Elbe, had, as early as 440, made conquests on the left bank of the Rhine. In 486 their leader, Clovis, or Ludwig (Louis)—who had been left by his father in possession of Tournay, in Belgium, and who was the true type of a young German warrior, brave, ardent, ferocious, and with long flaxen hair flowing down his back—made himself master of all Roman Gaul by one great victory gained over the Gallo-Romans at Soissons. He was then but nineteen years of age, but he seems to have already conceived the design of a Frankish monarchy. As a step to this end, though still a pagan himself, he obtained in marriage the Christian princess Clotilda, of the royal house of the Burgundians (493). Clotilda did her best to convert her heathen husband to her own faith. But though he yielded so far as to let the sons he had by her be baptised, he could not be persuaded to abandon his own gods. At length, while opposing (496) a host of new German adventurers, at a moment when the battle seemed to be going against him, Clovis vowed that if he obtained the victory, he would give up his idols, and worship the God of Clotilda. Accordingly, having repelled and subdued the invaders, he made open profession of the Christian faith, and caused himself to be publicly baptised, along with 3000 of his Frankish warriors, by Remigius, archbishop of Rheims.

After a series of wars and intrigues, Clovis overcame the Burgundians, who occupied the south-east of Gaul, and the Visigoths, who had established themselves in the south, and secured the supremacy of Gaul. In the year 507, he removed his capital from Soissons to Paris; and from that year may be dated the commencement of the Frankish monarchy.

The conquering Franks, comparatively a mere handful, dispersing themselves over the country, and seizing the best lands, constituted a class of landed proprietors. The Gallo-Romans were still permitted to be governed by the Roman laws; the Franks, Burgundians, and Visigoths had each their own code.

On the death of Clovis (511), his dominions were divided among his four sons; but after fifty years of quarrels and wars, the Frank Empire was again united (558) under Clotaire. A like division, followed by wars, poisonings, and other violent means, ending again in reunion, took place on the death of Clotaire, and was continually repeated throughout the bewildering history of the first Frankish dynasty—called the *Merovingian kings*, after Merowig, the supposed grandfather of Clovis. In the meantime, each monarch was becoming more cruel and debauched, and at the same time more weak and imbecile than his predecessor; and the real authority came to be wielded by an officer styled Mayor of the Palace, who was a sort of leader of the aristocracy attached to the court. At last, one of these, Pepin d'Heristal, attained such power as to be the virtual king; and the

nominal monarchs are styled in history the Rois Fainéans or 'Sluggard Kings.' Pepin was succeeded (714) in power by his son Charles, surnamed Martel. Charles's son, Pepin le Bref ('the Short'), put an end to the anomalous rule of the mayors of the palace, by shutting the puppet-king up in a monastery, and causing himself to be formally invested with the title of 'King of the Franks' (752). The dynasty founded by Pepin is known as that of the *Carlovingian kings.*

Before proceeding to sketch the occurrences that took place under that dynasty, it will be necessary to cast a retrospective glance at certain important events that had in the meantime altered the face of other parts of the conquered Roman world.

Lombard Invasion of Italy.—The Empire of the West had been extinguished in 476 by the Visigoths, who had left their settlements on the Danube, and penetrated into Italy as early as the beginning of the fourth century. Odoacer, who deposed the last emperor, had continued since that time to rule Italy, pretending, however, to derive his authority from the emperor of the East. In the meantime, the Ostrogoths had penetrated from the northern borders of the Black Sea, and, under their young hero-king, Theoderic or Dietrich, had established an Ostrogothic kingdom between the Black Sea and the Adriatic. Instigated by the Greek emperor Zeno, who wished to get rid of so powerful a neighbour, Theoderic now invaded Italy, took Ravenna, Odoacer's capital, put that monarch to death, and became himself king of Italy (493). Though illiterate, he was a man of large and enlightened views, and his conduct, during his long reign of thirty-three years, earned for him the name of 'Great.' But under his worthless successors, Italy fell into anarchy, and the Greek emperor sending his great general Belisarius, and then Narses, succeeded in wresting the country from its Gothic masters, and annexing it to the Empire of the East (553). Eighteen years before, Africa had shared the same fate, having been wrested from the Vandals by Belisarius. Thus, three of the ancient dioceses of the Latin Empire—Italy, Western Illyricum, and Africa—were incorporated with the Eastern Empire; while Gaul, Spain, and Britain remained in the hands of the barbarians.

It was while Italy was thus a dependency of Constantinople, and governed by an exarch residing at Ravenna, that it was invaded by the Lombards,* a German nation, settled since 527 in Pannonia on the Danube. Under their king Alboin, they took possession (568), with little resistance, of the northern part of the peninsula, and made Pavia their capital. The dominion they established was of the nature of a confederacy of dukedoms presided over by an elective sovereign. The centre and south of Italy remained subject to the exarchs of Ravenna; but the Lombards continued gradually to extend their sway southward at the expense of the exarchate. Among the Lombard kings may be mentioned Rothari (638–654), who caused a code of laws for Lombardy to be composed; and Luitprand (713–744), the most illustrious of all, eminent both in peace and war, and the friend of Charles Martel.

* Lango-bards, which may mean either Long-beards, or having long battle-axes; in the latter case the root, *bard* or *bart*, is the same as appears in hal*bert* and *part*isan.

The Arabic Conquests.—Arabia had never formed part of the Roman Empire, and though the Arabs were and are in every way a fine race of men, they had, about six centuries after Christ, sunk into a comparatively degraded condition. Suddenly, however, a man appeared, who was destined to restore the Arabic name, and to lead the Arabs into a career of unexampled glory. This was the famous Mahomet, or Mohammed Ibn Abdallah. Born at Mecca in 570 or 571, of the highest branch of the noble tribe of Koreish, to whom belonged the government of Mecca, and the guardianship of the *Kaaba*, or central temple of all Arabian worship, Mohammed lived to the age of forty without exciting much remark. It was in the year 613, that, at a meeting of his kinsmen, the chiefs of Mecca, he made the startling announcement that he had received a divine commission to reform the faith and practice of the whole Arabian nation. His account was, that, three years before, while he was holding the fast of the sacred Arabic month Ramadhan, alone in the desert, an angel had appeared to him, and told him that God had chosen him to be the prophet of the Arabs. This miraculous call he had kept secret at first; but gradually convinced of its genuineness, he had at length communicated it to his most intimate friends. His wife, Kadijah, had been his first convert; his relatives, Ali and Abubeker, had followed; and now he called upon all his other kinsmen and friends to acknowledge his authority, forsake their idols and their habits of unbelief and profligacy, and worship the one only true God, who had made the heavens and the earth, and who would judge the world at the last day.

The kinsmen of Mohammed laughed at him, and the Meccans denounced him as either a madman or an impostor. But he persevered in his design, and daily preached to all who would hear him the doctrines of a future life and of the unity of God. These doctrines, written down from time to time, were collectively known as the Koran—that is, the 'Reading,' and the religion itself was called *Islam*—that is, 'Resignation' or 'Submission,' *i.e.* to the will of God. (See MOHAMMEDANISM, HINDUISM, &c.)

Islam had made but little progress in Mecca, when Mohammed was obliged to flee from the city to save his life. He betook himself, with his disciples, to what is now Medina. The date of this flight, or *hejira*, as the Arabians call it—the 16th of July 622—has ever since been recognised in all Mohammedan countries as the commencement of the Mohammedan era.

At Medina, Mohammed was received with open arms. He was invested with the supreme command; and adapting his conduct to his new position, he began to propagate his religion with the sword. Tribe after tribe was subdued; and before the lapse of ten years, the whole peninsula acknowledged the sovereignty of Mohammed, and could boast of an unmixed population of *Moslems* or True Believers. Mohammed was preparing to disseminate Islam beyond the bounds of Arabia, when he was cut off by a fever at Medina (632).

The impulse communicated to the Arabian race by the enthusiasm of Mohammed did not cease with his death. The whole nation had been roused to an unexampled pitch of religious zeal, and were eager to continue the work which

Mohammed had begun. Accordingly, the reigns of the *Califs*—as the successors of Mohammed in the conjunct spiritual and temporal sovereignty of Arabia were called—were one long series of invasions, wars, and conquests, undertaken for the express purpose of adding new countries to the Mohammedan Empire. In the reign of Abubeker, the first of the califs, Syria and Mesopotamia were subdued by Arabic armies; and under his successor, Omar, Egypt was conquered, and the northern coast of Africa overrun as far as Tripoli. By these conquests, the limits of the Empire of the East were considerably curtailed. Nor was it only westward that the Arabians extended their victories; after several invasions, Persia was obliged to succumb. The seat of the califate was first at Kufa, on the Euphrates; but under the second dynasty, or *Ommiade* califs, it was transferred to Damascus.

The Mohammedan Empire attained its fullest extent in the reign of Walid I. the second of the Ommiade califs (705-715). Tarik ben Zaid, a Mohammedan leader in Africa, crossed over into Spain, landing at a spot afterwards named *Jibel Tarik*, or the 'Mountain of Tarik,' a name which has been corrupted by usage into *Gibraltar*. Tarik defeated the Visigothic king, Roderic, in a battle fought at Xeres de la Frontera, on the 19th of July 711, and thus established the dominion of the Arabs over Murcia, Granada, Andalucia, and other parts of Southern Spain. Meanwhile, other emirs of the calif Walid were extending his power in Asia. Bokhara, Turkestan, and other countries lying east of the Caspian, were rapidly subdued; and under one bold leader, the Arabians even penetrated into Northern India. In the califate of Soliman, the successor of Walid (715-717), the Greek Empire was still further weakened by the seizure of the greater portion of Asia Minor by the Arabs, who even proceeded to lay siege to Constantinople. The incompetence, however, of Soliman and his successors, Yezid II. and Hesham (720-743), arrested the progress of the Arabic conquests in the East.

In Spain, the emirs ('commanders') soon extended their dominion over the whole peninsula with the exception of the mountainous districts in the north, where a Gothic chieftain, Pelayo, was able to found the little Christian kingdom of the Asturias. The Arabs of Spain, or, as they now began to be called, the *Saracens* ('Eastern people'), next ventured on an incursion into Gaul (718); and in a few years their language and their religion prevailed over a large tract to the north of the Pyrenees, and 'the vineyards of Gascony and the city of Bordeaux were possessed by the sovereign of Damascus and Samarcand.' Even these limits, however, did not satisfy them. In the year 728, Abd-el-rahman, a Saracen of great abilities, was appointed by the calif to the emirship of Spain. Full of the conquering spirit of his race, he resolved that not only France, but all Europe, should be included within the sway of the Moslems. Accordingly, invading France (732) at the head of the largest Mohammedan army that had ever been assembled in Europe, he pushed on, carrying all before him, as far as the river Loire. Between Tours and Poitiers, however, his career was arrested by Charles Martel, Mayor of the Palace for the Frankish Empire, who in a bloody battle defeated and slew him in October 732.

Shortly after these events, a new dynasty (the Abbasides) seized on the califate, and the Saracens of Spain espousing the cause of the old dynasty, the Mohammedan power split into two—the Arabic Empire proper, stretching from India to the Atlantic shores of Africa; and the kingdom of Spain. The Abbaside calif, Al-mansur, transferred the capital of his empire to Bagdad, on the Tigris (753).

The Arabic invasions which we have thus narrated are not to be regarded as a mere series of violent or barbaric exploits that produced no good effects. No sooner were the first conquests over, than the believers in the Koran began to direct their energies towards the cultivation of the arts and sciences. The accession of the Abbasides to the califate was the epoch of a splendid intellectual outburst among the Arabs. Law, astronomy, mathematics, medicine, and philosophy, were studied with zeal at Bagdad, and in other cities of the califate; books were multiplied by native authors on all these subjects; and the best works in the Greek language were translated into Arabic. Architecture, and the arts of polished and luxurious life, had likewise their devotees; and the fertility of the Arabic mind displayed itself in numerous manufactures and inventions. Nor were the Arabs of Spain behind their brethren of the East in these respects: they not only embellished the land they had subdued by noble architectural edifices, but also introduced into it new trees, new fruits, and new processes in the arts. Cordova became a seat of Arabic learning, and a place celebrated for civilised magnificence. In short, were we to compare the Arabic invaders of the seventh and eighth centuries with our Celtic or Teutonic ancestors, we should certainly be obliged to assign the palm of superior culture to the former. It was the 'Dark Ages' everywhere in Europe, except in Spain.

The Franks—resumed.—The most important event in the reign of Pepin (752-768) was his laying the foundation of the temporal power of the papacy. The pope and the Lombards had quarrelled, and the former sought the help of Pepin, king of the Franks, the policy of whose family had always been to favour the interests of the church. Pepin responded to the call. Twice he invaded Italy, defeated Astolphus, and compelled the Lombards to cede all the territories they had taken in Central Italy. These territories were given up by Pepin, not to the Byzantine emperors, but to the popes themselves, or, according to the formal expression of the treaty, to 'the Holy Church of God and the Roman Republic.' The original deed by which the Frankish king thus conveyed over to the popes of Rome so large a portion of the lands of Central Italy has, unfortunately, been lost; but the dotation itself (756) is recognised as one of the most important transactions in the history of the modern world. It laid the foundation of the temporal power of the papacy.

Pepin's son and successor, Charlemagne (Ger. Karl der Grosse), was the most illustrious monarch of the middle ages, and in every respect a great man. In activity, in a craving desire to be ever doing something, he resembled Napoleon. From the affairs of his own household to the state of the markets or the monasteries in the most distant parts of his empire, he made himself acquainted with everything, intermeddled with everything.

He wearied out all about him by his astonishing powers of invention and labour, and the amount of work he exacted from them. His favourite place of residence was Aix-la-Chapelle, in the present Prussian province of the Lower Rhine. Wherever he was, he was usually surrounded by learned churchmen, whom he drew to his court from all quarters, and with whom he delighted to hold conversations on literary and other subjects. The man in whom he placed most confidence, and who, during the greater part of his reign, acted as his most intimate friend and adviser, was Alcuin, an Englishman by birth, and perhaps the most cultivated scholar of his time. Charlemagne gave him three abbeys, and employed him as a kind of prime minister, in all matters connected with the church or with the education of his subjects.

In the course of Charles's long reign of forty-six years, he carried out no less than fifty-three expeditions, most of which he commanded in person. Eighteen of these were against the fierce pagan nations of Germany, especially the Saxons, who, after much bloodshed, and being repeatedly baptised by thousands at Charles's order, were at last reduced to submission and the profession of Christianity. Charles continued to act, as his father had done, as the patron and defender of the popes against the Lombards, who were again assailing the Roman territory. Called upon by Pope Adrian I. he crossed the Alps (773), defeated the king of the Lombards, shut him up in a monastery, and assumed himself the Lombard crown. At the same time, he confirmed the donation of his father, Pepin, whereby all those portions of Central Italy that had belonged to the Greek exarchate, as well as certain towns and cities of the Lombards, were bestowed on the papal see; in return for which act of generosity, the pope acknowledged him as Patrician of Rome, and Suzerain of Italy, with the right of ratifying the elections of the popes. Thus, almost at the beginning of his reign, Charles found himself master of Italy. The Lombards, however, especially those of the duchy of Benevento, continued to give him some trouble; and it required several subsequent expeditions to subdue them.

Charlemagne led or sent seven expeditions against the Arabs of Spain, adding portions of Northern Spain to the Frankish Empire. In returning from the first of these expeditions (778), his army was defeated by the Saracens and Basques in the famous battle of Roncesvalles, the subject of so many legends.

The general result of all the wars and conquests which we have described was, that by the year 800, Charlemagne, who had inherited from his father, Pepin, a kingdom scarcely equal to all Gaul, found himself lord of an empire as large as the ancient Roman Empire of the West, and extending from the Ebro, in Spain, to the Oder and the Baltic, and from the coasts of Brittany to the Elbe and the Save. That year may be selected as the climax of his reign, as in it he visited Italy in great state, and was solemnly crowned 'Emperor of the West,' by Pope Leo III., the successor of Adrian I., with the title of 'Carolus I., Cæsar Augustus.' His power being thus confirmed, all the world hastened to pay him homage. The Arabian calif himself, the celebrated Haroun al Raschid, the fifth of the Abbaside dynasty, exchanged courtesies with his great Christian brother of the West, sending him, among other presents, an ape, an elephant, and a curious clock which struck the hours.

Up to the time of Charlemagne, the Romans had in a vague way regarded the Greek emperor as the true monarch of Rome; but when Constantine VI. was deposed by his mother Irene, who put out the eyes of her son, and reigned in his stead, it was thought a good opportunity to throw off the authority of the Eastern ruler, and the greatness, as well as the services of Charlemagne pointed him out as the right man for the vacant imperial dignity. Freeman, in his *General Sketch of European History*, points out that Charlemagne was always considered, in his own time, the successor of Constantine.

The great monarch died at Aix-la-Chapelle, in January 814. His son and successor, Louis le Débonnaire ('the Gentle'), was unable to manage the vast empire, and began to partition it among his sons during his lifetime. This led to quarrels and civil war; and after Louis's death (840), his three surviving sons came to a formal agreement at Verdun (843), and divided the empire among them. Lothaire received the kingdom of Italy, including Switzerland, Provence, and Lorraine; Louis the German, the kingdom of Germany; and Charles, styled the Bald, the kingdom of France. Charles is thus the first king of modern France; his ancestors having been kings of 'the Franks.'

But the process of dismemberment did not stop here; from the incapacity of the sovereigns, the local dukes and chieftains became virtually independent; and in the course of forty years after the treaty of Verdun, each of the three kingdoms was broken up into fragmentary states, having little or no connection with one another. Charles the Fat, the son of Louis the German, contrived, amid the universal anarchy, to get possession of the sovereignty of France, in addition to that of Germany and Italy (884), and thus momentarily reunited the empire of Charlemagne. But he was soon deposed, and died (887), and with him ended the line of the Carlovingian emperors.

Church History.

Origin of the Monastic System—Separation of the Greek and Latin Churches—Rise of the Papacy.—The practice of religious retirement was of great antiquity, being known among the heathen and the Jews. Among Christians in the East, it had become a prominent usage as early as the middle of the third century, having spread first from Egypt. To regulate the abuses of the practice, St Basil, bishop of Cæsarea, established a model monastery in Pontus, and framed a set of regulations for the government of such institutions in general. This code, or Rule of St Basil, was extensively adopted throughout the East, and imparted to monastic life the form in which it was introduced into the West. At first, monks were generally laymen, but in time they all belonged to the priestly order, and came under vows of perpetual chastity and of submission to the higher ecclesiastical authorities. The monastic system received its most perfect organisation from St Benedict, an Italian who formed a monastery on a new and severe rule. In addition to the usual monastic vows, this rule included that of unquestioning obedience to superiors, and the novel

feature of industrious occupation. Agriculture was especially recommended, and in the middle ages the Benedictine monks were the best husbandmen in Europe. Before the death of St Benedict (543), his Rule had found its way into every part of Europe. The clergy now went in crowds into the monasteries, and monks took holy orders in the church. Clergymen who thus lived under *Rule* in a monastery were called the *regular* clergy; while bishops and parish priests were distinguished as the *secular* clergy, from their living in the world.

The Eastern and Western, or, as they are also called, the Greek and Latin Churches, began early to manifest different tendencies. The main doctrines held by both as orthodox were the same; but in the West a belief in purgatory seems to have prevailed as early as the sixth century, whereas the Greek Church never admitted it. The Latin Church began also to enforce the celibacy of the clergy, while the Greek permitted them to marry; and in the West the use of carved images was encouraged as an aid to devotion, a practice which the Greek Church utterly condemned.

There was a still greater difference in their external relations. The Greek Church continued to retain its original connection with and subjection to the civil power. But the disruption of all civil authority in the Western Empire threw an immense sway into the hands of the Latin clergy. The individual bishops at first exercised this sway without control. But in the end, the whole came to be organised into a system, the centre of which was the Roman pontiff. On the overthrow of the Western Empire, the very position of the bishop of Rome, as the first personage in what had been the capital of the world, would naturally invest him with great influence, and make him be looked up to for counsel and direction. The moral power thus arising was soon converted into a right, and a theory of supremacy was set up, claiming for the bishops of Rome the 'power of the keys,' as the successors of St Peter. It took centuries, however, to turn this theory into a fact; and it was not till the papacy of Nicholas I. (858-868) that the Frankish clergy submitted to the authority of the Romish see. The universal primacy of the Roman pontiffs in the West was from that date established. About the same time, the Latin and Greek churches came to a decided rupture. Photius, patriarch of Constantinople, had annexed the newly converted Bulgarians to his patriarchate. Nicholas claimed them as belonging to the Roman see, and excommunicated Photius (862); and Photius retaliated by excommunicating the pope, and declaring the creed of the Western Church to be in some points heretical.

II. THE FEUDAL PERIOD: 888–1300 A.D.

History of the West.

During the ninth and tenth centuries, there occurred the irruption of two invading races—the Magyars or Hungarians, and the Normans. The Magyars, a people of the same family of nations as the Turks, leaving their native region to the north of the Caspian, moved gradually westward till, about the year 889, under a chief of the name of Arpad, they settled on the Danube, and subjugating the Slavonians round about, formed the kingdom of Hungary—a kingdom the ruling caste of which was the Magyar invaders, and the subject caste the native Slavonians. From that time forward, the Hungarians were a formidable power in Europe.

The Normans.—The Scandinavians had continued in their primitive condition, under a multitude of independent and equal chiefs, until Harold Haarfager, subduing the neighbouring petty kings, succeeded in making himself monarch of all Norway (870–895). By a similar process, about the same time, Sweden and Denmark were formed into kingdoms. Many of the dispossessed chiefs, rather than submit to the new rule, took to a life of roving adventure. A band of Swedes, led by Ruric, penetrated into the very heart of Russia, and there established the Grand Dukedom of Muscovy, which constituted the beginning of the power of Russia. The Norwegian and Danish adventurers, known as Vikings, betook themselves to their ships, and became the terror of the populations along the coasts of Western Europe. Some of them settled in Iceland; others conquered the Shetland and Orkney Islands, the Isle of Man, and parts of the coasts of England, Scotland, and Ireland; and even ravaged the coasts of France and the Mediterranean, where they were known as *Normans* or 'Northmen.' One of these bands, under their chief, Rolf or Rollo, established themselves (898) at Rouen, on the Seine, and compelled (912) the French king to cede to Rollo, as a dukedom, the territory thenceforward called Normandy. Rollo married the daughter of the French king, and embraced the Christian religion; and his companions, intermarrying also with the French, became the progenitors of the French-Norman race.

Adverting now to the several states into which Europe became divided on the final dissolution of the empire of Charlemagne, the histories of the more important during the tenth and eleventh centuries may be thus briefly sketched:

Spain.—The Ommiade califs of Spain continued their independent rule in the south of that peninsula from 749 till 1027, when the califate was extinguished in revolution; and the various Saracen viceroys set up a number of petty kingdoms at Cordova, Seville, Toledo, Lisbon, Saragossa, &c. In the north, again, the Christian kingdom of Asturias, Oviedo, or Leon, increased in power as the power of the califs waned. Another Christian kingdom, also, that of Navarre, which had been part of the empire of Charlemagne, arose to be the ally and rival of Leon; to which was added (1035) a third—Aragon.

France.—This kingdom was split up into a number of fiefs, the holders of which were almost independent princes. There was still a succession of kings, of the blood of Charlemagne, but the allegiance paid them by the powerful dukes of Normandy, Francia, Burgundy, &c. was only nominal. The accession of a new dynasty in the person of Hugh Capet, Duke of Francia (987), gave greater strength to the crown, the real root of national unity.

Germany.—The 'states' or noble houses in Germany acquired from the first a more regular and independent authority than in other feudal countries; accordingly, on the deposition of

Charles the Fat, the nobles asserted their right to *elect* each successive sovereign. The first chosen was Arnulph (887-899), Duke of Carinthia, who was thus but one German noble selected by the rest to wear the German crown. The early German emperors were incessantly occupied in confirming their power within Germany, and in extending the empire at the expense of the contiguous countries. Henry I. of the House of Saxony, elected in 918, annexed Lorraine to Germany, and extended his dominion at the expense of the Slavonians, from the Elbe to the Oder. His son, Otho I. 'the Great' (936-973), made the Danes and Bohemians submit to the empire, and renounce paganism; but his greatest achievement was the reduction of Italy to a fief of the German Empire. He assumed the crown of Italy at Milan (961), and visiting Rome, revived in his own favour the dignity of Emperor of the West, and was consecrated as such by the pope (962). This pope having become a scandal to Europe by his licentiousness, Otho caused him to be deposed, and another to be elected; and claimed for the emperors the right of veto on all future appointments. From this time, every German emperor contined to receive a triple coronation—as king of Germany, as emperor of the West, and as king of Rome. After three more emperors of the Saxon line, the states chose Conrad II. (1024-1039), of the house of Franconia.

We can only afford space to note in passing the rise of the Norman power in Sicily; the conversion of the Hungarians to Christianity, under their monarch Stephen, in the year 1000; the establishment of a Polish Christian kingdom about the same time; and above all, the introduction of the new religion into Russia (988), through the marriage of Vladimir the Great with a Byzantine princess.

Scandinavian Kingdoms.—Sweyn, king of Denmark (1000), renounced the Christianity and allegiance imposed upon his father by Otho of Germany, and extended his sway over Norway and England; this sway was retained by his son, Canute (1014), who reintroduced Christianity into Denmark. On the death of Hardicanute (1042), England threw off the Danish yoke, as did also Norway. Norway and Sweden were both Christianised about 1000.

The history of the *British Islands* will be given in succeeding numbers.

The Feudal System and the Church.—Amid this multiplicity of independent petty states into which Europe was parcelled out, there were two grand influences at work, producing social resemblances, and also a feeling of mutual connection; these were the feudal system and the church. The Feudal System was in existence in a rudimentary condition among the Franks as early as the time of Clovis, and also among the Lombards in Italy. But it soon acquired a more exact and legal form; and by the eleventh century, had spread into all the countries to which the German conquests extended, and even to others. Every free German who had assisted his chief in conquering the country received, as his share of the spoil, a particular estate, which was called his *allodium* or *freehold*—this estate being absolutely his own property. The holders of such allods were subject to the king only in this respect, that they were amenable to the general laws established for the government of the state. But as it so happened that the king, who in the general division of the land received, of course, a very large domain as *his* share, did not usually keep all this land to be farmed by himself as one great estate, but gave portions of it away to his favourites, on certain conditions mutually agreed upon; and as, in a similar manner, the holders of extensive allods gave away portions of these allods for a like consideration, the result was, that there arose in all the Germanic countries a second kind of property called *beneficium*, *fief*, or *leasehold*. This kind of property was not hereditary by right, but was held only during the pleasure of the real owner, and so long as the conditions on which it was granted were duly fulfilled. Holders of this kind of property were called vassals or liegemen, to distinguish them from freeholders; and the real owner of the property which the vassals occupied as tenants was called the liege, the seigneur, or the suzerain. The usual tenure by which vassals held their fiefs was that of military service and homage—in other words, the proprietors who held fiefs from the king were bound to attend his court on occasions of ceremony, and to assist him in case of war with a stipulated number of men, armed and furnished in a stipulated manner; and the smaller proprietors, who held fiefs under great lords, were bound after the same fashion to appear at the castles of their lords when summoned, and to give them military assistance. The seigneurs, on the other hand, were bound to protect their vassals.

It very soon happened that the feudal tenure of property prevailed over every other. The great nobles were but too glad to become vassals of the kings, in return for the rich gifts which they had to bestow on them; and it very frequently happened that the holder of a small allod, or freehold, voluntarily gave it up to a powerful lord in his neighbourhood, whose protection he wished to secure, receiving it back from him as a fief. Gradually, therefore, almost the whole property of a country became a connected system of fiefs: the lands were fiefs; the offices and dignities, from the governorship of a province down to the pettiest function, were fiefs; and society, from the king down to the poorest freeman, consisted of a chain of ranks, each retaining from that above it.

In addition to the influence of this universally prevalent system of feudalism, there was the influence of the Church, contributing in a different manner to the same result. It was customary at this period for churchmen and scholars, born in one country, to leave that country in early or mature life, and either to settle in another country as bishops, monks, or teachers, or to devote themselves to a missionary life, and wander, as ministers of the Gospel, into the remote and still heathen corners of Europe. We have only to conceive this fact distinctly, and to fancy German and French, and Italian and English ecclesiastics, distributed over Europe, all engaged in the same intellectual or spiritual labours, all using the Latin tongue for learned purposes, all considering themselves members of the great institute of the church, and all communicating, by means of letters and books, with distinguished men of their own order in the chief cities of Europe; and we shall have a vivid idea of that powerful system of religious communion which pervaded a society, otherwise

torn and disunited, and spread like a network from the Mediterranean to the Icy Sea.

Struggle of Emperors and Popes.—We have already seen by what steps the sovereigns of Germany had risen into ascendency, and acquired the title of Emperors of the West. Their right to this title was recognised by all the sovereigns of Europe; there was not a king of Northern Europe who did not regard the German emperor as the political head of the civilised nations, and Germany as the ruling power; and the notion began to gain ground, and was sedulously inculcated both by the emperors themselves and the popes, that all Christendom consisted in reality of one great confederation of states, of which the emperors were the secular, and the popes the spiritual chiefs. No one can understand the state of Europe at this time, without keeping distinctly before his mind the two words *pope* and *emperor*, with the meanings thus attached to them.

The political position of the German emperor was inherently weak. Not only was the office elective, but it depended on the concurrence of the 'states' or nobles to supply the emperor with troops to carry out his schemes. The dukes, counts, and margraves, who governed the provinces or defended the marches, had been at first regarded as imperial officers, removable by the emperor; but they gradually contrived to render their offices or fiefs hereditary, and became almost independent princes. The same was the case with the great dignitaries of the German Church; they became temporal nobles with permanent jurisdictions.

But the weakest point of the German Empire was Italy. When Otho had established his authority over the chaos of fragments into which the kingdom of Italy had fallen, he and his successors not unnaturally conferred the fiefs and other honours on Germans, rather than on native Italians; and hence there was kept alive a spirit of vehement hostility to German influence. This anti-German feeling naturally gathered round the pope, who, as temporal magistrate of Rome, was a vassal of the German crown, but, as spiritual head of Christendom, had an advantage over all the other temporal lords owing allegiance to the emperors. Thus the dealings of the popes with the emperors, and of the emperors with the popes, assumed in the eyes of all parties a high degree of importance; and the struggle that arose between them affected the whole history of Europe for several centuries.

The election of the popes as bishops of Rome had from the earliest times been vested in the college of *cardinals*, composed of the principal clergy of Rome; their choice being confirmed or annulled by the acclamations of the people in the streets. In the anarchical period between Charlemagne and Otho (814–962), the elections had been the occasion of much turbulence and bloodshed; and the papal chair had been generally filled by profligates, or by men of weak minds managed by others. At one time, the papacy was actually in the patronage of two sisters, women of infamous character, named Marozia and Theodora, who appointed their paramours and illegitimate children. The extension of the German power into Italy produced a change in this state of things. The ratification of the German emperor was made necessary to the election of a pope, and the emperors naturally sought to have popes elected that were favourable to their views. This policy was fully carried out by Henry III. of the house of Franconia, under whom the empire attained the highest prosperity. He looked upon the popes as his viziers in spiritual things; and on the occasion of a contention for the papal chair (1046), he set all the parties aside, and appointed a German bishop, Clement II. whose three successors were also nominees of Henry.

But the imperial policy was thwarted by the most illustrious man of the middle ages—Hildebrand, who became pope as Gregory VII. in 1073. The first blow he struck was at the right of *investiture* claimed by the temporal sovereigns—that is, the right of bestowing on bishops and abbots the ring and staff, which were the symbols of their office, a right by virtue of which the sovereign had the clergy completely under his control. A papal decree was now issued (1074) forbidding, under pain of excommunication, all sovereigns from exercising investiture, and all ecclesiastics from accepting it at the hands of laymen. At the same time, he pursued another measure tending to detach the church from worldly influences. The *celibacy* of the clergy had long been a favourite doctrine of the Church of Rome; but though encouraged, it had never become a positive rule, and it was as common, especially in the north of Christendom, for a priest to have a wife as not. Gregory now (1074) decreed that all the married clergy must either quit their wives or renounce the priestly order. The decree was violently resisted; but with the aid of the monks and of the populace—who, strange to say, sided with them against the married clergy—Gregory triumphed, and celibacy became the law of the church.

The emperor Henry IV. at first set the decree against the right of investiture at defiance. Gregory thundered out a sentence of excommunication and suspension against him; and such was the appalling effect, that Henry, whose tyrannical conduct had made him many enemies, seeing the universal defection, was obliged to submit. Humiliated and grieved, he crossed the Alps in the depth of winter (1077), to seek the pardon of his pontifical enemy. He found the pope in the Modenese territory, where he was residing with the Countess Matilda of Tuscany, one of the most devout friends of the church, at her castle of Canossa. Here it was only after the most abject confessions of his error, and standing as a penitent for three days in an outer court of the castle, barefooted, and clad only in a woollen shirt, that he obtained absolution, and the removal of the sentence of interdict. Such a spectacle had never before been seen in Europe.

Gregory henceforth asserted the superiority of the spiritual over the temporal power; he urged on all kings the duty of acknowledging themselves vassals of the Holy See, and even demanded tribute in the name of 'Peter's pence.' Many of the minor princes actually made the required submission, and all were careful not to offend the pope by any display of independence. But Henry IV. had not forgot his humiliation at Canossa. Having defeated a rival emperor, set up by the pope's party, he declared Gregory deposed, appointed a new pope, Clement III. (1080), marched into Italy, took Rome after a siege of three years, and was crowned by the anti-pope, Gregory being obliged to take refuge with Guiscard

at Salerno, where he died (1085). The remainder of Henry's life was imbittered by the rebellions of his sons, at the head of the partisans of the successors of Gregory. At last, his second son, Henry, defeated his father, stripped him of his robes, and turned the aged monarch adrift on the world. He was refused admission into a church built by himself, and died a beggar at Liege (1106), where his body lay for long in a cellar, no one daring to bury an excommunicated man.

The peace of the empire continued to be distracted by the controversy between popes and emperors about the right of investiture. The papal party in Germany were headed by the Duke of Bavaria, the opposing nobles by Conrad of Hohenstaufen. After a great battle fought in 1140, the house of Hohenstaufen secured the imperial crown. It is from this battle that the names of *Guelphs* and *Ghibellines*, so famous in Europe during the twelfth and thirteenth centuries, are said to have taken their rise. The war-cry of the army opposed to Conrad on this occasion was 'Welf' or 'Guelph,' the name of their leader, and the family name of the house of Bavaria; that of Conrad's army was 'Waiblingen,' the name of a small town in Franconia from which the Franconian dukes traced their origin. Hence, ever afterwards these names were used to distinguish the two great parties into which the inhabitants of Germany and of Italy were divided—a partisan of the popes against the emperors being called a Guelph, and a partisan of the emperors against the popes, a Ghibelline.

The most prominent figures in the remaining history of the struggle are Frederick I. of Hohenstaufen—better known as Barbarossa ('Redbeard')—Pope Innocent III., and Frederick II. Barbarossa was an emperor of extraordinary energy and ability, and devoted himself to the re-establishment of the imperial supremacy in Italy, where he subjugated the most of the Lombard towns, which had become almost independent republics. At the invitation of Pope Adrian IV. he marched to Rome, and put down an insurrection that had arisen against the papal rule; on this occasion, the emperor held the pope's stirrup, and the pope in return placed the imperial crown on the head of the emperor. But the feud again broke out; the emperor appointed anti-popes, and the real popes and their partisans enabled the Lombard cities to assert the right of self-government.

On the death of Henry VI. son of Barbarossa (1197), there were two claimants for the imperial crown, and the struggle between them is chiefly interesting as having been contemporary with the papacy of Innocent III. (1198–1216), the greatest pontiff, after Gregory VII. that ever sat on the papal throne. No pontiff carried his prerogative higher than Innocent III. He affirmed even more explicitly than Gregory VII. had done the maxim, that 'the pope, as the successor of St Peter, was set up by God to govern, not only the church, but the whole world.' He was the first also to promulgate the doctrine, that the popes have a plenary power, enabling them to dispense with established laws, and to overrule them. Nor did he confine his views to theory. He issued decrees, and sent legates to all parts of Christendom; he summoned lords and bishops to Rome, to answer for their conduct; he compelled the kings of France and Leon to put away their wives; and the kings of Portugal, Aragon, and England paid him tribute as vassals.

The reign of Frederick II. (1215–1250) was the dying struggle between the empire and the church. Frederick was a man of strong character and of considerable culture, but the partisans of the papacy have represented him in a dark light. Frederick's exertions, continued over a period of thirty-five years, were all in vain. In the complex wars in which he was engaged in Italy—wars in which the Sicilians, the Lombards, and the popes had all a share—he often gained great successes, but always suffered in the end a greater loss. Ever in the midst of the turmoil, the popes were present to watch the progress of the conflict, and to interpose with their excommunications. Frederick was excommunicated so often, that he became accustomed to it; and very probably the scepticism of which he was accused arose from the necessity thus imposed upon him of going through life as an outcast from the church. But the sentence of excommunication, though it did not terrify Frederick himself, never lost its power over the majority of his subjects. Even the Ghibelline cities and houses wavered in their allegiance, and his own son rebelled against him. When he died (1250), the struggle may be considered to have ended.

Italy had in like manner by the end of the thirteenth century become studded over with a multitude of independent city-republics, divided between the Guelph and Ghibelline interests, and in continual hostilities with one another. Two of these republics were the great maritime powers in Europe. Venice, whose constitution was rather a permanent oligarchy than a republic, conquered the coast of Dalmatia, and the islands of Corfu, Cephalonia, and Crete, and was the acknowledged sovereign of the Adriatic. Genoa, the commercial rival of Venice, had possession of several islands and ports in the Grecian Archipelago and the Black Sea, as well as numerous commercial stations in the Mediterranean. In Central Italy, the temporal sovereignty of the popes had been definitely established over 'the Patrimony of St Peter,' by Innocent III. (1198–1216). The kingdom of Naples and Sicily, which had passed by marriage to the German emperors of the Hohenstaufen line, was wrested from them, at the instigation of the pope, by Charles of Anjou (1265), who brought with him a great retinue of Frenchmen. But the insurrection known as the *Sicilian Vespers*, in which 8000 French were massacred, deprived Charles of Sicily, which was taken possession of by the king of Aragon.

In France, as elsewhere at this period, the chief subject of interest was the struggle carried on between the kings and their great vassals. During the reigns of the earlier monarchs of the line of Hugh Capet, France was in reality a cluster of independent sovereignties. Philip-Augustus (1180–1223), the seventh of that dynasty, was the first that curbed the power of the nobles, and became to some extent the head of the French nation. In the reign of his successor occurred the final persecution of the Albigenses in the south of France—a sect who, among other heretical opinions, disowned the supremacy of the pope. Louis IX. (1226–1270) was one of the most exemplary and conscientious monarchs that ever reigned. Under his wise government, the royal prerogative gained strength.

In Spain, the Christian kingdoms of the north continued to gain on the Mohammedans, now called the Moors, in the south; and by 1236, there remained to the latter only the kingdom of Granada. Out of a portion of the peninsula thus wrested from Mohammedan rule, was formed the kingdom of Portugal (1095).

State of Feudal Society.—Every feudal country was parcelled out into a number of fiefs or feudal estates, each of which had a complete social organisation of its own. A fief consisted properly of two things—the *castle*, in which the lord or proprietor lived with his family and men-at-arms; and the *village* or *attached domain*, inhabited by the agricultural population, subject to the proprietor. Some of these were actual slaves or serfs, the born property of the lord of the soil, but the greater part were *villeins*—that is, free-born men serving for a consideration or renting land. Theoretically, the lord had not full power over such villeins; but if they were aggrieved by him as proprietor, he was the sole magistrate within the fief, and thus his power was practically absolute.

The three influences that gradually undermined the feudal system were *royalty*, the *municipalities*, and the power of the *clergy*. At the outset, the monarch was merely to the great suzerains what these were to their vassals—the head of a system of fiefs. The idea of nationality was foreign to the feudal system, which tended to segregation. The first, from his position, to be inspired with that idea would be the king, who naturally looked at the nation as a whole, and tried to pierce down through the intermediate ranks of barons, counts, &c. to the heart of the subject population, and establish a direct communication between the crown and the people at large. By issuing decrees also to be put in force over the whole kingdom, the throne became the fountain of *law*, as something distinct from the mere will of the feudal chiefs for the time being.

Many of the municipalities of the Roman Empire survived the shock of the German invasions, which destroyed all the rest of the fabric, and formed little republics or self-governing bodies in the midst of the feudal society. In addition to these, feudalism gradually created similar communities for itself. During the turbulence and insecurity of those times, people naturally congregated in large numbers around the castles of powerful chiefs. Any lord on whose property such a concentration of population, with its attendant industry, took place, found it advantageous to him, both in respect of wealth and of influence, and hence sought to foster and augment it, by relaxing his feudal authority over it, and granting privileges and immunities to its inhabitants. Hence arose *towns*, governed by bailiffs or provosts appointed by the suzerain of the territory, and the still more highly privileged *boroughs*—that is, towns possessing regular charters of enfranchisement, empowering them to govern themselves by mayors, aldermen, and the like, chosen by the burghers from their own body. These towns and boroughs were oases of freedom amid the general desert of feudal despotism, and constituted the nurseries of that social power which we now call the commonalty of a country.

The Clergy.—It has been estimated that every twentieth man in the thirteenth century belonged to the clerical order; and that the clergy held more than *one-half* of the entire landed property of most European countries. The possession of this wealth, added to their moral and spiritual influence, gave them immense sway; and the connection of the clergy everywhere with the central authority of Rome, made the church a great independent empire, superimposed upon the kingdoms of the earth, and able to control and modify all temporal and local authorities.

Chivalry.—This sentiment was the natural and gradual product of feudalism. It was the custom for the sons of the various vassals of a suzerain to form a little court or school in his castle, where they were educated under his eye and along with the members of his family in military exercises and feudal etiquette. When these youths—called *squires* while in training—arrived at manhood, they were admitted to the dignity of full-grown warrior, styled *miles* (Lat.) or *knight* (Ger. implying 'service'), and the admission was attended by an imposing ceremonial tending to invest it with religious interest, and to inspire ideas of something higher and nobler than was expected of ordinary men. Under this feeling, the conviction would grow in generous minds, that the power which their arms and training gave them ought to be exercised in the defence of the weak and oppressed; and what was at first mere individual feeling, soon became matter of rule. The knights of each country as an order bound themselves to observe certain regulations; and different countries vied with each other as to which should produce the most perfect specimens of knighthood. There was no virtue, actual or conceivable, which was not in theory associated with the character of a perfect knight; and however far short the practice may have fallen of the theory, there can be no doubt that some of the noblest characters of the middle ages were nursed by the ideas of chivalry. The institution attained its highest form during those great historical occurrences known as the Crusades, of which we now proceed to give a brief sketch.

History of the East.

The Turkish Conquests and the Crusades.—It had been customary from an early period in the history of Christianity for believers from every part of the Christian world to make pilgrimages to the Holy Land of Palestine. After the Mohammedan conquest of the East, the earlier califs, notwithstanding their fanaticism, had, in return for certain tribute, suffered the patriarchate of Jerusalem to remain, and the Christians to exercise their worship; the later califs were more liberal still, and pilgrims continued to arrive from all parts of Christendom.

But about the beginning of the tenth century, pilgrimage had become precarious. The condition of the Mohammedan world was by that time greatly changed. While the refined Abbaside califs were cultivating literature at Bagdad, the emirs of the provinces had succeeded in establishing themselves as independent sovereigns. In the very vicinity of the capital, 'the Bowides,' as the emirs of Shiraz called themselves, became so powerful that, by the middle of the tenth century, the califs of Bagdad were mere puppets in their hands, and nothing remained to them but their nominal dignity as spiritual heads of the Mohammedan world. In Africa, again, an extensive

Mohammedan empire had been formed under the dynasty of the *Fatimites*, claiming descent from Fatimah, the daughter of the Prophet. They built Cairo (970), which became the capital of their dominions; conquered Palestine, and contested the possession of Syria with the Byzantine emperors, who, taking advantage of the decrepitude of the califate of Bagdad, had begun to re-extend their power over part of their former dominions.

About this time a new power made its appearance on the arena of the oriental world—namely, that of the Turks. The name Turks was a general appellation for the numerous tribes inhabiting the region to the east of the Caspian Sea, now called Independent Tatary. Many of these tribes had embraced the religion of the Koran, and from them the califs drew their best soldiers. These Turkish mercenaries, introduced as servants of the califate, soon found that they could become its masters. One of them, Alepteghin, originally a slave, became an independent military chief (961); took the town of Ghuznee in the east of Persia; and founded the dynasty of the sultans of Ghuznee. Mahmoud, the son of Sabactagi (successor to Alepteghin), carried his arms into Hindustan (1001), and led the way to the Mohammedan conquest of that country. Another race, called *Seljuk Turks*, from the name of the founder of the dynasty, established themselves in Khorasan, and under Togrul Beg, the grandson of Seljuk, overthrew the power of the Bowides (1055), and assumed their place as administrators of the empire in the name of the califs of Bagdad.

The career of Eastern conquest which had been begun by Togrul Beg, was continued by his immediate successors, Alp-Arslan (1063-1073) and Malek-Shah (1073-1093). Alp-Arslan carried on a vigorous warfare against the Greek Empire, from which he wrested not only what remained to it in Syria, but also the greater part of Asia Minor, called by the Turks 'Roum'—that is, the country of the Romans. From the Fatimite califs of Egypt he also wrested Palestine (1070). These conquests were confirmed and increased by Malek-Shah, an able and even cultivated prince, in whose reign the empire of the Seljuks extended from the Ægæan and the Levant to the confines of Chinese Tatary. On his death (1093), the empire of the Seljuks fell asunder, different dynasties of the Seljuk stock establishing themselves in different parts of it. Of these, the most powerful were the sultans of Iran, who were masters of Upper Asia, and the sultans of Roum, who retained all the Turkish conquests in Asia Minor, and continued the wars against the Greeks on the one hand, and the Fatimite califs of Egypt on the other. The first sultan of Roum was Soliman, called also Kilidge Arslan, the great-grandson of Seljuk. After securing his power by his own military activity, he established his headquarters at Nice, in Bithynia, within one hundred miles of Constantinople. He was unable, however, to retain Palestine, which again (1096) passed into the hands of the Fatimites of Egypt.

In the midst of these wars and revolutions with which the East was distracted, Palestine had fared worse than almost any other country. No sooner had the Fatimite califs of Cairo become its masters, than the Christian inhabitants found the difference between their rule and that of the mild Abbaside califs of Bagdad. But even the cruelties of the Fatimite califs were insignificant, compared with those which had to be endured when Palestine came into the hands of the Turks. Full of ferocious zeal for the religion to which they were but recent converts, the Turks delighted in persecuting the Christians of Palestine, whether residents or pilgrims, and in committing outrages on the shrines and holy places which the Christians frequented.

The news of the cruelties perpetrated by the Turks on the Christians of Palestine, produced a deep feeling of indignation among the Christian nations of the West, and a desire to arrest the progress of the hated religion of Mohammed, and recover the Holy Land from the desecration of the infidel. At the same time, the Greek emperors, the very existence of whose empire was menaced by the Turks, sent repeated embassies to the popes and temporal potentates, imploring the Christian powers of the West to come to their aid.

By the enthusiasm of a monk, called Peter the Hermit, a native of Amiens, in France, who had made a pilgrimage to Jerusalem, and witnessed the cruelties perpetrated by the Turks, and the help of the pope, the Crusade fever spread over Europe like an epidemic. After some preliminary failures on the part of undisciplined rabbles, the chivalry of Europe mustered for the enterprise in 1096. The feudal chiefs, each at the head of his own vassals, ranged themselves under distinguished leaders—Godfrey of Bouillon; Robert, Duke of Normandy, son of William the Conqueror; Count Robert of Flanders; Bohemond, Prince of Tarentum, second in command to whom was Tancred, the flower of chivalry, and the favourite hero of the Crusade; Count Raymond of Toulouse; and others. Six separate armies were thus formed, which marched separately by different routes to the common rendezvous, Constantinople. The appearance of this vast force—amounting to at least 600,000 men, exclusive of women and priests—alarmed the Greek emperor, who, though he had repeatedly invoked the aid of the West, was now afraid lest the Latin princes might seek to secure the mastery of the East for *themselves*, and not for *him*. It was only by the threat of attacking Constantinople that he was made to withdraw his opposition, and further the transit of the Crusaders into Asia Minor. Here their first step was the siege and capture of Nice, the capital of Soliman, sultan of Roum (1097), and the defeat of his army in a great battle. They then marched on to Antioch, the capital of Syria, the siege of which consumed seven months, and melted away the army of the Crusaders. No sooner was Antioch captured (1098), than the Crusaders were in their turn besieged by an army of 200,000 Mohammedans, sent by the Persian sultan; but this host was defeated, and the way was now open to Jerusalem. It was on a morning in the summer of 1099 that the 40,000 Crusaders—who were all that war, famine, pestilence, and desertion had left out of the 600,000 who, two years before, had crossed from Europe into Asia—first came in sight of the Holy City. The emotion produced by the sight was intense. Some leaped and shouted; some threw themselves on the earth and kissed it; some gazed and wept; 'all had much ado,' says an old historian, 'to manage so great a gladness.' The siege of Jerusalem

began on the 7th of June 1099. The city was obstinately defended for six weeks by a garrison of 40,000 Turks, in the employment of the Fatimite califs of Egypt, into whose power Palestine had reverted three years before. A terrible massacre followed the capture of the city.

The Crusades are usually reckoned seven in number, and extend over a period of two centuries, the first and greatest, now sketched, beginning in 1096, and the last and least terminating in 1291. One result of the First Crusade was to restore the best part of Asia Minor to the Greek Empire. Out of the Syrian territories conquered from the Turks and Egyptian califs, there were formed three feudal sovereignties—the *kingdom of Jerusalem*, conferred on Godfrey of Bouillon; the *principality of Antioch*, conferred on Bohemond of Tarentum; and the *principality of Edessa*, in Mesopotamia, conferred on Baldwin, the brother of Godfrey. Such of the Crusaders as resolved to remain in the East, attached themselves to one or other of these princes, receiving lands from them, and yielding them feudal allegiance; while thousands of immigrants and merchants from the various countries of Europe, arrived by sea to partake of the same benefits.

During a period of fifty years, the three Latin principalities in the East maintained themselves against the attacks of the surrounding Mohammedans, and even increased their power, Jerusalem being naturally the most important. It was at Jerusalem, and during the generation that succeeded the First Crusade, that the two famous orders of the Knights Hospitallers of St John and the Knights Templars took their origin. Their object was to deliver Palestine from the bands of Mohammedans to whose inroads it was still liable. The Hospitallers had their name from the Hospital of St John, which had been converted from a monastic foundation into a military institution; the Templars, from having their quarters near the Temple.

But after the lapse of fifty years, dangers began to arise, threatening the very existence of the Latin kingdoms in the East, and calling for a Second Crusade. The empire of the Seljukian Turks had passed away; but in the emirs or governors of provinces there was always a fresh source of conquering adventurers ready to raise a new structure of power on the ruins of the old. One of these, named Zenghi, emir of Mosul, took Edessa (1144), slaughtered the Christian inhabitants, and extinguished the principality. His son, Noureddin, a man of extraordinary abilities and noble character, from being simple emir of Aleppo, became sultan of a kingdom extending from the Tigris to the Nile. The Christians of Syria were trembling for their safety; and to arrest the progress of Noureddin, Europe sent 1,200,000 men (1147) under her two most powerful monarchs, Louis VII. of France, and Conrad III. emperor of Germany. Yet the Crusade was a total failure. The Greek emperor was hostile; his emissaries misled the Western armies on their way through Asia Minor, and they were either cut to pieces by the Turks or perished among the mountains. The relics that made their way into Syria in no way arrested the activity of Noureddin, who pressed upon the kingdom of Jerusalem as much as ever. But the death-blow came from another quarter. Salah-Eddin, generally called Saladin, a young Kurdish chief, sent by Noureddin on a political mission into Egypt, contrived to get the power into his own hands, put an end to the dynasty of the Fatimite califs, and aspired to the presidency of the Mohammedan world. Taking advantage of the distracted state of the kingdom of Jerusalem, arising from a disputed succession to the throne, Saladin invaded Palestine, took town after town, and lastly Jerusalem, after a siege of fourteen days (1187). The only place that remained to the Christians in Palestine was Tyre, which was defended by Conrad, Marquis of Montferrat.

The news of the extinction of the kingdom of Jerusalem called forth a *Third Crusade*, led by Frederick I. (Barbarossa) of Germany, King Philip-Augustus of France, and King Richard I. of England. Barbarossa led his army through Asia Minor, but was himself drowned while fording a river in Syria, and only a wreck of his army reached Tyre. The kings of France and England conveyed their forces by sea. The Christians in Syria had in the meantime rallied, and were laying siege to Acre, a town of such importance, that its capture was regarded as almost equivalent to a reconquest of the country. In vain Saladin now attempted to raise the siege and relieve Acre. Numerous battles were fought in the plains around between the chivalry of the West and the Moslem myriads; and after a siege of twenty-three months, Acre surrendered to the Crusaders. But this was the sole result of the Crusade. Rivalries and jealousies sprang up among the Christian leaders, and especially between the kings of France and England; and the progress of the war against Saladin was impeded. At length, Philip abandoned the Crusade, and returned to France. The Lion-hearted Richard remained, and continued the struggle for some time with various success; but at last he agreed to a truce with Saladin, the terms of which were on the whole favourable to the Christians, and creditable to the liberality and tolerance of the Mohammedan. He took his departure from the East in October 1192; but being detained on the way as a prisoner of the Duke of Austria at Vienna, did not reach England till March 1194. His great antagonist, Saladin, between whom and Richard there had been established a mutual admiration and regard, died in 1193.

Of the remaining Crusades, the only one that produced any result was that undertaken in 1228 by the German emperor, Frederick II. who entered Jerusalem in triumph, and compelled the sultan of Egypt to cede that city and several others to the Christians. But the fruits of this and of the Crusades in general were once more lost by the irruption of a new race of conquering Turks, who established themselves in Syria in alliance with the sultans of Egypt, defeated the Christian forces, and burned and pillaged Jerusalem (1244). Palestine thus again relapsed into the dominion of the infidel. The unfortunate expedition of St Louis of France (1249), usually considered the *Seventh* and *Last* Crusade, in which the king himself and the relics of his army were made prisoners in Egypt, had no other effect than to produce a revolution in that country. The Mamalukes—that is, the Turkish or Tatar slaves who served as the officers and body-guards of the sultans—offended that the French invaders were

allowed to ransom themselves so easily, murdered the Ayoubite sultan, and set their own commander, Ibek, on the throne of Egypt (1250).

Although the Crusades utterly failed in their immediate object—the recovery of the Holy Land from the Mohammedans—they yet produced important results, and reacted, in many respects favourably, upon the intellectual condition of the Western nations. By having to act in concert, these nations were brought to know one another better, to interchange chivalrous courtesies, to feel mutual sympathies, and entertain more liberal sentiments. The Crusaders also brought from the East the knowledge of many products and processes tending to promote the arts and manufactures; and it was during these expeditions that modern commerce was first developed. Another effect was to diminish the strength of the feudal aristocracy, by occasioning the breaking up and sale of many feudal properties. At the outset, the Crusades seemed to rivet and extend the power of the popes, for they brought the best knights and warriors of Europe directly under the banner of the church; but in the end, the effect was to weaken the influence of fanaticism and of the papacy. Instead of the mere feeling of abhorrence with which Mohammedans had at first been regarded, many of them had inspired the Christian knights with esteem and admiration; the crusading spirit flagged; men began to ask the reasons, and to count the costs; and in the latter half of the thirteenth century, Peter the Hermit himself might have preached a crusade in most parts of Europe, and found but cold audiences. About this time, in fact, as is proved by the institution of the Inquisition in various countries, Europe began to be full of sceptics, who questioned both the doctrines of the Romish Church, and the methods by which she acted upon society.

III. NATIONAL MONARCHIES: 1300–1517 A.D.

History of the West: Formation of Modern European Governments.

Spain and Portugal.—During the fourteenth and fifteenth centuries, the Spanish peninsula continued to be divided into four parts—the three Christian kingdoms of Aragon, Castile, and Portugal, and the Moorish kingdom of Granada. At last, by the marriage of Ferdinand of Aragon with Isabella of Castile, these two important kingdoms were united under one government (1479)—an event of great importance in the history of Spain. The Moorish kingdom of Granada had gradually been reduced to narrow and narrower limits. A final crusade against the Moors was now undertaken by the united chivalry of Aragon and Castile, and after a sanguinary war of ten years, the city of Granada was taken, and Moorish supremacy in Spain was at an end (1492). From this time, the peninsula has continued to be divided into the two kingdoms of Spain and Portugal. The close of the fifteenth and the beginning of the sixteenth century form the most splendid era in the annals of these countries. Under John II. (1481–1495), Portugal rose to eminence in commerce and maritime discovery. It was in the service of Ferdinand and Isabella of Spain that Columbus discovered the New World (1492); and before the death of Ferdinand in 1516, the West India islands of Haiti, Cuba, and Jamaica had been added to the Spanish crown. Joanna, daughter of Ferdinand and Isabella, had been married to Philip, Archduke of Austria, and her son, Charles, became, on his father's death, sovereign of the Netherlands. To this Austrian grandson, then, already Prince of the Netherlands and Franche-Comté, Ferdinand bequeathed a real *Spanish empire*, consisting of Spain Proper, together with the kingdom of Naples and Sicily, Sardinia, and the West Indies.

France.—The successors of St Louis (1270) inherited a kingdom compact, well arranged, and accustomed to the rule of royalty, and such it continued till the direct line of the Capetian kings terminated in Charles IV. (1322–1328), when a period of anarchy and disaster begins. Two competitors appeared for the crown—Edward III. of England, whose mother, Isabella, was Charles's sister; and Philip of Valois, who was cousin-german to Charles. The English king was undoubtedly the nearer in kin had not the Salic Law interfered, which was held to debar female succession. Edward, while admitting that his mother could not personally ascend the throne, maintained that she could transmit the inheritance to her son; but the states decided in favour of Philip, who took the crown as Philip VI. Edward, after acquiescing for a time, revived the dispute in 1337, and commenced a series of campaigns, which made the English at one time all but masters of France. These wars were signalised by three splendid victories—that of Sluys (1340), in which the whole French fleet of 200 ships was taken by the English; of Cressy (1346), where 30,000 English defeated 100,000 French; and of Poitiers (1356), in which 8000 English, led by the Black Prince, defeated 60,000 French. This led to a treaty of peace (1360), by which a large portion of France was ceded in full sovereignty to England. But under Charles V. (1364–1380), the French rallied, and a series of reverses deprived the English of all their conquests, except a few important towns. Charles VI. (1380–1422) becoming insane, the kingdom was plunged into the confusion of civil war by the factions of the Dukes of Orleans and of Burgundy contending for the regency. Henry V. of England seized the opportunity of reviving his pretensions to the crown of France, and the great victory of Agincourt (1415) made him master of the north of France. The Burgundian party, entering into alliance with the English, it was agreed (1422) that Henry should marry Catherine, the daughter of Charles, and succeed to the kingdom, to the exclusion of the dauphin. Henry, however, died suddenly (1422), leaving an infant son by Catherine; and Charles VI. dying soon after, the dauphin was proclaimed king by his adherents as Charles VII. The whole of the country north of the Loire was in possession of his enemies the Burgundians and of the English, and though the hero of Agincourt was dead, the Duke of Bedford, as regent for the young king Henry VI. was leading the English to fresh victories. Orleans was about to fall into the hands of the foreigners, and the fortunes of Charles seemed at the lowest ebb, when a deliverer appeared in the person of a simple peasant-girl, Joan of Arc, who believed herself commissioned by Heaven to save her country. She put herself at the head of the French soldiers,

and partly by real boldness, partly by the moral effect of her example, and the terror inspired by her supposed supernatural character, she soon turned the tide of war, and drove the English from post to post. At last, she was taken by the Burgundians, and sold by them to the English, who put her to death at the stake on a charge of witchcraft (1431). After this disgraceful event, Charles, by little and little, recovered his dominions; and in 1453, all that remained to the English of the French territory was Calais. Charles VII. was the first modern sovereign that substituted a standing army for the service of mere feudal bands. The reigns of his three immediate successors—except that of Louis XI. (1461–1483), whose policy of humbling the barons, and exalting the power of the crown, required that he should favour and foster the growth of civic communities—possess little general interest; that of Francis I. (1515–1547) forms an important era in the history of France.

The German Empire and Austria.—The death of Frederick II. (1250) was followed by what is called the *Great Interregnum*—a period of anarchy, from which the empire was delivered by the accession to the crown of the energetic Rudolph of Hapsburg (1273–1291). In the reign of Charles IV. was promulgated the *Golden Bull* (1356), which fixed the constitution of the German empire—the mode of election of emperors, and the composition and procedure of the diet or common parliament of the states.

The component parts of the empire were, in respect of internal government, independent states, some of them of great magnitude. Austria, especially, from small beginnings, rose to be the preponderant power in Germany. Originally a mere military frontier or 'mark' of the empire of Charlemagne, and therefore called Oester-reich, or 'Eastern government,' it had been raised to the rank of a duchy; and when Rudolph of Hapsburg came to the empire, he took this Austrian duchy from its possessor, who had opposed his election, and conferred it on his own son Albert (1283), afterwards emperor. Around this small nucleus the Austrian Hapsburgs gathered from time to time new acquisitions, mostly by marriage with heiresses, until their possessions attained the dimensions of an empire. In 1438, Albert II. Duke of Austria, was chosen Emperor of Germany; and from that time the German emperors were all Austrians, so that the history of the Austrian dynasty becomes henceforward identical with the history of the German Empire.

A great accession to the possessions of the house of Austria was made by the marriage of Maximilian, son of Frederick III. to the heiress of Charles the Rash, Duke of Burgundy. At Charles's death, Burgundy Proper was appropriated by the French monarch, but the rest of the duke's dominions, including the whole of what we now call the Netherlands and Belgium, came into the possession of Maximilian's son, Philip, and finally of Philip's son, Charles (Charles V.), who by his mother's side was also heir of the Spanish monarchy.

Switzerland.—Helvetia, up to the end of the thirteenth century, had formed part of the German Empire, governed in some districts by lords and bishops, and in others by municipal corporations, as in other parts of the empire. Three districts, under the name of *cantons*, enjoyed a sort of self-government under a peculiar imperial grant—the cantons of Uri, Schweitz, and Unterwalden. Albert, son of the Helvetian count, Rudolph of Hapsburg, who had been made Emperor of Germany, sought to convert the whole of Helvetia into a principality of his own. The mountaineers rose in insurrection (1308), and the three cantons forming a league, the new people were called Swiss, after the name of one of the cantons. According to tradition, the popular hero in this war was the famous William Tell. Other cantons were soon added to the confederacy, and the two great battles of Morgarten (1315) and Sempach (1386) convinced the Austrian dukes that further efforts against the Swiss were vain. In 1500, the independence of the Swiss as a nation was formally recognised by the emperor Maximilian.

Italy.—The Italian Republics.—On the decay of the imperial authority, the cities of Northern Italy formed a congeries of small independent states, bearing the name of republics, though some of them were more aristocratic than democratic. It frequently happened that ambitious individuals raised themselves to the position of petty despots. Of the families that thus rose to importance in the fourteenth and fifteenth centuries, the most remarkable were the Visconti, and afterwards the Sforzas in Milan, and the Medici in Florence. Cosmo and Lorenzo dei Medici (1448–1492), whose great fortune arose from commerce, rivalled princes in their munificent patronage of learning and the arts; and a son of Lorenzo's became Pope Leo X. (1513–1521).

The histories of *Genoa* and *Venice*, during the period in question, consist chiefly of mutual wars, occasioned by commercial rivalry. At first the Genoese were the more successful; but in 1380, the loss of a great sea-battle near Chioggia crippled their power, and gave the sovereignty of the sea to the Venetians. From that time, Genoa, torn by political factions among its citizens, was obliged to lean on foreign support. Meanwhile, the Venetians, growing wealthy and wealthier by their commerce with the East, extended their domain at home, detaching Verona, Padua, Cremona, and other cities from the dukedom of Milan, and adding them to their own republic.

The States of the Church.—In the pontificate of Nicholas III. Rudolph of Hapsburg formally relinquished the feudal rights of the German emperors over the territories of the Church (1278), and made the popes the acknowledged temporal sovereigns, as they had long been the virtual. Still the state was distracted by the contentions of the powerful families, the Colonnas, Orsini, and others. In the beginning of the fourteenth century, a quarrel broke out between Pope Boniface VIII. and King Philip of France, which led to important consequences. Boniface, who rivalled Gregory VII. in asserting the papal power, interfered between Philip and his vassals. When the king asserted the independence of the French crown, the pope retaliated by excommunicating him; but the French, including the clergy, gathered manfully round their monarch, and laughed at the pope and his fulminations. The most important result of this struggle was, that it produced a permanent antagonism between the French crown and the papacy; so that it became the object of the French king to procure the election of a Frenchman to

the papal chair. In this he triumphed in 1305, and Bertrand, archbishop of Bordeaux, became pope as Clement V. Clement fixed on the French town of Avignon as the seat of his court; and for a period of seventy years (1305–1376), known in history as the Babylonish Captivity, the popes, who were all Frenchmen, resided at Avignon, and attempted to govern Rome by legates.

It was during this period that the old republican spirit of the Romans blazed up for a moment under the famous Cola di Rienzi, who governed Rome for a year (1347) as tribune, and was afterwards appointed senator by the pope, but was finally murdered by the fickle populace (1354).

Gregory XI. (1376) at last restored the papal see to Rome. On his death (1378), two rival popes were elected—a Neapolitan, named Urban VI. by the Italian party; and a Frenchman, named Clement VII. by the French party, who desired that the papacy should be transferred back to Avignon. Both popes proceeded to exercise the papal functions—Urban at Rome, and Clement at Avignon; and thus began what historians call the Great Schism of the Latin Church. This schism lasted forty years, or from 1378 to 1417, during which period the Catholic world found its allegiance divided between two distinct lines of popes —the one residing at Rome, the other at Avignon. The nations of Europe chose which pope they should obey, and called the other an anti-pope. The Romans, of course, took the side of the Roman line of pontiffs. This scandal was terminated in 1417 by the Council of Constance, which cleared away the rival popes and appointed a new one. But it was not till the pontificate of Nicholas V. (1447–1455) that Rome experienced a cessation of civil disorder. This illustrious pope crushed the factions, and established his government on a firm basis. He was the first pope who systematically appointed ecclesiastics to civil offices—a policy which has been pursued by all subsequent popes.

In regard to *Hungary*, it is only necessary to note that in the fifteenth century it became the battle-field of Europe against the Turks, and that its monarchs, John Hunyady and his son, Matthias, filled Christendom with the fame of their valour and their victories.

Russia.—The grand-dukedom of Russia continued under princes of the line of Ruric, till it was overrun (1237) by a host of half a million men under Jujy, a son of Genghis Khan, and thence constituted the westernmost province of the Mongolian Empire. On the breaking-up of this empire, at the death of Kublai Khan (1294), Russia fell to the share of the khans of a horde of Tatars, called the Golden Horde; who, from their place of encampment between the Caspian and Volga, continued to tyrannise over the country for nearly two centuries, plundering, burning, and destroying at pleasure. At last, a native prince, Ivan III. of Moscow, taking advantage of the dissensions and weakness of the Golden Horde, destroyed the last vestiges of their power (1480), and with his reign (1462–1505) the modern history of Russia begins. Under Ivan and his son Basil (1505–1533), Moscow became the capital of an empire covering an area nearly corresponding to that of modern Russia in Europe.

The Scandinavian Kingdoms.—In 1389 a temporary union took place of the three crowns of Denmark, Norway, and Sweden, under Margaret, called the 'Semiramis of the North;' but although an attempt was made at a convention held at Calmar (1397) to perpetuate the union, the settlement was soon broken through, and Denmark and Sweden chose separate kings.

Progress of Civil Society.—During this period, the feudal system continued more and more to crumble down, and its elements to melt into one another. The power formerly exercised by the great feudal lords over their inferior vassals was gradually concentrated in the person of royalty, and distributed by means of courts of law. Another important movement was the enfranchisement of the serfs. The manumission of serfs had always been encouraged by the clergy; and a king, as soon as he rose to the idea of being the head of a nation, and not merely of a system of fiefs, naturally favoured the same movement, and facilitated it by legal enactments. In this way, and without any direct attempts at general enfranchisement, absolute slavery had nearly died out in some parts of Europe—particularly in Italy —before the middle of the fourteenth century. In other countries, it required more direct acts of enfranchisement. An edict of Louis X. of France (1315) orders that 'freedom be given on good and fitting conditions,' meaning reasonable composition. Gradually, therefore, serfdom ceased to exist in France and in the Germanic countries; although in some parts of Northern Europe, and even in Britain, there were traces of personal serfdom as late as the seventeenth century. In the Slavonian countries, the example was not followed.

It was during this period that the first germs of constitutional government shewed themselves. In England, *parliaments;* in Germany, the *diets;* in France, the *states-general;* and in Spain, the *cortes* —all date their regular organisation from the fourteenth and fifteenth centuries. In their origin, too, all these assemblies were identical; they were at first nothing more than the great councils of the kings, in which they took advice with their chief nobles on matters of importance. They have since taken very different developments according to the genius of the several nations.

History of the East: the Progress of Maritime Discovery.

After the subversion of the power of the Seljuk sultans in Roum or Asia Minor by the Mongol invasions (1258), one of the petty Turkish emirs who shared the territories with the conquerors, soon began to build up a new Turkish Empire out of the ruins. His name was Osman or Ottoman (1289–1326), and the new power that he formed was called that of the Osmanlis or Ottoman Turks. Having established their dominion over Asia Minor, the Ottoman sultans crossed into Europe (1358), and inundated Thrace and Greece. Sultan Amurath I. reduced the Byzantine empire to a corner of Thrace, 1500 miles square. His son, Bajazet I. surnamed Ilderim, or 'Lightning,' reduced the Greek emperor to the condition of a tributary. The irruption of the Tatar hordes under Timur checked for a few years the progress of the Ottoman arms, but in the beginning of the fifteenth century, the successors of Bajazet commenced anew their aggressions on the Greek

Empire and on Europe; and under Bajazet's great-grandson, Mohammed II. Constantinople was besieged and taken (1453), and the Ottoman Empire took the place of the Greek. Sultan Selim, in 1516, extended his dominion over Mesopotamia and Egypt.

Discovery of the Sea-route to the East Indies.—Till towards the close of the fifteenth century, the whole trade of Europe with the East was in the hands of the Venetians and Genoese. The conveyance of the goods to the ports of the Levant and of the Black Sea, where the Venetian and Genoese ships received them, was chiefly by caravans overland, the sea-traffic by the Indian Ocean and the Red Sea being of inferior importance. But the Portuguese had been gradually extending their discoveries along the west of Africa, and at last Vasco da Gama doubled the Cape of Good Hope, and, crossing the Indian Ocean, landed on the western coast of India at Calicut (1498). To reach these same East Indies, the mysterious lands of silks, gems, and spices, Columbus had, in 1492, carried out the bold idea of sailing westward across the Atlantic, and thus discovered the New World.

History of the Church.

Three events of this period, more especially relating to the church, deserve notice. 1. *The establishment of Friars*, a new ecclesiastical body distinct from the ordinary monks. The higher secular clergy were rolling in wealth, and neglecting their office of spiritual guides; the monasteries also had become immensely rich, and their inmates were leading lazy, luxurious lives. To infuse fresh life into the church, there were formed communities of Friars (Fr. *frère*, brother) or Mendicant orders, differing from the ordinary monks in not secluding themselves, but roaming about as itinerant preachers, mixing with the people, and living upon their voluntary alms. They soon cast the monks and secular clergy into the shade, and became the zealous allies of the popes, by whom they were exempted from ordinary church rule. The numerous orders of this kind that sprang up at first, beginning with that founded by the Spaniard, Dominic de Guzman, in 1215, were in 1274 consolidated into four—the Dominicans, or Black Friars (from the colour of their robes); the Franciscans, or Gray Friars; the Augustinians or Austins; and the Carmelites, or White Friars.

2. *Rise of the Inquisition.*—In the early ages of the church, the duty of inquiring into and punishing heresy devolved on the local bishops and clergy. But the Crusades gave an impetus to the church in this sort of work; and the old process being too slow, special inquisitorial commissions were appointed by the popes. The first was appointed by Innocent III. for the extermination of the heretical Albigenses in the south of France (1215). In this commission the most active agent was St Dominic, the founder of the order of friars of that name; and the Dominicans became ever after the special agents of the popes in this odious function. Following the example of Innocent III. his successors soon planted, with consent of the civil authorities, tribunals of Dominicans in all the cities and states of Italy, then full of heretics. In the year 1416, no fewer than 300 persons were burnt in the diocese of Como alone, the average annual number being 100. The Inquisition was extended into other countries; but in some—such as England, where the rulers were adverse to it—it never took root. In Spain, it was organised into a permanent institution (1483), under a terrible functionary appointed for life, called an Inquisitor-general.

3. *Movement for a Reform in the Church.*—The inordinate power of the popes, which had all along been resisted by the civil rulers, began to press upon the bishops and clergy, now that they found their influence swamped by those papal emissaries, the Mendicant Friars. This begot a desire to revive the authority of general councils of the church, and to subordinate the popes to this authority. The result was the convening of the council of Constance (1414), and afterwards that of Basle (1431); in which, however, all attempts at reform were rendered abortive by a strong party in the papal interest.

But not merely was there dissatisfaction with the administrative abuses of the system; doctrines and ideas began to prevail contrary to the usual teaching of the church, and aiming at the very foundations of the papacy. Among the chief promulgators of those views were John Wycliffe in England (died 1384), and his disciples, John Huss, and Jerome of Prague, in Bohemia. The doctrines of Wycliffe (called Lollardism) and of Huss were almost identical with modern Protestantism. Though kept down for a time by persecution, they were never entirely rooted out, but burst forth anew in the more successful 'Reformation' of the sixteenth century.

HISTORY OF GREAT BRITAIN AND IRELAND.

BRITAIN BEFORE THE ROMAN CONQUEST.

ALTHOUGH it was to the ambition of the Romans that the British Islands owed their introduction within the pale of authentic history, there is yet reason to believe that they were known more or less vaguely to other nations before the time of Julius Cæsar. When Hecatæus speaks of a large island off the coast of Gaul inhabited by a sacred race of Hyperboreans, there can be little doubt that it is the island subsequently known as Britannia that he refers to, and it is a moot-point whether Britain or Iceland is the Ultima Thule of the ancients. The Phœnicians, the chief traders of the ancient world, were the first to make any use of the knowledge that the British Islands existed, if they did not discover them. The tin ores of Spain beginning to fail, certain Phœnician adventurers from Cadiz were induced to explore the south-western coasts of Britain, and found what they wanted in a group of ten islands, called, on account of their chief product, Cassiterides or the Tin Islands, the Scilly Isles of modern history. So carefully did the Phœnicians, for the purposes of trade, conceal their discovery, that Herodotus, about five centuries before the birth of Christ, acknowledged that he had been unable to ascertain the geographical position of the Cassiterides. Ultimately, however, they were re-discovered by the Carthaginians, the Grecian colonists of Marseilles, and others; and at the time of the Roman invasion, the inhabitants of Britain exported, to a considerable extent, not only tin, but hides, lead, and even iron, receiving in exchange such articles as salt, earthenware, and brass.

The ancient British tribes, whom the Romans encountered when they crossed the English Channel, belonged, no doubt, to the Aryan race, which came into Europe from the east, and to the Celtic branch of it. The probability is, that they were originally immigrants from Gaul and Belgium, although it is possible that the south-western portions of the island were colonised, as suggested by the historian Tacitus, from Spain. There is also a strong probability, from the weapons and tools found in British tombs, that the Celtic tribes conquered and extirpated or absorbed another and still more ancient savage people. These tribes were about forty in number, according to the most ancient accounts, and divided into two important sections, the Gael in the north, and the Cymri in the south and south-west. Each tribe had its chief or king, who lived in a wooden hut, defended by boughs of trees, while his subjects dwelt in poorer huts or in caves. They had little knowledge of agriculture, and lived very much as the North American Indians do, upon animals caught in hunting and upon fruits. The exigences of climate had made them singularly patient of fatigue and privation, but had also made them sanguinary, vindictive, and rapacious. They stained their bodies blue with the plant woad, to render them formidable in battle; and they used in warfare both cavalry and chariots.

The religion of the British tribes is known as Druidism. There is no evidence that they worshipped images, although they are said to have had both principal gods and local deities or genii; but the great objects of their veneration were the oak and the mistletoe. The bulwark of this religious system was the priests or Druids, who knew and administered the laws, had a high reputation for learning, and were the most powerful class in the island. By their persuasion, human sacrifices were frequently offered up to the gods, these being captives, or, more commonly, malefactors. The island of Anglesea (Mona) was considered the sacred centre of the Druidical system.

CONQUEST BY THE ROMANS.

It was the sword and the pen of Caius Julius Cæsar that first made Britain something more than a myth to the rest of the world. In the year 55 B.C. this great commander, statesman, and historian found himself on the north coast of Gaul (now France), which he had traversed in triumph from the foot of the Alps to the mouth of the Rhine. From thence he descried the white cliffs of the island, separated from Gaul by what is now known as the English Channel. Desirous to add to his own knowledge, and ambitious to conquer a new province for Rome, he took advantage of the pretext that the Britons had given assistance to a Gallic tribe (the Veneti), with whom he had been engaged in hostilities; and, sailing from Portus Itius, he invaded Britain, landing near Deal. The Britons offered a gallant resistance, doing much execution with their javelins; but the discipline of the Roman legions prevailed, and they effected a footing on the island. They did nothing more, however; and after staying twenty days, Cæsar, fearing the approach of winter, returned to Gaul. Next year (54 B.C.), he landed again with a force of five legions, defeated the Britons, under Cassivellaunus, in several engagements, and conquered a large portion of what now forms the counties of Middlesex and Essex. The Britons sued for peace, and obtained it on condition of paying an annual tribute. This promise was disregarded by the Britons; Cæsar, being fully employed elsewhere, was unable to punish the neglect, and his conquests produced little or no effect upon Britain.

For about a hundred years after the second invasion of Cæsar, Britain enjoyed peace. In the year 43 A.D. however, when the Emperor Claudius was reigning at Rome, another large army, commanded, first, by Aulus Plautius, and subsequently by Claudius himself, invaded the island, and subdued several tribes. A British

prince, the king of the Silures, a tribe dwelling on the banks of the Severn, called Caradoc, or Caractacus, who had made a noble defence against their arms, was finally betrayed into their hands, and sent prisoner to Rome. His bold bearing in Rome, however, so struck the emperor, that he gave him his freedom, and allowed him to return to his country. In 61 A.D. the Roman governor or legate, Suetonius Paulinus, reduced the sacred Druidical island of Mona (Anglesea), destroyed its altars, and cut down its groves. The extortions and outrages of the Romans roused the subject Britons, and under Queen Buddug or Boadicea, they fell upon and destroyed the Roman settlements of Londinium (London), Camalodunum (Colchester), and Verulamium (St Albans), massacring their garrisons. She was defeated, however, in a bloody battle by Suetonius, and is believed to have poisoned herself.

Julius Agricola, the father-in-law of the historian Tacitus, who was governor of Britain from 77 to 85 A.D., was the true conqueror of the country. A beneficent ruler as well as an able general, he not only conquered England, but extended the influence of Rome to the Firths of Forth and Clyde, which he connected by a chain of forts. He was the first to sail round the island, discovering the Orkneys. He even pushed north of the Forth, and was opposed, according to Tacitus, by a large army of the inhabitants, under a chief named Galgacus, whom he completely overthrew at a place called by the historian *Mons Graupius*.* Agricola did much by the fairness of his administration to conciliate the Britons to Roman rule. He induced them to adopt the Roman language, religion, and dress; under him, good roads, some of which still remain, were made; and temples, courts of justice, dwelling-houses, and even towns were built.

It appears that Agricola, while on the west coast of Scotland, was desirous of making the conquest of Ireland, which he thought would be useful, both as a medium of communication with Spain, and as a position whence he could overawe Britain. He formed an acquaintance with an Irish chief, who, having been driven from his country by civil commotions, was ready to join in invading it. By him, Agricola was informed that the island might be conquered by one legion and a few auxiliaries. The inhabitants, according to Tacitus, bore a close resemblance to the Britons. Prudence, however, prevented Agricola from attempting the conquest of this other island.

Although the Romans had now effectually conquered the Britons, they were baffled in all their attempts upon the northern part of Scotland, which was then called Caledonia. The utmost they could do with the inhabitants of that country was to build walls across the island to keep them by themselves. The first of these was built in the year 120, by the Emperor Hadrian, between Newcastle and the Solway Firth. Parts of this are still in existence, under the name of the Picts' Wall. Under the reign of Antoninus Pius, however, and in the year 139, a fresh rampart, called now Graham's Dike, was made along Agricola's line, from near Blackness on the Forth to West Kilpatrick on the Clyde. The Caledonians still proving troublesome, the Emperor Severus marched in person into the north of Scotland, and, about the year 210, built a chain of forts along the line of Hadrian's Wall. Frequent attempts were afterwards made to extend the Roman Empire north of Hadrian's Wall, and under Lollius Urbicus and other commanders, the Romans must have penetrated Scotland beyond the more northerly rampart, and from remains it is believed they reached the north-east end of Loch Ness, near the present town of Inverness. There is, on the other hand, historical ground for believing that the Caledonians or Picts, as they were otherwise called, penetrated southward as far as Kent.

Under the Romans, Britain assumed all the appearance of a Roman province. Most of the towns which arose during this rule sprung from colonies, as Lincoln (Lat. *colonia*, the colony of Lindum, as the Romans originally named the place), or from stationary camps, as Chester (Lat. *castra*, a camp). Both agriculture and trade made some progress, but Roman luxury and vice demoralised a once hardy race. Christianity was introduced probably by missionaries from Asia Minor, although it is not exactly known when. The first martyr is believed to have been St Alban, who was put to death at Verulam in 304. In 314, and in the reign of Constantine, British bishops attended the council of Arles; and after that date, Christians, whether Roman or Briton, were allowed to live peacefully on the island.

CONQUEST BY THE SAXONS.

The Roman Empire was already in its decadence when Agricola made Britain one of its provinces, and that decay became more rapid as the empire grew older. Hard pressed by the attacks of enemies in almost all quarters, the emperors, after the time of the Antonines, were unable to defend Britain as before against the Picts and the Scots—the latter a Celtic tribe which had immigrated into Scotland from the north of Ireland. At the same time, new enemies assailed Britain from the sea. These were Teutonic tribes, who came chiefly from the mouths of the Elbe and the Weser, in North Germany, and spoke a Low-German or Low-Dutch dialect. There seems good ground to believe that, before this, Teutonic mercenaries had served in the Roman armies in Britain, as in other portions of the empire, and that settlements of such soldiers became small though permanent colonies. Whether these attracted kinsmen from Germany or not, three tribes of pirates at this time became famous—the Angles, the Saxons, and the Jutes. Matters in Britain grew worse and worse, and in 409 the Emperor Honorius withdrew the Roman legions, and left the Britons to themselves. They, rendered unwarlike and effeminate by the long continuance of Roman dominion, and divided among themselves, were unable to make head against the assailants both by land and sea. The popular story is, that, taking the advice of Gwrtheyrn or Vortigern, one of their chiefs, they called in the aid of Hengest and Horsa, two princes of the Jutes, in the year 449, against

* The accepted reading of the text until quite recently was *Grampius*; and as the battle was assumed to have been fought near the great central ridge of the country, that central ridge came to be called the Grampians—a name quite unknown to native history or tradition. A more careful examination of the manuscripts shews that Tacitus wrote *Graupius*; and the locality of the battle is thought to be indicated by the remains of a Roman camp at Ardoch, between Dunblane and Auchterarder, in Perthshire.

the barbarians of North Britain; and it is probable enough that they had recourse to Teutonic mercenaries, as the Romans had done. The remedy, however, was found no better than the disease. The Teutons, indeed, defeated the Picts; but having acquired a footing in the island, the traditional account is, that the isle of Thanet was ceded to the followers of Hengest and Horsa, as a reward for their assistance. These hardy adventurers sent over for fresh swarms of their countrymen from North Germany, and made war, on their own account, against the Britons. The war lasted for 150 years, and there is some reason to believe that the victory was not always with the invaders; on the contrary, the British prince, Arthur, now celebrated more in romance and poetry than in history, would seem to have defeated the Saxons at Badbury, in Dorsetshire, in the year 520, and to have checked their conquests for a considerable time. Finally, however, the Britons or Welsh (that is to say, strangers), as their opponents styled them, were completely overthrown. In many districts, they were absolutely extirpated or enslaved; and so completely was the population changed, that, excepting in the names of some of the hills and rivers, the British language was extinguished, and even the name of the country was changed from what it originally was to Angleland or England, the land of the Angles. By the end of the sixth century, the Teutonic dominion extended from the German Ocean to the Severn, and from the English Channel to the Firth of Forth. Some of the Britons fled to France, giving their name to the province of Little Brittany; but the majority of them sought shelter in what is now known as Wales, the peninsula containing Cornwall, Devon, and part of Somerset, and in what was subsequently styled the kingdom of Strathclyde, stretching from Dumbarton to Chester.

After a time, and about the end of the sixth century, seven kingdoms of the Teutonic settlers became pre-eminent—Kent, founded by the Jutes under Hengest; Sussex (South Saxons), founded by the Saxons under Ella; Wessex (West Saxons), founded by Cerdic; Essex; Northumbria (which extended from the Humber to the Forth), founded by the Angles under Ida; East Anglia, founded by Offa; and Mercia, founded by Crida. These seven kingdoms have sometimes been called the Heptarchy, but historical criticism has shewn that they were never under the supremacy of a single overlord, although occasionally one chief gained a certain authority over the others, and was called a Bretwalda, or leader of Britain.

The Anglo-Saxons were heathens; their chief deities were Wodin or Odin—the giver of valour and victory—and Thunder or Thor, the ruler of the sky (whose names are still perpetuated in the two days of the week, Wednesday and Thursday); and they believed in a Walhalla, or heaven, in which the brave were to continue their favourite earthly pursuits, such as war and the chase. Their kings were taken from the royal house, but still were elected. The king was guided by a sort of parliament, called the Witan or Witena-gemôt, or Meeting of the Wise, in which all freemen could take part. The freemen were divided into Earls and Churls, corresponding very much to 'gentle' and 'simple.' There were also *thralls*, or slaves, many of whom had been originally Welshmen or Britons. The king had his *thegns*, or thanes, warriors specially devoted to his service. The chief district divisions were the *shire*, or county; the *hundred*, a division of the county; and the *mark*, or township.

In the northern part of the island were the Picts, first mentioned in 296, and generally believed to be of Celtic origin, and who held the east of Scotland; the Britons, who held Strathclyde or Cumbria, stretching from Lancashire to the Clyde, having as their chief seat Alclyd or Dumbarton; the Scots or Dalriads, a Gaelic tribe who, in 503, under a famous chief, Fergus Mor MacEarca or Loarn More, crossed in leathern coracles from the north-eastern coast of Antrim to the coast of Southern Argyll; and the Saxons, who struggled much with the Picts, often extending their conquests to the Forth, while the former often extended theirs to the Humber. The Picts and Scots continued distinct until the latter proved the superior race, and Kenneth united both under himself in 843. Kenneth's successors conquered Strathclyde, and made further progress, until one of them, Malcolm II. held nearly the whole of Scotland north of the Tweed, and even laid claim to Cumberland and Northumberland.

The conversion of the Teutonic population to Christianity was due, not to the Welsh, but directly to Rome. Pope Gregory the Great, in 597, sent a band of monks, having at their head the celebrated Augustine, into Britain. He converted Æthelbert, king of Kent, then the chief prince in Southern Britain, partly through his wife Bertha, who was a Christian, and the daughter of Charibert, a Frankish king in Gaul. He gave Augustine and his monks a home in Canterbury, and the former became the first archbishop of Canterbury. Edwin of Deira, who ascended the Northumbrian throne in 617, and who was the most powerful monarch of his time in England, was converted by Bishop Paulinus, whom his wife, the daughter of Æthelbert, brought with her, and he founded York Minster. The Northumbrians subsequently lapsed into heathenism, and were reconverted by Aidan, a monk from the Scotch monastery of Iona, who fixed his episcopal see in Lindisfarne, since called Holy Island. The other kingdoms of England were converted to Christianity during the seventh century. It is not certain how Christianity was introduced into Scotland, but the first great name that occurs is that of Ninian, who founded a religious house at Whithorn, in Wigtownshire, and who is said to have died in 432, the same year that St Patrick evangelised Ireland. It was from Ireland, then a land of peace and enlightenment, that the great missionary of Christianity to Scotland, Columba, came. Excommunicated by the Irish church, on account, it is said, of a deadly quarrel between two Irish clans about the appropriation of a Psalter, Columba, who was connected with chiefs in Argyll, sailed from Ireland to Iona in 563, and founded there a monastery, which became both a missionary centre and an ecclesiastical training college. The original Columbites, whose successors the simple brotherhood of Culdees were believed to be, did not acknowledge the supremacy of Rome, and it was not till 716 that they conformed to the Roman ritual.

For a time three of the Anglo-Saxon monarchies,

Mercia, Northumbria, and Wessex, struggled for the supremacy; but ultimately the last, under Ecgberht, or Egbert, who succeeded to the throne in 802, obtained the first place. He conquered the Saxons and Jutes, the Welsh in Cornwall; and Wales submitted to him, and the kings of Mercia, East Anglia, and Northumbria became his vassals. In his reign began the incursions of the Danes or Northmen, a Teutonic race, speaking a kindred tongue to that of the English, and among whom piracy was a highly esteemed profession. It was in 864, and in the reign of Æthelred, one of Egbert's grandsons, that they made a formidable invasion under two famous chiefs, Ingvar and Ubba, overrunning Northumbria and Mercia. Æthelred was succeeded, in 871, by the celebrated Ælfred or Alfred, then twenty-two years of age. He reigned for seven years, until his sovereignty was virtually overturned in 878, by Guthrum, a Danish chief, who suddenly overran Wessex; and for a time he had to hide himself in the swamps of Somersetshire. Gathering strength, however, he fell upon the Danes, and gave them a crushing defeat, when they thought themselves in no danger, and regained a considerable part of his kingdom. Alfred spent the rest of his life in literary study, of which he was very fond, and in forming laws and regulations for the good of his people. He was one of the most able, most virtuous, and most popular princes that ever reigned in Britain. He died in the year 901, in the fifty-third year of his age.

SAXON AND DANISH KINGS.

Alfred's son, Eadward or Edward, who succeeded him on the throne, was perhaps the most powerful of the Saxon kings. He was called Lord of all Britain; the Northumbrians, the Scots, and the Welsh of Strathclyde, doing him homage. The Danes had, however, obtained a firm footing in the time of Alfred, having received, by a treaty concluded with him, East Anglia and part of Essex and Mercia. For many reigns there was a perpetual struggle with varying success between them and the English. In the reign of Æthelred II. (surnamed *the Unready*), who reigned from 979 to 1016, their invasions increased to such an extent that the king endeavoured to buy them off with money, obtained by a tax called *Danegeld*. In 994, Swend or Swegen, the king of the Danes, himself invaded England, and, after a severe struggle, in which Æthelred sought shelter with his brother-in-law Richard, Duke of Normandy, and London four times drove off the invaders, became in 1013 master of England. After Swend's death the struggle was renewed between his son Cnut or Canute, and the son of Æthelred, Edmund, surnamed *Ironside*. Ultimately, the two divided England between them. On Edmund's death, Cnut, who was also monarch of Denmark, and had conquered Norway and a portion of Sweden, became sole monarch of England. After him, there reigned two other Danish kings, Harold and Harthacnut. When the latter died, in 1042, the old Saxon line was restored, the people electing to the throne Eadward or Edward, the son of Æthelred, and surnamed *the Confessor*. Edward had been brought up in Normandy, and shewed a decided preference for the Normans, many of whom he brought to England and loaded with honours. The Saxons were jealous of the Normans, and their jealousy found a champion in Godwin, the powerful earl of the West Saxons. He was at one time banished, but returned with such a powerful following, that the Norman adventurers fled, and Edward, to make peace with his powerful subject, married his daughter Edith. Godwin was succeeded in the earldom by his son Harold, who in reality ruled England, and who gained many victories over the Welsh.

THE NORMAN CONQUEST.

Edward died in 1066, and although he was said to have promised the throne of England to William, Duke of Normandy, he also seems, on his death-bed, to have recommended to his people and nobles his brother-in-law, Harold. The latter, in spite of his having, according to report, sworn allegiance to William himself, and although Edgar Ætheling, the grandson of Edmund Ironside, might be considered to have the most legitimate title to the throne, was elected king by the Witan on the day of Edward's death. Duke William resolved to contest the throne, and being recognised by Pope Alexander II. as the rightful heir, made preparations for an invasion of England. Before he landed, Harold had other enemies to encounter in Harold Hardrada, a gigantic warrior, and king of Norway; and his own brother Tostig, who had been banished from his government of Northumberland during the previous reign, and now invaded the north of England together with Hardrada. Harold met them at Stamford Bridge, in Yorkshire, on 25th September; the invaders were completely defeated, and both the leaders of the invasion were left among the slain. William landed on the 28th at Pevensey, on the Sussex coast, and occupied Hastings. Harold marched southward with all haste, and pitched his camp on the field of Senlac. On the 14th October, the conflict for the supremacy of England took place. It was long and doubtful, but the English king falling, pierced in the eye with an arrow, his army gave way, and the day was William's. The English even in London were so completely paralysed by Harold's defeat, that, although for a time they made a show of making young Edgar king, they ultimately tendered the crown to the Norman duke, who was formally crowned at Westminster on Christmas Day.

THE EARLY NORMAN KINGS.

WILLIAM, surnamed *the Conqueror*, reigned from 1066 to 1087, being chiefly engaged all that time in completing the subjugation of the Saxons, especially in the north, which he harried mercilessly. He is allowed to have been a man of much sagacity, and a firm ruler; but his temper was violent, and his disposition brutal. At the time of his death, which took place in Normandy, WILLIAM, who was the second son, seized upon the crown, which it was also the wish of his father that he should have, Robert, the eldest son, having been frequently in rebellion against him, and having received besides the dukedom of Normandy. William, who was an unpopular monarch, and much addicted to sensual vice, was shot accidentally, it was maintained, by Walter

Tyrrel, in the New Forest, in the year 1100. Towards the close of this reign, the whole of Christian Europe was agitated by the first Crusade—an expedition for the recovery of the Holy Land from the Saracens. Robert of Normandy had a high command in this enterprise, and gained much fame as a warrior, having even mortgaged his dukedom for the means with which to go to Palestine; but while he was in Italy, on his return, his youngest brother Henry usurped the throne left vacant by William, so that he was again disappointed of his birthright. HENRY I. —surnamed *Beauclerc*, from his being a fine scholar—was a prince of some ability; but he disgraced himself by putting out the eyes of his eldest brother, whom he defeated at Tinchebrai in Normandy, in 1106, wresting his dukedom from him, and keeping him nearly thirty years in confinement.

It was in the reign of William II. or *Rufus*, that Scotland came first into notable connection and collision with England. Allusion has been already made to Malcolm II. as the first monarch who could claim anything like supremacy over the whole of Scotland, although even he had but scant obedience from communities of mixed but mainly Celtic origin in the north, which were generally under chiefs called Maarmors, and were also generally engaged in hostilities with each other. Malcolm, who had obtained the throne by slaying his predecessor Kenneth IV. seems to have been succeeded by his grandson Duncan. He in turn was slain by Macbeda, the Maarmor of Ross, whose wife, Gruach, was, according to tradition, the grand-daughter of Kenneth IV. Macbeda is the Macbeth of Shakspeare; but although in popular belief a monster, he was the most powerful monarch that had yet ruled in Scotland, holding sway over the whole of the country, except the isles and a portion of the Western Highlands; and, curiously enough, he appears in history as the first Scotch monarch that was a benefactor of the church and offered his allegiance to Rome. Duncan had married a sister of Siward, Earl of Northumberland, and on the death of the former, his two sons sought refuge with their uncle. Fifteen years after Duncan's death, the elder of these, Malcolm, invaded Scotland with a large army. A battle was fought at the famed Dunsinane; but the decisive engagement of the war was at Lumphanan in Aberdeenshire, in 1056, where Macbeda was killed. The war was carried on for a short time by Lulach, a son of Queen Gruach by a former marriage. But he also was slain; and MALCOLM (surnamed *Canmore*, or Bighead) was crowned at Scone, this being the first Scottish coronation mentioned in history. In the reign of Malcolm, a number of Saxons, on account of the Norman Conquest, sought refuge in Scotland. Among these were Edgar Ætheling, the Saxon pretender to the throne, his mother, and two sisters. Malcolm married Margaret, one of these sisters, and endeavoured to assist Edgar, his brother-in-law, against the Conqueror. After a struggle, the ancient chronicle informs us that 'Malcolm became agreed with King William, and became his man.' In the reign of Rufus, however, the struggle was renewed; and in the course of an invasion into the north of England, in 1093, Malcolm was surprised and slain near Alnwick, by Robert, Earl of Northumberland. Both Malcolm, who was a sagacious and energetic ruler, and his wife Margaret, who was a woman of high culture and great piety, did a great deal to improve Scotland. At Malcolm's death, the crown was contested for a time by Donald Bane, a brother of Malcolm, and by Duncan, a son by a former wife; but in 1097, EDGAR, a son by Margaret, ascended the throne. He, in turn, was succeeded by his two brothers, ALEXANDER I. in 1107, and DAVID I. in 1124, who, as Earl of Huntingdon, had been a powerful English nobleman. In the reign of David, the Church of Rome gained complete ascendency in Scotland, and a large number of churches and monasteries were founded.

Henry Beauclerc of England, in order to strengthen his claim to the throne of England and the loyalty of its people by a Saxon alliance, married Matilda or Maud, the daughter of Malcolm Canmore and of the Princess Margaret. By her he had an only daughter of the same name, whom he married first to the Emperor of Germany, and then to Geoffrey Plantagenet, eldest son of the Earl of Anjou, in France. Through the death by drowning, in the English Channel, in 1120, of Henry's only son William, this lady, and her children by Plantagenet; were properly the heirs of the English crown; but on the death of Henry, in 1135, it was seized by STEPHEN of Blois, Count of Boulogne, and son of Henry's sister Adela, and a man of easy and popular manners, who reigned for nineteen years, during which the country was rendered almost desolate by civil contests, in which David of Scotland joined in the interests of Matilda. The most remarkable conflict of the war was 'The Battle of the Standard,' which was so named from a tall cross raised on a car accompanying the English army which ventured to oppose David, and which was fought at Northallerton in Yorkshire, in 1138. After a severe engagement, David, baffled rather than beaten, withdrew from the field.

On the death of Stephen, in 1154, the crown fell peacefully to HENRY II. who was the eldest son of Maud, and the first of the Plantagenet race of sovereigns. Henry's reign was principally marked by a series of measures for reducing the power of the clergy, in the course of which some of his courtiers, in 1171, thought they could not do him a better service than to murder Thomas-à-Becket, archbishop of Canterbury, who had been the chief obstacle to his views, and a man of great ability and ambition. For his concern in this foul transaction, Henry had to perform a humiliating penance, receiving eighty lashes on his bare back from the monks of Canterbury.

Henry was the most powerful king that had yet reigned in Britain. Besides the great hereditary domains which he possessed in France, and for which he did homage to the king of that country, he exacted a temporary homage from WILLIAM of Scotland, the grandson of David, a monarch of great valour, who took the surname of *the Lion*, and who reigned from 1165 to 1214. Henry also added Ireland to his dominions. This island had previously been divided into five kingdoms —Munster, Leinster, Meath, Ulster, and Connaught. The people were perpetually quarrelling among themselves; and this fact, taken in conjunction with their heathen religion, furnished

a flimsy pretext for invading them from England. Dermot Macmorrough, king of Leinster, having been dethroned by his subjects, introduced an English warrior, Richard, Earl of Pembroke, generally called *Strongbow*, for the purpose of regaining his possessions. A body composed of 50 knights, 90 esquires, and 460 archers, in all 600 men, was enabled by its superior discipline to overthrow the whole warlike force that could be brought against it; and the conquest was easily completed by Henry in person, who went thither in 1171. The military leaders were left to rule over the country; but they managed their trust so ill, that the Irish never became peaceable and improving subjects of the Norman king, as the English had gradually done.

RICHARD CŒUR DE LION—JOHN—MAGNA CHARTA.

Henry II. was much troubled in his latter years by the disobedience of his children. At his death, in 1189, he was succeeded by his son RICHARD, styled *Cœur de Lion*, or the *Lion-hearted*, from his headstrong courage. At his coronation, the people were permitted to massacre many thousands of unoffending Jews throughout the kingdom. Almost immediately after his accession, he joined the king of France in a second Crusade. To obtain funds, he sold crown lands and even state offices, and for 10,000 marks gave up to William the Lion 'all the conditions which Henry by new deeds and by his capture had extorted.' Accompanied by Philip Augustus of France, he landed in Palestine (1191), and fought with prodigious valour, but with no good result. On one occasion, being offended at a breach of truce by his opponent Saladin, he beheaded 5000 prisoners, whose deaths were immediately revenged by a similar massacre of Christian prisoners. In 1192, he returned with a small remnant of his gallant army, and being shipwrecked at Aquileia, wandered in disguise into the dominions of his mortal enemy, Leopold, Duke of Austria, who, with Henry VI. Emperor of Germany, detained him till he was redeemed by a ransom, which impoverished nearly the whole of his subjects. This prince spent the rest of his life in wars with Philip of France, and was killed by an arrow at the siege of a castle in Limousin, in 1199, after a reign of ten years, of which he had spent only about three months in England.

JOHN, the younger brother of Richard, succeeded, although Arthur, Duke of Brittany, the son of his elder brother Geoffrey, was the lawful heir. John, a vain, cruel, and weak prince, alienated the affections of his subjects almost at the very first by his conduct towards his nephew, who suddenly disappeared, and whom he was said to have assassinated with his own hands. The tyranny and wickedness of John, shewn in his imposition of oppressive taxes and his revival of the forest laws, as well as in his cruelty, his licentiousness, and his struggles with the church, caused his barons to rise against him, and the result was, that, on the 15th June 1215, he was compelled by them to sign what is called the *Magna Charta*, or Great Charter, granting them many privileges and exemptions, and generally securing the personal liberty of his subjects. The principal point concerning the nation at large was, that no tax or supply should be levied from them without their own consent in a Great Council.

John, however, induced the pope (Innocent III.) to annul the Great Charter, and renewed his struggle with the barons, who even offered the throne to Louis, eldest son of Philip of France. The struggle between John and Louis continued till the death of the former in 1216. Some time after his death, Louis, deserted by the barons, withdrew from England.

HENRY III.—ORIGIN OF PARLIAMENT.

John was succeeded by his son, HENRY III. a weak and worthless prince, who ascended the throne in his boyhood, and reigned fifty-six years, without having performed one worthy act of sufficient consequence to be mentioned. In his reign was held the first assemblage approaching to the character of a parliament. It was first called in 1225, in order to give supplies for carrying on a war against France. Under the earlier Norman kings, and even, it is believed, under the Saxons, an assembly called the Great Council had shared with the sovereign the power of framing laws; but it was only now that the body had any power to balance that of the sovereign, and it was not till 1265 that representatives from the inhabitants of towns were introduced.

EDWARDS I. AND II.—ATTEMPTED CONQUEST OF SCOTLAND.

Henry III. at his death in 1272 was succeeded by his son, EDWARD I. a prince as warlike and sagacious as his father was the reverse, and who had distinguished himself, even in his father's reign, by relieving him from the barons, into whose hands he had fallen, and defeating them and their leader, Simon of Montfort, Earl of Leicester, at the battle of Evesham in 1265. Early in his reign Edward reduced Wales, whose prince, Llywelyn, had refused to do what his predecessors had done, swear fealty to the English monarch. An insurrection by Llywelyn's brother, David or *Daffyd*, was crushed, and David executed in 1283. In the meantime, from the death of William the Lion in 1214, Scotland had been ruled by two princes, ALEXANDERS II. and III. under whom it advanced considerably in wealth and civilisation. On the death of Alexander III. in 1285, the crown fell to his grand-daughter, MARGARET, a young girl whose father was Eric, king of Norway. Edward formed a treaty with the Estates of Scotland for a marriage between this princess and his son Edward, styled Prince of Wales. Unfortunately, 'the Maid of Norway,' as the young queen was styled, died at Orkney, on her way to Scotland, in 1290; and the crown was left to be disputed by ten distant relatives, of whom JOHN BALIOL and ROBERT BRUCE seemed to have the best right. Edward, being resolved to make Scotland his own at all hazards, interfered in this dispute, and being appointed arbitrator among the competitors, persuaded them to own in the first place an ill-defined claim put forward by himself of the right of paramountcy or superior sovereignty over Scotland. When this was done, he appointed Baliol to be his vassal-king, an honour which the unfortunate man was not long

permitted to enjoy. Having driven Baliol to resistance, and alliance with the king of France, he invaded the country, overthrew the Scotch army, and stripping Baliol of his sovereignty, assumed to himself the dominion of Scotland, as a right forfeited to him by the rebellion of his vassal.

It is at this time that the celebrated William Wallace, the Scottish national hero, appears on the scene. Wallace's father was a knight and landowner, having the estate of Ellerslie, in Renfrewshire, and a representative of the Saxon element in the population, as opposed to the Norman, to which the nobility belonged, and which was ranged on the side of Edward. Whether or not the stories as to Wallace's personal bulk and strength are true, he must have been a military and political genius of the first order, while his name is synonymous with the purest patriotism. From the first, he chafed under the rule of Edward, and as he became known as a daring opponent of English authority, other patriots joined him, and proceeding from small successes to great, he was able to reduce nearly all the strongholds held for Edward. On the 11th September 1297, he utterly routed at Stirling Bridge an army sent against him and commanded by Warenne, Earl of Surrey, who had been appointed by Edward governor of Scotland. After this defeat he cleared the country of the English invaders, and ruled the country as Guardian of the kingdom. Edward himself, however, marched into Scotland, and on the 22d July 1298, defeated Wallace at Falkirk, in spite of a gallant resistance with an inferior army. After this defeat, Wallace unaccountably vanishes from Scotch history, and certainly from the Guardianship of Scotland; and there is some reason to believe that for a time he lived in France. The war was continued, however, and ultimately Edward again established his authority in Scotland. Wallace, who still held out with a small following, was captured in Glasgow, having been betrayed, it is stated, by his man, John Short, to Alexander de Monteith, Edward's governor of Dumbarton Castle. He was taken to London, tried for treason, and executed on the 23d August 1305.

Some time after the death of Wallace, while Edward was engrossed with his French wars, ROBERT BRUCE, Earl of Carrick, grandson of him who had competed with Baliol, conceived the idea of putting himself at the head of the Scots, and endeavouring by their means at once to gain the crown, and to recover the independence of the kingdom. After a series of adventures, beginning with the stabbing of his rival, Comyn of Badenoch, in Dumfries in 1306, Bruce was crowned at Scone. For some time after, he had to skulk as a fugitive, being unable to maintain his ground against the English officers; but at length he became so formidable, that Edward found it necessary (1307) to lead a large army against him. The English monarch, worn out with fatigue and age, died on the coast of the Solway Firth, at Burgh-on-the-Sands, in 1307, when just within sight of Scotland, leaving his sceptre to his son EDWARD II. That weak prince immediately returned to London, leaving Bruce to contend with his inferior officers.

After several years of constant war, in which one English fortress after another fell into the hands of Bruce, Edward resolved to make a decisive effort to reduce Scotland to subjection, and save Stirling Castle, which held out. In the summer of 1314, he invaded it with an army of 100,000 men. Bruce drew up his troops, which were only 30,000 in number, at Bannockburn, near Stirling. Partly by steady valour, and partly by the use of stratagems, the Scots (June 24) were victorious, and Edward fled ignominiously from the field. The Scottish king gained an immense booty, besides securing his crown and the independence of his country. He next year sent his brother Edward with a body of troops to Ireland, to assist the native *septs*, or clans, in resisting the English. This bold young knight was crowned king of Ireland at Carrickfergus, and for some time held his ground against the English forces, but was defeated at Athenree in 1316, and two years afterwards fell in battle near Dundalk.

The weakness of Edward II. was chiefly shewn in a fondness for favourites, into whose hands he committed the whole interests of his people. At length Queen Isabella and the Prince of Wales raised an insurrection against the king, and he was deposed by parliament as being unworthy to reign. The prince was then crowned as EDWARD III. (1327), being as yet only about fourteen years of age; and in the course of a few months the degraded sovereign was cruelly put to death in Berkeley Castle, the chief instrument in causing his death being Roger Mortimer, the queen's favourite and paramour.

During the minority of the young king, the reins of government were held ostensibly by guardians, but in reality by the queen and Mortimer. Under their administration, a peace was concluded, in 1328, with King Robert of Scotland, of which one of the conditions was a full acknowledgment of the independence of the Scottish monarchy.

EDWARD III.—RICHARD II.

Edward III. who soon after assumed full power by overthrowing and executing Mortimer, was a warlike monarch, and inspired by all his grandfather's desire of conquest. In 1329, Robert Bruce died, and was succeeded by his infant son DAVID, to whom Isabella, a young sister of the English king, was married, in terms of the late treaty. Notwithstanding this connection, Edward aided a son of John Baliol in an attempt to gain the Scottish crown. Edward Baliol overthrew the Regent of Scotland at Dupplin, September 1332, and for two months reigned as King of Scots, while David and his wife took refuge in France. Baliol was, however, obliged to flee, it being believed that he had consented to cede some of the southern counties to England; but an incessant border warfare was kept up, the Scots being assisted by France.

But for his attention being diverted to France, Edward III. would have made a more formidable effort to subdue Scotland. He was led into a long course of warfare with France, to the crown of which he made a claim on the death of Charles IV. without issue, because his mother was a daughter of Philip IV. against the actual monarch, Philip VI. In the victories which he gained at Crecy (August 26, 1346) and Poitiers (September 19, 1356), the national valour, his own, and that of his celebrated son, the Black Prince, were

shewn conspicuously; but this lavish expenditure of the resources of his kingdom, in which he was supported by his parliament, was of no permanent benefit, even to himself, for whom alone it was made. John, king of France, who had been made captive at Poitiers, and David, king of Scotland, who had been taken at Nevill's Cross in 1346, while conducting an invasion of England, were prisoners in England at the same time. In 1360, after about twenty years of active fighting, the English king left France with little more territory than he had previously enjoyed. Edward had invaded Scotland with a powerful army in 1356, but without making any impression. The Scots, under David's nephew, Robert Stewart, effectually protected themselves, not only from his arms, but from a proposal which David himself basely undertook to make, that Lionel, the second son of the English king, should be acknowledged as his successor. Edward died in 1377, a year after the decease of his son, the Black Prince.

England was at this time affected more than at any other by the fashions of chivalry—a military enthusiasm which for some centuries pervaded all Christian Europe, which prompted, as one of its first principles, a heedless bravery in encountering all kinds of danger. Its votaries were expected to be particularly bold in behalf of the fair sex, insomuch that a young knight would sometimes challenge to mortal combat any one who denied his mistress to be the loveliest in the world. It was a system full of extravagance, and tending to bloodshed; but nevertheless it maintained a certain courtesy towards females, and a romantic principle of honour, which we may be glad to admire, considering how rude was almost every other feature of the age. In 1363, John Wycliffe, an Oxford doctor, became famous for the attacks he made on the orders of Begging Friars. He questioned some of the doctrines of the church, and hence he has generally been considered the herald of the Protestant Reformation. He also translated the Bible. His disciples, nicknamed Lollards, were frequently burned as heretics. He died in 1384.

EDWARD III.—in whose later days the government had been conducted chiefly by his third son, John of Gaunt or Ghent, Duke of Lancaster—was succeeded by his grandson, RICHARD II. then a boy of eleven years of age, and who proved to be a person of weak character. The Commons took advantage of the irregularity of his government to strengthen their privileges, which they had with difficulty sustained during the more powerful rule of his predecessor. Early in this reign, they assumed the right, not only of taxing the country, but of seeing how the money was spent. Indignant at the severity of a tax imposed upon all grown-up persons, the peasantry of the eastern parts of England rose, in 1381, under one Walter, a tiler, of Dartford, commonly called Wat Tyler, and advanced, to the number of 60,000, to London, where they put to death the chancellor and primate, as evil counsellors of their sovereign. They demanded the abolition of villeinage or slavery, the free exercise of trades, fixed rents in place of compulsory service, and a general pardon. The king came to confer with them at Smithfield, where Walworth, Mayor of London, stabbed Wat Tyler with a dagger—a weapon which has since figured in the armorial bearings of the metropolis. The peasants were dismayed, and submitted, although not before the king had conceded their demands, which concessions, however, he afterwards got parliament to annul.

The country was misgoverned by Richard II. till 1399, when he was deposed by his subjects under his cousin, Henry, Duke of Lancaster, whom he had sent into exile, and Percy, the powerful Earl of Northumberland. Lancaster was crowned as HENRY IV.; and his predecessor, Richard, soon after disappeared mysteriously, the general belief being that he was murdered in Pontefract Castle.

In the meantime, David of Scotland died (1371), and was succeeded by his nephew, ROBERT STEWART, who was the son of Marjory Bruce, daughter of Robert I. and the first monarch of that family. ROBERT II. dying in 1390, was succeeded by his son ROBERT III. who was a good and gentle prince. He had two sons, David and James: the former was starved to death by his uncle, the Duke of Albany; and the latter, when on his way to France for his education, was seized by Henry IV. of England, and kept captive in that country for eighteen years. Robert III. then died of a broken heart (1406), and the kingdom fell into the hands of the Duke of Albany, at whose death, in 1419, it was governed by his son, Duke Murdoch.

HOUSE OF LANCASTER.

Henry IV. proved a prudent prince, and comparatively a good ruler. As Edmund, Earl of March, great-grandson of Lionel, the second son of Edward III. had a better right to the throne, Henry was much troubled by insurrections, the most formidable of which were those of the Percies. Hotspur, the celebrated son of the Earl of Northumberland, was, however, slain in battle at Shrewsbury; and Northumberland himself, after being the moving power in two other insurrections, was also slain. At the same time, Owen Glendower, who claimed to be descended from the ancient princes of Wales, rose against English authority, and kept his ground for many years. Somewhat strange to say, Glendower died a peaceful death.

On the death of Henry IV. in 1413, he was succeeded by his son, who was proclaimed under the title of HENRY V. The young king attained high popularity, on account of his impartial administration of justice, and his zeal to protect the poor from the oppressions of their superiors. His reign is less agreeably marked by the persecutions of the Lollards, the most notable of whom was a Sir John Oldcastle, Lord Cobham, who was executed as a traitor and a heretic. Being determined to use every endeavour to gain the crown of France, which he considered his by right of birth, he landed in Normandy with 30,000 men (August 1415), and gave battle to a much superior force of the French at Agincourt, October 25. He gained a complete victory, which was sullied by his afterwards ordering a massacre of his prisoners, under the apprehension that an attempt was to be made to rescue them. The war was carried on for some years longer, and Henry would have probably succeeded in making good his claim to the French crown, if he had not died prematurely of a dysentery (August 31, 1422), in the thirty-fourth

year of his age, leaving the throne to an infant nine months old, who was proclaimed as HENRY VI. king of France and England.

Under Henry VI. whose power was for some time in the hands of his uncle, the Duke of Bedford, the English maintained their footing in France for several years; and at the battle of Verneuil, in 1424, rivalled the glory of Crecy and Poitiers. In 1428, when France seemed completely sunk beneath the English rule, the interests of the native prince were suddenly revived by a peasant-girl of sixteen, named Joan of Arc, who declared herself to have been commissioned by Heaven to save her country; and entering into the French army, was the cause of several signal reverses to the English. By her enthusiastic exertions, and the trust everywhere reposed in her supernatural character, Charles VII. was crowned at Rheims in 1430. Being soon after taken prisoner while heading a sally from Compiègne, the heroic maiden was, by the English, condemned for witchcraft, and burned, May 30, 1431. Nevertheless, about the year 1453, the French monarch had retrieved the whole of his dominions from the English, with the exception of Calais.

Henry VI. was remarkable for the extreme weakness of his character. His cousin, Richard, Duke of York, descended from an elder son of Edward III. and therefore possessed of a superior title to the throne, conceived that Henry's imbecility afforded a good opportunity for asserting what he thought his birthright. Then commenced the famous *Wars of the Roses*, as they were called, from the badges of the families of York and Lancaster—the former of which was a white, while the latter was a red rose. In 1455, at St Albans, the duke gained a decisive victory over the forces of Henry. In some succeeding engagements the friends of Henry were victorious; and at length, in the battle of Wakefield (December 24, 1460), the forces of the Duke of York were signally defeated, and himself, with one of his sons, taken and put to death. His pretensions were then taken up by his eldest son Edward, who, with the assistance of the Earl of Warwick, gained such advantages next year that, entering London, he was declared king, 1461. Before this was accomplished, many thousands had fallen on both sides. Henry, who cared little for the pomp of sovereignty, was confined in the Tower.

Scotland, in the meantime (1424), had redeemed her king from his captivity in England; and that prince, styled JAMES I. had proved a great legislator and reformer, not to speak of his personal accomplishments in music and literature, which surpassed those of every contemporary monarch. James did much to reduce the Highlands to an obedience under the Scottish government, and also to break up the enormous power of the nobles. By these proceedings, however, he excited a deep hatred in the bosoms of some of his subjects; and in 1437 he fell a victim to assassination at Perth. He was succeeded by his infant son, JAMES II. who was unfortunately killed, in the flower of his age, by the bursting of a cannon before Roxburgh Castle. His successor, JAMES III. was also a minor, and on reaching man's estate, proved to be a weak, though not ill-meaning prince. He fell a victim, in 1488, to a conspiracy formed by his subjects, and which was led by his eldest son.

HOUSE OF YORK.

Edward, of the House of York, styled EDWARD IV. who commenced his reign in the nineteenth year of his age, was for ten years perpetually disturbed by renewed attempts of the Lancastrian party, of which he mercilessly sacrificed many thousands who fell into his hands. At length, his marriage with the widow of Sir John Grey, a Lancastrian; the honours he showered on her relatives; and the marriage concluded by him between his sister Margaret and the Duke of Burgundy, while the Earl of Warwick was in France—sent there to obtain the hand of a French prince for that princess—offended Warwick, who had been chiefly instrumental in placing him on the throne. That nobleman, aided by Edward's own brother, George, Duke of Clarence, who had married one of his daughters, raised an insurrection against him, and in eleven days was master of the kingdom, while Edward had to take refuge in the dominions of the Duke of Burgundy. Henry VI. was then restored, and Warwick acquired the title of King-maker. Nine months after (1471), Edward landed with a small body of followers, and having called his partisans around him, overthrew and killed Warwick, who had been deserted by Clarence. Margaret of Anjou, who had fought battles for her husband in almost every province of England, gathered a new army, and opposed Edward at Tewkesbury, where she was completely defeated. Her son and husband were taken; the former was murdered in cold blood; and the latter died in the Tower, assassinated, it is said, by Edward's younger brother, Richard, Duke of Gloucester; and she herself spent the remainder of her singular life in France. Edward reigned, a profligate and a tyrant, till 1483, when he died in the forty-second year of his age. He had previously caused his brother, the equally profligate Duke of Clarence, to be drowned, according to the popular story, in a butt of Malmsey wine.

During the reign of Edward IV. the plague frequently broke out in England, and carried off immense numbers of the people. It was particularly fatal in London, and in all other places where many houses were huddled closely together, with imperfect means of cleaning and ventilation. It was calculated that the disease, on one occasion in this reign, destroyed as many lives as the fifteen years' war.

EDWARD V. the eldest son of Edward IV. was a boy of eleven years when he fell heir to the crown, which he never wore. His uncle, Richard, Duke of Gloucester, called 'Crook-back,' and pictured as a blood-thirsty and deformed wretch, soon after contrived to obtain the chief power, and also to cause the murder of the young king and his still younger brother in the Tower, in less than three months after the former had been crowned. He then himself mounted the throne under the title of RICHARD III. and reigned for two years. In 1485, Henry Tudor, Earl of Richmond, who on the father's side was a grandson of Owen Tudor and Katharine, widow of Henry V. and on the mother's, a descendant, through the Beaufort line, of John of Gaunt, resolved to make an attempt upon the English crown, as the representative of the House of Lancaster. Having landed with about 2000 followers at Milford-

Haven, he advanced into the country, and speedily gained such accessions of force as enabled him to meet and overthrow Richard at Bosworth Field, where the tyrant was slain, and the victorious Richmond was immediately proclaimed king, under the title of HENRY VII. The new monarch in 1486 sought to strengthen his title by marrying Elizabeth, the daughter and heir of Edward IV. by which it was said the families of York and Lancaster were united.

It was during the struggles between the rival Houses of York and Lancaster that printing was introduced into England, William Caxton, a native of Kent, who had probably learned the art in the Netherlands, setting up a press in 1474. A large number of Caxton's books were translations from the French, and were in what is styled black-letter type.

HOUSE OF TUDOR—HENRY VII.

The reign of Henry VII. was much disturbed by insurrections, in consequence of his imperfect title. A baker's boy, named Lambert Simnel, and a Jew's son, named Perkin Warbeck, were successively set up by the York party—the one as a son of the late Duke of Clarence, and the other as Richard Plantagenet, Duke of York, younger brother of Edward V.—but were both defeated. Warbeck, who, some even yet maintain, was no impostor, was hanged at Tyburn in 1499; and about the same time, Henry procured, by forms of law, the death of the Earl of Warwick, the real son of the late Duke of Clarence, a poor boy, whom he had kept fifteen years in confinement, and whose title to the throne, being superior to his own, rendered him uneasy.

Henry, though a cruel prince, as were most of the sovereigns of his age, was a sagacious and peaceful ruler. The greatest fault in his character was his excessive love of money, of which he amassed an immense sum by extortions, having for his instruments two lawyers, Empson and Dudley. During his reign, Ireland was made more dependent on the English crown by a statute prohibiting any parliament from being held in it until the king should give his consent.

HENRY VIII.

Henry VII. died in April 1509, in the fifty-third year of his age. His eldest surviving son and successor, Henry VIII. was in his eighteenth year. Young, handsome, and supposed to be amiable, he enjoyed at first a high degree of popularity; and gratified many by beheading Empson and Dudley. Some years before, he had been affianced to Catharine, a Spanish princess, who had previously been the wife of his deceased brother Arthur: he was now married to this lady, the pope having previously granted a dispensation for that purpose. The chief administration of affairs was committed to the celebrated Cardinal Wolsey, son of a burgess of Ipswich. The king became much engaged in continental politics; and during a war which he carried on against France, his brother-in-law James IV. who sided with that state, made an unfortunate irruption into the north of England, and was overthrown and slain, with the flower of his nobility (September 9, 1513), at Flodden.

THE REFORMATION IN ENGLAND.

About this time some changes of great importance to European society took place. Almost ever since the destruction of the Roman Empire, the nations which arose out of it had remained in subjection to the see of Rome. With knowledge, the rise of a commercial and manufacturing class, and ready access to knowledge given through the invention of printing, came a disposition to inquire into the authority of this great religious empire. Meanwhile an important event took place in Germany. At Wittenberg, in Germany, there was an Augustine monk, named Martin Luther, who became incensed at the Roman see, the immediate cause of his anger being the fact of the pope having granted the privilege of selling indulgences to the Dominican order of friars. Being a man of a bold and inquiring mind, he did not rest satisfied till he had convinced himself, and many others around him, that the indulgences were sinful, and that the pope had no right to grant them. This happened about the year 1517. Controversy and persecution gradually extended the views of Luther, till he at length openly disavowed the authority of the pope, and condemned some of the most important peculiarities of the Catholic system of worship.

Henry VIII. as the second son of his father, had been originally educated for the church, and still retained a taste for theological learning. He now distinguished himself by writing a book *On the Seven Sacraments*, against the Lutheran doctrines; and the pope of the day, Leo X. was so much pleased with it as to grant him the title of *Defender of the Faith*. In the year 1527, however, he became enamoured of a young gentlewoman named Anne Boleyn, who was one of his wife's attendants. He immediately conceived the design of annulling his marriage with Catharine, who had only one living child, Mary, born in 1516, and marrying this younger and more attractive person. Finding a pretext for such an act in the previous marriage of Catharine to his brother, he attempted to obtain from the pope a decree declaring his own marriage unlawful, and that the dispensation upon which it had proceeded was beyond the powers of the former pope to grant. The pontiff (Clement VII.) was much perplexed by this request of King Henry, because he could not accede to it without offending Charles V. Emperor of Germany, one of his best supporters, and the nephew of Queen Catharine, and at the same time humbling the professed powers of the papacy, which were now trembling under the attacks of Luther.

Henry desired to employ the influence of his minister, Cardinal Wolsey, who had become in succession archbishop of York, chancellor, a cardinal, and the papal legate. But Wolsey, with all his greatness, could not venture to urge a matter disagreeable to the pope, who was more his master than King Henry. The process went on for several years, and still his passion for Anne Boleyn continued unabated. Wolsey at length fell under the king's displeasure for refusing to serve him in this object, was stripped of all his places of power and wealth, and in November 1530, expired at Leicester Abbey in disgrace. Henry having consulted the universities and scholars both at home and abroad, privately married Anne Boleyn. His chief adviser

in this step, Thomas Cranmer, who had been appointed archbishop of Canterbury, pronounced (1533) the marriage with Catharine to have been void from the beginning. Henry now became, after a fashion, a Reformer. In the same year, 1533, it was declared, by the Statute of Appeals, that there should be no appeals to the pope or to any authority outside the kingdom; the king was declared to be the supreme head of the Church of England, which was thus withdrawn from the authority of the pope.

In 1536, Henry became as anxious to put away Queen Anne as he had ever been to rid himself of Queen Catharine. He had contracted a passion for Jane Seymour, the daughter of a Wiltshire knight. In order to gratify this new passion, he accused Anne, truly or falsely, of infidelity; and within a month from the time when she had been an honoured queen, she was beheaded (May 19) in the Tower, leaving a daughter, Elizabeth. On the very next day, he married Jane Seymour, who soon after died in giving birth to a son (afterwards Edward VI.). His daughters, Mary and Elizabeth, were declared illegitimate by act of parliament, and therefore excluded from the succession.

Hitherto, though professing independence of Rome, Henry still maintained, and even enforced by severe and bloody laws, the most of its doctrines. He now took measures for suppressing the numerous monasteries throughout the country. As many as 645 monasteries, 2374 chantries and chapels, 90 colleges, and 110 hospitals, enjoying altogether a revenue of £161,000, were broken up. Part of the revenues thus acquired he kept to himself; part went to some of his courtiers; while the remainder was used in founding new bishoprics, and fortifying the coast. By this act, which took place in 1539, the Reformation was completed in England, although for many years Henry so vacillated in his opinions that many persons of both religions were burnt as heretics.

After the death of Jane Seymour, Henry married (1540) Anne of Cleves, a German princess, with whose looks, however, he was not pleased; and he therefore divorced her by an act of parliament. He next married Catharine Howard, niece to the Duke of Norfolk; but had not been long united to her when he discovered that she had committed a serious indiscretion before marriage. This was considered a sufficient reason for beheading the unfortunate queen (1542), and attainting all her relations. He succeeded in obtaining for his sixth wife (1543) Catharine Parr, widow of Lord Latimer, who, it is certain, only contrived to escape destruction by her extraordinary prudence. Almost all who ever served Henry VIII. as ministers, either to his authority or to his pleasures, were destroyed by him. Wolsey died of a broken heart; Thomas Cromwell, Earl of Essex, who chiefly aided the king in bringing about the Reformation, being styled for his zeal in suppressing monasteries, 'The Hammer of the Monks'—Sir Thomas More, Lord Chancellor, the ablest, most virtuous, and most consistent man of his time—the Earl of Surrey, who was one of the most accomplished knights of the age, and the first poet who wrote the English language with perfect taste—all suffered the same fate as Anne Boleyn and Catharine Howard.

When James IV. died at Flodden, in 1513, the Scottish crown fell to his infant son, JAMES V. His uncle, Henry VIII. endeavoured to bring him into his views respecting religion; but James, who was much in the power of the Catholic clergy, appears to have wished to become the head of the popish party in England, in the hope of succeeding, by their means, to the throne of that country. A war latterly broke out between the two monarchs; and the Scottish army having refused to fight, from a dislike to the expedition, James died (December 1542) of a broken heart, leaving an only child, MARY, then not above a week old. Henry immediately conceived the idea of marrying his son Edward to this infant queen, by which he calculated that two hostile nations would be united under one sovereignty, and the Protestant Church in England be supported by a similar establishment in Scotland. This project, however, was resisted by the Scots, of whom very few as yet were inclined to the Protestant doctrines. Henry, enraged at their hesitation, sent a fleet and army, in 1544, to inflict vengeance upon them. The Scots endured with great patience the burning of their capital city, by Edward Seymour, Earl of Hertford, brother of Queen Jane Seymour, and many other devastations, but still refused the match. The government of Scotland was now chiefly in the hands of Cardinal Beaton, a man of great energy, although a religious bigot, who zealously applied himself to suppress the Reforming preachers, and regarded the English match as likely to bring about the destruction of the Catholic religion. Henry was also twice at war with France, having mixed himself up with the continental quarrels of Francis I. of France and Charles V. Emperor of Germany; but nothing came of two invasions except the capture in 1544 of Boulogne, which by a subsequent arrangement was given back in eight years on payment of a sum of money.

During this reign, considerable attention was paid to the navy, the Admiralty and Navy Office being constituted. In 1536, Wales was incorporated with England; and in 1542, Ireland, from being a lordship, was made a kingdom.

EDWARD VI.—QUEEN MARY.

Henry died January 28, 1547, leaving the throne to his only son, a boy of ten years of age, who was immediately proclaimed king under the title of EDWARD VI. The Duke of Somerset, maternal uncle to the young king, became supreme ruler under the title of Protector, and continued to maintain the Protestant doctrines. Under this reign, the Church of England assumed its present form, and the Book of Common Prayer was composed nearly as it now exists. Somerset being resolved to effect, if possible, the match between Edward VI. and Mary of Scotland, invaded that country in the autumn of 1547, and was met at Pinkie, near Musselburgh, by a large army under the governor, the Earl of Arran. Somerset gained an easy victory, and wasted a portion of the country, but failed in attaining his original object. Previous to this period, Cardinal Beaton had been assassinated by religious opponents; but the Scotch were encouraged to persevere by the court of France, to which they now sent the young queen (the betrothed of the Dauphin, afterwards Francis II.) for protection.

In the reign of Edward VI. the government was

conducted mildly though wastefully, until the Protector Somerset was degraded from his authority by the rising influence of Dudley, Duke of Northumberland, the son of the extortioner Dudley, who caused the Protector soon after to be tried and executed. Northumberland, who is believed to have had no religious convictions, but who, professing to be a keen Protestant, was much favoured by members of that party, was an unpopular and tyrannical ruler. Edward VI. died on the 6th of July 1553, and the crown now belonged by birthright to MARY, the eldest daughter of Henry VIII. who was a zealous Catholic. Northumberland, however, assuming the illegitimacy of that princess and her sister Elizabeth, set up as queen the Lady Jane Grey, cousin of Edward, and granddaughter of Mary Tudor, whom he had married to his son Guilford, Lord Dudley. Lady Jane, who was firmly attached to the doctrines of the Reformation, was, perhaps, the most beautiful, amiable, and accomplished of all the females who appear prominently in the history of England. Unfortunately, her father-in-law, Northumberland, was so much disliked, that the Catholics were enabled to displace her from the throne in nine days, and to set up in her stead the Princess Mary. Northumberland, Lady Jane, and her husband Guilford, Lord Dudley, were all beheaded by this fanatical princess, who soon after took steps for restoring the Catholic religion, and married Philip II. king of Spain, in order to strengthen herself against the Protestant interest. As soon as she had replaced the Catholic system, and found herself in possession of sufficient power, she began that career of persecution which has rendered her name so infamous. Five out of fourteen Protestant bishops, including the revered names of Cranmer, Hooper, Latimer, and Ridley, were committed to the flames as heretics; and during the ensuing part of her reign, which was closed by her death, November 17, 1558, nearly 300 persons suffered in the same manner. In the latter part of her reign, Mary was drawn by her husband into a war with France, of which the only effect was the loss, in the beginning of 1558, of Calais, the last of the French possessions of the sovereigns of England. The natural sourness of Mary's temper was increased by this event, as well as by her want of children and neglect on the part of her husband; and she died in a state of great unhappiness.

ELIZABETH—MARY, QUEEN OF SCOTS—REFORMATION IN SCOTLAND.

A more auspicious scene opened for England in the accession, in her twenty-sixth year, of ELIZABETH, a princess of great native vigour of mind, and who had been much improved by adversity, having been kept in prison during the whole reign of her sister. The court of France, backed up by English Roman Catholics, professed to consider the Queen of Scots, who was descended from the eldest sister of Henry VIII. and had recently been married to the Dauphin, as the Queen of England. Under these circumstances, Elizabeth found no chance of safety except in restoring and maintaining the Protestant religion in her own country, and in seeking to support it in all others where the people were favourable to it. The supremacy of the crown in the church was restored by act of parliament, though not the title of Head of the Church. The *Oath of Supremacy* declared the queen to be the supreme ruler in things ecclesiastical and spiritual as well as temporal; while the *Act of Uniformity* forbade the use by a clergyman of any other Prayer-book than that of Edward, which was now, with some alterations, restored; and punished with a fine those who absented themselves from church. The Scottish nation being now engaged in a struggle with their Regent, Mary of Guise, in behalf of Protestantism, Elizabeth gladly acceded to a proposal made by the nobles of that country, and sent a body of troops, by whose assistance the Reformed religion was established (1560). In bringing about this change, the chief native leaders were James Stewart—a natural son of King James V.—and John Knox, who had once been a friar, but was now a Protestant preacher. About this time, Mary of Guise breathed her last. The young queen, reckoned the most beautiful woman of her time, and who had married Francis II. of France, returned to Scotland on his death, in 1561.

The change of religion in Scotland was of a more decisive kind than it had been in England. The clergy were placed on a footing of perfect equality; they were all of them engaged in parochial duties, and only a small part of the ancient ecclesiastical revenues was allowed to them. In imitation of the system established at Geneva, their general affairs, instead of being intrusted to the hands of bishops, were confided to courts composed of themselves and lay elders. What was of perhaps still greater importance—while a large part of the ancient revenues was absorbed by the nobles, a very considerable portion was devoted to the maintenance of parish schools, under the express control of the clergy. These institutions disseminated the elements of learning more extensively over this small and remote country than it had ever been over any other part of the world.

Queen Mary, having little power in her own country, was obliged to govern by means of her natural brother, James Stewart, whom she created Earl of Moray, and who was the leader of the Protestant interest in Scotland. Personally, however, she was intimately connected with the great Catholic powers of the continent; and became a party, in 1564, to a coalition formed by them for the suppression of Protestantism all over Europe. She had never yet resigned her pretensions to the English throne, but lived in the hope that, when the Catholics succeeded in everywhere subduing the Protestants, she would attain that object.

A succession of unfortunate events threw Mary into the hands of Elizabeth. In 1565, she married her cousin, Lord Darnley, and by that means alienated the affections of her brother and chief minister, the Earl of Moray, as well as of other Protestant lords, who raised a rebellion against her, and were obliged to flee into England. Soon after, the jealousy of Darnley respecting an Italian musician named Rizzio, who acted as French secretary to the queen, united him in a conspiracy with the banished Protestant noblemen for the murder of that humble foreigner, which was effected under very barbarous circumstances, March 9, 1566. Mary, who was delivered, in the succeeding June, of a son, James, afterwards James VI. of Scotland and I. of England, withdrew her affections entirely from her husband.

She subsequently, however, attended him as he was recovering from an attack of small-pox at Glasgow, and on his convalescence, placed him, not in Holyrood, but in a solitary house near Edinburgh, called Kirk-of-Field. He had not been there many days, when the house was blown up, and his body found a short distance off. A licentious nobleman, named Bothwell, afterwards Duke of Orkney, who had become a favourite of the queen, was considered the instigator of the crime, and yet in a few months after Darnley's death she married Bothwell according to the rites of the Protestant Church. This excited so much indignation among her subjects, that the same Protestant lords who had effected the Reformation, and were the friends of Elizabeth, easily obtained the possession of her person, and having deposed her, crowned her infant son as king, under the title of JAMES VI. while the regency was vested in the Earl of Moray. In May 1568, Mary escaped from her prison in Lochleven, and put herself at the head of a body of her partisans; but was defeated by the Regent at the battle of Langside, near Glasgow, and was then compelled to seek refuge in England. By placing her rival under strict confinement, and extending an effectual protection to the Regents Moray, Lennox, Mar, and Morton, who successively governed Scotland, Elizabeth fortified herself in a great degree against the Catholic confederacy.

GOVERNMENT OF ELIZABETH.

At this time parliament was much more under the control of the sovereign than it had formerly been. An idea was now beginning to arise, very much through the supremacy which the sovereigns had acquired over the church, that the right of the crown was one derived from God, and that the people had nothing to do with it, except to obey what it dictated to them. Of this notion, no one took so much advantage, or was at so much pains to impress it, as Elizabeth. Her government consisted entirely of herself and her ministers. All her ministers, the chief of whom were Lord Burghley, his second son, Lord Robert Cecil, and Sir Francis Walsingham, were of one complexion—circumspect and penetrating men, ardently devoted to their country, their mistress, and to the Protestant religion. That religion Elizabeth continued to support by the most rigorous means. She established a High Commission Court to carry into effect the Act of Supremacy, which was directed fully more against the extreme Protestants or Puritans, who obtained their views of ecclesiastical polity from Geneva, than against the Roman Catholics. Yet, of the latter, one hundred and eighty suffered death for violation of the law during this reign.

The Catholic powers of the continent formed many schemes for annoying or dethroning Elizabeth; and the imprisoned Scottish queen or her adherents were generally concerned in them. Philip II. of Spain, whose offer of marriage she had refused, determined at length to make a decisive effort, and commenced the preparation of a vast fleet, which he termed the Invincible Armada, with which he designed to invade the English shores. Elizabeth, her ministers, and people, beheld the preparations with much concern; and with a view to guard against plots by Catholics at home, an act was passed in 1585 declaring that any person, by or *for* whom any plot should be made against the Queen of England, should be guilty of treason. When, soon after, a young gentleman named Babington formed a conspiracy for assassinating Elizabeth, and placing Mary on the throne, the latter queen became of course liable to the punishment for treason, although herself innocent. She was subjected to a formal trial in her prison of Fotheringhay Castle, and found guilty. Elizabeth hesitated for some time to strike an unoffending and unfortunate person, related to her by blood, and her equal in rank. But at length fears for herself got the better of her sense of justice, and, it may be added, of her good sense, and she gave her sanction to an act which leaves an ineffaceable stain upon her memory. On the 8th of February 1587, Mary, Queen of Scots, was beheaded in the hall of the castle, after a confinement of more than eighteen years.

James VI. was now, after a turbulent minority, in possession of the reins of government in Scotland, but with little real power, being very dependent on Elizabeth, who, besides, had no personal liking for him, while he was much controlled by the Presbyterian clergy, who asserted a total independence of all temporal authority, and considered themselves as the subjects alone of the Divine founder of the Christian faith.

SPANISH ARMADA—REBELLIONS IN IRELAND.

In 1588, the Spanish Armada, consisting of 130 great vessels, with 20,000 land-forces and 8000 sailors on board, and commanded by the Duke of Medina Sidonia, set sail against England, while 34,000 more land-forces prepared to join from the Netherlands. Active measures were taken to defend the country; thirty vessels prepared to meet the Armada, and another fleet endeavoured to block up the Netherlands forces in port. The command was taken by Lord Howard of Effingham, with whom were Drake, Hawkins, Frobisher, and other celebrated naval captains of the day. Troops were also mustered on land to repel the invaders, and disposed in three armies. The English Roman Catholics came patriotically forward to defend their country. The English fleet attacked the Armada in the Channel, and was found to have a considerable advantage in the lightness and manageableness of the vessels. As the Armada sailed along, it was infested by the English in the rear. On the 27th of July, the Armada anchored off Calais, where the Duke of Parma with his army was to go on board. At midnight, however, eight ships were set on fire, and sent drifting among the Spanish vessels, which put to sea in a panic. At daybreak they were attacked by Howard and his captains. The unwieldy Spanish ships proved no match for their smaller and more active adversaries, and at length fled. They proceeded northward, and were followed by the English fleet as far as Flamborough Head, where they were terribly shattered by a storm. Seventeen of the ships, having 5000 men on board, were cast away on the Western Isles and the coast of Ireland. Of the whole Armada, fifty-four ships only returned to Spain, and these in a wretched condition.

Though the Protestant Church had meanwhile

been established in Ireland, the great bulk of the people continued to be Roman Catholics. Sir John Perrot, the deputy, proposed to improve the country by public works and English laws. A series of rebellions under chiefs named O'Neill was the consequence, and the English government was maintained with great difficulty, and at an enormous expense. The rebellion of Hugh O'Neill, whom Elizabeth had tried to conciliate by making Earl of Tyrone, was particularly formidable. The English officers were at first unsuccessful, and met with some serious defeats. In 1598, Tyrone gained so great a victory, that the whole province of Munster declared for him. He then invited the Spaniards to make a descent on Ireland, and join him. The queen sent over her favourite, the Earl of Essex, with 20,000 men; but he did not proceed with vigour, and soon after found it necessary to return to England to justify himself. Next year, Tyrone broke a truce he had formed with Essex, overran the whole country, and acted as sovereign of Ireland.

Elizabeth now selected as her deputy for Ireland, Blount, Lord Mountjoy, who was in every respect better fitted than Essex to conduct such a warfare. In 1601, 6000 Spaniards landed in Kinsale harbour, for the purpose of supporting the Irish. Mountjoy immediately invested the place, and prevented them from acting. Tyrone marched from the south of Ireland to their relief, and was met and overthrown by a much inferior English force, after which Kinsale was surrendered. About the time when Elizabeth died (1603), Tyrone submitted, on condition of his life being spared, and Ireland was once more reduced under the authority of the English crown.

CONCLUSION OF THE REIGN OF ELIZABETH.

It is remarkable, that while Elizabeth increased in power and resources, she became more noted for feminine weaknesses, and it even seemed likely that she would bestow her hand upon some mere court-minion of handsome exterior—her favourites were Robert Dudley, Earl of Leicester, and Robert Devereux, Earl of Essex. The latter acquired popularity by acquitting himself brilliantly as the leader of an expedition which took Cadiz. After his failure in Ireland, however, and the humiliations which were in consequence inflicted upon him, he made a desperate attempt at an insurrection in London, with the view of seizing the queen's person, failed, was captured, found guilty of treason, and beheaded (1601), at the age of thirty-three.

About the close of 1601, Elizabeth fell into a deep hypochondria or melancholy. On the 24th of March 1603, she expired, after a reign of nearly forty-five years, during which England advanced—politically and commercially—from the condition of a second-rate to that of a first-rate power, and the Protestant religion was established on a basis from which it could never afterwards be shaken.

The reign of Elizabeth saw the commencement of the naval glory of England. The rise of a commercial spirit in Europe, which in 1492 had caused the discovery of America, and was again acted upon by the scope for adventure which that discovery opened up, had latterly caused great attention to be paid to nautical affairs in England. Englishmen of all ranks supported and entered into enterprises for discovering unknown territories; and under Drake, Cavendish, Raleigh, and Frobisher, various expeditions of less or more magnitude were sent out, Drake being the first man to sail round the world in one voyage, and Raleigh introducing the potato-plant and the practice of tobacco-smoking. The colonies of North America were now founded. On the last day of the year 1600, a charter of privilege was granted to a Company of London merchants trading to the East Indies, which developed into the celebrated East India Company.

The chief articles exported from England to the continent were wool, cloth, lead, and tin; formerly, these had been sent in vessels belonging to the Hanse Towns—certain ports of the north of Europe, possessing great privileges—but now English vessels were substituted for this trade. Stocking-weaving and the making of sailcloth, serge, and baize, took their rise in this reign. The progress of other arts was much favoured by the bloody persecution of Protestants in the Netherlands, which drove into England great numbers of weavers, dyers, cloth-dressers, and silk-throwers. Theatrical amusements became popular in this reign, although, of course, only in London. At the end of Elizabeth's reign, the population of London was about 160,000; and the whole kingdom probably contained about 5,000,000 inhabitants.

THE STUARTS—JAMES I.

The successor of Elizabeth, by birthright, was JAMES VI. OF SCOTLAND (styled JAMES I. OF ENGLAND), although by the will of Henry VIII. the crown should have been given to the descendants of Mary, Duchess of Suffolk. This prince had now arrived at the prime of life, and had been married for some years to the Princess Anne of Denmark, by whom he had two sons, Henry and Charles, and one daughter, named Elizabeth. He immediately removed to London, and assumed the government of England; while his native kingdom, though thus united under the same sovereignty, still retained its own peculiar institutions. At the suggestion of the king, who wished to obliterate the distinction of the two countries, the common name of *Great Britain* was now conferred upon them. King James was an oddity in human character. His person was naturally feeble, particularly in the limbs, and he had no physical courage. He had, however, considerable capacity for learning, some acuteness, and even wit; but was pedantic, vain, and weak. He believed kings to be the deputies of God, and accountable to God alone for their actions.

Notwithstanding the energy of Elizabeth, the popular spirit had gradually been acquiring force in her reign. It was chiefly seen in the acts of the Puritans, who, from the fervour of their devotions and the strictness of their manners, were not unlike the Scotch Presbyterians. King James found considerable difficulty at the very first in controlling this party, and evading their demands.

The disappointment of the Catholics, on the other hand, who looked for kindness, if not patronage at the hands of the son of Queen Mary, on finding that the severe laws against them were not to be relaxed, led to a conspiracy on the part of thirteen gentlemen of that persuasion, of whom the chief was Robert Catesby. It was arranged

that, on the day of the meeting of parliament, November 5, 1605, the House of Lords should be blown up by gunpowder, at the moment when the King, Lords, and Commons were all assembled in it; thus destroying, as they thought, all their chief enemies at one blow, and making way for a new government, probably under one of the king's younger children, which should be more favourable to them. Accordingly, thirty-four barrels of powder were deposited in the cellars beneath the House, and a soldier of fortune, named Guido or Guy Fawkes, was prepared to kindle it at the proper time. The plot was discovered, in consequence of the receipt of a letter by Lord Mounteagle, a Romanist, warning him not to attend the meeting of parliament. He shewed the letter to the king's chief adviser, Robert Cecil, Earl of Salisbury, and, in consequence, an investigation took place during the night between the 4th and 5th of November, when the gunpowder was discovered, and Fawkes taken into custody. He confessed his intentions; and the rest of the conspirators fled to the country, where most of them were cut to pieces in endeavouring to defend themselves.

PLANTATIONS IN IRELAND.

James was the first king who extended the English law over the whole of Ireland, by making judicial appointments suited to the extent of the country. He passed an act of oblivion and indemnity, by which all persons who had committed offences, coming to the judges of assize within a certain day, might claim a full pardon. At the same time, toleration was virtually refused to the Catholic persuasion, and much discontent therefore still existed. Some of the chieftains, particularly Tyrone, O'Donnel, Earl of Tyrconnel, and O'Dogherty, having conspired against the crown, were attainted in 1608, and their lands, which were in Ulster and Leinster, were given to English and Scotch settlers, with a view to improving the population of the country by an infusion of civilised persons. But this experiment, though well meant, was managed in a partial spirit, and gave rise to much injustice. In 1613, the first Irish parliament was held in which there were any representatives of places beyond the 'Pale.'

Apart from this pacification of Ireland, which, however, only caused the Irish to sigh for their old landlords and laws, the reign of James was not marked by what are called great events. This was greatly owing to his timid character, which induced him to maintain peace, at whatever sacrifice, throughout the greater part of his reign. The prime leaders of his government were youthful favourites, who possessed no merit but personal elegance, and of whom the chief were Robert Carr, a Scotchman, who was made Earl of Somerset, and George Villiers, who became Duke of Buckingham. Nevertheless, although no great event occurred at this period, there was gradually growing up a spirit of constitutional freedom. The Commons began to combat the prerogative of the king, and to remonstrate on the score of public grievances. In 1621, a parliament met which attacked various corruptions and abuses; Bacon, then Lord Chancellor, being charged with taking bribes, and being dismissed from his office in consequence. These and many other instances of bold resistance were the shadows of coming events.

English literature, which first made a decisive advance in the reign of Elizabeth, continued to be cultivated with great success in the reign of King James. The excellence of the language at this time as a medium for literature, is strikingly shewn in the translation of the Bible now executed; it is also shewn in the unequalled dramatic writings of Shakspeare, in the poetry of Edmund Spenser, and in the valuable philosophic works of Bacon. Very great praise is also due to Napier of Merchiston, in Scotland, for the invention of *logarithms*, a mode of calculating intricate numbers, essential to the progress of mathematical science.

It was in this reign that a great number of the most important British colonies took their rise. In 1607, James Town, in Virginia, was founded by some emissaries of a London Company of merchants. In 1610, Newfoundland was colonised; and in 1620, a number of Puritan Nonconformists, known as the 'Pilgrim Fathers,' founded the New England States.

THE KING'S CHILDREN.

In 1612, the king had the misfortune to lose his eldest son, Henry, a youth of nineteen, who was considered as one of the most promising and accomplished men of the age. The second son, Charles, then became the heir-apparent. Elizabeth, the king's other child, was married, in 1613, to Frederick, Prince Palatine of the Rhine, who subsequently lost his dominions, in consequence of his placing himself at the head of the Bohemians, in what was considered as a rebellion against his superior, the Emperor of Germany. This discrowned pair, by their youngest daughter Sophia, who married the Duke of Brunswick, were the ancestors of the family which now reigns in Britain.

CHARLES I.—HIS CONTENTIONS WITH THE HOUSE OF COMMONS.

King James died in March 1625, in the fifty-ninth year of his age, and was succeeded by his son CHARLES, now twenty-five years of age. One of the first acts of the young king was to marry the Princess Henrietta Maria, daughter of Henry IV. of France, and a Catholic. The alliance was highly unpopular.

Britain at this time became involved in a war with Spain, chiefly on account of the breaking off in the last reign of a match between Charles and the Princess Mary of that country. To supply the expenses of this contest, and of a still more unnecessary one into which he was driven with France, the king applied to parliament, but was met there with so many complaints as to his government, and such a keen spirit of popular liberty, that he deemed it necessary to revive a practice followed by other sovereigns, and particularly Elizabeth, of compelling his subjects to grant him gifts, or, as they were called, *benevolences*, and also to furnish ships at their own charge, for carrying on the war. Such expedients could not be endured in this age, when the people and the parliament were so much more alive to their rights. A general discontent spread over the nation, and the Commons resolved to take every measure in their power to check the king's proceedings. Having made an inquiry into the

ancient powers of the crown, before these powers had been vitiated by the tyrannical Tudors, they embodied the result in what was called a PETITION OF RIGHT, which they presented to him as an ordinary bill, or rather as a second Magna Charta, for replacing the privileges of the people, and which consisted of four articles: 1. That no man should be compelled to pay any money to the state unless ordered by an act of parliament. 2. That no man should be imprisoned for refusing to pay such money, and that no free man should be imprisoned without cause being shewn. 3. That soldiers and marines should not be billeted on private persons. 4. That no more commissions should be issued for punishing persons by martial law. With great difficulty, Charles was prevailed upon to give his sanction to this bill (1628); but his disputes with parliament soon after ran to such a height, that he dissolved it in a fit of indignation, resolving never more to call it together. About the same time, his favourite minister, the Duke of Buckingham, was assassinated at Portsmouth by a fanatic named John Felton. Charles's chief counsellors now were Laud, archbishop of Canterbury, a man of narrow and bigoted spirit, and Thomas Wentworth, afterwards Earl of Strafford, who endeavoured to make the king absolute by a scheme which was called 'thorough.' For some years, Charles governed the country entirely as an irresponsible despot, levying taxes by his own orders, and imprisoning such persons as were obnoxious to him, in utter defiance of the Petition of Right. The Puritans, or church-reformers, suffered most severely under this system of things. They were dragged in great numbers before arbitrary courts, called the High Commission and the Star Chamber, which latter professed to take cognisance of offences against the king's prerogative and against religion.

Among the devices which were ultimately resorted to, to raise money, was a levy of 'ship-money,' which had formerly been levied in times of war on the maritime counties, and which it was now proposed to levy on every shire. At length, John Hampden, a gentleman of Buckinghamshire, resolved to undergo any personal inconvenience rather than pay his twenty shillings of ship-money. The case was tried in the Exchequer (1637); and as the judges could then be dismissed at the royal pleasure, and were the humble servants of the king in everything, Hampden lost his cause. He roused, however, more effectually than ever, the attention of the people to this question, and means were not long wanting to check the king in his unfortunate career.

TROUBLES IN SCOTLAND—THE NATIONAL COVENANT.

An attempt had been made by King James to introduce Episcopacy into Scotland, because it was thought dangerous to the English Church that a form of worship resembling that of the Puritans should be permitted to exist in any part of the king's dominions; and Charles settled 13 bishops over the Scottish Church, by whom he hoped to govern its clergy as he did those of England. But when he attempted, in 1637, to introduce a new Book of Common Prayer into the Scotch churches, the spirit of the people could no longer be kept within bounds. On the Liturgy being opened in the principal church at Edinburgh, the congregation rose in a violent tumult, and threw their clasped Bibles, and the very stools they sat on, at the minister's head; and it was not till the whole were expelled by force, that the worship was permitted to proceed. Similar scenes occurring elsewhere, it was found necessary, by the Scottish state-officers, to withdraw the obnoxious Liturgy, till they should consult the king, who, not dreading any mischief, gave orders that it should be used as he had formerly directed, and that the civil force should be employed in protecting the clergymen. It was found quite impossible to obey such an order in the face of a united people, who, by committees assembled at Edinburgh, representing the nobles, ministers, gentry, and burghers, endeavoured to awe the king into an abandonment of the late innovations. Finally, the Scotch bound themselves (March 1638), under a bond called the *National Covenant*, which was signed by nineteen-twentieths of the adult population, to resist their sovereign in every attempt he might make to bring in upon them the errors of Popery—for such they held to be the forms of worship and ecclesiastical government which Charles had lately imposed upon their church. This was followed by the calling together of a General Assembly of the church. This body formally purified the church from all the late innovations, excommunicating the bishops, and declaring the government of the clergy to rest, as formerly, in the General Assembly, which consisted of a selection of two clergymen from each presbytery, with a mixture of lay elders, and nothing to control its proceedings but their interpretation of the will of the Divine founder of the Christian religion. Early in the succeeding year, the king, with great difficulty, collected an army of 20,000 men, whom he led to the border of Scotland, for the purpose of reducing these despisers of his authority. The Scotch, however, strengthened by devotional feeling, formed an army equal in number, which was placed under the command of General Alexander Leslie, an officer who had served with distinction in the long Protestant war carried on against the Emperor of Germany. The Scottish army was encamped on Dunse Law, a hill overlooking the Border, where the duties of military parade were mingled with prayers and preachings, such as were never before witnessed in a camp. The king, seeing the wavering of his own men, and the steadfastness of the Scotch, was obliged to open a negotiation, in which it was agreed to disband both armies, and to refer the disputes once more to a General Assembly and a Scottish parliament.

The king now adopted a new policy with the turbulent people of Scotland. Having formerly gained over some of the English patriots, he thought he might be equally successful with the lords of the Covenant, whom he therefore invited to attend him at Berwick. A few obeyed the summons; but he failed with all except the Earl (afterwards Marquis) of Montrose, a nobleman of vigorous genius, whose ambition had been wounded by his not having so high a place in the councils of his countrymen as he thought he deserved. In the new General Assembly and parliament (1640), the votes were equally decisive against Episcopacy. The king collected a second

army, and in order to raise money for a second expedition against the Scots, was reduced to the necessity of calling an English parliament—the first that had met for eleven years. It met (April 13), but, without listening for a moment to a request for subsidies, began to discuss the national grievances. Finding parliament quite intractable, the king dissolved it (May 5), and endeavoured to obtain supplies in other quarters. A convocation of the clergy granted him £20,000 per annum for the next six years. The nobility and gentry advanced £300,000; but when the city of London was asked for a loan of £200,000, it absolutely refused.

The Scots did not, on this occasion, wait to be attacked by the king, but in August 1640 marched into the north of England, in the expectation of being supported in their claims by the English people in general. A victory gained by them at Newburnford over Lord Conway, and their taking possession of Newcastle, together with the manifest disaffection of his own troops, made it necessary that Charles should once more resort to negotiation. It was agreed at a council of peers that all the present dissensions should be referred to the parliaments of the two countries, the Scottish army being in the meantime kept up on an English weekly subsidy of £5600 till such time as they were satisfied with the state of their affairs.

THE LONG PARLIAMENT—REBELLION IN IRELAND.

The English parliament met in November 1640, and immediately commenced a series of measures for effectually and permanently re-establishing constitutional liberty. The first acts of the parliament had little or no immediate reference to Scotland. The Earl of Strafford was impeached of treason against the liberties of the people, and executed (May 12, 1641), notwithstanding a solemn promise made to him by the king that he should never suffer in person or estate. Archbishop Laud was impeached and imprisoned, but reserved for future vengeance. The Star Chamber, the High Commission, and another court called the Council of the North, were abolished, and the levies of ship-money were declared to be illegal. The remaining ministers of the king only saved themselves by flight. Some of the judges were imprisoned and fined. The abolition of Episcopacy was taken into consideration. The Catholics fell under a severe persecution; and even the person of the queen, who belonged to this faith, was not considered safe.

It was not till August 1641, when the English parliament had gained many of its objects, that they permitted the treaty of peace with Scotland to be fully ratified. They then gratified the troops not only with their full pay, but with a vote of no less a sum than £300,000 besides, of which £80,000 was paid down, as an indirect way of furnishing their party with the means of future resistance. The king, on his part, also took measures for gaining the attachment of this formidable body of soldiery, and of the Scottish nation in general. In Edinburgh, which he visited in August, he squared his conduct carefully with the rigour of Presbyterian manners, and in parliament he was exceedingly complaisant, ratifying all the acts of the preceding irregular session; and yielding up the right of appointing the state-officers of Scotland. The men who had acted most conspicuously against him in the late insurrections now became his chief counsellors. He created General Leslie Earl of Leven; while the Earl of Argyll, who had been the chief political leader of the Covenanters, was made a marquis. At the same time, however, he kept up a correspondence with a royalist party which had been embodied by the Earl of Montrose, who was now suffering confinement in Edinburgh Castle for his exertions in favour of the king.

The policy already mentioned, by which large portions of Ireland were depopulated, and then planted with colonies of English and Scotch settlers, had been continued during the reign of Charles by Strafford, appointed Viceroy in 1633, who, besides, had imposed arbitrary taxes, and levied them by military force; had established monopolies for his own benefit; and had forbidden any person to leave the island without his permission. Penal laws were established against the profession of Catholicism, and a court of Star Chamber was instituted to carry these into execution.

The Irish Catholics, who formed a large majority of the nation, only waited an opportunity to rebel, and were stimulated thereto by the example of the Scotch Covenanters. On Strafford's departure, in 1640, to attend the king in England, a conspiracy, involving most of the country without the Pale, and including many persons within it, was formed, chiefly under the direction of a gentleman named Roger Moore, who possessed many qualities calculated to endear him to the people. The 23d of October 1641, being a market-day, was fixed on for the capture of Dublin Castle. During the previous day, nothing had occurred to alarm the authorities. In the evening of the 22d, the conspiracy was accidentally discovered, and measures were taken to save Dublin; but a civil war broke out next morning in Ulster, and speedily spread over the country.

The design of Sir Phelim O'Neill and the other leaders of this insurrection is believed to have been simply political. They could not, however, allay the hatred with which the Catholics looked upon their adversaries; and a spirit of revenge broke out among their followers, which was aggravated to cruel outrage when they heard that the conspiracy was discovered in Dublin. The spirit of retaliation was let loose, and political wrongs, unfeelingly inflicted, were, as is often the case, ferociously avenged. The massacre, sometimes with frightful tortures, of between forty and fifty thousand Protestants, of all ages and sexes, held forth an awful lesson of the effects which oppressive laws produce on the human passions. This rebellion, which Charles was blamed with secretly fostering, continued for many years; and it is worthy of note that the Scottish Covenanters, themselves so recently emancipated from a restraint upon their consciences, contributed 10,000 troops to assist in restoring a similar restraint upon the Irish!

THE CIVIL WAR.

It was generally allowed by moderate people that, in the autumn of 1641, if the king could have

given a guarantee that he never would seek to restore any abuses, or attempt to revenge himself upon the men who had been chiefly concerned in causing him to give them up, there would have been no further contention; and, indeed, when he returned from Scotland, he was welcomed heartily by the people of London. Unfortunately, the character of the king for fidelity to his engagements was not sufficiently high to induce the leaders of the House of Commons to depend upon him, and they prepared a paper called *The Remonstrance*, containing an elaborate view of all the grievances that had ever existed, or could now be supposed to exist. This they not only presented to the king, but disseminated widely among the people, with whom it served to increase the prevailing disaffection.

From this time it was seen that the sword could alone decide the quarrel between the king and the parliament. Charles made an unsuccessful attempt (January 4, 1642) to seize five of the most distinguished leaders of the parliamentary party, including Hampden and Pym, for the purpose of striking terror into the rest. This served to widen still further the breach, and at last, upon a demand of the parliament for the command of the army —a privilege, it should be remembered, always before and since resting with the crown—the king broke off all amicable intercourse, retiring with his family to York.

The parliament found its chief support in the mercantile classes of London and of the eastern coast of England, which was then more devoted to trade than the west, and in the Puritan party generally, who were allied intimately with the Presbyterians of Scotland. Charles, on the other hand, looked for aid to the nobility and gentry, who were able to bring a considerable number of dependents into the field. The parliamentary party was by the other styled *Roundheads*, in consequence of their wearing short hair; while the friends of the parliament bestowed upon their opponents the epithet of *Malignants*. The royalists were also, in the field, termed Cavaliers, from so many of them being horsemen. On the 25th of August 1642, the king erected his standard at Nottingham, and soon found himself at the head of an army of about 10,000 men. The parliament had superior forces and a better supply of arms; but both parties were very ignorant of the art of war. The king commanded his own army in person; while the parliamentary forces were put under the charge of Robert, Earl of Essex, son of the favourite of Queen Elizabeth.

The first battle took place, October 23, at Edgehill, in Warwickshire, where the king had rather the advantage, though at the expense of a great number of men. He gained some further triumphs chiefly by means of his cavalry, which were under the command of Prince Rupert, son of the queen of Bohemia, before the end of the campaign, but still could not muster so large an army as the parliament. During the winter, the parties opened a negotiation at Oxford; but the demands of the parliament being still deemed too great by the king, it came to no successful issue.

Early in the ensuing season, the king gained some considerable advantages; he defeated a parliamentary army, under Sir William Waller, at Stratton, and soon after took the city of Bristol; while Hampden, who had become a parliamentary officer, fell in a skirmish with Rupert. It only remained for Charles to take Gloucester, in order to confine the insurrection entirely to the eastern provinces. It was even thought at this time that he might have easily obtained possession of London, and thereby put an end to the war. Instead of making such an attempt, he caused siege to be laid to Gloucester, which the army of Essex relieved when it was just on the point of capitulating. As the parliamentary army was returning to London, it was attacked by the royal forces at Newbury, and all but defeated. Another section of the royal army in the north, under the Marquis of Newcastle, gained some advantages; and, upon the whole, at the close of the campaign of 1643, the parliamentary cause was by no means in a flourishing condition.

In this war there was hardly any respectable military quality exhibited besides courage. The first appearance of a superior kind of discipline was exhibited in a regiment of horse commanded by Oliver Cromwell, a Huntingdonshire gentleman of small fortune, who had been a brewer. Cromwell, though himself inexperienced in military affairs, shewed from the very first a power of drilling and managing troops which no other man in either army seemed to possess. Hence his regiment, called the 'Ironsides,' and belonging mostly to the sect of the Independents, soon became famous for its exploits.

SOLEMN LEAGUE AND COVENANT.

The royal successes of 1643 distressed alike the English parliament and the Scottish nation. The two parliaments therefore agreed to prosecute the war in concert, both Houses signing the Solemn League and Covenant for the extirpation of popery and prelacy. A good deal of persecution followed this, and the aged Archbishop Laud, who had long lain in the Tower, was condemned for high treason, and beheaded in 1645. In terms of this bond, the Scots raised an army of 20,000 men, who entered England in January 1644; and on the 2d of July, in company with a large body of English forces, overthrew the king's northern army on Long Marston Moor, Cromwell's Ironsides being admittedly the main cause of victory.

The Episcopal Church being now abolished, the Presbyterian form of government was adopted, though in England it was provided that the new church should not have any connection with or influence over the state.

The defeat at Long Marston was severely felt by the king. He gained a victory over Waller at Cropredy Bridge, and caused Essex's army to capitulate in Cornwall (September 1); but in consequence of a second fight at Newbury (October 27), in which he suffered a defeat, he was left at the end of the campaign with greatly diminished resources. A new negotiation was commenced at Uxbridge; but the terms asked by the parliament were such that the king did not accept them.

The English parliament, fearing that some of its military leaders were becoming lukewarm, passed a self-denying ordinance that no member of parliament should in future hold any command either civil or military. Essex resigned in consequence of this, and the chief command of the army was given to Sir Thomas Fairfax, who

had led the parliamentary forces at Marston Moor. The real guiding spirit in the army, however, was Cromwell, now commander of the cavalry, and he shewed his genius in introducing proper discipline into the army. In June 1645, the reorganised army inflicted a crushing defeat on the royalists at Naseby; and although the king still held out, it was plain that his cause was hopeless.

MONTROSE'S CAREER IN SCOTLAND.

Meanwhile the Marquis (formerly Earl) of Montrose produced a diversion in Scotland in favour of the king. Having got 1500 foot from Ireland, to which he added a few Perthshire Highlanders, he descended upon the Lowlands, and on the 1st of September (1644) gained a complete victory over a larger and better-armed force at Tippermuir. At Aberdeen, whither he went for the purpose of increasing his army, he gained another victory over a superior body of Covenanters. The following winter Montrose burst into the country of his rival Argyll, and falling upon him at Inverlochy (February 2, 1645), gained a complete victory. He then moved along the eastern frontier of the Highlands, where he found himself opposed by a fourth army under General Baillie. After sacking the town of Dundee, and eluding Baillie's troops, he encountered at Auldearn, in Nairnshire (May 4), a greatly superior force, which he also overthrew. Then turning upon Baillie, whom he met at Alford, in Aberdeenshire (July 2), he gained a fifth victory, almost as complete as any of the rest.

Montrose now descended to the Lowlands; and at Kilsyth, near Glasgow, was opposed by an army of 6000 men, whom the Scotch government at Edinburgh had hastily assembled from Fife and Perthshire. These, with a much smaller force, he also defeated (August 15), killing great numbers in the pursuit. The committees of church and state then broke up, and left the kingdom, leaving him in appearance its sole master. Montrose had, however, in reality gained no real advantages. Besides his small army of mingled Irish and Highlanders, there was hardly any portion of the nation who did not regard him as only a great public enemy. While lying with a diminished force at Philiphaugh, near Selkirk, he was surprised (September 13) by a detachment of the regular Scottish army, under General David Leslie, who completely defeated his troops, and obliged him to leave the kingdom.

CONCLUSION OF THE CIVIL WAR.

The king, who had retired first to Wales, and thence to Oxford, now put himself under the protection of the Scottish army, which had advanced south as far as Newark. The English parliament thereupon made repeated and strenuous demands for the surrender of his person by the Scots into their hands. The Scots, however, though acting partly as a mercenary army, asserted their right, as an independent nation under the authority of the king, to retain and protect him. At length, despairing of inducing him to establish Presbyterianism throughout his dominions, and tempted by the sum of £400,000, which was given to them as remuneration for past military services, they consented to deliver up their monarch, but certainly without any apprehension of his life being in danger, and, indeed, to a party different from that by which he afterwards suffered. The Scottish army then retired (January 1647) to their native country, and were there disbanded.

The king was now placed in Holmly House, near Northampton, and negotiations were opened for restoring him to power, under certain restrictions. Meanwhile the troops, who were composed mainly of Independents, began to hold something like a parliament in their own camp; and a party of them, under Cornet Joyce, seized the king's person, and brought him to Hampton Court. They at last made a demand for the dismissal of the leaders of the Presbyterian party, and a general right of new-modelling the government and settling the nation. The House of Commons, supported by the city of London, made a bold opposition to these demands, but was ultimately obliged to yield to a force which it had no means of resisting.

TRIAL AND EXECUTION OF THE KING.

The leaders of the army, being anxious to fortify themselves by all possible means against the Presbyterians, opened a negotiation with the king, whose influence, such as it now was, they proposed to purchase, by allowing Episcopacy to be the state religion, and leaving him in command of the militia. Charles carried on at the same time a negotiation with the Presbyterians, and even with the Scots, which, being discovered by the military chiefs, caused them to break off all terms with him. Under dread of their resentment, he made his escape from Hampton Court (November 11, 1647); and after an unsuccessful attempt to leave the kingdom, was obliged to put himself under the charge of the governor of Carisbrooke Castle, in the Isle of Wight. Here he entered upon a new negotiation with the House of Commons, to whom he made proposals, and from whom he received certain proposals in return; all of which were, however, rendered of non-avail by a secret treaty which he at the same time carried on with a moderate party of the Scottish Presbyterians.

He finally agreed with the latter party, but under strict secrecy, to give their form of church-government a trial of three years, and yield to them in several other points; they, in return, binding themselves to unite their strength with the English royalists, for the purpose of putting down the Independent party, now predominant in the English parliament. With some difficulty, the Duke of Hamilton and others, who conducted this negotiation, succeeded, by a vote of the Scottish parliament, in raising an army of 12,000 men, with which they invaded England in the summer of 1648. The more zealous of the clergy and people of Scotland protested against the enterprise, which appeared to them as neither deserving of success, nor likely to command it. Before this army gained any accession of strength in England, Cromwell, with 8000 veteran troops, attacked and overthrew it at Preston, while Fairfax put down other insurgents in Kent and Essex. Hamilton was himself taken prisoner, and very few of his troops ever returned to their native country.

During the absence of Cromwell and his army, the Presbyterian party in the House of Commons regained its ascendency, and it was coming to a

good understanding with the king, when the troops returned to London breathing vengeance against him for this last war, of which they considered him as the author. Cromwell sent to the House three regiments, under Colonel Pride, who forcibly excluded from it about 200 members of the Presbyterian party; a transaction remembered as *Pride's Purge*. The remainder, being chiefly Independents, were ready to give a colour of law to whatever further measure might be dictated by the military leaders, and it was now resolved to bring the king to trial. The House of Lords disapproving of the step, the Commons passed a resolution that the chief power resided with themselves, and closed the Upper Chamber. A High Court of Justice, as it was called, was appointed by ordinance, consisting of 133 persons, named indifferently from the parliament, the army, and such of the citizens as were known to be well affected to the Independent party. This body sat down in Westminster Hall (January 20, 1649), under the presidency of a barrister named Bradshaw, while another named Coke acted as solicitor for the people of England. The best known of its members are Cromwell and his son-in-law, Henry Ireton. Charles, who had been removed to St James's Palace, was brought before this court, and accused of having waged and renewed war upon his people, and of having attempted to establish tyranny in place of the limited regal power with which he had been intrusted. He conducted himself with great firmness and dignity: denied the authority of the court, and protested against the whole of the proceedings, but was nevertheless found guilty, and the commissioners pronounced the verdict, 'that Charles Stuart, as a tyrant, traitor, murderer, and public enemy to the good people of this nation, be put to death by having his head severed from his body.' On the 30th of January, he was accordingly beheaded in front of his palace of Whitehall. The people were in general horror-struck at this event; but they were too effectually kept in check by the army to have any influence in preventing or resenting it. The Church of England publicly styled him *martyr*.

Charles I. was a man of slender person, of the middle size, and of a grave and somewhat melancholy cast of countenance. He had not a gracious manner, but possessed considerable dignity. The general opinion of modern times respecting his political conduct is unfavourable; though few deny that his death was an unjustifiable as well as imprudent act on the part of those who brought it about. The worst point of his character was his insincerity. In private life he was a virtuous man, and he is entitled to much credit for the taste which he displayed in the encouragement of the fine arts. He left three sons—Charles, Prince of Wales, born 1630; James, Duke of York, afterwards James II.; and Henry, Duke of Gloucester, who died in early life. He also left several daughters, one of whom, named Elizabeth, was treated with much harshness by the new government, and died not long after him in prison; while another, Mary, married Prince William of Nassau, Stadtholder of Holland; her son afterwards became William III. of England.

In the reign of Charles I. the chief literary men were Ben Jonson and Philip Massinger, dramatists; and Samuel Daniel, Michael Drayton, and William Drummond, poets. The most eminent man of science was Dr William Harvey, who discovered the circulation of the blood. The king patronised the Dutch artists, Rubens and Van Dyck, and collected many fine pictures, which were afterwards sold by his enemies. The excise and the tax upon landed property were introduced by the parliament, in order to support the war against the king. When the parliamentary party became triumphant, it suppressed the theatre, which was not again set up till the restoration of monarchy.

THE COMMONWEALTH—SUBJUGATION OF IRELAND AND SCOTLAND.

Though the execution of the king produced some reaction in favour of royalty, the small remaining part of the House of Commons, known by the nickname of the *Rump*, was able to establish a republic, under the title of the COMMONWEALTH, the executive being trusted, under great limitations, to a Council of State, containing forty-one members. Of this council, Bradshaw was the President, and Milton the Foreign Secretary; but all real power was in the hands of Cromwell. The House of Peers was voted a grievance, and abolished, and the people were declared to be the legitimate source of all power. Soon after the king's death, the Duke of Hamilton and a few other of his chief adherents were executed.

During the progress of the civil war, Ireland had been the scene of almost ceaseless contention among the various parties of the king, the English House of Commons, and the Catholics, none of which could effectually master the rest. At the time of Charles's execution, the royalists were in considerable force under James Butler, Marquis of Ormond, the royalist Lord-lieutenant, who proclaimed Charles's eldest son king, under the title of Charles II. Cromwell, appointed Lord-lieutenant by parliament, landed (August 1649) with 12,000 horse and foot, and although at the time only Dublin, Belfast, and Londonderry were held by the parliamentary party, he easily gained a series of victories over his opponents, and succeeded in asserting the sway of the Commonwealth. One of his most important actions was the capture of Drogheda, where he put the garrison and a number of Catholic priests to the sword, in order to strike terror into the nation.

The people of Scotland, who had had scarcely any other object in the civil war than the establishment of their favourite form of worship, heard of the death of the king with the greatest indignation, and immediately proclaimed his eldest son Charles. Early in 1650, the young monarch, who had taken refuge in Holland, sent Montrose with a small force to attempt a Cavalier insurrection in Scotland; but this nobleman being taken and put to death, Charles found it necessary to accede to the views of the Scotch respecting the Presbyterian religion, and he was accordingly brought over, and having signed the Solemn League and Covenant, was put at the head of a considerable army, though under great restrictions. Cromwell, who had now nearly completed the conquest of Ireland, lost no time in returning to London, and organising an army for the suppression of this new attempt against the Commonwealth, leaving Ireland to his son-in-law, Ireton.

Crossing the Tweed with a force of 16,000 men,

he advanced through a deserted country to Edinburgh, and found the Scottish army under General Leslie in a fortified camp. His army suffering from sickness and want of provisions, he retreated, followed by Leslie, to Dunbar, when it seemed likely he would be compelled to surrender. In the midst of his perplexities (September 3), he beheld the Scots, who had been stimulated to move by the Presbyterian clergy in the camp, advancing from the neighbouring heights to give him battle, and, in a transport of joy, exclaimed: 'The Lord hath delivered them into our hands!' In the fight which ensued, the veteran troops of Cromwell proved victorious. The Scots fled in consternation and confusion, leaving 3000 dead and 10,000 prisoners. This gained for Cromwell the possession of the capital and of all the south-east provinces.

Cromwell spent a whole year in the country, vainly endeavouring to bring on another action. During the interval (January 1, 1651), the Scots crowned the young king at Scone. In the ensuing summer, Charles marched suddenly with a body of troops he had collected into England, and made a very threatening advance upon the capital. Ere the royalists had time to rally around him, Cromwell overtook Charles at Worcester, where, after a stoutly contested fight (September 3, 1651), he proved completely victorious. Charles, after many wanderings and numerous hairbreadth escapes, reached Fécamp in Normandy, and Scotland submitted to the conqueror. The country was finally reduced by an army under General Monk, and in a short time was declared by proclamation to be united with England. Thus was Cromwell, who, after Worcester, proclaimed an amnesty, left without a single armed enemy.

THE PROTECTORATE.

The republican leaders now resolved upon commencing hostilities against Holland, which had offended them on various grounds. In the summer of 1652, the Dutch fleet, under its famous commanders, Van Tromp, De Ruyter, and De Witt, had several encounters with the English ships, under Admirals Blake and Ayscue, without any decided success on either side. But in the ensuing spring, an action was fought between Blake and Van Tromp, in which the latter lost eleven ships. The Dutch then sued for peace, which the Rump Parliament did not wish to grant, from a conviction that the war tended to restrict the power of the army and Cromwell. Cromwell, perceiving their design, proceeded with 300 soldiers to the House (April 20, 1653), and entering with marks of the most violent indignation, loaded the members with reproaches for their robbery and oppression of the public; then stamping with his foot, he gave signal for the soldiers to enter, and addressing himself to the members, 'For shame!' said he; 'get you gone! Give place to honester men! I tell you, you are no longer a parliament: the Lord has done with you!' He then commanded 'that bauble'—meaning the mace—to be taken away, turned out the members, and, locking the door, returned to Whitehall with the key in his pocket.

Being still willing to keep up the appearance of a representative government, Cromwell summoned 144 persons in England, Ireland, and Scotland, to assemble as a parliament. These individuals, chiefly remarkable for fanaticism and ignorance, were denominated the *Barebones Parliament*, from the name of one of the members, a leather-seller, whose assumed name, by a ridiculous usage of the age, was Praise-God Barebones. As the assembly obtained no public respect, Cromwell took an early opportunity of dismissing it. His officers then constituted him (December 16, 1653) PROTECTOR of the Commonwealth of Great Britain and Ireland, with most of the prerogatives of the late king.

The war against Holland was still carried on with great spirit. It resulted ultimately in the triumph of the English, and the complete humiliation of the Dutch, who obtained peace on the condition of paying homage to the English flag, expelling the young king from their dominions, and paying a compensation for certain losses to the East India Company. In a war which was subsequently made against Spain, the fleets of the Protector, under Blake, performed some exploits of not less importance, among other things, capturing the island of Jamaica. But while generally successful abroad, he experienced unceasing difficulties in the management of affairs at home. The pure Republicans detested him, and his own officers could scarcely be kept in subordination; while the royalists, on the other hand, never ceased to conspire for his destruction.

The last parliament called by Cromwell met in January 1658; when, besides the Commons, he summoned the few remaining peers, and endeavoured, by ennobling some of his officers, to make up a kind of Upper House. This assembly proved as intractable as its predecessors, and he dissolved it with the words: 'Let God judge between you and me.' His health sank under the various worries and labours of his life. Finally he succumbed to an attack of ague, on the 3d September 1658, the anniversary of two of his greatest victories, Dunbar and Worcester. His eldest son, Richard, a docile young man of little or no ability, quietly succeeded him as Protector, and was at first treated with respect; but he could not long maintain his authority, being despised by the army. He quietly slunk out of public view, leaving the supreme authority to be bandied about for some time between the Rump and the officers of the army, of whom General John Lambert was the chief. Richard Cromwell lived partly abroad and partly at Cheshunt, dying there in 1712.

RESTORATION—DUTCH WAR.

The bulk of the people of England had been by this time thoroughly disgusted with irregular governments by adventurers, and longed for the restoration of the old monarchy. Aware of this sentiment, General Monk left Scotland with his troops, and, reaching London (February 3, 1660), caused a free parliament to be assembled. By this body, notwithstanding some opposition from the Cromwellian officers, the king was invited to return. On the 29th of May, being his thirtieth birthday, Charles II. entered London amidst such frantic demonstrations of public joy, that he could not help thinking it his own fault, as he said, that he had been so long separated from his people.

One of the first measures of the new monarch

was the passing of a bill of indemnity, by which all persons concerned in the late popular movements were pardoned, excepting a few who had been prominently concerned in bringing the king to the block. Harrison, Scrope, and a few other regicides, were tried and executed; and the bodies of Cromwell, Ireton, and Bradshaw were raised from the grave, and exhibited upon gibbets. In Scotland, only three persons suffered — the Marquis of Argyll, Johnston of Warriston, and Mr Guthrie, a clergyman: it was considered remarkable, that the marquis had placed the crown upon the king's head at Scone in the year 1651. The parliament which called the king home was constituted a legal one by his own ratification of an act for that purpose. The Episcopal Church was established both in England and Scotland, though not without about a third of the clergy in both countries resigning their charges. The stern and enthusiastic piety which prevailed during the civil war, was now treated with ridicule, and most of the people vied with each other in profligacy of every description.

Ireland, which, during the Protectorate, had been managed by Henry, a younger son of Cromwell, acceded to the Restoration with as much readiness as any other part of the British dominions. An act was passed for settling property, by which the Catholics obtained some slight benefits.

Though Charles had been restored with the approbation of a very large portion of his subjects, his most zealous friends were the royalists and Episcopalians; hence he almost immediately subsided into the character of a party ruler. He caused several horse-regiments to be embodied under the name of Life Guards, being chiefly composed of royalist gentlemen upon whom a perfect dependence could be placed; and he afterwards added two or three foot regiments, the whole amounting to about five thousand men. The king paid these troops chiefly out of the money allowed for his own support, for parliament did not sanction his keeping up such a force. This was the commencement of a *standing army* in England.

A mere man of pleasure, Charles was not qualified to retain the sincere respect of a people whose habitual character is grave and virtuous. His extravagant expenditure soon cooled the affections of his parliament, and he began to find difficulties in obtaining money. To relieve himself, he accepted £40,000 from the French king for Dunkirk, a French port which had been acquired by Cromwell. For the same purpose, he married a Portuguese princess of the Catholic religion, who possessed a dowry of half a million, besides the fortress of Tangier in Africa, and the island of Bombay in India. The former was abandoned before the end of the year as worthless; while Bombay was, in a short time, made over to the East India Company. He also commenced (1664) a war against Holland, for apparently no better reason than that, in applying the parliamentary subsidies necessary for keeping up hostilities, he might have an opportunity of converting part of the money to his own personal use.

This Dutch war was chiefly conducted by sea. On the 3d of June 1665, an English fleet of 114 sail, under the command of the king's younger brother, James, Duke of York, met and defeated a Dutch one near Lowestoft; and in subsequent engagements the English were on the whole successful. Owing, however, to a failure of the supplies, the king was obliged to lay up his best vessels, and to send only an inferior force to sea. The Dutch took advantage of this occurrence to sail up the Medway (June 11, 1667), burn twenty English vessels, and blockade the Thames. This disgrace was much felt by the people, and the king soon after concluded a peace.

PLAGUE AND FIRE OF LONDON—PERSECUTION IN SCOTLAND.

In the meantime, two extraordinary calamities had befallen the metropolis. In the summer of 1665, London was visited by the Plague, which swept off about 100,000 people, and did not experience any abatement till the approach of cold weather. On this occasion, the city presented a wide and heart-rending scene of misery and desolation. Rows of houses stood tenantless, and open to the winds; and the chief thoroughfares were overgrown with grass. Since 1665, the Plague has not again occurred in London, or in any other part of the kingdom. The second calamity was a conflagration, which commenced on the night of Sunday, the 2d of September 1666, in Pudding Lane, near Fish Street, in the eastern and more crowded part of the city. Favoured by various circumstances, the fire raged for three days, and burnt all that part of the city which stretches from the Tower to the Temple and Smithfield. By this calamity, 13,200 houses and 89 churches, covering in all 430 acres of ground, were destroyed. It had one good effect in causing the streets to be formed much wider than before, by which the city was rendered more healthy. The column known as the 'Monument' marks the spot near which the fire originated. Among the buildings burnt was Old St Paul's, which was replaced by the existing structure, designed by Sir Christopher Wren.

In Scotland, the re-introduction of Episcopacy, and the harshness of the measures required to support it amongst an unwilling people, created great dissatisfaction. Tired of suffering, a few of the peasantry of Galloway rose in rebellion (November 1666), and advancing through the disaffected districts of Ayrshire and Lanarkshire, gradually assumed a threatening appearance. An unfortunate movement towards Edinburgh, where they expected accessions, thinned their numbers, and they were overpowered by General Dalyell at the Pentland Hills. Thirty-four of the prisoners were executed as rebels, chiefly at the instigation of Sharp, archbishop of St Andrews, who, with the other prelates, was peculiarly zealous in behalf of the government. Besides these sufferers, fifty persons, including fifteen clergymen, forfeited lands and goods.

Some attempts were now made, at the desire of the king, to induce the ejected clergy to connect themselves with the church; but very few took advantage of a leniency which they believed would have been extended also to Catholics, and which involved their acknowledgment of the king's supremacy in spiritual affairs. About the year 1670, some divines began to hold conventicles in secluded parts of the country, to which the country people used to come with arms. At

these places, a far warmer kind of devotion was felt than could be experienced under tamer circumstances; and, as may be supposed, such meetings were not calculated to diffuse or foster a sentiment of loyalty. Sensible of this, the government obtained an act imposing very severe fines on all who should preach or listen at conventicles; but without producing any effect. The penalties with which they were threatened seemed only to make the people more attached to their peculiar modes of worship and church-government.

THE TRIPLE ALLIANCE—THE FRENCH ALLIANCE.

The kingdom of France was at this period under Louis XIV. rising into a degree of power and wealth which it had never before known. Louis had some claims through his wife upon the Netherlands (since called Belgium), which were then part of the Spanish dominions. He accordingly endeavoured to possess himself of that country by force of arms. A jealousy of his increasing power, and of the Catholic religion, professed by his people, induced the English to wish that his aggressions should be restrained. To gratify them, Charles entered into an alliance with Holland and Sweden, for the purpose of checking the progress of the French king. In this object he was completely successful, and consequently he became very popular. The parliament, however, having disappointed him of supplies, he soon after entirely changed his policy, and, with the assistance of five corrupt ministers—Clifford, Ashley, Buckingham, Arlington, and Lauderdale, who were called the CABAL, from the initials of their names forming that word—resolved to render himself, if possible, independent of parliament; in other words, an absolute prince. Charles now sold himself by the Treaty of Dover, concluded secretly, May 22, 1670, to Louis, engaging, on the receipt of an annual subsidy of £120,000, to join in a war against Holland, and also, as soon as was considered prudent, to declare himself a Roman Catholic.

War was accordingly declared in May 1672, and the naval force of England was employed in meeting that of the Dutch by sea; while Louis led a powerful army across the Rhine, and in a very short time had nearly reduced the whole of the Seven Provinces. The English people, however, who had not entered heartily into this war, soon began to be alarmed for the fate of Holland, which was almost their only support against the dread of popery; and though forbidden, under severe penalties, to censure the government measures, they soon contrived to exhibit so much dissatisfaction, as to render a change of policy unavoidable.

The king found it necessary to assemble his parliament (February 1673), and it was no sooner met than it passed some acts highly unfavourable to his designs. Among these was the famous Test Act, so called because it enacted the imposition of a religious oath upon all persons about to enter the public service—the design being to exclude the Catholics from office. Above all things, the House of Commons declared that it would grant no more supplies for the Dutch war. The king resolved to prorogue the assembly; but before he could do so, they voted the alliance with France, and several of his ministers, to be *grievances*. Charles, who, in wishing to be absolute, had been inspired by no other motive than a desire of ease, now saw that there was a better chance of his favourite indulgence in giving way to his subjects than in any other course; and he at once abandoned all his former measures, and concluded, in 1678, a separate peace with Holland, which, under its stadtholder, William, Prince of Orange, had made a gallant defence against the French. The Prince of Orange, in the previous year, had married the Princess Mary, eldest daughter of the Duke of York, and educated in the Reformed faith—an alliance which greatly pleased the English, from its strengthening the Protestant interest.

THE POPISH PLOT.

For a century past, one of the grand moving-springs of the public conduct had been a strong detestation and dread of the adherents of the Roman Catholic Church. This feeling was now intensified by the fact that the Duke of York, heir to the throne, had avowed himself a Roman Catholic. In 1678, a wild account of a plot supposed to have been formed by the Papists, for burning London, massacring the Protestants, and destroying the king and the Protestant religion, was circulated by various persons, of whom the chief was Titus Oates, a Protestant clergyman, but a man of the most infamous character. The circumstances attending this pretended discovery were so unlike reality, that if the nation had not been in a state of hallucination at the time, they never could have been for a moment listened to. Nevertheless, the Popish Plot, as it was called, was not only generally believed by the people, but also by the parliament and the court; and such was the extent of the excitement, that a general massacre of the Catholics was apprehended. Even as things were, many innocent Catholics were condemned to death, their lives being sworn away by Oates and others, who made a business of perjury. An act was also passed shutting out all Papists, with the exception of the Duke of York, from either House of Parliament, and from the royal presence.

THE HABEAS CORPUS ACT—THE EXCLUSION BILL.

In the year 1679, the House of Commons appears for the first time formally separated into the two parties who have ever since been recognised in it. The appellation *Tory*, said to be derived from the Irish *tora, tora*, 'give, give,' was first used of certain Romanist outlaws and banditti, and was afterwards extended to the whole of the Cavalier or royalist party. The term *Whig*, which fell to the lot of the opposition, is said to have originated in Scotland, being first generally applied to the sterner portion of the Presbyterian party, although formerly it had been a nickname of the Lowland peasantry in the west.

The parliament having impeached Danby, the king's minister, he dissolved it, and called another. The new assembly proved equally uncontrollable as the last. It passed in 1679, by a majority of seventy-nine, a bill excluding the Duke of York

from the succession; declared the king's Guards and standing army illegal; and passed the *Habeas Corpus* Act, which, limiting the time between the apprehension of a supposed criminal and his trial, rendered it impossible for this or any future sovereign to keep individuals in prison at his pleasure, as had formerly been done. The last measure is still justly looked upon as the great bulwark of personal liberty in Britain. Though the bill for excluding the Duke of York was thrown out by the Upper House, that prince found it necessary to evade the popular odium, first by retiring to Brussels, and afterwards to Scotland. At the same time, the Duke of Monmouth, eldest natural son of the king, and believed by many to be legitimate, began to be regarded by the Whig party in general as a preferable heir to the crown.

PERSECUTION IN SCOTLAND.

The persecution in Scotland for field-meetings was so severe, that before the year 1678 it was supposed that 17,000 persons had suffered by it in fine, imprisonment, and death. As was natural, this persecution inspired a strong feeling of resentment against the government and the prelates. On the 2d of May 1679, as Archbishop Sharp, the most obnoxious of these, was going in his coach to St Andrews, he was beset by a body of desperate men, among whom were Balfour of Burleigh and Hackston of Rathillet, who cruelly slew him. An insurrection of the west-country conventiclers immediately followed; and a party of dragoons sent against them, under Captain Graham of Claverhouse, was gallantly repulsed at Loudon Hill. The insurrection proving formidable, the Duke of Monmouth was sent down to head the troops for its suppression. He found the insurgents posted advantageously at Bothwell Bridge (June 22); but divisions on certain religious and political points unfitted them for making a good resistance. After defending the bridge for a while, they turned in a panic, and fled; 300 were killed in the pursuit, and 1200 taken prisoners.

Notwithstanding this overthrow, the more enthusiastic Presbyterians refused to be at rest, and many publicly renounced their allegiance to the king.

REACTION IN FAVOUR OF THE KING.

In the meantime, an extraordinary revolution took place in England. About the time that popular feeling was recovering from the mania respecting the Popish Plot, the House of Commons had shewn an ardent determination to seek the exclusion of the Duke of York from the throne. The time was unfortunate, for men were beginning to suspect that they had been deceived in many of their surmises about danger from the Catholics.

The king called a new parliament to meet at Oxford, resolved, in the event of its not proving more tractable, to take advantage of the popular feeling, dissolve the assembly, and never call another. It met on the 21st of March 1681, and the Whigs soon shewed that the Exclusion Bill was still uppermost in their minds. Charles, after various attempts at compromise had been made, dissolved the parliament as utterly intractable, and, as he expected, he was generally applauded for the act. Popular feeling had now taken a turn in favour of royalty, and Charles henceforth ruled entirely without control.

THE RYE-HOUSE PLOT—DEATH OF CHARLES II.

Taking advantage of the popular feeling in his favour, Charles caused all the corporations in the kingdom to give up their old charters, and accept of new ones, by which he became all-powerful over the elections of magistrates, and, consequently, over those of parliamentary representatives, should ever another election of that kind take place. The leaders of the late majority in parliament, comprising the Duke of Monmouth, Lord William Russell (son of the Earl of Bedford), the Earl of Essex, Lord Howard, the ardent Republican Algernon Sydney, and John Hampden, grandson of the patriot who first resisted Charles I. being reduced to absolute despair, formed a project for raising an insurrection in London, to be supported by one in the west of England, and another under the Earl of Argyll in Scotland, and the object of which should be confined to a melioration of the government. They were betrayed by an associate named Rumsay, and implicated, by certain unfortunate circumstances, in a plot of some of the more desperate opponents of the king, for assassinating the king (styled the Rye-house Plot), of which they were perfectly innocent. By the execution of Russell and Sydney, and some other severities, the triumph of the king might be considered as completed. Monmouth fled to the continent, and the Duke of York was allowed to resume his former important office of Lord High Admiral. After having been an absolute sovereign for nearly four years, Charles died of apoplexy (February 6, 1685), professing himself at the last to be a Catholic, and was succeeded by the Duke of York.

During the reign of Charles II. the nation advanced considerably in the arts of navigation and commerce. The post-office, set up during the Commonwealth as a means of raising money, was advanced in this reign. Roads were greatly improved, and stage-coach travelling was commenced, though not carried to any great extent. During this reign, tea, coffee, and chocolate were first introduced. In 1660, the Royal Society was established in London, for the cultivation of natural science, mathematics, and all useful knowledge. The science of astronomy was greatly advanced by the investigations of Flamsteed and Halley. But the greatest contribution to science was made by Sir Isaac Newton, whose *Principles of Natural Philosophy* were published in 1687: in this work, the true theory of planetary motions was first explained, in reference to the principle of gravitation. Amongst the literary men of the period, the first place is to be assigned to John Milton, author of the *Paradise Lost* and other poems: Samuel Butler, author of *Hudibras*, shines as a humorous and satirical poet, and Edmund Waller as a lyrist. Amongst divines, the highest names connected with the church are those of Jeremy Taylor and Isaac Barrow; while the highest among the Nonconformists are those of Richard Baxter and John Bunyan. The theatre, which had been suppressed during the Commonwealth, was revived in this reign; but the drama exhibited less talent and more licentiousness than it did in the previous reigns.

JAMES II.—EXPEDITION OF MONMOUTH.

JAMES II. was sixty-eight years of age when he ascended the throne. He was a much more respectable and industrious man than his brother, but utterly deficient in the tact and easy carriage which made Charles so popular. He began his reign by declaring before the privy-council his intention to govern solely by the laws, and to maintain the existing church; and such was the confidence in his sincerity, that he soon became very popular. Addresses poured in upon him from all quarters, professing the most abject devotion to his person. The parliament called by him voted an ample revenue, and expressed the greatest servility towards him in all things.

The remains of the Whig party still existed, though in exile in Holland, and there were some districts of the country where they were supposed to have considerable influence. The Duke of Monmouth and the Earl of Argyll met in Holland, and projected two separate invasions, for the purpose of expelling King James. Argyll landed in Scotland in May, but finding he could make little impression among the people, he gave up the enterprise, and tried to escape—he was captured, however, and executed at Edinburgh. A few days before Argyll's capture Monmouth landed in Dorsetshire, and the peasantry flocked to his standard. At Taunton, June 20, he caused himself to be proclaimed king. Having attacked the king's troops at Sedgemoor, near Bridgewater, July 6, his infantry fought with some spirit, but being deserted by the cavalry and by the duke himself, were obliged to give way. Monmouth was taken and executed. Many of his followers were hanged without form of trial by the royal troops, under the Earl of Feversham, and a brutal officer, Colonel Percy Kirke; and others were afterwards put to death, with hardly any more formality, by the celebrated Chief-justice Jeffreys, whom the king sent down with a commission to try the offenders. The butchery of several hundred men of low condition, who were unable of themselves to do any harm to the government, was looked upon as a most unjustifiable piece of cruelty, even if it had been legally done; and the principal blame was properly ascribed to the king.

ARBITRARY MEASURES OF THE KING.

Encouraged by his successes, James conceived that he might safely begin the process of getting rid of those portions of the constitution which were obstacles in his way towards absolute power. On the plea of his supremacy over the church, he took the liberty of dispensing with the test-oath in favour of some Catholic officers, and thus broke an act which was looked upon, under existing circumstances, as the chief safeguard of the Protestant faith. His parliament, servile as it was in temporal matters, took the alarm at this spiritual danger, and gave the king so effectual a resistance that he resorted to a dissolution.

Heedless of these symptoms, he proclaimed, April 4, 1687, a Declaration of Indulgence, suspending all penal laws against Nonconformists, for the purpose of relieving the Catholics, and thus assumed the unconstitutional right of dispensing with acts of parliament. The nation was thrown by this measure into a state of great alarm; even the clergy, who had been so eager to preach an implicit obedience to the royal will, began to see that it might be productive of much danger. When James commanded that his proclamation of toleration should be read in every pulpit in the country, only 200 of the clergy obeyed. Six of the bishops, with William Sancroft, archbishop of Canterbury, joined in a respectful petition against the order; but the king declared that document to be a seditious libel, and threw the seven petitioners into the Tower. In June 1688, they were tried in Westminster Hall, and not one of the judges venturing to say that the Declaration of Indulgence was legal, to the infinite joy of the nation they were acquitted.

Blinded by religious zeal, the king proceeded on his fatal course. In defiance of the law, he held open intercourse with the pope, for the restoration of Britain to the bosom of the Romish Church. A court of High Commission—a cruel instrument of power under Charles I.—was erected, and before this every clergyman who gave any offence to the king was summoned. He also excited great indignation by violently thrusting a Catholic upon Magdalen College, at Oxford, as its head, and expelling the members for their resistance to his will. He intrusted the government of Ireland to a Romanist, Richard Talbot, Earl of Tyrconnel, who hated the Protestant settlers. Public feeling was wound to the highest pitch of excitement by the queen, James's second wife, Mary of Modena, being delivered (June 10, 1688) of a son, who might be expected to perpetuate the Catholic religion in the country, and whom many believed to be a supposititious child, brought forward solely for that purpose.

The disaffection produced by these circumstances extended to every class of the king's subjects, except the small body of Roman Catholics, many of whom could not help regarding the royal measures as imprudent. The Tories were enraged at the ruin threatened to the Church of England, which they regarded as the grand support of conservative principles in the empire. The Whigs, who had already made many strenuous efforts to exclude or expel the king, were now more inflamed against him than ever. The clergy, a popular and influential body, were indignant at the injuries inflicted upon their church; and even the Dissenters, though comprehended in the general toleration, saw too clearly through its motive, and were too well convinced of the illegality of its manner, and of the danger of its object, as affecting the Protestant faith, to be exempted from the general sentiment. But for the birth of the Prince of Wales, the people at large might have been contented to wait for the relief which was to be expected, after the death of the king, from the succession of the Princess of Orange, who was a Protestant, and united to the chief military defender of that interest in Europe. But this hope was now shut out, and it was necessary to resolve upon some decisive measures for the safety of the national religion.

THE REVOLUTION.

In this crisis, some of the principal nobility and gentry, with a few clergymen, united in a secret

address to William, Prince of Orange, calling upon him to come over with an armed force, and aid them in protecting their faith and liberties. This prince, who feared that England would soon be joined to France against the few remaining Protestant powers, and also that his prospects of the succession in that country, as nephew and son-in-law of the king, were endangered, listened readily to this call, and immediately collected a large fleet and army, comprising many persons, natives of both Scotland and England, who had fled from the severe government of the Stuart princes. The preparations for the expedition were conducted with great secrecy. When James, who had at first disbelieved the reports regarding the expedition, was assured of their truth, he ordered a fleet and large army to be collected, and, that he might regain the affections of his subjects, he abolished the Ecclesiastical Commission, called a parliament, and undid many of his late measures. It was now too late, however, for such concessions to be of any avail.

On the 19th of October, the Prince of Orange set sail with 50 ships-of-war, 25 frigates, 25 fireships, and 500 transports, containing 15,000 landtroops. A storm occasioned some damage and delay; but he soon put to sea again, and proceeded with a fair wind along the British Channel, exhibiting from his own vessel a flag, on which were inscribed the words, 'THE PROTESTANT RELIGION AND THE LIBERTIES OF ENGLAND,' with the apposite motto of his family, *Je maintiendrai*—'I will maintain.' The English fleet being detained at Harwich by the same wind which was so favourable to the prince, he landed (November 5) without opposition at Torbay, and immediately proceeded to circulate a Declaration stating that he had come to protect the liberties of England, and to secure the calling of a free parliament to redress grievances and inquire into the truth of the Prince of Wales.

Being almost immediately joined by many persons of consequence, the prince marched towards London. The king saw himself deserted by his nobility, his chief military officers, and even his daughter Anne, who, with her favourite, Lady Churchill, joined the insurgents. In great perplexity, he summoned a council of peers, by whose advice writs were issued for a new parliament, and commissioners despatched to treat with the prince. A kind of infatuation now took possession of the king; and, after one unsuccessful attempt, he got, with the connivance of the supporters of William, whom his presence in the country would have embarrassed, on board a ship, which conveyed him to France, having previously sent his queen and her infant to the same country. He was most kindly received by Louis XIV.

The same day that the king left Whitehall for the last time, his nephew and son-in-law arrived at St James's. The public bodies immediately waited on him, to express their zeal for his cause; and such of the members of the late parliaments as happened to be in town, having met by his invitation, requested him to issue writs for a convention, in order to settle the nation. He was in the same manner, and for the same purpose, requested to call a convention in Scotland. The English convention met on the 22d of January 1689, and during its debates the prince maintained a magnanimous silence and neutrality. The Tory party, though it had joined in calling him over, displayed some scruples respecting the alteration of the succession, and seemed at first inclined to settle the crown on the princess, while William should have only the office of regent; but when this was mentioned to the prince, he calmly replied, that in that event he should immediately return to Holland. A bill was then passed, declaring James, by breaking the *original contract* between the king and people, to have abdicated the throne. To the bill was added what was called a *Declaration of Rights*—namely, an enumeration of the various laws by which the royal prerogative and the popular liberties had formerly been settled, but which had been violated and evaded by the Stuart sovereigns. WILLIAM and MARY, having expressed their willingness to ratify this Declaration, were proclaimed king and queen jointly—the administration to rest in William; and the convention was then converted into a parliament.

In Scotland, where the Presbyterians had resumed an ascendency, the convention declared that James, by the abuse of his power, had *forfeited* all right to the crown—a decision also affecting his posterity; and William and Mary were immediately after proclaimed. By a bill passed in the English parliament, the succession was settled upon the survivor of the existing royal pair; next, upon the Princess Anne and her children; and finally, upon the children of William by any other consort—an arrangement in which no hereditary principle was overlooked, except that which would have given a preference to James and his infant son. The sovereignty of Ireland went with that of England.

By the Revolution, as this great event was styled, it might be considered as finally decided that the monarchy was a human institution dependent on the people, and established and maintained for their benefit. Many advantages, of smaller importance, though of more direct and practical utility, resulted from the change. The Episcopal Church, which in Scotland had occasioned incessant discontent and disturbance for the last twenty-eight years, was abolished in that kingdom as an establishment, and the favourite Presbyterian forms were established. Dissenters from the church in England were freed from the severities to which they had been exposed during the last two reigns. The royal revenue, which had formerly been fixed at the beginning of each reign, was now settled annually by the House of Commons, so that the king was more under the control of his people than formerly. The independence and impartiality of the judges were now secured by their being appointed for life, or during good behaviour, instead of being removable at the royal pleasure as heretofore.

RESISTANCE IN SCOTLAND AND IRELAND.

The new government was at first extremely popular in Scotland; but one portion of the people was much opposed to it. This consisted of the Highland clans—a primitive race, unable to appreciate the rights which had been gained, prepossessed in favour of direct hereditary succession, and of such warlike habits, that though a minority, they were able to give no small trouble to the

peaceful Lowlanders. When the Scottish convention was about to settle the crown on William and Mary, Viscount Dundee, formerly Graham of Claverhouse, and celebrated for his severity upon the recusant Presbyterians, raised an insurrection in the Highlands in favour of King James, which threatened at first to be successful. General Mackay, who was sent with a body of troops to suppress it, encountered Dundee at Killiecrankie (July 27, 1689), and, though his troops were greatly superior in number and discipline, experienced a complete defeat. Dundee, however, fell by a musket-shot in the moment of victory, and his army was unable to follow up its advantage. In a short time the Highland clans were induced to yield a nominal obedience to William and Mary.

In Ireland, where, since the accession of James, Catholicism had been virtually predominant, a much more formidable resistance was offered to the Revolution Settlement. In March 1689, James proceeded in person from France to Ireland, where he found himself at the head of a large though ill-disciplined army, which had been assembled by the Earl of Tyrconnel, who had been viceroy in the previous reign. He immediately ratified an act of the Irish parliament for annulling that settlement of the Protestants upon the lands of Catholics which had taken place in the time of Cromwell, and another for attainting between two and three thousand Protestants. The Protestants or Englishry, finding themselves thus dispossessed of what they considered their property, and exposed to the vengeance of a majority over whom they had long ruled, fled to Londonderry, Enniskillen, and other fortified towns, where they made a desperate resistance, in the hope of being speedily succoured by King William. That sovereign now led over a large army to Ireland, and (July 1, 1690) attacked the native forces under his father-in-law at the fords of the river Boyne, near the village of Dunore, where he gained a complete victory.

James was completely dispirited by this disaster, and lost no time in sailing again to France. The Duke of Berwick, a natural son of James, and the Earl of Tyrconnel, still kept the field with a large body of cavalry, and the infantry were in the meantime effectually protected in the town of Limerick. The Irish army next year, on 12th July, fought a regular battle at Aghrim, when, partly owing to the loss of their brave French leader, St Ruth, they were totally routed by the Dutch general Ginkell, who was afterwards created Earl of Athlone. The remains of the Catholic forces took refuge in Limerick, where, with their gallant commander, Sarsfield, they finally submitted.

The supremacy of the colonists was now secured beyond the possibility of a doubt, and an act was passed in England making it necessary for all members of the Irish parliament, and all persons filling civil, military, and ecclesiastical offices in Ireland, to take an oath abjuring the most important doctrines of the Catholic faith.

REIGN OF WILLIAM III.

Though all military opposition was thus overcome, William soon found difficulties of another kind in the management of the state. The Tories, though glad to save the established church by calling in his interference, had submitted with no good grace to the necessity of making him king; and no sooner was the danger past, than they reasserted their doctrine of hereditary right. From the name of the exiled monarch, they now began to be known by the appellation of *Jacobites*. James's hopes of a restoration were thus for a long time kept alive, and the peace of William's mind was so much imbittered, as to make his sovereignty appear a dear purchase. Perhaps the only circumstance which reconciled the king to his situation, was the great additional force he could now bring against the ambitious designs of Louis XIV. Almost from his accession he entered heartily into the combination of European powers for checking this warlike prince, and conducted military operations against him every summer in person. The necessity of having supplies for that purpose rendered him unfit, even if he had been willing, to resist any liberal measures proposed to him in parliament, and hence his passing of the famous Triennial Act in 1694, by which it was appointed that a new parliament should be called every third year. In this year died Queen Mary, without offspring; after which William reigned as sole monarch.

While William was treated in England with less than justice, he lost all his popularity in Scotland, in consequence of two separate acts, characterised by great cruelty and injustice. An order had been issued, commanding all the Highland chiefs, under pain of fire and sword, to give in their submission before the last day of the year 1691. One chief, M'Ian—the head of the Macdonalds of Glencoe—was prevented by accident from observing the day; and Dalrymple, the secretary for Scotland, made his delay a pretext for obtaining from William letters of fire and sword, decreeing the destruction of the whole clan. The military party intrusted with this duty, instead of boldly advancing to the task, came among the clan as friends, partook of their hospitality and amusements, and never indicated their intentions till the morning of the 13th of February (1692), when they attacked the unsuspecting people in their beds, and mercilessly slew all that came in their way. Thirty-eight persons, including the chief and his wife, were slaughtered, and many others died in the snow, as they vainly tried to escape. A more atrocious action does not stain modern history, though the barbarous circumstances of the slaughter were more owing to feelings of private revenge on the part of some of the officials of government in Scotland, than to the intentions of William. As, however, he did nothing more than dismiss Dalrymple, when the circumstances of the massacre were made known to him, his name was unfortunately associated with it in the minds of the Scotch people.

Two or three years after, the Scottish people began to turn their attention to commerce, by which they saw great advantages gained by neighbouring states, and they subscribed among themselves £400,000 for the founding of a colony on the Isthmus of Darien, which they thought might become an emporium for American and Indian produce. The scheme was at first sanctioned by an act of parliament, but on account of the jealousy of English trading companies, and the remonstrances of the Spaniards, who feared their colonies

would be interfered with, the king withdrew his countenance from it. Nevertheless, in 1698, a gallant expedition was sent out by the Scots, who founded a town called New Edinburgh, about midway between Puerto Bello and Carthagena, and under the ninth degree of latitude. During the winter months, everything seemed likely to answer the expectations of the colonists; but summer brought disease; and on their provisions running low, they found, to their infinite consternation, that they could get no supplies, the Spanish and English colonists of the neighbouring countries being forbidden to deal with them. In May and September 1699, ere intelligence of these circumstances could reach home, two other expeditions had sailed, containing 1800 men, who were involved on their arrival in the same disasters, and ultimately, being attacked by the Spaniards, the unfortunate colony was obliged to surrender. Very few ever regained their native country, and the large sums vested in the undertaking were irrecoverably lost. The massacre of Glencoe and the Darien expedition caused the king to be bitterly hated by the Scotch nation, and largely increased the ranks of the Jacobites.

The war with France, which commenced in 1690, was carried on both by land and sea till 1697, with varying success on land, but complete success for the English and Dutch fleets, which gained in particular the great battle of La Hogue. In September of that year, both sides being exhausted, the Peace of Ryswick was concluded, by which it was agreed that the fortresses taken by Louis in Flanders and to the south of the Pyrenees should be restored to Spain, and that neither sovereign should countenance conspiracies against the other. Before this, Louis had agreed to acknowledge William as king of England. In 1700, in consideration that he and his sister-in-law Anne had no children, her only surviving son, the Duke of Gloucester, having died that year, the famous Act of Succession was passed, by which the crown, failing these two individuals, was settled upon the next Protestant heir, Sophia, Duchess of Hanover, daughter of Elizabeth, the eldest daughter of James I.

About this time the causes of a new war took their rise in certain disputes respecting the succession to the crown of Spain. The title to that sovereignty, in the event of the death of the existing king, Charles II. without heirs, was claimed by the king of France, the Elector of Bavaria, and the Emperor of Germany, through various female lines of descent. A secret treaty, to which England was a party, was entered into for preventing the whole from falling into the hands of the reigning family of France, whose possessions would then have been so great as to be inconsistent, it was thought, with the independence and safety of neighbouring states. At the death of the king of Spain, however, a will was produced, in which it appeared that he had appointed the Duke of Anjou, second son of the Dauphin, to be his successor. The French king lost no time in enforcing the pretensions of his grandson, who, under the title of Philip V. became the founder of the Bourbon dynasty in Spain.

About the same time (September 1701), James, the exiled English king, died at St Germain, leaving his pretensions to his son, James, Prince of Wales, now a boy of thirteen years of age, and henceforth generally recognised in Britain by the epithet of the *Pretender*. Without regard to the Treaty of Ryswick, Louis XIV. acknowledged this young person as JAMES III. King of Great Britain, by which he added greatly to the hostile feeling which his other proceedings had already created in the British king and people. A war was accordingly in preparation, when King William died in his fifty-second year (March 8, 1702), in consequence of a fall from his horse.

William was a prince of commanding ability, particularly in military affairs. His ruling sentiment was a wish to reduce the power of the king of France, which he was able in no small degree to effect. His person was thin and feeble, and his ordinary demeanour was cold, silent, and somewhat repulsive. It was only in battle that he ever became animated or easy. He was a man of undoubted sincerity and conscientiousness, and sincerely attached to toleration in religion.

The reign of King William is remarkable for the first legal support of a standing army, and for the commencement of the national debt. It is also distinguished by the first establishment of regular banks for the deposit of money and the issue of a paper-currency. Formerly, the business of banking, as far as necessary, was transacted by goldsmiths, or through the medium of the public exchequer, by which plans the public was not sufficiently insured against loss. In 1695, the first public establishment for the purpose, the *Bank of England*, was founded by William Paterson, a scheming Scotsman; and next year the Bank of Scotland was set on foot by one Holland, an English merchant; the capital in the former case being only £1,200,000, and in the latter, the tenth part of that sum.

The most profound writer of this reign was John Locke, author of an *Essay on the Human Understanding*, an *Essay on Toleration*, and other works. The greatest name in polite literature is that of John Dryden, remarkable for his energetic style of poetry, some dramas, and his translations of Virgil and Juvenal.

QUEEN ANNE—MARLBOROUGH'S CAMPAIGNS.

William was succeeded by his sister-in-law, ANNE, second daughter of the late James II.; a princess now thirty-eight years of age, and chiefly remarkable for her zealous attachment to the Church of England. Her husband was Prince George of Denmark, a person of insignificant character. The movement against the king of France had not been confined to Great Britain; it was a combination of that power with the Emperor of Germany and the states of Holland. Queen Anne found it necessary to maintain her place in the Grand Alliance, as it was termed; and John Churchill, Earl, and afterwards Duke, of Marlborough, the husband of her favourite, Sarah Jennings, was sent over to the continent with a large army to prosecute the war in conjunction with the allies. Now commenced that career of military glory which has rendered the reign of Anne and the name of Marlborough so famous. In Germany and Flanders, under this commander, the British army gained some signal successes, particularly those of Blenheim, gained on the 2d of August 1704; and Ramillies, on the 12th of May 1706; in Spain, a smaller army,

under the chivalrously brave but eccentric Earl of Peterborough, performed other services of an important kind.

UNION OF ENGLAND AND SCOTLAND.

The treatment, by English traders, of the Darien expedition, had now inspired the Scottish people with the most unfriendly feeling against their southern neighbours, and they resolved to shew their power of counter-annoyance by holding up threats of dissenting from England in the matter of the succession. In 1703, their parliament passed the famous *Act of Security*, by which it was ordained that the successor of her majesty in Scotland should not be the same with the individual adopted by the English parliament, unless there should be a free communication of trade between the countries, and the affairs of Scotland thoroughly secured from English influence. The English ministers then saw that an incorporating union would be necessary to prevent the Pretender from gaining the Scottish crown, and to protect England from the attacks of a hostile nation. For this purpose they exerted themselves so effectually in the Scottish parliament, as to obtain an act enabling the queen to nominate commissioners for the arrangement of a union. These commissioners, who, with scarce an exception, were friends of the court, drew up a treaty which, in October 1706, was submitted to the Scottish parliament. The principal points were these: That the two nations were to be indissolubly united under one government and legislature, each, however, retaining its own civil and criminal law; the crown to be in the House of Hanover; the Scottish Presbyterian Church to be guaranteed; forty-five members to be sent by the Scottish counties and burghs to the House of Commons, and sixteen elective peers to be sent to the Upper House by the nobles; the taxes to be equalised, but, in consideration of the elevation of the Scotch imposts to the level of the English (for the latter people already owed £16,000,000), an equivalent was to be given to Scotland, amounting to nearly £400,000, which was to aid in renewing the coin and other objects. These terms were regarded in Scotland as miserably inadequate; and the very idea of the loss of an independent legislature and a place among governments raised their utmost indignation. Nevertheless, by dint, mainly, of bribery, the union was carried through parliament; and from the 1st of May 1707, the two countries formed one state, under the title of the Kingdom of Great Britain.

HIGH CHURCH ENTHUSIASM.

Since the Revolution, the Whigs might be considered as the predominant party in England. They almost exclusively constituted the ministries, and a large majority in the parliaments, of King William. The sentiments of the queen were of a different cast from theirs, and she disliked the Revolution Settlement, by which she reigned. As the remembrance of the errors of King James faded from the public recollection, the people began to partake more generally of the Tory spirit. The parliament which they returned at the beginning of the new reign, contained a much larger admixture of that party than the former one. The Tory feeling of both people and parliament chiefly took the direction of a strong attachment to the Church of England, which they wished, as did the queen herself, to maintain in uncompromising supremacy, and in all its privileges; while the Whig party, in general, were favourable to the toleration called for by the Dissenters. The distinction of High Church and Low Church now became conspicuous, the one phrase implying the ecclesiastical views of the Tories, while the other referred to those of the Whigs. In this parliament, the House of Commons passed a bill against *occasional conformity*, by which penalties were imposed on all persons in office who should attend dissenting places of worship; but it was thrown out by the Upper House, in which the bishops created by William voted against it.

An imprudent act of the ministry raised the High Church enthusiasm to an extraordinary height. A High Church divine of no great ability named Dr Henry Sacheverel, had preached in 1709 two sermons, in which he spoke violently against the toleration granted to Dissenters, and asserted with much vigour the Tory doctrine of *non-resistance*, according to which nothing can justify a subject in taking up arms against his legal sovereign. The ministers, headed by Lord Godolphin, were so weak as to give this man a solemn trial, on the ground that he had spoken evil of the Revolution; but the people rose so tumultuously in his favour, that, though declared guilty, it was found impossible to inflict upon him more than a nominal punishment. After the trial, he received more marks of public reverence and honour than were ever bestowed on the greatest national benefactor. In proportion to the popularity of Dr Sacheverel, was the loss of public favour experienced by the Whig party. About the same time, through some court intrigues, they forfeited all remaining favour with their royal mistress. Mrs Masham, a lady of the court, who had supplanted the Duchess of Marlborough as favourite of the queen, had contrived to introduce into the cabinet two Tory statesmen, Mr Robert Harley, afterwards Earl of Oxford, and Mr Henry St John, afterwards Lord Bolingbroke. The queen having dismissed the Whig ministry, Harley and St John came into power in August 1710, at the head of a decidedly Tory ministry. The queen at the same time called a new parliament, to which a larger majority of Tories were returned.

PEACE OF UTRECHT—DEATH OF QUEEN ANNE.

The members of the new cabinet immediately applied themselves, though very secretly, to the business of bringing about a peace. They had a majority in the Lower House, and by the creation of twelve new peers, they succeeded in overpowering the Upper. Among their acts was the dismissal of Marlborough from his command, on a charge of peculation being preferred against him. After a tedious course of negotiation, Britain and Holland concluded a peace at Utrecht (1713), leaving the Emperor of Germany still at war. By this arrangement, Philip V. was permitted to retain Spain and the Indies, but it was provided that he and his descendants should never inherit the kingdom of France, nor any future king of France accede to the crown of Spain. Britain obtained nothing tangible by all her exertions,

except the possession of Gibraltar and Minorca, the island of St Christopher, and the French colony of Acadie or Nova Scotia. At the same time the French king acknowledged Anne as Queen of Great Britain, guaranteed the succession of the House of Hanover, and engaged to make the Pretender withdraw from the French dominions. For the gratification of their High Church supporters, the ministers obtained an act for preventing Dissenters from keeping schools, and another for establishing church-patronage in Scotland, the former of which was repealed in the following reign.

It is believed that Queen Anne and her Tory ministers were in secret willing to promote the restoration of the main line of the Stuart family, and Harley and St John, who, from friends, had become bitter rivals, are now known to have intrigued for that purpose. But before any plan could be formed, the queen fell ill, and died (August 1, 1714), not, however, before she had shattered the hopes of Bolingbroke and the friends of the Pretender by giving up the Treasurer's staff to the Duke of Shrewsbury, who had taken a leading part in calling over the Prince of Orange. The Electress Sophia being recently dead, her son, George Louis, then Elector of Brunswick-Lüneburg, was proclaimed under the title of GEORGE I.

The reign of Queen Anne is not more distinguished by the wonderful series of victories gained by Marlborough, than by the brilliant list of literary men who then flourished. Alexander Pope stands unrivalled in polished verse on moral subjects. Jonathan Swift is a miscellaneous writer of singular vigour, and an extraordinary but ungenial kind of humour. Joseph Addison wrote on familiar life, and on moral and critical subjects, with a degree of elegance before unknown. Sir Richard Steele was a lively writer of miscellaneous essays. This last author, with assistance from Addison and others, set on foot the *Tatler*, *Spectator*, and *Guardian*, the earliest examples of small periodical papers in England, and which continue to this day to be regarded as standard works. Cibber, Congreve, Vanbrugh, and Farquhar were writers of sparkling but essentially immoral comedy. In graver literature, this age is not less eminent. Dr Berkeley shines as a metaphysician; Drs Sherlock, Atterbury, and Clarke as divines; and Bentley as a critic of the Roman classics.

ACCESSION OF THE HOUSE OF HANOVER —REBELLION OF 1715–16.

Although the new sovereign allowed six weeks to elapse before he came to this country, there was no demonstration on the part of the Jacobites against him. He was fifty-four years of age, honest, well intentioned, and steadfast in his political principles. He was totally ignorant of the English language, and was passionately attached to his native dominions. He imprisoned his wife on a mere suspicion of her fidelity, while his own private life was far from reputable. Knowing well that the Whigs were his only true friends, he at once called them into the administration. A committee of the House of Commons was appointed to prepare articles of impeachment against Oxford, Bolingbroke, the Duke of Ormond, and the Earl of Strafford. Bolingbroke, perceiving his life to be in danger, fled to the continent; and his attainder was in consequence moved and carried by his rival Walpole. Ormond suffered a similar fate. Oxford, after a protracted trial, was only acquitted in consequence of a difference between the Lords and Commons.

During the first year of King George, the Tories kept up very threatening popular disturbances in favour of High Church principles; but the Whigs, gaining a majority in the new House of Commons, were able to check this a little by the celebrated enactment called the *Riot Act*, which permits military force to be used in dispersing a crowd, after a certain space of time has been allowed.

The more extreme Tories now resolved to attempt bringing in the Pretender by force of arms. The Earl of Mar, who had been a Secretary of State in the late administration, raised his standard in Braemar (September 6), without any commission from the Pretender, and was soon joined by Highland clans to the amount of 10,000 men, who rendered him master of all Scotland north of the Forth. There, however, he permitted himself to be cooped up by the Duke of Argyll, who, with a far less numerous force, had posted himself at Stirling. Mar expected support from an invasion of England by the Duke of Ormond, and a rising of the people of that country. But the duke completely failed in his design, and no rising took place, except in Northumberland, where Mr Foster, one of the members of parliament for the county, and the Earl of Derwentwater, with some other noblemen, appeared in arms, but unsupported by any considerable portion of the people. The government, although ill provided with troops, sent such a force against Mr Foster as obliged him, although reinforced by a detachment from Mar's army, to retire into the town of Preston, in Lancashire, where, after an obstinate defence, the whole party (November 13) surrendered to General Carpenter. On the same day, the Earl of Mar encountered the Duke of Argyll at Sheriffmuir, near Dunblane. The battle was a drawn one, but, as Mar was unable to make any further movement, it was practically a victory for the royal troops. The Pretender himself landed in Scotland later in the year, but finding that he could do nothing, sailed back in February 1716, with Mar, to France. For this unhappy appearance in arms, the Earl of Derwentwater, Viscount Kenmure, and about twenty inferior persons, were executed; and forty Scottish families of the first rank lost their estates.

CHARACTER OF THE GOVERNMENT UNDER GEORGE I.

From the Peace of Utrecht, Britain remained free from foreign war for nearly thirty years, excepting that, in 1719, the ministry was called on to interfere for the repression of an attempt on the part of Spain to regain her Italian territories. A Scotchman, named Law, who had become Controller-general of France, and amused that country with financial schemes, which at first promised to enrich, but finally almost ruined the country, was the means, in 1720, of inspiriting the British people with a similar visionary project, called the South Sea Scheme. This might be described as a joint-stock company, professedly trading in the South Seas, but chiefly engaged in a scheme for buying

up annuities that had been granted in the reign of William and Mary, for the purpose of reducing the national debt. It seemed for a time to prosper, and many realised large fortunes by selling their shares at a premium to others; but in a short time its unsoundness was discovered, the price of shares fell, and thousands were utterly ruined. With great difficulty, and by an extremely complicated adjustment, the House of Commons equalised as nearly as possible the state of gain and loss among the innocent parties, and credit was restored. Sir Robert Walpole, who was chiefly concerned in effecting this arrangement, became Premier and Chancellor of the Exchequer, and for upwards of twenty years from that period (April 1721), he must be looked on as the prime mover and manager of the public affairs. Among the measures of this reign was a bill, carried in 1716, for repealing King William's Triennial Act, and giving to parliaments a duration of seven years.

The commerce and manufactures of England continued to advance steadily during this reign; but Scotland and Ireland remained in an unimproved state. Roads were now for the first time made in the Highlands. The most notable literary man of the time was Daniel Defoe, a voluminous writer of pamphlets on the Nonconformist side, but far more noted in later times on account of his admirable tale of *Robinson Crusoe*. Few writers have shewn so great a knowledge of human nature in all phases of life as he has.

GEORGE II.—WAR WITH SPAIN AND FRANCE.

George I. at his death, June 10, 1727, was succeeded, in his 44th year, by his son, GEORGE II. who, like his father, was German at heart, although he could speak English fluently. He was methodical, economical, and courageous, but passionate, and his private life was not free from reproach. His wife, Caroline, of Brandenburg-Anspach, was handsome, well educated, and clever, and for many years virtually ruled the country. In the early part of his reign, Walpole effected some useful measures, and upon the whole was a vigorous and enlightened administrator of public affairs, though nothing can justify the extensive system of bribery by which alone he pretended to manage the House of Commons. After a peace of extraordinary duration, he was urged, in 1739, much against his will, and on account of a trifling dispute between Spanish and British merchants, into a war with Spain. This war proving almost everywhere unsuccessful, Walpole resigned, and was called to the Upper House in 1742, as Earl of Orford. He died three years later. After the death of the Emperor Charles VI. of Germany, his dominions fell by inheritance to his daughter, the celebrated Maria Theresa, Queen of Hungary. She was opposed in this succession by the sovereigns of France, Saxony, and Bavaria, all of whom pretended to have some claims on her dominions. A war was commenced against her; the Elector of Bavaria was crowned emperor, under the title of Charles VII.; and such was the success of the French arms, that she was soon reduced to the greatest distress. With this quarrel Britain had little reason for interfering; but the king thought his dominions in Germany endangered, and many of the people were animated by their usual hostility to the French. Others, however, like William Pitt, then rising into notice as the leader of the discontented Whigs or 'Patriots,' denounced the war, declaring that Britain was being made a province of an electorate.

In 1743 the king joined the Earl of Stair, who had entered Germany at the head of a considerable army, and who had allowed himself to be shut up by the French in a valley near Dettingen, on the Main, and defeated the latter, fighting himself at the head of the first line. In May 1745, however, Marshal Saxe defeated an army under the king's second son, the Duke of Cumberland, at Fontenoy, owing to the desertion, by the continental allies, of the British infantry, which behaved most gallantly.

REBELLION OF 1745–46.

The Pretender had married, in 1719, the Princess Clementina Sobieski of Poland, and was now the father of two sons in the bloom of youth, the elder of whom has been distinguished in history by the title of Prince Charles Stuart. The misfortunes of the British arms on the continent, and the dissensions which prevailed among the people and the parliament, encouraged this prince to make an attempt to recover the throne of his ancestors. In 1745, he landed in Inverness-shire, with only seven attendants, and on the 19th August he raised his standard at Glenfinnan, within a few miles of the government station of Fort-William, and found himself surrounded by about 1500 men. A reward of £30,000 was offered for the head of the young prince, who, with all his family, was under attainder by act of parliament; and Sir John Cope, commander of the forces in Scotland, was ordered to advance with what troops he had into the Highlands, and suppress the insurrection. The prince pushed rapidly southward, took possession of Perth and Edinburgh in succession, and on the 21st of September a rencontre took place between him and Cope at Prestonpans. Seized with a panic, the royal troops fled disgracefully from the field, leaving the prince a complete victory. With the lustre thus acquired by his arms, he might have now, with 4000 or 5000 men, made a formidable inroad into England. Before he could collect such a force, six weeks passed away, and when at length (November 1) he entered England, a large body of troops had been collected to oppose him under the Duke of Cumberland. Eluding Cumberland, however, he advanced boldly to Derby, and created a kind of panic in the metropolis. His adherents, however, were disheartened by the small accessions to their strength they received in England, and determined to go no farther. The prince, therefore, reluctantly retreated to Scotland, followed by the army of the Duke of Cumberland.

After a flash of success on January 17, 1746, when he defeated General Hawley and a body of English troops at Falkirk, Prince Charles was completely defeated by Cumberland, April 16, at Culloden, near Inverness. He had himself the greatest difficulty, and encountered many romantic adventures, in escaping from the country, and the Highlands were subjected for several months to the horrors of military violence in all its worst forms. Three of the insurgent nobles, the Earl of Kilmarnock, and Lords Balmerino and Lovat, suffered death on Tower Hill, and a large number of meaner men were hanged at Carlisle

and at Kennington Common. For the mercilessness of his treatment of the conquered, Cumberland was called 'The Butcher.' Various measures were also passed by parliament for completing the subjugation of the Highlands; among these being acts prohibiting the use of tartan, and abolishing the tenure of ward-holdings, by which landed proprietors commanded, in peace and war, the personal services of those who lived on their estates.

PEACE OF AIX-LA-CHAPELLE.

During the remainder of the war in which Britain and other powers were now engaged with France, the latter was generally successful by land, and unfortunate at sea; the contrary being the case with Britain. In 1748, the two countries agreed, by a treaty formed at Aix-la-Chapelle, mutually to restore their respective conquests, and to go back to almost exactly the same condition in which they stood before the war.

COLONIES AND DEPENDENCIES OF BRITAIN—THE SEVEN YEARS' WAR.

For several years after this period, the national resources underwent rapid improvement. The ablest minister who immediately followed Walpole, was the Honourable Henry Pelham, First Lord of the Treasury and Chancellor of the Exchequer, whose commercial and financial schemes were usually very successful. Since the reign of Elizabeth, the British had been active in planting and rearing colonies, of which a considerable number now existed in the West Indies and in North America. The East India Company had also obtained large possessions in Hindustan, which proved the source of great wealth to Britain. The exclusive spirit in which Britain managed the commerce of those territories provoked the cupidity of the French, who commenced a system of aggression both in India and North America. The British government submitted to this for a short time, but at length, in 1756, it was determined to declare war. At first the French, who had drawn a chain of forts along the back settlements of the American colonies, were successful. But, on the accession of the celebrated William Pitt (afterwards Earl of Chatham) to the office of Secretary of State, a more auspicious era commenced. One after another, the French forts fell into the hands of the British troops, and a diversion was created by an attack upon Canada. In September 1759, General Wolfe, whose powers were first recognised by Pitt, reduced the town and fort of Quebec, though he himself fell in the moment of victory, and the whole colony soon after submitted to the British arms.

Meanwhile, Colonel Clive, an officer of the East India Company, who, although he had previously had no military training, developed rapidly into a great general and statesman, had been equally successful in the East Indies. He had destroyed the French settlement at Pondicherry, thereby securing to his country the whole coast of Coromandel; and by a decisive victory at Plassy (June 23, 1757), over a combination of French and native forces, he made the Company the lords of Bengal, and laid the foundation of the great territorial power which the British have since acquired in Hindustan.

While Britain was thus successful in two remote quarters of the world, she experienced a different fortune in Europe. Austria, Russia, and Poland had combined with France against the new and rising power of Prussia, which was at present directed by Frederick II. commonly called Frederick the Great. Britain, on this occasion, became the ally of the Prussian monarch, not from any regard to her own interests, but in order that the king might be able to protect his Hanoverian dominions. Immense sums of money were raised for the purpose of paying the troops of those countries which the king was anxious to defend; and the Duke of Cumberland was appointed their commander. This prince was so unfortunate (September 1757) as to bring an army of 40,000 men into an angular piece of country, from which there was no escaping, so that the whole were obliged to lay down their arms to the French, who then became masters of Hanover. Notwithstanding this failure on the part of his ally, Frederick was able, by his extraordinary military genius, and by British subsidies, to defend his dominions for several years against all the forces that Austria, France, and Russia could bring against him. In the midst of this war (October 25, 1760), George II. died suddenly, in the seventy-seventh year of his age, and was succeeded by his grandson GEORGE III. then only in his twenty-third year.

MISCELLANEOUS CIRCUMSTANCES CONNECTED WITH THE REIGN OF GEORGE II.

One of the leading domestic events of the reign of George II. was the rise of the religious sect called Methodists. The name was first given in ridicule, it is said, to some young members of the university of Oxford, who were noted, in a time in which there was little religious fervour, for their rigidly decorous life, their religious devotions, and their habit of visiting the sick. The chief among them were John and Charles Wesley and George Whitefield. The last, by his earnest eloquence, which was aided by a singularly fine voice, did a great deal for the spread and success of the movement by open-air meetings. The Methodists, who were at first much ridiculed, have now become a large body, and although originally within the pale of the Church of England, have separated from it.

Newspapers first acquired political importance in this reign. They originated in the time of the Commonwealth, but none of a regular periodical nature appeared till after the Restoration, when a busy writer, named Roger L'Estrange, established in London a weekly one called *The Public Intelligencer.* Till the Revolution, such small and unimportant newspapers as existed were trammelled by a licensing power and censorship. When these restrictions were removed, newspapers increased in number, till, in 1709, they were again restricted by the imposition of a penny-stamp. The influence which newspapers were calculated to have over the public mind was first recognised by Sir Robert Walpole, who, while he never thought of giving the least encouragement to literature on its own account, liberally pensioned various editors who supported his government. About the beginning of this reign, there were in London one daily paper, fifteen three times a week, and one twice a week, besides a few country papers. A monthly

pamphlet, begun in 1731 by Edward Cave, a London bookseller, under the name of the *Gentleman's Magazine*, was composed of the best articles from the newspapers, and thus originated the periodical works termed magazines and reviews, which are now conspicuous as vehicles of light literature and political discussion.

The peculiar literary genius of the age was shewn in the fictitious prose-writings of Fielding, Smollett, and Sterne, and in the pictures of Hogarth, all of which represent the national character in its greatest breadth. The novels of Richardson are also accurate as descriptions of manners, but contain no trace of the same humour. Next in distinction to these writings must be placed the essays of John Hawkesworth and Samuel Johnson, the latter of whom, besides being an essayist and poet, did a great service to literature in compiling a Dictionary of the English Language. James Thomson, William Collins, and Thomas Gray rank high as poets; and philosophy was represented chiefly by Francis Hutcheson and David Hartley. Drs Conyers Middleton, Joseph Butler, and Isaac Watts were the principal writers on religious subjects.

GEORGE III.—BUTE ADMINISTRATION—PEACE OF 1763.

Soon after his accession, George III.—eldest son of Frederick, Prince of Wales, who died before his father—espoused the Princess Charlotte of Mecklenburg-Strelitz, by whom he had a large family. His chief adviser was the Earl of Bute, a Scottish nobleman of Tory predilections, who had been his preceptor, and possessed a great influence over his mind. Partly through Bute, who was made a Secretary of State, more peaceful counsels now began to prevail in the government. Pitt, the Great Commoner, resigned in 1761, because his proposal to declare war against Spain, then the ally of France, was opposed by his colleagues. War broke out again, however, and was carried on with much success on the part of this country till 1763, when peace was made with both France and Spain by the Treaty of Paris. By this treaty, Great Britain gave up a certain portion of her conquests, in exchange for others which had been wrested from her; but she was nevertheless a gainer to an immense amount. She acquired from the French —Canada; that part of Louisiana east of the Mississippi; Cape Breton; Senegal; the islands of Grenada, Dominica, St Vincent, and Tobago; with all the acquisitions which the French had made upon the Coromandel Coast in the East Indies since 1749. From Spain she acquired Minorca, East and West Florida, with certain privileges of value.

TRANSACTIONS IN IRELAND.

Since the pacification at Limerick, Ireland had been ruled exclusively by the Protestant party, who, under the influence of feelings arising from local and religious antipathies, had visited the Catholics with many severities. They naturally became very discontented, and the contentions of the patriotic party with the adherents of the English ministry were carried on with the utmost keenness in parliament, when the rebellion in Scotland (1745) alarmed the government for the loyalty of Ireland. The celebrated Earl of Chesterfield was, in this exigency, sent for a short time as Lord-lieutenant, and allowed to hold forth all possible encouragement to the Catholics and patriotic party. So successful was he in his mission of conciliation that Ireland, though full of Roman Catholics, and bound to the Jacobite cause by many associations, remained perfectly faithful to the Hanover dynasty. When the danger was over, the earl was recalled, and the former system resumed.

CASE OF MR WILKES.

Ever since the accession of the Brunswick family in 1714, the government had been chiefly conducted by the Whig party, who formed a very powerful section of the aristocracy of England. George III. however, who had imbibed high notions of the royal prerogative from the Earl of Bute, shewed, from the beginning of his career, an anxious desire to extend the power of the crown, and to shake off the influence of the great Whig families. A Scotsman, with no connection in England, a favourite, and, moreover, a man of unprepossessing manners, the Earl of Bute had neither the support of the aristocracy nor of the people. He was assailed in parliament, and through the newspapers, with the most violent abuse — the peace, which was disliked by the people, furnishing a powerful topic against him. To this storm he at length yielded, by retiring (April 8, 1763).

Among the public writers who assailed the ministry, none was more virulent than Mr John Wilkes, member for Aylesbury, and editor of a paper entitled the *North Briton*. Mr George Grenville, who succeeded Bute, commenced his career by prosecuting Wilkes for a libel, and arrested him on a 'general warrant,' which was illegal. Wilkes was subsequently expelled from the House of Commons, and outlawed. A few years afterwards, he came back to England, and, in 1768, he was returned for Middlesex. Not being allowed to take his seat, he became, in the eyes of the mob, the champion of popular liberty, and riots followed in various parts of the country, resulting in loss of life. In 1774, Wilkes was allowed to take his seat.

AMERICAN STAMP-ACT.

The administration of Mr Grenville is also memorable for the first attempt to tax the American colonies. An act passed under his influence (March 1765) for imposing stamps on those countries, appeared to the colonists as a step extremely dangerous to their liberties, considering that they had no share in the representation. They therefore combined almost universally to resist the introduction of the stamped paper by which the tax was to be raised. Resolutions were passed in the various assemblies of the States, protesting against the assumed right of the British legislature to tax them. The home government was then induced to agree to the repeal of the act, but with the reservation of a right to impose taxes on the colonies. Between the Stamp-act and its repeal, a change had taken place in the administration: the latter measure was the act of a new ministry under the Marquis of Rockingham, which, however, did not long continue in power, being

supplanted by one in which Mr Pitt, now created Earl of Chatham, held a conspicuous place.

At the suggestion of Mr Charles Townshend, a member of this cabinet, it was resolved, in 1767, to impose taxes on the Americans in a new shape—namely, upon British goods imported into the colonies, for which there was some show of precedent. An act for imposing duties on tea, glass, and colours was accordingly passed with little opposition. Soon after this, Mr Townshend died, and the Earl of Chatham, who had been prevented by illness from taking any share in the business, resigned. The Americans met the new burdens with the same violent opposition as formerly.

JUNIUS—MINISTRY OF LORD NORTH.

At this time (1769), an unknown writer, styling himself Junius, commenced a series of letters in the *Public Advertiser* newspaper, animadverting in the most powerful manner on both the men and measures of the government, and particularly on the prime minister, the Duke of Grafton, who had succeeded Lord Chatham. The publisher of the newspaper was prosecuted for publishing these letters; but the author remained concealed, and his name, though still an object of curiosity, has never been discovered. The general belief is now that Sir Philip Francis, a keen politician of the time, was the author of the letters.

The Duke of Grafton having retired from the cabinet, his place was supplied by Lord North, son of the Earl of Guildford. This was the beginning of a series of Tory administrations which, with few and short intervals, conducted the affairs of the nation down to the close of the reign of George IV.

THE AMERICAN WAR OF INDEPENDENCE.

Meanwhile, the remonstrances of the American colonists had induced the ministry to give up all the new taxes, with the exception of that on tea, which it was determined to keep up, as an assertion of the right of parliament to tax the colonies. In America, this remaining tax continued to excite as much discontent as the whole had formerly done, for it was the principle of a right to impose taxes which they found fault with, and not the amount of the tax itself. Matters reached a crisis in 1773, when a number of men, disguised as Indians, boarded three ships which, laden with tea, had arrived in Boston harbour, and threw the cargoes into the sea. This act of violence was resented by the passing of a bill in parliament for interdicting all commercial intercourse with the port of Boston, and another for taking away the legislative assembly of the state of Massachusetts. The former measure was easily obviated by local arrangements; and in reference to the latter, a Congress of representatives from the various States met at Philadelphia, in September 1774, when it was asserted that the exclusive power of legislation, in all cases of taxation and internal policy, resided in the provincial legislatures. The colonists still avowed a desire to be reconciled, on the condition of a repeal of the obnoxious statutes. But the government had now resolved to attempt the reduction of the colonists by force of arms. Henceforth, every proposal from America was treated with a haughty silence on the part of the British monarch and his advisers, although the ablest men in parliament, such as Chatham, Bute, and Fox, then rising into fame, supported the colonists.

The war opened in the summer of 1775, by skirmishes between the British troops and armed provincials, for the possession of certain magazines. At the beginning, there seemed no hope of the contest being protracted beyond one campaign. The population of the colonies was at this time under three millions, and they were greatly inferior in discipline and appointments to the British troops. They possessed, however, an indomitable zeal for the cause they had agreed to defend, and in George Washington, whom the congress at Philadelphia had appointed commander-in-chief, they obtained a chief of not less military capacity than patriotism and probity. At Bunker's Hill, near Boston (June 17, 1775), they had the superiority in a well-contested fight with the British troops, of whom between two and three hundred were killed.

On the 4th of July 1776, the American congress took the decisive step of declaring their independence.

The first serious alarm for the success of the contest in America, was communicated in December 1777, by intelligence of the surrender of an army under General Burgoyne at Saratoga. This disaster, followed by the acknowledgment of the States by France, led to deep dejection in the country; and yet, when Mr Fox, now leader of the Opposition, made a motion for the discontinuance of the war, it was lost by 165 to 259.

In 1778, the government found it necessary, in order to appease the popular discontent, to send out commissioners, almost for the purpose of begging a peace. As if to avenge themselves for the indignities of 1775, the Americans received these commissioners with much haughtiness; and, being convinced that they could secure their independence, would listen to no proposals in which the acknowledgment of that independence, and the withdrawal of the British troops, did not occupy the first place. The ministry, still unwilling to submit to such terms, resolved to continue the war. The distress of Britain in this contest led to her various enemies and rivals in Europe declaring against her. Spain followed the example of France, and declared war; and in 1780, Holland was added to the number of her enemies. Russia then put herself at the head of what was called an Armed Neutrality, embracing Sweden and Denmark, the object of which was indirectly hostile to Britain. The Opposition in parliament now began, however, to gain in strength. After some votes, in which the ministerial majorities appeared to be gradually lessening, Mr Dunning, on the 6th of April 1780, carried, by a majority of eighteen, a motion, 'that the influence of the crown had increased, was increasing, and ought to be diminished.' This was looked upon as a severe censure of the government.

In the year 1778, an act had been passed relieving the Roman Catholics in England from some of the severe penal statutes enacted against them during the reign of William III. The apprehension of a similar act for Scotland caused the people of that country to form an immense number of associations, with a view to opposing it; and in the early part of 1779, the popular

spirit broke out at Edinburgh and Glasgow in several alarming riots, during which one or two Catholic chapels, and some houses belonging to Catholics, were pillaged and burnt. In England, the anti-Catholic party was headed by Lord George Gordon, a half-witted member of parliament, and son of the Duke of Gordon. Along with a mob of about 60,000 persons, he went to Westminster and demanded the repeal of the act in favour of the Roman Catholics. When this was refused, the mob attacked and destroyed the Catholic chapels, burned the prisons, including Newgate, and released the prisoners. The streets were in their possession for about a week, and it was not until about 500 persons had been killed or wounded, that the military succeeded in restoring order. Many of the ringleaders were executed, but Lord George Gordon, who was tried for high treason, was acquitted, on the ground of insanity.

In 1781, after some successes, Lord Cornwallis, the chief commander of the British forces in America, was besieged in Yorktown, Virginia, by the American and French troops, and, after a few weeks, was compelled to surrender.

When parliament next met, many of those who had formerly supported the war, began to adopt opposite views; and early in 1782, a motion, made by General Conway, for the conclusion of the war, was carried by a majority of nineteen. The necessary consequence was, that, on the 20th of March, Lord North and his colleagues resigned office. As usual in such cases, a new administration was formed out of the Opposition. The Marquis of Rockingham was made Prime-minister, and Mr Fox one of the Secretaries of State. The new ministers lost no time in taking measures for the restoration of peace. Before this was accomplished, however, Admiral Sir George Rodney had gained an important victory over the French fleet off the island of Dominica, April 12, 1782. On this occasion, thirty-seven British vessels encountered thirty-four French; and chiefly by the dexterous manœuvre of a breach of the enemy's line, gained one of the most complete victories recorded in modern warfare, the admiral, Count de Grasse, being compelled to strike. The triumph was necessary to recover in some measure the national honour, and enable the ministers to conclude the war upon tolerable terms. In November of the same year, provisional articles for a peace with the United States of America, now acknowledged as an independent power, were signed at Paris, and the treaty was concluded in the ensuing February. Peace was soon after concluded with France, Spain, and Holland. The two Floridas and Minorca were given back to Spain, although Gibraltar, which for three years and a half General Eliott had gallantly defended against the combined fleets of France and Spain, was retained. France obtained Chandernagore, Pondicherry, the island of St Pierre, and other possessions; and the Dutch had restored to them what they had lost.

On the unexpected death of the Marquis of Rockingham, in July 1782, the king chose as his successor the Earl of Shelburne, who, though nominally a Whig, was not sufficiently inclined to the general measures of that party to be agreeable to Mr Fox and other leading members of the cabinet. On their consequent resignation, the vacancies were filled up by the friends of Shelburne, among whom was Mr William Pitt, a younger son of the Earl of Chatham, who had already distinguished himself as an advocate of parliamentary reform.

COALITION MINISTRY.

This ministry was opposed by two parties of very different principles — namely, the adherents of the North administration, and the friends of those Whigs who had lately retired from the cabinet. These two parties, notwithstanding that they had been opposed to each other throughout all the late war, coalesced; and being triumphant over the ministry, forced themselves upon the king's counsels. Then was formed (April 2, 1783) what was called the Coalition Ministry, in which Lord North and Mr Fox acted together as Secretaries of State. The coalition, however, pleased neither the king nor the nation. Mr Fox had prepared and carried through the Lower House a bill for the regulation of the East India Company, by which all authority was to devolve on seven directors, chosen by the House of Commons; in other words, by which the immense patronage of this offshoot of the empire was to fall into the hands of the ministry. The India Bill, as it was called, being generally supposed to aim at fixing the ministry in power beyond the control of both king and people, roused much indignation; and His Majesty, therefore, fully confident of support from the people, used his personal influence, in no covert way, to induce the House of Lords to reject the bill, and (December 18) sent a messenger to demand the seals of office from his over-ambitious ministers, appointing Mr Pitt to be the Prime-minister and Chancellor of the Exchequer of a new cabinet, consisting chiefly of His Majesty's friends. The king and his new ministers, backed by a decided majority of the public, were opposed by two powerful aristocratic factions in the House of Commons, who defeated every measure that was introduced, refused the usual supplies, and voted again and again resolutions against the continuance of the present men in office, which they denounced as unconstitutional. But in the course of a few weeks, the influence of the Opposition was sensibly reduced; and when at length the majority had been worn down by the influence of the public and the court to *one*, which happened on a motion by Mr Fox, the king dissolved the parliament. The new House of Commons was so favourable towards the king and ministry, as to enable the public service to go on without further interruption.

LEGISLATIVE MEASURES IN IRELAND.

From the end of the reign of George I. a patriotic party in Ireland, composed of a mixture of Catholics and Protestants, had been exerting itself to reduce the influence of the English ministry in their country. Under the pretext of arming for the defence of the country, volunteer corps of 'patriots' were formed, which held meetings and passed resolutions in which they openly avowed their determination, at the hazard of life and fortune, to achieve the independence of the native legislature, and a complete participation in the commercial rights of the British. The government, being then too feeble to resist, repealed various

measures which had given the English parliament a right to interfere with Ireland. In 1783, however, the government now began to regain strength, and in a short time, by skilful measures, it prevailed upon the corps to dissolve.

MINISTRY OF MR PITT—FROM 1784 TO THE COMMENCEMENT OF THE FRENCH REVOLUTION.

In April 1785, Mr Pitt asked leave of the House to bring in a bill for reforming the House of Commons; but it was refused by a large majority. The desire of parliamentary reform nevertheless continued to animate a large portion of the community. In 1784, a regular society had been instituted in Scotland, for the purpose of obtaining such a measure; and in the succeeding year, forty-nine out of the sixty-six boroughs had declared in favour of it. There were also numerous associations of a similar character throughout England.

In 1786, commenced the parliamentary proceedings against Mr Warren Hastings—the first governor-general of India, and a man of conspicuous abilities and energy—for alleged cruelty and robbery exercised upon the natives of India during his governorship of that dependency of Great Britain. These proceedings were urged by the great orator Burke and other members of the Whig party, and excited so much public indignation against Mr Hastings, that the ministry was obliged to lend their countenance to his trial, which took place before parliament in the most solemn manner, and occupied in the aggregate one hundred and forty-nine days, extending over a space of several years. The proceedings resulted in the acquittal of Mr Hastings.

The king and queen had in the meantime become the parents of a numerous family of sons and daughters. The eldest son, George, Prince of Wales, had now for several years been of age, and exempted from the control of his father. He made himself remarkable by his extravagance and debaucheries, and by siding with the Whigs, thereby alienating the affections of his father, who was about this time seized with a mental malady, which ultimately compelled him to retire from active public life.

MISCELLANEOUS CIRCUMSTANCES FROM 1760 TO 1790.

At the beginning of the reign of George III. both the commerce and the manufactures of the country might be considered as in a highly flourishing condition. In Scotland, since the year 1746, great improvements of various kinds had taken place: the linen manufacture had been much advanced; a trade with the colonies had sprung up; agriculture was undergoing great changes for the better; the Highlands were now peaceful, and throughout the whole country were seen conspicuous symptoms of increasing wealth and comfort.

During the first ten years of the reign of George III. some discoveries and inventions were made, by which the prosperity of the whole empire received a new impulse. By the improvements effected in the steam-engine by James Watt, a superior mechanic power was obtained for the driving of machinery and other purposes. By means of the *spinning-jenny*, invented by Mr Hargreaves of Blackburn, the *spinning-frame*, invented by Mr Richard Arkwright, and finally the *power-loom*, invented by Mr Cartwright, the cotton manufacture was brought to a pitch of prosperity in Britain, such as no particular branch of manufacture had ever experienced before in any country.

The early part of the reign of George III. was distinguished by the discoveries of Captain Cook in the Pacific Ocean, by the formation of many canals for internal navigation, and by the foundation of the Royal Academy for the Promotion of the Fine Arts. This period derives lustre from the admirable paintings of Barry, Blake, Hoppner, and Reynolds. Astronomy was cultivated by Dr William Herschel, who, in 1781, discovered the planet Uranus. Chemistry was improved by Dr Joseph Black and Mr Cavendish. The science of medicine was advanced by Dr Cullen of Edinburgh; and natural history by Sir Joseph Banks. In literature, the chief place is due to Dr Samuel Johnson, who had flourished also in the preceding reign. Oliver Goldsmith and William Cowper in England, and Robert Burns in Scotland, were the most eminent poets. The leading historians of the time were Dr William Robertson, David Hume, and Edmund Gibbon; Hume and Adam Smith figure as philosophical writers; Sir William Blackstone wrote on English law; and amongst divines, the most eminent were Bishops Warburton, Jortin, and Hurd. The science of political economy may be said to have been created by Adam Smith, whose famous work on the *Wealth of Nations* is still a standard book upon the subject.

FRENCH REVOLUTION, AND CONSEQUENT WAR WITH FRANCE.

The country had for several years experienced the utmost prosperity and peace, when it was roused by a series of events which took place in France. The proceedings of the French nation for redressing the political grievances under which they had long laboured, commenced in 1789, and were at first very generally applauded in Britain, as likely to raise that nation to a rational degree of freedom. Ere long, the violence shewn at the destruction of the Bastille, the abolition of hereditary privileges, the open disrespect for religion, and other symptoms of an extravagant spirit, manifested by the French, produced a considerable change in the sentiments of the British people. The proceedings of the French were still justified by the principal leaders of Opposition in parliament, and by a numerous class of the community, democratic clubs being formed in various parts of the country; but they inspired the government, and the propertied classes generally, with great alarm and distrust.

When at length the coalition of Austria and Prussia with the fugitive noblesse had excited the spirit of the French people to a species of frenzy, and led to the establishment of a Republic, and the death of the king, the British government and its supporters were roused to a sense of the danger which hung over all ancient institutions, and a pretext was found (January 1793) for declaring war against France. Although Fox and Sheridan objected in parliament to this course, all who continued to make open demonstrations for political reform were now branded as enemies to religion and civil order. In Scotland, Mr Thomas Muir, a

barrister, Mr Palmer, a Unitarian clergyman, and others, were tried for sedition, and sentenced to various terms of banishment.

After alliances had been formed with the powers on the continent hostile to France, the British ministers despatched an army to the Netherlands, under the command of the king's second son, the Duke of York, to co-operate in reducing the fortresses in possession of the French. On the 1st of June 1794, the French Brest fleet sustained a severe defeat from Lord Howe; but as a counterbalance to this, the republican troops invaded Holland, and converted that country into a republic under their own control.

In the course of the year 1795, many belonging to the lower orders in the country began to appear violently discontented with the progress of the war, and to renew their demands for reform in the state. As the king was passing (October 29) to open the session of parliament, a stone was thrown into his coach, and the interference of the Horse-guards was required to protect his person from an infuriated mob. The ministers consequently obtained acts for more effectually repressing sedition, and for the dispersion of political meetings. They at the same time commenced a negotiation with the French Directory, which was broken off by the refusal of France to restore Belgium to Austria. In the ensuing year, the northern states of Italy were overrun by the French armies, and formed into what was called the Cisalpine Republic. The great Napoleon Bonaparte made his first conspicuous appearance as the leader of this expedition, which terminated in Austria submitting to a humiliating peace. At the close of 1796, a French fleet sailed for Ireland, with the design of revolutionising that country, and detaching it from Britain; but its object was defeated by stress of weather. To add to the distresses of Britain, while Austria was withdrawn from the number of her allies, Spain, by a declaration of war in 1797, increased in no inconsiderable degree the immense force with which she had to contend.

THREATENED INVASION—SUBSEQUENT EVENTS.

For some time an invasion of Britain had been threatened by France; and the successes of the republicans had hitherto so greatly exceeded all previous calculation, that the execution of their design did not appear improbable. Just as the interference of the neighbouring powers had, in 1792, roused the energies of the French, so did this proposed invasion stimulate the spirit of the British people. Volunteer corps were everywhere formed, and the desire of continuing the war became the ruling passion throughout the nation. The ministers, perceiving the advantage which was to be derived from the tendency of the national spirit, appeared seriously to dread an invasion, and this led unfortunately to a run on the Bank of England for gold, in exchange for its notes. The Bank, unable to meet this run, was obliged, February 25, 1797, to suspend cash payments—that is, to refuse giving coin on demand for the paper-money which had been issued—Bank of England notes were consequently much depreciated in value; and the currency was seriously deranged for some years.

In April, the seamen on board the Channel fleet, and also on board that at the Nore, mutinied for an advance of pay and the redress of some alleged grievances. Happily, by the firmness of the government, and some skilful dealings with the seamen, a loyal party was formed, by whom the more turbulent men were secured, and the vessels restored to their respective officers. The ringleaders, the chief of whom was a young man named Richard Parker, were tried and executed.

The same year was remarkable for several victories gained by the British fleets. A Spanish fleet of twenty-seven ships was attacked by fifteen vessels under Admiral Jervis (February 14), off Cape St Vincent, and completely beaten, with the loss of four large vessels. In this engagement, Commodore Horatio Nelson greatly distinguished himself. A fleet under Admiral Harvey, with a military force under Sir Ralph Abercromby, captured the island of Trinidad, a Spanish colony. In October, a Dutch fleet, under Admiral Van Winter, was attacked off the village of Camperdown, upon their own coast, by Admiral Duncan, who, after a desperate battle, captured nine of the enemy's vessels. These naval successes had the good effect of sustaining the spirit of the British nation under this unfortunate contest.

In 1798, the French overran and added to their dominions the ancient republic of Switzerland, which gave them a frontier contiguous to Austria. The same year the directors of the Republic, beginning to be afraid of the ambition of their general, Bonaparte, sent him at the head of an expedition to reduce and colonise Egypt, intending from that country to act against the British empire in the East Indies. The expedition was successful in its first object; but the fleet which had conveyed it was attacked in Aboukir Bay, by Admiral Nelson (August 1), and almost totally destroyed or captured. While so much of the strength of the French army was thus occupied in a distant country, Austria, Naples, and Russia entered into a confederacy, and, being subsidised by Britain, recommenced war.

The new confederacy was so successful in 1799, as to redeem the greater part of Italy; but a Russian army, under the famous Suwaroff, attempting to expel the French from Switzerland, was nearly cut to pieces in one of the defiles of that mountainous country. In August of the same year, Great Britain made a corresponding attempt to expel the French from Holland. Thirty-five thousand men, under the Duke of York, formed the military part of the expedition. The fleet was successful at the first in taking the Dutch ships; but the army, having landed under stress of weather at an unfavourable place for their operations, was obliged to make an agreement with the French, purchasing permission to go back to their country by the surrender of 8000 prisoners from England.

In 1799, Bonaparte suddenly returned from his army in Egypt, and, by a skilful management of his popularity, overturned the Directory, the Republican executive, consisting of five members, and caused himself to be appointed the sole depositary of the executive power of the state, under the denomination of First Consul. He immediately wrote a letter to King George, making overtures of peace; but was answered by the British secretary, that no dependence could be placed by Great Britain on any treaty with France, unless her government were again consolidated

under the Bourbons. Further overtures were also rejected.

The events of 1800 were of a very different nature from what had been calculated upon in England. In Egypt, the French overthrew a large Turkish army at Grand Cairo, and made themselves more effectually than ever the masters of the country; so that Britain was obliged to send an army next year, under Sir Ralph Abercromby, to accomplish at an immense expense, and a great waste of human life, what the French had formerly agreed to do. In Europe, the presence of Bonaparte was the signal for fresh successes. Defeating the Austrians at Marengo (June 14) and in other engagements, he obliged Austria (1801) to sue for peace, by which France became mistress of all continental Europe west of the Rhine and south of the Adige.

REBELLION IN IRELAND—UNION WITH GREAT BRITAIN.

The commencement of the revolutionary proceedings in France excited the wildest hopes of the Irish, already ardently desirous of a reform in their parliament. Towards the close of the year 1791. they formed an association, under the title of the United Irishmen, comprehending persons of all religions, and designed to obtain 'a complete reform of the legislature, founded on the principles of civil, political, and religious liberty.' Acts were passed for putting down the meetings of the association, although, on the other hand, measures were passed enabling Catholics to intermarry with Protestants, to practise at the bar, and to educate their own children.

The ministry, however, having been persuaded by the Protestant party to return to their former policy, and the patriotic party having despaired of effecting any improvement by peaceable means, an extensive conspiracy was entered into for delivering up Ireland to the French Republic. The scheme was managed by a directory of five persons, and though half a million of men were concerned in it, the most strict secrecy was preserved. The losses at Camperdown in 1797, however, crippled the naval resources of France, and prevented a renewal of the expedition. Losing all hope of French assistance, the conspirators resolved to act without it; but their designs were betrayed by one Reynolds; and three other members of the directory, Emmett, Macnevin, and Bond, were seized. Still the Union persisted in the design of rising on a fixed day. Lord Edward Fitzgerald, another of its leaders, was then arrested, and being wounded in a scuffle with his captors, soon after died in prison. On the 21st of May 1798, Lord Castlereagh, secretary to the Lord-lieutenant, discovered and exposed the whole plan of insurrection, which had been fixed to commence on the 23d. The conspirators, although thus thwarted, rose in various parts of the country, and in greatest force in Wexford. On the 21st of June, their whole force was collected upon Vinegar Hill, near Enniscorthy, where an army of 13,000 men, with a proportionate train of artillery, was brought against them by General Lake. They were completely overthrown and dispersed. From this time the rebellion languished, and in July it had so far ceased to be formidable, that an act of amnesty was passed in favour of all who had been engaged in it, except the leaders. On the 22d of August, when the rebellion had been completely extinguished, 900 French, under General Humbert, were landed at Killala, in the opposite extremity of the country from that in which the insurgents had shewn the greatest strength. On the 8th of September, they were met at Carrick-on-Shannon by an enormously larger force, to which they yielded themselves prisoners of war.

During the ensuing two years, the British ministers exerted themselves to bring about an incorporating union of Ireland with Great Britain; a measure to which the Irish were much opposed, but which, by the use of bribes and government patronage largely employed amongst the members of the Irish legislature, was at length effected. From the 1st of January 1801, the kingdom of Ireland formed an essential part of the empire, on which was now conferred the name of the United Kingdom of Great Britain and Ireland. The act of union secured to the Irish most of the commercial privileges which they had so long sought. One hundred commoners were to be sent by Ireland to the British (now called the Imperial) parliament; namely, two for each county, two for each of the cities of Dublin and Cork, one for the university, and one for each of the thirty-one most considerable towns. Four lords-spiritual, by rotation of sessions, and twenty-eight lords-temporal, elected for life by the peers of Ireland, were to sit in the House of Lords; and the cross of St Patrick, the patron saint of Ireland, was at the same time added to those of St George and St Andrew on the national flag.

The union, though, upon the whole, effected in a spirit of fairness towards Ireland, increased the discontent of the people, which broke out in 1803 in a new insurrection, under Robert Emmett and Thomas Russell. It came to nothing more, however, than a disturbance in the streets of Dublin, in the course of which Lord Kilwarden, a judge, and his nephew, Mr Wolfe, were dragged from a carriage and killed. The mob was dispersed by soldiery, and Emmett and Russell, being seized, were tried and executed.

CHANGE OF MINISTRY, AND PEACE OF AMIENS, 1802.

At the commencement of 1801, Britain had to reckon among her enemies the whole of the northern states of Europe, which had found it necessary to place themselves on a friendly footing with Bonaparte, and though they did not declare war against Britain, yet acted in such a manner as to render hostilities unavoidable. Nelson sailed in March with a large fleet for Copenhagen, and proved so successful against the Danish fleet, as to reduce that country to a state of neutrality. The death of the Russian Emperor Paul, which took place at the same time, and the accession of Alexander, who was friendly to Britain, completely broke up the northern confederacy. Yet the great achievements of France on the continent, joined to the distresses of a famine which at this time bore hard on the British people, produced a desire for peace. With the view, apparently, of facilitating the declaration of peace, a new ministry was appointed under Mr Addington, by whom a peace was at length, in March 1802,

concluded with France. By this peace, Britain gave up all her colonial conquests except Ceylon and Trinidad, and agreed to restore Egypt to Turkey, Malta to the Knights of St John, and the Cape of Good Hope to Holland.

WAR RENEWED WITH FRANCE, 1803—SUBSEQUENT EVENTS.

It was soon manifest that Bonaparte did not relish peace. By taking undue advantage of several points left loose in the treaty, he provoked Great Britain to retaliate by retaining possession of Malta; and the war was accordingly recommenced in May 1803. Britain immediately employed her superior naval force to seize the French West India colonies; while France took possession of Hanover, arrested all the English travellers, 10,000 in number, in France, and excluded British commerce from Hamburg. Bonaparte collected an immense flotilla at Boulogne, for the avowed purpose of invading England; but so vigorous were the preparations made by the whole British population, 400,000 men enrolling themselves as volunteers, and so formidable the fleet under Lord Nelson, that he never found it possible to put his design in execution. In the year 1804, he took the title of Emperor of the French. In April of the same year, the Addington administration was exchanged for one constructed by Mr Pitt.

In 1805, under the influence of Great Britain, a new coalition of European powers, consisting of Russia, Sweden, Austria, and Naples, was formed against Napoleon. He, on the other hand, had drawn Spain upon his side, and was making great exertions for contesting with Britain the empire of the sea. A fleet of thirty-three sail, partly French and partly Spanish, under Admiral Villeneuve, met a British fleet of twenty-seven, under Nelson, off Cape Trafalgar, October 21, 1805, and was completely beaten, though at the expense of the life of the great commander. At this time, however, Napoleon had carried all before him on the continent. By a sudden, rapid, and unexpected movement, he conducted an army into Germany, where the Austrians were already making aggressions upon neutral territory. He entered Vienna, and pursuing the royal family, and the allied armies of Russia and Austria, into Moravia, he gained, 2d December 1805, his greatest victory, that of Austerlitz, which put an end to the coalition, and rendered him the dictator of the continent. This series of events caused much gloom in the British councils, and with several other painful circumstances, among which was the impeachment of his colleague, Lord Melville, for malpractices in the Admiralty, proved a death-blow to Mr Pitt, who expired on the 23d of January 1806, completely worn out with state business, at the early age of forty-seven, half of which time he had spent in the public service.

Mr Pitt's ministry was succeeded by one composed of Lord Grenville, Mr Fox, and their friends; it was comprehensively called Whig, although Lord Grenville was in every respect a Tory, except in his advocacy of the claims of the Catholics for emancipation. In the course of 1806, the new cabinet made an attempt to obtain a peace from France, which now threatened to bring the whole world to its feet. But the Grenville administration encountered serious difficulties from the king, who never could be induced to look with the least favour on the Catholic claims, or those who advocated them. Exhausted by his useless labours, Mr Fox died, September 13, 1806.

A new coalition, excluding Austria, but involving Prussia, had been subsidised by Britain, and was now preparing to act. With his usual decision, Napoleon led what he called his 'Grand Army' by forced marches into Prussia; gained, on the 14th of October, the battles of Jena and Auerstadt, which at once deprived that country of her army, her capital, and her fortresses; and then proclaimed the famous 'Berlin Decrees,' by which he declared Great Britain in a state of blockade, and shut the ports of Europe against her merchandise. The king of Prussia, Frederick-William III. took refuge with his court in Russia, which now was the only continental power of any importance that remained unsubdued by France.

Towards that country, Napoleon therefore bent his steps. After a series of skirmishes and battles of lesser importance, he met the Russian army in great strength (June 14, 1807), at Friedland, and gave it a total overthrow. He might now have easily reduced the whole country, as he had done Austria and Prussia; but he contented himself with forming a treaty—called the Treaty of Tilsit, from the place where it was entered into—by which Russia agreed to become an ally of France, and entered into his views for the embarrassment of Britain by the exclusion of her commerce from the continental ports.

The Grenville administration was displaced in the spring of 1807, in consequence of the difference between its members and the king on the subject of the Catholic claims, which had long been urged by the Whig party, with little support from the people. The next ministry was headed by the Duke of Portland, and included Lords Hawkesbury and Castlereagh (afterwards Earl of Liverpool and Marquis of Londonderry), and Mr Canning, as secretaries; Mr Spencer Perceval being Chancellor of the Exchequer. One of the first acts of the ministry was the despatch of a naval armament to Copenhagen to seize and bring away the Danish fleet, which, it was suspected, was to be employed in subserviency to the designs of France, and for the injury of Britain. The end of the expedition was easily obtained.

FIRST PENINSULAR CAMPAIGN—SUBSEQUENT EVENTS.

The amazing successes of Napoleon had now inspired him with the idea of universal empire; and so great was the influence he had acquired over the French, and so high their military spirit, that the attainment of his object seemed by no means impossible. He was now, however, looked upon as the enemy of freedom and humanity, and any opposition that was offered was much more desperate than it had been before. It was in Spain, the crown of which Napoleon had given to his elder brother Joseph, that the first revolt took place; and the Spanish patriots appealed to Britain for help. In terms of a treaty entered into with a provisional government, a small army was landed, August 8, 1808, in Portugal, which had been recently taken possession of by the French. Sir Arthur Wellesley, who afterwards

became so famous as Duke of Wellington, was the leader of this force. In an engagement at Vimieira, on the 21st, he repulsed the French, under Junot, who soon after agreed, by what was called the Convention of Cintra, to evacuate the country. Sir Arthur being recalled, the British army was led into Spain under the command of Sir John Moore; but this officer found the reinforcements poured in by Napoleon too great to be withstood, and accordingly, in the end of December, he commenced a disastrous, though remarkably well-conducted retreat towards the port of Corunna, whither he was closely pursued by Marshal Soult. The British army suffered on this occasion the severest hardships and losses, but did not experience a check in battle, or lose a single standard. In a battle which took place at Corunna, January 16, 1809, for the purpose of protecting the embarkation of the troops, the gallant Sir John Moore was killed.

In 1809, Austria was induced once more to commence war with France, but was beaten in the decisive battle of Wagram. Peace was followed by the marriage of Napoleon to Maria Louisa, daughter of the Emperor of Austria, for which purpose he divorced his former wife, Josephine.

In the autumn of 1809, the British government despatched an armament of 100,000 men, for the purpose of securing a station which should command the navigation of the Scheldt. The expedition was placed under the command of the Earl of Chatham, elder brother of Mr Pitt, a nobleman totally unacquainted with military affairs on such a scale. The army, having disembarked on the insalubrious island of Walcheren, was swept off in thousands by disease. The survivors returned in December without having done anything towards the object for which they set out. This sad affair became the subject of inquiry in the House of Commons, which, by a majority of 272 against 232, vindicated the manner in which the expedition had been managed.

SUCCESSES OF WELLINGTON IN SPAIN.

A new expedition in Spain was attended with better success. Taking advantage of the absence of Napoleon in Austria, a considerable army was landed, April 22, 1809, under the command of Sir Arthur Wellesley, who immediately drove Soult out of Portugal, and then made a rapid move upon Madrid. On the 28th of July was fought the battle of Talavera, in which the British and Spanish troops had the advantage over the French under Marshal Victor.

Early in 1810, Napoleon reinforced the army in Spain, and gave orders to Massena to 'drive the British out of the Peninsula.' Wellesley, now raised to the peerage under the title of Lord Wellington of Talavera, posted his troops on the heights of Busaco—80,000 in number, including Portuguese—and there, on the 27th of September, was attacked by an equal number of French. Both British and Portuguese behaved well: the French were repulsed with great loss, and for the first time in the war, conceived a respectful notion of the British troops. Wellington now retired to the lines of Torres Vedras, causing the whole country to be desolated as he went, for the purpose of embarrassing the French. When Massena observed the strength of the British position, he hesitated; and ultimately, in the spring of 1811, performed a disastrous and harassed retreat into the Spanish territory.

It now became an object of importance with Wellington to obtain possession of the Spanish fortresses which had been seized by the French. He succeeded in capturing Almeida, and defeating Massena at Fuentes de Onoro; while Generals Beresford and Graham won the battles of Albuera and Barrosa. Wellington then retired into Portugal.

THE REGENCY.

The intellect of the king gave way completely at the close of the year 1810, and the Prince of Wales was, in consequence, appointed Regent. He did not, however, shew his former liking for the Whigs, but allowed them to remain in opposition.

EVENTS OF 1812 AND 1813.

In 1812, the events that had taken place in Spain having somewhat impaired Napoleon's prestige, Alexander, Emperor of Russia, ventured upon a defiance of his decrees against British merchandise, and provoked him to a renewal of the war. With upwards of half a million of troops, appointed in the best manner, Napoleon set out for that remote country, determined to reduce it into perfect subjection. A stratagem on the part of the Russians defeated all his plans. The city of Moscow, after being possessed by the French troops in September, was destroyed by incendiaries, so that no shelter remained for them during the ensuing winter. Napoleon was obliged to retreat; but, overtaken by the direst inclemency of the season, his men perished by thousands in the snow, while they were harassed by the Russian troops in their retreat. Of his splendid army, a mere skeleton regained Central Europe. Returning almost alone to Paris, he contrived, with great exertions, to reinforce his army, though there was no replacing the veterans lost in Russia.

Early in 1813, he opened a campaign in Northern Germany, where the Emperor of Russia, now joined by the king of Prussia and various minor powers, appeared in the open field against him. After various successes on both sides, an armistice was agreed to on the 1st of June, and Bonaparte was offered peace on condition of restoring only that part of his dominions which he had acquired since 1805. Inspired with an overweening confidence in his military genius, he refused these terms, and lost all. In August, when the armistice was at an end, his father-in-law, the Emperor of Austria, joined the allies, whose forces now numbered 500,000 men; while an army of 300,000 was the largest which Napoleon could at present bring into the field. By steady, though cautious movements, the allies advanced to France, driving him reluctantly before them, and increasing their own force as the various states became emancipated by their presence. At the close of 1813, they rested upon the frontiers of France; while Lord Wellington, after two brilliant campaigns in Spain, had advanced in like manner to the Pyrenees.

HOME AFFAIRS—WAR WITH AMERICA.

On the 11th of May 1812, the premier, Mr Perceval, was shot in the lobby of the House of Commons, by a man named Bellingham, whom some private losses had rendered insane. Lords Liverpool and Castlereagh then became the ministerial leaders in the two Houses of Parliament, but were quickly voted down by a majority of four. Some changes in the Cabinet were made, Lord Liverpool continuing as Premier, and Lord Castlereagh as Foreign and War Secretary. Neither the Regent nor his ministers, however, were popular; and the former, whose morals were far from being free from reproach, made himself very unpopular by fixing a criminal charge on his consort.

In this unhappy state of affairs, the United States, provoked by orders in council prohibiting the commerce of neutral states, as well as by a right assumed by British war-vessels to search for and impress English sailors on board the commercial shipping of the United States, declared war, June 1812, against Britain. Before the news had reached London, the orders had been revoked by the influence of Lord Liverpool; but the Americans, nevertheless, were too much incensed to retrace their steps. During the summer and autumn, several encounters took place between single American and British ships, in which the former were successful. It was not till June 1, 1813, when the *Shannon* and *Chesapeake*, the one a British, the other an American frigate, met on equal terms, that the British experienced any naval triumph in this war. On land, the Americans endeavoured to annoy the British by assaults upon Canada, but met with no decisive success. The British landed several expeditions on the coast of the States; and were successful at Washington, at Alexandria, and at one or two other points, but experienced a bloody and disastrous repulse at New Orleans. The war ended, December 1814, without settling any of the principles for which the Americans had taken up arms.

PEACE OF 1814—SUBSEQUENT EVENTS.

At the close of 1813, it was evident that Bonaparte could hardly defend himself against the vast armaments collected on all hands against him. Two months were spent in almost incessant conflict with the advancing allies, who, on the 30th of March, entered Paris in triumph; and in the course of a few days, ratified a treaty with Napoleon, by which he agreed to resign the government of France, and live for the future as only sovereign of Elba, a small island in the Mediterranean. Peace was proclaimed in London on the 20th of June. France was deprived of all the acquisitions gained both under the Republic and the Empire, and restored to the rule of the ancient royal family in the person of Louis XVIII. Wellington, now created a Duke, received a grant of £400,000 from the House of Commons, in addition to one of £100,000 previously voted; and received in person the thanks of the House for his services. Representatives from the European powers concerned in the war met at Vienna, October 2, in order to settle the disturbed limits of the various countries, and provide against the renewal of a period of war so disastrous.

In March 1815, however, their proceedings were interrupted by intelligence that Napoleon had landed in France, and was advancing in triumph to the capital. So unpopular had the new government already become, that, though he landed with only a few men, he was everywhere received with affection, his old soldiers rallying round him, and on the 20th of March was reinstated in his capital, which had that morning been left by Louis XVIII. Bonaparte then took the votes of the nation for his restoration; on which occasion he had a million and a half of affirmative, against less than half a million of negative voices, the voting being performed by ballot. His exertions to reorganise an army were successful to an extraordinary degree. On the 1st of June he had 559,000 effective men under arms, of whom 217,000 were ready to take the field.

A Prussian army of more than 100,000 men, under Blücher, a veteran general, and one of about 80,000 British, Germans, and Belgians, under Wellington, were quickly rendezvoused in the Netherlands; while still larger armies of Austrians and Russians, making the whole force above 1,000,000, were rapidly approaching. Napoleon, knowing that his enemies would accumulate faster in proportion than his own troops, crossed the frontier on the 14th of June, with 120,000 men, resolved to fight Blücher and Wellington separately, if possible. The rapidity of his movements prevented that concert between the Prussian and English generals which it was their interest to establish. On the 16th, he attacked Blücher at Ligny, and compelled him to retire upon a point nearly a day's march from the army of Wellington.

After some further fighting next day, Napoleon brought his forces to bear, on the 18th against Wellington alone, who had drawn up his troops across the road to Brussels, near a place called Waterloo. The battle consisted of a constant succession of attacks by the French upon the British lines. These assaults were attended with great bloodshed, but nevertheless were resisted with the utmost firmness, till the evening, when Blücher came up on the left flank of the British, and turned the scale against the French, who had now to operate laterally as well as in front. The flower of the French army, the Imperial Guard, made a desperate charge upon the British troops, but were beaten back; and the whole army then retired, the Prussian cavalry cutting down the fugitives in great numbers during the flight. On his return to Paris, Napoleon made an effort to restore the confidence of his chief counsellors, but in vain. After a fruitless abdication in favour of his son, he retired to Rochefort, with the intention of proceeding to America; but, finding no means of escape, was obliged to surrender to Captain Maitland of the *Bellerophon*, a British ship of war. He was condemned by his triumphant enemies to perpetual confinement on the island of St Helena, in the Atlantic, where he died in 1821. The conquests kept by Great Britain at the end of the war were the Cape of Good Hope, the Dutch possessions in Ceylon and Berbice, and other Dutch settlements in Guiana; Mauritius and Seychelles taken from the French; and Malta and Heligoland in Europe.

Louis XVIII. was now restored, and the arrangements of the Congress of Vienna were completed. The expenses of Great Britain during

this last year of hostilities exceeded seventy millions; and the national debt, which in 1793 had been £230,000,000, now amounted to the vast sum of £860,000,000.

The reaction in Europe during the latter years of Napoleon's reign against revolutionary doctrines, which led on the continent to what was styled a 'Holy Alliance' between Austria, Russia, and Prussia—these powers agreeing to help each other in the event of another crisis like that of the French Revolution—had also its effect in Great Britain, in fixing the power of the aristocracy, which, by composing the whole of the Upper House, and influencing the election of a major part of the Lower, might be said to constitute the government.

THE PRINCESS CHARLOTTE—POPULAR TUMULTS.

In May 1816, the Princess Charlotte, only child of the Prince-regent, was married to Prince Leopold of Saxe-Coburg, a young officer who had gained her affections when attending the allied sovereigns at the British court. In November 1817, to the great grief of the whole nation, the young princess died, immediately after having given birth to a dead son.

In August 1816, a British armament under Lord Exmouth bombarded Algiers, and reduced that piratical state to certain desirable conditions respecting the treatment of Christian prisoners.

The year 1816, and the four following years, have a melancholy reputation as a period of extraordinary distress, affecting almost every class of the community, and caused chiefly by the liberation of European commerce at the end of the war, and the consequent diminution of the trade which England had previously enjoyed through her exclusive possession of the seas. In the autumn of 1819, the misery of the working-classes had reached its greatest height, and parliamentary reform was then urgently demanded, as the only measure which could permanently improve their prospects. On the 16th of August, a vast body of operatives assembled at Manchester, in an open space of ground called St Peter's Field, professedly to petition for parliamentary reform. As they came in regular array, bearing banners with inscriptions, the magistrates professed to consider the meeting as dangerous to the public peace, and ere the proceedings were far advanced, a body of troops, consisting chiefly of yeomanry, dashed into the mass, trampling down many persons of both sexes under the horses' feet, and killing and wounding others with their sabres. The meeting was dispersed by these means, and Messrs Hunt and Johnston, the principal orators, were apprehended. The tragic nature of this event produced some marks of public resentment, but the magistrates who conducted the attack received the immediate and cordial thanks of the government; and when parliament reassembled in November, in addition to the strong measures already taken for suppressing popular discontent, acts were passed to suppress unstamped political publications, to prevent secret training to arms, and to restrict the right of calling a public meeting to magistrates.

On the 29th of January 1820, George III. died at Windsor, in his eighty-second year, having been insane since 1810. The Prince-regent was immediately proclaimed as GEORGE IV.; but there was no other change to mark the commencement of a new reign. A few days before (23d) the decease of George III. the Duke of Kent, his fourth son, died suddenly, leaving an infant daughter, Victoria, with a very near prospect to the throne. In 1772 had been passed the Royal Marriage Act, which incapacitated the descendants of George II. from marrying without the consent of their sovereign.

MISCELLANEOUS CIRCUMSTANCES FROM 1790 TO 1820.

This period is especially memorable for the introduction of the use of steam in navigation. A model vessel, with a small steam-engine on board, was tried in 1788 by Mr Patrick Miller of Dalswinton, in Dumfriesshire. The idea fell asleep for a few years, but was revived by Mr Fulton, an American, who, in 1807, set agoing a steam-vessel on the Hudson River, the first in the world which was regularly employed in conveying passengers. In 1812, Mr Henry Bell of Helensburgh launched a similar vessel on the Clyde, being the first seen in Europe; and from that period steam-vessels quickly became numerous.

The latter part of the reign of George III. was distinguished by marked improvements in the dress and social condition of the people. In the year 1750, cocked-hats, wigs, swords, and buckles were generally worn, and all gentlemen used hair-powder. From the year 1790 to about 1800, these and many other oddities completely disappeared. Speedy travelling by stage-coaches, and the rapid transmission of letters by mail-carriages, became at the same time general in all parts of the United Kingdom.

At no period did a more brilliant class of literary men flourish in Britain. Poetry assumed new and attractive forms in the works of Campbell, Moore, Southey, Coleridge, Wordsworth, Byron, Shelley, and Scott. The novel or fictitious tale was advanced to a dignity it had never known before, in consequence of the production, by Sir Walter Scott, of a series of such compositions, in the highest degree dramatic and entertaining. In the Edinburgh and Quarterly Reviews, periodical criticism acquired an importance it never before possessed. The name of Sir Humphry Davy stands pre-eminent in science, which was also cultivated with distinguished success by Wollaston, Leslie, Playfair, and Robison. In philosophical literature, the names of Dugald Stewart and Thomas Brown merit peculiar respect; and in art occur the great names of Reynolds, Lawrence, Gainsborough, and Wilkie.

REIGN OF GEORGE IV.

At the time when George IV. commenced his reign, the Manchester affair and the recent proceedings of the ministry, had inspired a small band of desperate men with the design of assassinating the ministers at a cabinet dinner, and thereafter attempting to set themselves up as a provisional government. On the 23d of February 1820, they were surprised by the police in their place of meeting in Cato Street, London; and, after a desperate resistance, five were seized, among whom one Thistlewood was the chief. These wretched men were tried for high treason, and executed. Nearly about the same time, an

attempt was made by the workmen in the west of Scotland to agitate for some alteration in the state; and two men were executed.

On the accession of the king, the name of his consort, Caroline, Princess of Brunswick-Wolfenbüttel, had been omitted from the liturgy. This and other indignities induced her to return from a voluntary exile in Italy, June 1820, to the great embarrassment of the king and his ministers, as she was received by the people with the warmest expressions of sympathy. The king ultimately caused a bill of pains and penalties against her to be brought (July 6) into the House of Lords, which thus became a court for her trial. Messrs Brougham and Denman, who afterwards attained high judicial stations, acted as counsel for Her Majesty, and displayed great ability, enthusiasm, and eloquence in her defence. The examination of witnesses occupied several weeks; but no evidence of criminality could soften the indignation with which almost all classes of the community regarded this prosecution. Though the bill was read a second time by a majority of 28 in a house of 218, and a third time by 108 against 99, the government considered it expedient to abandon it, leaving the queen and her partisans triumphant.

In July 1821, the coronation of George IV. took place under circumstances of great splendour. On this occasion, the queen made an attempt to enter Westminster Abbey, for the purpose of witnessing the ceremony, but was refused admittance by the military officers who guarded the door; an insult which gave such a shock to her health, as to cause her death in a few days (August 7). During the month of August, the king paid a visit to Ireland, where he was received with much cordiality by all classes of that excitable people, notwithstanding his known hostility to the Catholic claims. In August of next year he visited Scotland, and there also met with a most kind reception. During his absence in Scotland, his leading minister, the Marquis of Londonderry (formerly Lord Castlereagh), committed suicide, being weighed down by a sense of the difficulty of his position in regard to continental affairs. His successor was Mr George Canning.

JOINT-STOCK MANIA—COMMERCIAL EMBARRASSMENTS.

The two following years were characterised by an extraordinary activity in almost all departments of commerce, a number of measures tending to remove restrictions both on trade and labour being passed, mainly through the instrumentality of Mr Huskisson, an able financier introduced into the cabinet by Mr Canning.

Many joint-stock companies were now formed, as a means of giving capital a wider range than that to which it was usually limited. Some of these associations professed objects which were by long-established usage the proper business of individuals alone; and others involved hazardous and visionary projects, which were to be carried into effect in remote countries. The result was a serious commercial crisis. The first symptom of something being wrong was the turning of the exchange against England. A diminution of issues at the Bank followed. Then took place a run upon the banks, some of which, both in London and in the country, were obliged to stop payment. Between October 1825 and February 1826, fifty-nine commissions of bankruptcy were issued against English country banks, and four times the number of private compositions were calculated to take place during the same period. Some liberal pecuniary measures on the part of the Bank of England, helped in a short time, rather by inspiring confidence than by actual disbursement of money, to retrieve in some measure the embarrassed circumstances of the country.

CANNING'S ADMINISTRATION—CATHOLIC EMANCIPATION.

In the spring of 1827, the illness of Lord Liverpool (followed soon after by his death) opened the way for Mr Canning's promotion to the first place in the administration. Mr Canning, however, sank under the new load imposed upon him, and died in the ensuing August. His friend, Lord Goderich, succeeded as Premier, but resigned in January 1828, when the Duke of Wellington was appointed in his place, with Mr (afterwards Sir) Robert Peel as Secretary for the Home Department.

From the year 1805, the Catholic claims had been a prominent subject of parliamentary discussion, and since 1821 they had been sanctioned by a majority in the House of Commons. The Irish Catholics had in 1824 united themselves in an association, with the scarcely concealed purpose of forcing their emancipation by means of an exhibition of their physical strength. An act was quickly passed for the suppression of this powerful body, but it immediately reappeared in a new shape, and it became evident that Catholic emancipation must be granted sooner or later. In the spring of 1828, a kind of preparation was made for the concession, by the repeal of the test and corporation oaths, imposed in the reign of Charles II.; while the return of Mr Daniel O'Connell, the most distinguished orator of the Catholic party, for the county of Clare, shewed the strength of the Association, and alarmed the ministry. At the opening of the session of 1829, a bill was introduced for admitting Catholics to parliament, to most civil and military offices and places of trust, and to corporate offices, upon their taking an oath to support the existing institutions of the state, and not to injure the church; the Duke of Wellington admitting that he introduced it to avert civil war; and notwithstanding a great popular opposition, as well as the most powerful exertions of the older and more rigid class of Tories, this measure was carried by a majority of 353 against 180 in the House of Commons, and by 217 to 112 in the House of Lords. It received the royal assent on the 13th April 1829.

REIGN OF WILLIAM IV.

The agitations respecting the Catholic Relief Bill had in some measure subsided, when, June 26, 1830, George IV. died, and was succeeded by his next brother, the Duke of Clarence, who had passed his early life in the navy, under the title of WILLIAM IV. About a month after, a great sensation was produced in Britain by a revolution which took place in France, the main line of the Bourbon family being expelled, and the crown conferred

upon Louis-Philippe, Duke of Orleans. By this event, a great impulse was given to the reforming spirit in Britain, and the demands for an improvement in the parliamentary representation became very strong. The consequence was the retirement of the Wellington administration in November, and the formation of a Whig cabinet, headed by Earl Grey. This ministry succeeded, in spite of the opposition of the Tories, or Conservatives, as they now were called, in passing, June 7, 1832, measures for parliamentary reform in the three divisions of the kingdom. The acts disfranchised 56 boroughs; while 43 new ones, together with 30 county constituencies, were created; a £10 household qualification was established in boroughs, and the county franchise was extended to tenants of land with a rental of £50 a year. During the agitation, the country was visited by Asiatic cholera, which destroyed thousands.

During the few years which followed the passing of the Reform Bills, the attention of parliament was chiefly occupied by a series of measures, the most important of which, in a moral point of view, was the abolition of slavery in the colonies, which had been agitated for by Wilberforce and Clarkson, the sum of twenty millions being paid to the owners of the negroes, as a compensation for resigning a right of property which had long been a disgrace to humanity. By this act, eight hundred thousand slaves were (August 1, 1834) placed in the condition of freemen, but subject to an apprenticeship to their masters for a few years.

In the same year an act was passed for amending the laws for the support of the poor in England, which had long been a subject of general complaint. One of the chief provisions of the new enactment established a government commission for the superintendence of the local boards of management, which had latterly been ill-conducted, and were now proposed to be reformed. The able-bodied poor were also deprived of the right which had been conferred upon them, at the end of the eighteenth century, to compel parishes to support them, either by employment at a certain rate, or pecuniary aid to the same amount; they were now left no resource, failing employment, but that of entering poor-houses, where they were separated from their families.

In 1833, a reform took place in the mode of electing the councils and magistracies of the Scottish burghs. The parliamentary constituencies were now empowered to choose the requisite number of councillors, the latter, again, choosing the magistrates. The English and Irish municipal corporations were somewhat similarly reformed in 1835 and 1840.

During the summer of 1834, the ministry endeavoured to carry through parliament a bill to enable them to take unusual measures for restraining turbulence in Ireland. In consequence of a difficulty experienced in passing the measure, Lord Althorp and Earl Grey resigned. The place of the latter was supplied by Viscount Melbourne, and Lord Althorp was induced to resume office. The Irish Coercion Bill, with certain modifications, was then passed.

The Melbourne ministry continued in power for several years, the only other ministry during this reign being one which Sir Robert Peel constructed of the Conservatives who lost office in 1830, and which was compelled to resign after being only a few months in office. Among the measures passed by the Melbourne administration were an act for commuting tithes in England into a corn-rent charge payable in money; an act for enabling Dissenters in England to be married otherwise than by the established clergy; and another for a general registry of births, deaths, and marriages. This ministry also reduced the stamp-duty on newspapers to one penny, by which the circulation of that class of publications was very largely increased. In 1837, a bill was introduced into the House of Commons for settling the Irish tithe-question; but before this or any other measure of importance had been carried, the king died of ossification of the vital organs (June 20), which had also been the cause of his predecessor's death, in the seventy-third year of his age, and seventh of his reign, being succeeded by his niece, the PRINCESS VICTORIA.

REIGN OF QUEEN VICTORIA.

Queen Victoria, born May 24, 1819, began to reign June 20, 1837, and had, therefore, just completed her eighteenth year; was crowned on the 28th of June in the following year; and was married to her cousin, Prince Albert of Coburg and Gotha, February 10, 1840. This union was followed by the birth of four princes and five princesses; and as the marriage of the Prince of Wales, Albert Edward, who was born November 9, 1841, to the Princess Alexandra of Denmark (March 10, 1863) resulted erelong in the birth of two sons and three daughters, the amplest security has been given for the continuance of the present dynasty.

The Whig ministry, being on the decline, were obliged, in 1841, to yield to a vote of 'no confidence;' and Sir Robert Peel again took the helm of affairs. The parliament of 1841 was in many respects one of the most important during the reigning dynasty. Besides carrying out a great many reforms in the internal administration of the country, the corn-laws and other restrictive duties were abolished, and thus the great principle of *free-trade* was fairly established—a course in which Great Britain has since been more or less followed by other nations. Although the abolition of the corn-laws (1846) was received as a precious boon by the masses of the people, it alienated so many of Sir Robert's political supporters, that he was obliged to resign office, and was succeeded by Lord John Russell, to whom was assigned the further task of carrying out the principles of free-trade.

Among the internal commotions and difficulties that the nation had to pass through in this period, may be noticed the agitation of the Chartists (1838), who were chiefly working-men suffering from the prevalent distress, and so called because, at a meeting at Birmingham, they demanded a people's charter, containing six points—universal suffrage, vote by ballot, triennial parliaments, equal electoral districts, the abolition of property qualifications, and salaries for members of parliament. In the year 1848, when a revolution had driven from the throne of France its monarch, Louis-Philippe, and revolutionary movements had convulsed a large portion of the continent, the Chartists mustered on Kennington Common to the number of 20,000, intending to march through London to the House of Commons, carrying a

petition containing their demands, and said to be signed by more than 5,000,000 persons, which was to be presented by Feargus O'Connor, one of the members for Nottingham. London was very much alarmed, and a large number of special constables were enrolled. The whole affair, however, passed off quietly and happily without any conflict with the military, whom the Duke of Wellington had stationed out of sight, but at hand. After this, the Chartist agitation died down.

WARS OF THE PRESENT REIGN.

The wars of this reign, in which Britain has been engaged, if they have not been of such great importance as those in the time of George III. have been very numerous. In the year of the Queen's accession, some discontent in Lower Canada, on account of ill-defined political grievances, ended in open revolt. The rising, however, was quickly put down, and conciliatory and popular measures which were passed succeeded in restoring peace. In 1867, the provinces of Canada, Nova Scotia, and New Brunswick were, by statute, united federally into one Dominion, under the name of Canada, with a constitution similar to that of Great Britain and Ireland, being ruled by a Governor-general in name of the Queen, and by two Houses of Parliament. The Dominion now virtually embraces the whole of British North America.

In 1840, Great Britain, along with other powers, took the part of the Sultan of Turkey against Mehemet Ali, his pacha in Egypt, who had rebelled against him, and had even endeavoured to deprive him of a portion of his dominions. Acre was bombarded and taken by a British fleet under Admiral Stopford and Commodore Napier. A treaty was concluded by which Mehemet Ali was compelled to give up Syria, although he was permitted to retain Egypt.

Britain had no little trouble with China during this reign. Difficulties arose first in 1840, from the attempts of the imperial government in China to put down the contraband trade in opium carried on between that country and India. A war between China and Britain ensued, in which the latter was victorious, and China was compelled to sign a treaty at Nankin, by which the ports of Amoy, Foochow, Ningpo, Shanghai, and Canton were thrown open to foreign commerce, and the island of Hong-kong was ceded to Britain. Peace continued till 1856, when the seizure by the Chinese authorities at Canton of a ship and crew entitled to British protection, caused a fresh war, which continued with some interruptions until the 13th October 1860, when the allied British and French forces captured Pekin, the Chinese capital. The Chinese then submitted to a treaty, the most important of the stipulations of which were, that the Queen of Great Britain might appoint diplomatic agents to reside at the court of Pekin; that the Christian religion should enjoy the protection of the Chinese authorities; that British subjects should be permitted, under passports from their consuls, to travel in all parts of the interior of China; and that British ships should be allowed to navigate the Yang-tze. This war led to an expedition to Japan under Lord Elgin, and the opening to some extent of that interesting empire to foreign commerce.

After a peace of forty years, Britain again became involved in a European war. This arose from the assertion, by the Czar Nicholas of Russia, of a right to a protectorate of the Christian population in Turkey. In 1853, he urged this claim in such a form as to render it impossible for Turkey to admit it without ceasing to be an independent state. The other great powers of Europe, which had now become very jealous of Russia's encroachments all along her frontier, interfered as mediators, but in vain. After a year spent in negotiations, England and France formally declared war against Russia on the 27th March 1854. The war was carried on for two years, and during that time the other powers of Europe remained neutral, with the exception of Sardinia, which joined the alliance. A considerable British and French army was sent to the Crimea, landing there on the 14th September. On the 20th they defeated a Russian army strongly posted on the Alma. They then settled down to the siege of the great fortress of Sebastopol. During the winter, the British troops suffered terrible hardships, mainly from the imperfect arrangements made to provide them with shelter and supplies. The Russians made two desperate efforts to dislodge the allies, but were beaten with heavy loss in the sanguinary engagements of Balaklava (October 25) and Inkermann (November 5). The brunt of both engagements was borne by the British troops. The Czar Nicholas died (March 1855), and the war continued under his son, Alexander II. Meanwhile, there had been two naval campaigns in the Baltic Sea, a powerful English and French fleet entering the Gulf of Finland, blockading the Russian coasts, and compelling the enemy's fleet to seek shelter behind the granite fortresses of Cronstadt and Sveaborg. The bombardment and partial destruction of the latter fortress in the second campaign was the most important service rendered by the fleets. At length, after a terrific cannonade, continued for three days, the French carried the key of Sebastopol by assault, and the allies captured the whole south side of the city (September 8, 1855). During the winter of that year, the opposing forces maintained their positions. Austria now came forward as a mediator, and the result of her interposition was a conference at Paris (March 1856), which in turn led to the conclusion of a treaty guaranteeing the independence of Turkey, and stipulating that Russia should maintain no naval force in the Black Sea. The rather unexpected termination of the war was learned with something like a feeling of disappointment in this country, as both the army and the navy were known to be in the beginning of 1856 in a thorough state of efficiency, and it was hoped that an attempt would be made to retrieve previous blunders at the beginning of the war, by which the military reputation of Britain had suffered. In 1871, by an agreement among the powers consenting to the Treaty of Paris, the clause in it prohibiting Russia from maintaining a naval force on the Black Sea, was practically rescinded. The marriage of the Queen's second son, Alfred, Duke of Edinburgh, to the Princess Marie Alexandrowna, daughter of the Czar Alexander II. which took place, January 23, 1874, led to great demonstrations of friendship between the courts of Russia and Britain.

As early as 1838, Great Britain became involved

in war through her Indian dependencies. In that year, war broke out with Afghanistan, upon which she had made aggressions, and, in consequence, a series of disasters befell her troops. In 1842, being compelled to retreat from Cabul, they were almost entirely cut off in the mountain passes. This misfortune was, however, retrieved, but no further attempt was made to encroach on Afghanistan. In 1843, a war broke out with the Ameer of Scinde, which resulted in the conquest of that country by Sir Charles Napier. In the neighbouring kingdom of the Punjab, a contention among the Sikh chiefs led, in 1845, to a collision with English troops. After a number of severe and bloody engagements, in which the Sikhs were defeated, and of which the last was that of Goojerat (February 21, 1849), the Punjab also became part of British India. To these annexations to the British empire was added that of Pegu, taken from the Burman Empire in 1852. In July 1857, the news startled England that the sepoys—the native soldiers of the East India Company—stationed at Meerut had mutinied against their officers, under the mistaken idea, that it was intended by the British authorities to interfere with their religion. There had been signs of disaffection among the native troops for some months before; but it was not till the rising at Meerut, followed by a barbarous slaughter of Englishmen and women, that the alarming character of the crisis was realised. The rebels at Meerut, after this atrocity, marched into Delhi, and proclaimed its native king Emperor of Hindustan. In numerous other places, the native troops rose, and committed similar barbarities. At Cawnpore, the British garrison were slain, after having surrendered to the rebel Nana Sahib, who, hearing that the English troops were approaching, murdered all the English women and children who were in his hands. The few European troops that were in India at the time shewed remarkable bravery; Sir Henry Havelock and Sir James Outram, after inflicting many defeats on the mutineers, succeeded in relieving the garrison of Lucknow, which had been attacked by the sepoys, although to be in turn besieged by the rebels, who numbered 70,000 men, and were, besides, assisted by a large friendly population. Great exertions were made to meet the crisis at home; and by the end of the year, 30,000 troops from England had arrived in India, under the command of Sir Colin Campbell, afterwards Lord Clyde, who had distinguished himself greatly in the Crimean war. This general succeeded in relieving Lucknow, and this having broken the back of the insurrection, it was put down in the course of next year. The most important result of the mutiny was the transfer, by act of parliament, August 2, 1858, of the government of India from the East India Company to the crown.

The imprisonment by Theodore, king of Abyssinia of the British consul and several other Englishmen, led to a war. A British army, under the command of Sir Robert Napier (now Lord Napier of Magdala), landed in Abyssinia about the end of 1867, and overcoming the peculiar physical difficulties of the country, stormed the capital in April 1868. The objects of the expedition having been fully accomplished, the British troops withdrew from the country.

In the end of 1873, war broke out on the Gold Coast of Africa with the Ashantees. A force under the command of Sir Garnet Wolseley, captured and burnt the capital of the country, Coomassie, in 1874. A treaty was then concluded, and the English troops returned at once to England.

In 1879, an English force invaded the territory of the Zulus. These warlike barbarians inflicted severe loss on the invaders, but before the end of the year, were utterly defeated; their king, Cetewayo, was captured, and their country parcelled out amongst numerous chiefs. In 1883 the king was restored, under certain limitations.

The immediate occasion of the Afghan war in 1878–79 was the repulsion of a mission sent to the Ameer by the Indian Government. Jelalabad and Candahar were occupied without much difficulty. Shere Ali having died, his son Yakoob Khan concluded a treaty in May 1879. But ere the English troops had wholly retired from the country, a rising took place at Cabul in September; and the newly appointed English resident and his guard were massacred. Cabul was occupied by the English in October. Abdurrahman became Ameer; and for a year there was desultory war, during which one English force sustained a severe defeat, and another gained a brilliant and conclusive victory. English troops were wholly withdrawn in 1881.

In the end of 1880 the Boers of the Transvaal, annexed in 1877, rose in arms and proclaimed a republic. They fought well, inflicting a serious reverse on a British force at Majuba Hill. Britain yielded to the wish of the little state, and it was agreed by midsummer of 1881, that their territory should possess autonomy, but remain under British suzerainty.

In 1882 occurred a short but brilliant Egyptian war. A military party under Arabi Pasha had superseded the ordinary civil powers. Riots occurred at Alexandria, in which European and native lives were lost. Arabi having declined to cease strengthening the fortifications, English war-ships bombarded the forts in July 1882. Next month an English force under Wolseley, with a strong Indian contingent, landed in Egypt; and on 10th September Tel-el-Kebir was taken, and Arabi's forces totally and hopelessly defeated. Cairo was occupied, and the reorganisation of Egyptian affairs superintended by Britain.

Britain has been a spectator merely of many recent wars. Difficulties arose between us and the United States during and after the great American civil war of 1860–65, on account of the injury done to American commerce by Southern privateers, rigged out in British waters. At last, an International Tribunal sat at Geneva, and, in 1872, Britain had to pay upwards of £3,000,000 for the injuries done to American commerce by the *Alabama* and her consorts.

The war in 1859, between Austria and Sardinia, which was assisted by France, resulted in the defeat of Austria, and the consolidation of the kingdom of Italy. About this time began the formation of Volunteer corps throughout Great Britain.

In 1866, Austria was completely defeated by Prussia at the great battle of Sadowa.

In the great war waged in 1870 and 1871 between France and Prussia, which was assisted by the whole Germanic fatherland, Germany was

signally victorious. By a treaty of peace, signed February 26, 1871, France ceded to Germany the province of Alsace and a part of Lorraine, besides agreeing to pay a war indemnity of upwards of £200,000,000. The Bonapartist dynasty was driven from the throne of France, and King William of Prussia was proclaimed Emperor of Germany.

The war between Russia and Turkey in 1877-78, in which at one time it seemed likely England might be directly engaged, greatly weakened the Ottoman Empire. At the Congress of Berlin the subject principalities were recognised as independent. Bulgaria was made a principality; and Batoum and parts of Bessarabia and Armenia were ceded to Russia. By a separate convention, England undertook to defend Asia Minor, and obtained the right to occupy and administer Cyprus.

POLITICAL EVENTS—MINISTERIAL CHANGES.

After the rupture between Sir Robert Peel and the Conservative party, the Liberal party, as the Whigs are now styled, for a series of years enjoyed power, the chief statesmen being Viscount Palmerston, Lord John (now Earl) Russell, and Mr W. E. Gladstone; while the Conservative party began to recover under the Earl of Derby and Mr Benjamin Disraeli. The Conservatives came into power in 1859, but only retained it for a short time, during which a resolution was carried admitting the Jews into parliament; a bill was passed for the abolition of the property qualification for members of parliament, and an agitation was commenced for further parliamentary reform. Upon this question Lord Derby's government was defeated, and Lord Palmerston was again called to form a ministry. Lord Palmerston continued at the head of affairs till his death, October 18, 1865; one of the most important measures passed during this period being that for the abolition of the duty on paper, which has given a great impulse to newspaper literature. Earl Russell then became Premier, and with Mr Gladstone, who was Chancellor of the Exchequer, brought forward, after a general election, a new Reform Bill, proposing to reduce the franchise in burghs to £5; but, as the bill did not, in some points, meet with the entire approval of parliament, the ministry resigned, in June 1866, and was succeeded by a Conservative administration under Lord Derby and Mr Disraeli. Next year, a Reform Bill for England was carried, which vastly extended the franchise in burghs, by giving it to householders who pay poor-rates, and to persons occupying lodgings of the value of £10, and which also considerably lowered the franchise in counties. In the beginning of 1868, Lord Derby, on account of failing health, retired from the post of Premier, and was succeeded by Mr Disraeli. During this session were passed Reform Bills for Scotland and Ireland, in essential respects identical with that of England. At this time, the country was greatly excited by the state of Ireland. In 1866, there appeared in Ireland a number of wild adventurers from America, members of what is known as the Fenian Brotherhood. These sought to rouse the native Irish to rebellion, and succeeded to the extent of causing risings in Ireland, which were, however, quickly suppressed, through the suspension of the Habeas Corpus Act and other vigorous measures. The perpetration of some dastardly outrages in various parts of England, especially the blowing down of part of the wall of Clerkenwell Prison, led to a general feeling of insecurity throughout the country. During the debate on the Irish Reform Bill, Mr Gladstone moved that the Irish Church should cease to exist as an establishment. Government opposed the proposal repeatedly, and it was ultimately agreed to take the opinion of the new constituencies on it. Parliament was, therefore, dissolved in November of that year; and the opinion of the country being found to be in favour of Mr Gladstone's policy, Mr Disraeli resigned before the new parliament met, and a new government was formed, with Mr Gladstone at its head. This government passed the Irish Church and Irish Land Acts; the former, which came into effect on January 1, 1871, disestablishing and disendowing the Church of Ireland; and the latter giving outgoing tenants in that country a title to compensation in respect of improvements made by them on their holdings. This government passed several other measures of importance. One, the Army Regulation Bill, made (1871) several important military reforms, at the same time that a royal mandate cancelled the regulations which authorised the purchase or sale of commissions in the army; another, supplementary to the Reform Acts, substituted (1872) the ballot for open voting in parliamentary and municipal elections; while by two comprehensive acts (1870 and 1872) primary education has been extended and organised in England and Scotland, being rendered, in the former almost, in the latter absolutely, compulsory.

In 1874, Mr Gladstone resigned, and a new Conservative administration was formed by Mr Disraeli (afterwards Earl of Beaconsfield). This administration was chiefly memorable for its 'imperialistic' foreign policy, of which the proclamation of the queen as Empress of India, in 1877, was a significant event. (See above for the wars in Zululand and Afghanistan.) A general election in 1880 returned a large Liberal majority, and Mr Gladstone became the chief of a new Liberal Cabinet. Its main occupation was the difficult task of maintaining order in Ireland, and remedying Irish grievances. (For the Transvaal and Egyptian wars, see above.) The violent agitation of the Land League was accompanied by murders and other outrages, rents being withheld over a large area; and in 1881, a Peace Preservation Bill was passed, conferring on the administration the power of imprisoning without trial persons reasonably suspected of crime. Several hundred persons, including ultimately several Irish members of parliament, were thus imprisoned for a time. Meanwhile, an Irish Land Act conferring unparalleled privileges on the Irish tenantry had been passed, in spite of much opposition, especially in the House of Lords. This act enables tenants to have judicial rents fixed by courts created for the purpose, recognises the tenant's right to sell his tenancy, and makes provision for advancing money to tenants willing to purchase their holdings. In 1882, the affairs of Ireland still mainly occupied parliament. A modification of parliamentary procedure was necessitated by the repeated and persistent obstruction of the Irish

members; and a bill was passed securing to a majority of the House of Commons the right of closing a debate. The newly appointed Irish Secretary, Lord Frederick Cavendish, was assassinated on his first visit to Dublin. A new Prevention of Crime Bill was agreed to; but a conciliatory measure was prepared dealing with arrears of rent, and designed to rescue poverty-stricken tenants from hardship. In the spring of 1883, the government unmasked a widespread conspiracy, supported by funds from without, to assassinate persons hostile to the schemes of the most extreme anti-English agitators. The chief event in home politics in 1884 was the debates on the Franchise Bill for the further extension of the franchise.

RETROSPECT: FROM 1820 ON.

The early part of this period is remarkable for the great efforts which were made to diffuse knowledge more generally amongst the people. *Mechanics' Institutions* were formed in most of the larger towns, for the instruction of that class of the community in mechanical and natural science. Various periodical works of a cheap nature were also set agoing with a similar design, in such forms as to be intelligible to the less educated classes. In this period began also the *sanitary movement*, or the directing of attention to the means of promoting the public health. Great improvement was likewise effected in prison-discipline, as also in the treatment of the insane, and Industrial Schools were generally established.

The dominion of man over the material world made, during this period, a number of most signal steps of advancement. Even in agriculture, the oldest of all the arts, a marked improvement was made: by means of thorough draining and the application of chemical principles in manuring and tilling, the produce over a great part of the arable surface of the kingdom was at least doubled. Steam-navigation, invented in the previous period, was now brought into full play; ordinary roads were greatly improved by the mode of paving invented by Mr Macadam; an altogether new mode of travelling and transport was invented—namely, by railways and steam-locomotives, and, to crown all, came the invention of the electric telegraph.

The great exhibition of 1851 and its numerous successors here and elsewhere have been eminently useful in stimulating technical education. The extraordinary development of our colonies in Australia, New Zealand, Canada, and the Cape, is one of the signs of the times.

In 1866, after several failures, a submarine telegraph cable was laid between Ireland and America; the importance of this cannot be exaggerated. Since then, many other cables have been laid; there is a line of electric communication right round the world; India, Australia, and the Cape are now directly connected with England. The introduction of a penny and half-penny postage, and the cheapening of telegrams, have increased to an almost incalculable extent the power of communication between both men and nations.

This period has been remarkable for the number of geographical discoveries and the daring of explorers. During the early part of it, numerous efforts were made to find a North-west passage, especially by Sir John Franklin, who perished in the attempt in 1845. The North-west passage has since been more than once discovered, though it cannot be of practical avail. The North-east passage has been made, though not by an Englishman. Our knowledge of Africa has been extended by Livingstone, Grant, Speke, Baker, Cameron, Stanley, and others. One of the best results of African exploration is the extensive suppression of the slave-trade on this great continent, the credit of which must be mainly given to Dr Livingstone, Sir Bartle Frere, Sir Samuel Baker, and Gordon Pasha. Central Australia and other dark places of the earth have been diligently explored. The annual meetings of the British Association for the Advancement of Science, and of the Social Science Congress, have done a great deal for the extension and consolidation of scientific, industrial, and social knowledge.

At no time in British history have literature in all departments, science, and art been so diligently cultivated. Among the chief poets are Tennyson (poet-laureate), Robert and Mrs Browning, Alexander Smith, Rossetti, Morris, Swinburne, Matthew Arnold, and Robert Buchanan. The novel has assumed various shapes in the hands of Dickens, Thackeray, Bulwer Lytton, George Eliot (Miss Evans), Charlotte Bronté, Mrs Oliphant, Anthony Trollope, Charles Kingsley, Charles Lever, Wilkie Collins, Blackmore, Black, and others. Never, probably, did a more brilliant and painstaking class of historians flourish: among the chief names are Grote, Macaulay, Hallam, Kemble, Palgrave, Stanhope, Alison, Thirlwall, Finlay, Milman, Buckle, Burton, Stubbs, Froude, and Freeman. Hamilton, James and John Mill, Bain, Lewes, Spencer, Maurice, Hutchison Stirling, Edward Caird, and Wallace, in philosophy; the younger Mill, M'Culloch, Fawcett, and Cairnes, in political economy; and Chalmers, Maurice, Newman, Pusey, Stanley, Lightfoot, and John Caird, in theology, have maintained the character of Great Britain for subtlety of speculation, thoroughness of research, and influence on the thought of the time. Among essayists, De Quincey, Jeffrey, Hazlitt, Sidney Smith, and Matthew Arnold take a first place. Apart from all other literary men, yet partaking of the character of essayist, historian, philosopher, and prophet, stood Thomas Carlyle, one of the most singular and powerful forces in British literature. John Ruskin has also taken a unique place in the history of English thinking and feeling; and by his brilliant and suggestive writings on art, and on social and political questions, has left his mark on the period. The scientific men of this period are distinguished for the thoroughness of their researches, the number and value of their discoveries, and the originality and boldness of their theories; among the chief are Faraday, Darwin, Carpenter, Owen, Lyell, Murchison, Huxley, Tyndall, Lockyer, and Sir William Thomson. In art, we have such names as Turner, Landseer, Millais, Faed, Holman Hunt, Noel Paton, Rossetti, Burne Jones, Watts, Leighton, and Alma Tadema. Music has also made remarkable progress during the reign of the present queen, and is enjoyed in its higher form by an ever-increasing proportion of the nation.

CONSTITUTION AND RESOURCES OF THE BRITISH EMPIRE.

THE British Empire consists of the United Kingdom of Great Britain and Ireland, some small islands off their coasts, and numerous colonies and possessions in every part of the world; these making it a kingly commonwealth on which 'the sun never sets.' Though Great Britain is not a republic, though it is ruled by a hereditary monarch, and some of its legislators are hereditary also, the central principle of its political system is, that the law in theory and practice is no respecter of persons, and that before it all classes, even those politically privileged, are on an equal footing. This practically insures for the people an amount of personal freedom, untainted by license, equal to that possessed by most democratic republics in the world. Personal freedom—freedom to do anything that is not detrimental or hurtful to one's neighbours, is enjoyed by all classes in Britain, from the highest to the lowest; and in no part of the empire or in any of its dependencies is slavery in any shape or form tolerated. Another cardinal principle of the political system of Britain is, that the only absolute power in the land is the power of public opinion. It is not merely that every British subject has the personal right of private judgment, but that he has the right of giving it free public expression, so long as he does not thereby infringe on the rights of his neighbours. The proved aggregate opinion of the majority of the nation crystallises itself into definitive law, by means of certain constitutional machinery hereafter to be described, and thus the government is carried on, even under a hereditary monarchy and aristocracy, in such a way that the country is practically as free and as much self-governed as any republic, and the people do not regard the commands of constitutional and recognised authority as unbearable and tyrannical restraints. One of the most jealously guarded of the constitutional privileges of all classes of British subjects is this right of forming and expressing their opinions on public affairs, of petitioning for the redress of grievances, or in favour of reforms; and it is only a logical consequence of this that they maintain their 'right of public meeting,' as it is called, for the purpose of forming and giving publicity to their wishes or their suggestions on all questions of practical importance to the commonweal. Hence Britain is a democratic monarchy, a kingly commonwealth, an aristocratic republic, in which the personal freedom of the individual, in respect of thought, speech, or action, is unhampered by pressure of hereditary caste privileges or unjust laws, the practical equality of all subjects before the law strictly maintained, and in which the unrestricted political liberty of a republic is preserved, in combination with the pageantry, the moral order, and concentration of controlling force characteristic of more despotic monarchical forms of government.

Great Britain and Ireland occupy a position as a first-rate power much higher than we should expect, considering the comparatively small amount of the population of the islands themselves. A glance at the statistics of her commerce and revenues, and even a superficial review of the history of Europe for the last two centuries, will lead to the conclusion, that Britain enjoys an influence, prestige, and power beyond that of other nations far more populous, and more highly favoured by nature. This is partly owing to physical, and partly to moral causes. Of the first, one of the most important is its insular position—'the streak of silver sea,' as Mr Gladstone called it, severs Britain from the continent, protecting it from the perils of invasion and aggression, which have done so much to impoverish other European states. Then the temperate climate and natural fertility of the country, and the extent of its mineral wealth, have enabled it to outstrip all competitors in agriculture and manufactures; whilst its extensive sea-board has given to the maritime genius of the people ample scope for development, and secured to its shipping the largest share of the carrying-trade of the world. Of the moral causes, we may say that the Teutonic origin of the British people has had much to do with their aptitude for orderly political and social progress. A passion for regulated freedom, and a reverence for law and justice, are inherent in the race. Their painstaking industry and perseverance developed their own internal resources; and the greater amount of personal freedom, the greater security from political revolutions and convulsions, attracted to the country not only large numbers of foreigners of ability, who were driven into exile by the more tyrannical governments of their own lands, but also drew to Britain the capital necessary for the development of commercial greatness, on account of the greater security the country offered for its employment.

FORM OF GOVERNMENT.

The British government is a constitutional monarchy. Regarding it as a law-making and law-enforcing power, we may divide it into two branches—(1) the *legislative*, consisting of Sovereign, Lords, and Commons; (2) the *executive*, which in theory at least consists of the sovereign alone, though in these days in practice it is vested in a committee of responsible ministers, called a cabinet, which has taken the place of the old Privy-council, or 'the King in Council.' The cabinet is chosen by the sovereign from the chiefs of the most powerful political party in the Houses of Lords and Commons, and its members, as privy-councillors, are sworn to 'advise the king (or queen) according to the best of their cunning and discretion,' and to help and strengthen the execution of what may be resolved. The sovereign, or head of the

executive branch, is sworn to govern in accordance with constitutional form and precedent, and preserve the Protestant religion and the church established by law in England and Scotland.

The legislative branch of the government is called *parliament.* It consists of the Sovereign, the Lords, and the Commons; and their united concurrence is necessary for the repeal of old, or the enactment of new laws. The colonial dependencies are not represented in parliament. The *House of Lords*, or *Peers*, or *Upper House* of parliament, consists of a class of persons who form the peerage, and enjoy certain exclusive hereditary rights and legislative privileges. They are divided into lords temporal and spiritual; the former being laymen, the latter, ecclesiastics, bishops, and archbishops of the state church, who sit in the House of Peers only *ex officio.* The members of the Upper House hold their seats (1) by virtue of hereditary right; (2) by creation of the sovereign; (3) by virtue of office, *e.g.* bishops; (4.) by election for life, *e.g.* Irish peers; (5) by election for the duration of parliament only, *e.g.* Scottish peers. In 1873, the House of Lords consisted of 479 members, of whom 4 were peers of the blood-royal, 2 archbishops, 20 dukes, 19 marquises, 109 earls, 24 viscounts, 24 bishops, 233 barons, 16 Scottish representative peers, and 28 Irish representative peers. There are nine ladies peeresses in their own right, but they take no part in the deliberations of the Upper House, though they are members of the peerage. The number of names on the roll of peers was 393 in 1830, 457 in 1840, 448 in 1850, 458 in 1860, 473 in 1870; so that, with the increase of the democratic power in the nation, we find going on a manifest increase in the aristocratic element of the legislative branch of the government. More than two-thirds of the hereditary peerages were created within the present century. Of existing peerages, the three oldest date from the latter part of the 13th century, four date from the 14th, and seven from the 15th century. Twelve go back to the 16th century, 35 to the 17th, 95 to the 18th, and 239 are of the present century. From 1830 to 1873, 188 peerages were created; 34 being created under the administration of Earl Grey, 39 under that of Lord Melbourne, 11 under that of Sir Robert Peel, 24 under that of Earl Russell, 23 under that of Lord Palmerston, 25 under that of Lord Derby, 4 under that of Mr Disraeli, and 28 under that of Mr Gladstone. In olden times, no peer could take his seat without a special writ from the king. It has long been held, however, that every hereditary peerage entitles the holder of it to sit in the House of Lords, and any one giving proof that he is the lawful heir of one who had been called in these early times to the Upper House by the old royal 'writ of summons,' may claim to sit as a hereditary peer. The creation of a new peerage is the act of the sovereign advised by the prime-minister or head of the cabinet, and is done by the issue of a royal patent, the writ summoning the peer to the Upper House 'ad consulendum et defendendum regem;' but the rights of a peerage are acquired whether the party so summoned ever sits in the House at all. The sovereign may create a life-peer, one, that is, whose heirs have not the succession to peerage rights, but the House of Lords have refused to recognise as valid the 'writ of summons' calling such a peer to the Upper House, and have prevented him taking his seat there. The peers could once vote by proxy, but this privilege was suspended by a standing order of the House on March 31, 1868.

The *House of Commons, or Lower House*, has been composed, since the reign of Henry III. of knights of the shire, or representatives of counties; burgesses, or representatives of boroughs; citizens, or representatives of cities. Though the number of constituencies in England and Wales, when Henry VIII. ascended the throne, was only 147, large additions were made in each reign, up to the time of Charles II. In early times, all members of the Lower House were paid by their constituents. When members introduced the custom of giving their services gratuitously, many constituencies that had been exempted from returning representatives, on the score of poverty, began to resume their franchises, and hence the additions to the House that raised its members up to about 500 in the reign of the Stuarts. When, in the time of Queen Anne, the Union of England and Scotland took place, 45 members from Scotland were added to the 513 members that then formed the House. The Irish Union, in the beginning of the present century, added 100 Irish members; and since that time the number of members has remained at 658, and there is a general feeling against this number being increased; so much so, that even the last Reform Bill left it unaltered. The members of the House of Commons are elected by that portion of the people possessing the electoral qualification. In English counties, previous to the Reform Bill of 1832, an elector required to have freehold property to the annual value of 40s. In boroughs, the qualification varied, according to local usage—freemen and burgesses only being in most cases entitled to vote; and in Scotland the parliamentary franchise was enjoyed only by members of town-councils. The Reform Bill of 1832 increased the English county constituencies from 52 to 82, and the number of members from 94 to 159, but left Scotland and Ireland unaltered as regards county representation. It disfranchised 56 English boroughs, containing a population of less than 2000 each, and returning 111 members; it made 30 boroughs, with a population of less than 4000 each, send only one representative instead of two. Twenty-two new boroughs, containing 25,000 inhabitants and upwards, each received the privilege of having two representatives; and 20 other new boroughs, containing 12,000 inhabitants and upwards, got the privilege of having one representative in parliament. In Scotland, the Reform Bill increased the borough members from 15 to 23, giving her 8 more members than she had received by the Act of Union. The old 40s. freeholders in English counties then existing were not deprived of the franchise, but those acquiring freeholds after 1832 were only to have the franchise when their freehold was of £10 annual value. Copyholders holding an estate of £10 a year, 60 years' leaseholders of property worth £10 a year, leaseholders of £50 with 20 years' leases, tenants at will of property rented at £50 a year, also had the franchise by the Reform Bill of 1832. In English boroughs, the franchise was conferred on the old freemen, and on all occupiers of houses of £10 annual value. In Scotland, the franchise was extended in the same way from

those infeft as crown vassals, in property of the annual value of 40s., to all owners of property worth £10 a year, and to certain leaseholders. In Scotch boroughs, there was also a £10 occupation franchise.

In 1867–68, another Reform Bill was passed, which is at present in force. It extended the freehold franchise in counties in England from property of £10 annual value to property of £5; also the franchise of copyholders and leaseholders from £10 to £5, and the occupation franchise from £50 to £12. As to boroughs, it swept away the old £10 occupation franchise, and established household suffrage pure and simple—giving votes to all occupiers of dwelling-houses paying poor-rates; also to lodgers occupying lodgings of the clear annual value, when unfurnished, of £10 and upwards. The Reform Act of 1868, in Scotland, extended the county franchise to proprietors of lands or houses worth £5 rent; and to occupiers, resident or non-resident, of property of £20 ratable value. In boroughs, it conferred the franchise on occupiers of houses bearing rates, and on lodgers, as in England. In Ireland, the Act of 1868 left the county franchise unchanged; that is, the franchise is enjoyed by certain classes of freeholders; occupiers of land rated for the poor at a net annual value of £12; persons entitled to estates in fee, or in tail, or for life, of ratable yearly value of £5. The borough franchise was, however, given to occupiers of houses rated at £4, and of lodgings of the annual value of £10 unfurnished. The franchise cannot be exercised by peers, or by persons labouring under certain disqualifications, from alienage, infamy, felony, &c. Of university constituencies—in Oxford and Cambridge the electors consist of the doctors of the various faculties, and the masters of arts; in Dublin, the fellows, scholars, and graduates of Trinity College; in London, the graduates; in Scotland, the members of the university councils. In cases where a constituency returns four members, each elector can only cast three votes; and in Glasgow, which returns three members, each elector has only two votes. The number of electors on the register, in May 1882, was 3,134,801—viz.: 2,591,402 in England and Wales, 315,121 in Scotland, 228,278 in Ireland. The number of county electors was 948,258 in England and Wales, 98,444 in Scotland, 166,294 in Ireland—total, 1,212,996. The number of borough voters was 1,629,373 in England and Wales, 204,365 in Scotland, and 57,981 in Ireland. The numbers in each constituency vary, from the county of Middlesex with its 34,982 voters, to the borough of Portarlington with its 141.

In 1872, as a check to illegitimate influences, the Ballot Act was passed, which was to continue in force till 31st December 1880, and which has since been continued from year to year. It provides that every elector shall vote for his representative in secret. Each elector is furnished with a ballot-paper, on which there are printed the candidates' names, with a number printed on the back, and a counterfoil attached having the same number. It provides that 'at the time of voting, the ballot-paper shall be marked on both sides with an official mark, and delivered to the voter within the polling-place; and the number of such voter on the register of voters shall be marked on the counterfoil; and the voter having secretly marked his vote on the paper, and having folded it up so as to conceal his vote, shall place it in a closed box in the presence of the officer presiding at the polling-station, after having shewn him the official mark at the back.' Any marks made on the ballot-paper tending to identify the voter, will render it invalid. The only personal qualifications required by a member of parliament are, that he be a native of the United Kingdom, and be twenty-one years of age. Commissioned officers in those departments of the civil service charged with the administration of the revenue, judges, priests and deacons of the Church of England and the Roman Catholic Church, government contractors, sheriffs or returning-officers, Scottish or English peers, aliens, persons convicted of treason or felony, naturalised foreigners (save when the privilege is specially conceded by act of parliament), are all disqualified from serving as members of the House of Commons. Irish peers are eligible. If any member accept an office of profit from the crown, by Act 6 Anne, his election is void; but he is eligible for re-election if the office he has accepted be not a new one created since 1705. No member can resign of his own accord; so, when a member wishes to vacate his seat, he accepts the stewardship of the Chiltern Hundreds, a nominal office in the gift of the Chancellor of the Exchequer, and thus ceases to be a member.

The House of Commons consists of 658 members, returned as follows:

England and Wales—	Members.
52 Counties and Isle of Wight	187
200 Cities and Boroughs	301
3 Universities	5
Total of England	493
Scotland—	
33 Counties	32
22 Cities and Groups of Boroughs	26
4 Universities	2
Total of Scotland	60
Ireland—	
32 Counties	64
33 Cities and Boroughs	39
1 University	2
Total of Ireland	105

In England and Wales, in 1883, the proportion of representation to population in the counties was one member to 5170 of the electors, and 73,260 of county population. In boroughs the average was one to 5,500 electors, and 42,000 inhabitants. The representation of the various constituencies is still very unequal.

There can be little doubt that the existing proportions in which the representation is shared by the three kingdoms, are far from fair—at least as regards Scotland. If population is taken as the basis of representation, England should have 476 members instead of 493, as at present; Scotland 70 instead of 60; and Ireland 112 instead of 105. If the respective contributions to revenue were made the basis of representation, then England should have 514 members, Scotland 79, and Ireland 65. If both considerations are allowed to influence equally the distribution of representation between the three countries, then, taking the mean

of the two sets of figures referring to population and revenue, we should have for England 494 members, for Scotland 75, for Ireland 89.

Functions of Parliament.—Sir Edward Coke says 'the power and jurisdiction of parliament is so transcendent and absolute, that it cannot be confined, either for causes or persons, within any bounds.' The sovereign is the head of parliament, and can alone summon, prorogue, or dissolve it. No parliament, save on the death of the sovereign, can assemble of its own accord. The legal limit to the duration of a parliament is seven years. Parliament is assembled by summons of the sovereign issued through the Lord Chancellor, at least thirty-five days previous to its assembling. In the reign of William and Mary, it was enacted that parliament must be summoned once in three years at least; but now, as the vote of supply for the army and the budget is only granted to the executive for a single year, parliament must be summoned annually, and of late this has always been done. Every session ends with the prorogation of parliament by the sovereign personally, or through royal commissioners, or by proclamation; and this quashes all bills not carried through, and all pending parliamentary proceedings, save impeachments and appeals and writs of error in the Lords. Should the term of prorogation elapse, and no summons to meet be issued by the sovereign, parliament cannot assemble of its own accord, and the summons must be issued six days before the time of meeting. Adjournment of parliament is merely the continuance of the session from one day to another, whereas dissolution is the civil death of parliament.

Both Houses of Parliament have high privileges for maintaining their authority and protecting their members. The Speaker or president of the House of Commons claims the privilege of free speech from the sovereign at the opening of a new parliament for members of the Lower House; but a member may be severely punished for contempt by the Speaker, if he abuse this privilege. Courts of law cannot inquire into or review cases of persons committed to prison for breach of the privileges of parliament, and even yet the publication of the debates of the House is a breach of privilege, though of late the privilege has been waived, save where the reports were maliciously perverted. Members of both Houses are, whilst parliament is sitting, free from arrest or imprisonment in civil matters; so are peeresses by creation, in their own right or by marriage. Parliamentary witnesses are also free from arrest. Persons not members or officials of the House have no right to be present at its debates. The two Houses with the sovereign pass laws, impose taxes, superintend the administration of public affairs, and though they cannot direct or control the conduct of the *executive*, they can watch and criticise it; and the Lower House, if it finds its remonstrances unheeded, can always force the executive to listen to its demands, by exercising its privilege of withholding the supplies, and refusing to vote the Mutiny Act, or act legalising the standing army—and thus bring the whole machinery of government to a dead-lock, till its demands are conceded. Indeed, what gives the Lower House preponderating influence is, that all bills relating to money for the public service must originate with the Commons, the Lords merely being able to give their formal assent, and not having power to alter or modify them. No act of the two Houses becomes valid till it is ratified by the sovereign. In the Lower House, the president is called the Speaker because he is the medium of communication between the House and the sovereign, and ranks as first commoner in Great Britain. In the Lords, the president is the Lord Chancellor, or premier judge of England. The Speaker is elected by the House; the Chancellor presides in the Lords *ex officio*. All proposals must come before either House in the form of a *bill*—this being the title given to an act of parliament when it is under discussion. Permission must first be got to introduce it. Then it is read and considered twice by the House. If it pass the second reading, it is considered the House is committed to the principle of the bill, and it is then scrutinised in detail by the whole House sitting as a committee, in which each member may speak as often as he likes, whereas in regular sittings he can only speak once—except to explain wherein any of his first statements have been misrepresented or misunderstood. Having passed through committee, the bill is then read for the third time; and if it has originated in the Commons, when it passes the third reading, it is sent to the Lords, where it goes through precisely similar stages of discussion and consideration. If it passes the Lords, it is sent to the sovereign for ratification, and then, when ratified by royal assent, it becomes a law of the land. Should either House make alterations on the bills passed by the other, they must be reported to the House wherein the bill originated. If the two cannot agree to the modification suggested, or if they cannot arrive at a compromise which satisfies both parties, the bill falls to the ground. The royal assent is never refused in modern times. No cabinet would hold office unless with the assurance of getting the assent of the crown to any bills they passed, and as the sovereign cannot reign without a ministry, and a ministry cannot exist without the support of parliament and of the Commons, who hold the supplies under control, the royal veto is never exercised. Votes by proxy are not allowed in the Commons.

Until 1873, the Upper House exercised judicial functions as a supreme court of tribunal, its law members forming a judicial committee, that gave final decisions in all appeals from judgments given in all inferior courts of law in the three kingdoms. The appellate jurisdiction of the House of Lords was finally reconstituted in 1867, and transferred to a professional tribunal, consisting of the Lord Chancellor and the Lords of Appeal in Ordinary. (There is no appeal in criminal cases from the Scottish Court of Justiciary.) The Lords try offenders impeached by the House of Commons. Questions concerning the privileges or rights of either House must be settled in that House, and nowhere else—*e.g.*, the Commons decide finally as to the validity of the election of a member of the Lower House. The speaker of the House of Commons does not vote or speak. In case of equality, however, he gives the casting vote. In the Lords, the Speaker or Chancellor votes and takes part in debates, but has no casting vote; and if there be an equality, the 'non-contents' or 'noes' are held to prevail over the 'contents' or 'ayes.'

The executive is nominally vested in the crown, really in the sovereign and responsible ministers of state, who form the Cabinet, and who are placed at the head of the great departments of the public service. The sovereign's share in the legislature consists in dissolving, proroguing, or summoning parliament, or giving assent to bills, and, as head of the executive, with managing the revenue. The sovereign's prerogative includes sending or receiving ambassadors, declaring war or peace, and entering into treaties with foreign powers. The crown is hereditary in the House of Brunswick; but should the sovereign become a papist, or join the Roman Catholic Church, the people are absolved by the 'Act of Settlement' from all allegiance. The sovereign is the fountain of honour, justice, and mercy. In legal parlance, he never dies. He is head of the Established Church, and generalissimo of the army and navy; but he cannot raise an army without consent of parliament, nor can it be maintained unless that consent be renewed, as it is from year to year. A maxim of the constitution is, that the king can do no wrong. The ministers forming the Cabinet are responsible for the actions and policy of the executive, and are intrusted with the duty of watching over the interests of the crown in the Houses of Parliament, and answering for and defending the acts of the government there. The chief of the ministry or Cabinet is the First Lord of the Treasury; it is at his recommendation the other great ministers of state are appointed; indeed, all the crown patronage is dispensed in accordance with his advice. His nominal duty is receiving and issuing public moneys. Next comes the Lord Chancellor, who presides in the highest law-courts in the country, and is Speaker of the House of Lords; then the Secretary of State for Home Affairs; the Secretaries for Foreign Affairs, Colonies, and War; the Chancellor of the Exchequer, or finance minister; First Lord of the Admiralty; Secretary for India; Lord President of the Privy Council; and Lord Privy Seal, are almost always in the cabinet. Some three or four of the following may have seats in the cabinet also, viz.: the Chief Commissioner of Works, Chancellor of the Duchy of Lancaster, President of the Board of Trade, President of the Local Government Board, Vice-president of the Privy-council, Postmaster-general, Chief Secretary for Ireland. Sometimes a statesman may have a seat in the Cabinet without undertaking any office. The Cabinet exists only as long as it can command the confidence of parliament, or work harmoniously with the crown. It is not recognised by the law—no record is kept of its proceedings—the names of those who compose it are never officially announced. Besides this, there is the Privy-council, consisting of men of proved eminence as politicians, or men of high rank and character. Indeed the Cabinet is an outgrowth of the Privy-council, and may be regarded as having been originally a select executive committee of that body, chosen as being more workable because less unwieldy. Gradually it became wedged into the parliamentary system, and moulded into its present form, the great distinction between Cabinet and Privy-council being that it is not necessary for members of the latter body, as it is for members of the former, to have seats in parliament. The Privy-council take no share in the government, save when summoned by the sovereign to give advice, in which case they are responsible for the consequences of it—it being a maxim of the constitution, that the king can never act alone without advice; which leads to the other maxim, the king can do no wrong.

JUDICIAL ADMINISTRATION.

The superior courts of common law, for the trial of civil cases, are the Court of King's (or, as at present, Queen's) Bench; the Court of Common Pleas; the Court of Exchequer, designed at first only to decide in cases concerning the revenue; and the Court of Chancery, presided over by the Lord Chancellor, which administers the law of equity. Courts under these designations sit both in Westminster and in Dublin. By the Supreme Court Judicature Act of August 5, 1873, modified or extended by additional acts in 1875, 1876, 1877, and 1879, the distinctions between common law and equity were abolished, and these superior courts, along with the High Court of Admiralty, Probate, and Divorce, and London Court of Bankruptcy, united in 'The Supreme Court of Judicature of England,' consisting of two divisions: (1) Her Majesty's High Court of Justice is to have original jurisdiction in all causes of action as regards common law and equity, and appellate jurisdiction from certain inferior courts. Since 1881 there are but three divisions—Chancery; Queen's Bench; Probate, Divorce, and Admiralty. Those of Common Pleas and of Exchequer have ceased to be separate divisions; and the titles of Lord Chief-justice of Common Pleas and Lord Chief-baron of Exchequer are abolished. (2) Her Majesty's Court of Appeal, which has appellate jurisdiction only in all causes from all quarters, and to which the old appellate jurisdiction of the House of Lords (except as regards Scotch causes) is transferred. In the former the title is 'Judge of Her Majesty's High Court of Justice;' but the titles, Lord Chief-justice of England, Master of the Rolls, are continued. The Court of Appeal consists of four *ex officio* judges, and as many others as the crown appoints, not exceeding nine. The *ex officio* judges are the Lord Chancellor, Lord Chief-justice of England, Master of the Rolls, and the President of the Probate, Divorce, and Admiralty Division. 'Additional judges,' unsalaried, may be appointed from the supreme courts of India and Scotland, or from the superior courts of Westminster—their titles being Lords-justices of Appeal.

The superior criminal courts are the House of Lords—in the cases of *impeachment*, and of the trial of peers for certain crimes—and the Court of Queen's Bench. The Central Criminal Court is devoted almost exclusively to the trial of crimes committed in the metropolis and surrounding districts. There are also courts of assize, which, in England, perform six provincial circuits, in some instances once, and in others twice a year. These courts exercise criminal jurisdiction, and at the same time try issues of fact in civil causes. Minor cases, criminal as well as civil, are judged by bodies of provincial magistracy, termed Justices of the Peace, who meet in session in every county once every quarter of a year. But in certain cases, individual justices act as judges, although not sitting in

session. There are also magistrates of police. In civil causes, the county courts—a modern institution—have, in England, jurisdiction where the debt in dispute does not exceed £50 in amount. For matters of bankruptcy and insolvency, there are courts both in London and Dublin, and in the provinces in England. Besides the civil and criminal courts, there are ecclesiastical courts which have jurisdiction in matters of church-discipline. Until lately, the ecclesiastical courts had jurisdiction in cases connected with marriage, wills, &c., and the courts of Admiralty superintended maritime causes, and questions between persons of different nations; but such cases now go before the Exchequer division, and the Probate, Divorce, and Admiralty division of the new 'High Court of Justice.' The Prosecution of Offences Act, 1879, sanctioned for the first time the appointment of a public prosecutor in England.

Guernsey, Jersey, Alderney, the Isle of Man, and other small islands in the British Channel, which politically belong to the United Kingdom, possess a variety of peculiar privileges and legal usages.

In Scotland, laws peculiar to itself, founded upon the principles of the Roman and the feudal law, are administered by a supreme civil tribunal, denominated the Court of Session, which remains fixed at Edinburgh, and by a criminal tribunal, named the Court of Justiciary, which not only sits in the same city, but makes circuits through the provinces. The sheriff or county courts exercise a very extensive jurisdiction in civil matters—it being almost unlimited, unless where the matter at issue involves a question of ownership of land, houses, or other heritage, or relates to the constitution of a marriage, or to divorce. The sheriffs are also criminal judges in cases not sufficiently important to come before the supreme court. Minor civil and criminal cases are also judged in Scotland by the justices of the peace, and by the magistrates of the boroughs. Scotland possesses the advantage of public prosecution of offences, the injured party being only a complainer to the public prosecutor. The chief public prosecutor is the Lord Advocate; the inferior public prosecutors, in connection with the various minor courts, are termed Procurators-fiscal. The whole expense of prosecution is defrayed by the national exchequer.

The peculiar boast of the criminal law of the British Empire is the *jury*. In England and Ireland, where the principle of the criminal law requires the injured party or his representative to prosecute, he can only do so by permission of a jury of accusation, called the grand jury; another jury sits for the purpose of deciding if the evidence against the accused has established the guilt. Juries of the latter kind consist, in England and Ireland, of twelve men, whose verdict must be unanimous; in Scotland, the jury upon the charge consists of fifteen men, who decide by a majority of votes. The jury is an institution of Teutonic origin, transmitted to Britain through the Saxons; and it is justly considered as a most efficient protection of the subject from the vindictiveness of power. Civil cases, turning upon matters of fact, are likewise decided in all parts of the United Kingdom by juries consisting of twelve men. Unanimity in the verdict is required in these civil cases, as well in Scotland as in England and Ireland, with this difference in Scotland, that, after the jury have been kept six hours in deliberation, the verdict of nine is sufficient.

CHURCH.

In Great Britain, the Protestant religion is established by law. But there is the broadest toleration of all creeds not offensive to public or private morals. Non-established churches are allowed to manage their own affairs as they please under protection of the law, though they have no subsidies or patronage conceded them by the state. In England, the Protestant Episcopal, in Scotland the Presbyterian churches are established by law. In Ireland, there is now no established church, the Protestant Episcopal Church, which was united to the Church of England, having been disestablished on and after 1st January 1871. The sovereign is supreme head and governor of the established churches in England and Scotland; and in the case of old sees, nominates the archbishops and bishops, the form being, to send to the dean and chapter of the vacant see the royal license to elect the crown nominee, and afterwards to confirm the appointment under the Great Seal. The bishoprics of Gloucester and Bristol, Chester, Peterborough, Oxford, Ripon, and Manchester are conferred by direct letters-patent from the crown.

In the colonies, no one church, as a rule, is favoured by the state more than another. The crown may appoint colonial bishops, but it can give them no jurisdiction, and it is only under special acts of parliament that the bishops in India have any jurisdiction at all. The Church of England can take no step out of the ordinary routine save by act of parliament. Laymen, save through parliament, cannot interfere with the doctrines or practice of the church—which doctrines, as defined by the 39 Articles and Book of Common Prayer, are, as regards disputes as to interpretation, liable to be adjudicated on by the Judicial Committee of the Privy-council, as a tribunal of final appeal. Each bishop has a diocese—the two archbishops of York and Canterbury have provinces, and the latter is 'Primate of all England and Metropolitan.' Other ranks in the hierarchy of the Anglican church are archdeacons, deans, and prebendaries, rectors, vicars, curates—though, strictly speaking, there are only three orders of clergy—bishops, priests, and deacons. The provinces of York and Canterbury have each a convocation of bishops, archdeacons, and deans, of proctors representing the inferior clergy, which assemblies are summoned by the archbishops in accordance with a royal mandate. They must have the sanction of the sovereign before their resolutions are binding. In England there are 12,000 parishes and 200 extra parochial places, and in every parish there is a parish church, ministered unto by the rector, who holds the living. He is sometimes called the parson—or *persona ecclesiæ*—that is, the jural person who holds the rights that inhere in a parish church. He has for life a freehold of parsonage, glebe, tithes, and other dues, which dues may be 'appropriated' in cases where the 'living' is spiritually annexed to some corporation which is patron of the benefice. In such cases, the minister appointed by the corporation

is not a rector, but a vicar, whose functions are the same as those of a rector in a 'non-appropriated' benefice. Patronage of livings, or *advowson*, is a species of real property, and it is *appendant*, as when it is a manorial possession and right, passing by grant of the manor only, without any other authority; or it is an *advowson in gross*, as when it has been severed from the property of the manor, and ceased to be an advowson appendant. An advowson may be bought like any other property; but if an alien purchases, the crown has to exercise the right of presentation to the living; if a Roman Catholic, the right is exercised by either Oxford or Cambridge alternately. In 1835, the right of corporate towns to present was abolished. Besides the Queen, Lord Chancellor, Prince of Wales, higher clergy, the chapters and universities, there are about 3850 lords, gentlemen, and ladies who hold advowsons. There are two archbishops, 30 bishops, with incomes ranging from £15,000 a year, the emoluments of the archbishop of Canterbury, to £2000, the income of the bishop of Sodor and Man. There are 30 deans, with salaries of from £3000 to £700. As assistants to the bishops, there are 82 archdeacons, who hold other preferments, their archdiaconal salaries being small. Under them are 613 rural deans, or unpaid supervisors of local clergy. The total number of clergy of all classes is about 23,000. It is difficult to fix what the total revenue of the church from all sources is—a probable estimate is about £8,000,000 a year. There are about 13,271 benefices, of which 1217 are under the value of £100 a year (many being under £50); 3231 range from £100 to £200; 6407 from £200 to £500; 1902 from £500 upwards; and there are 494, the incomes of which are not given in the *Clergy List*. A large part of the church property is managed by the Ecclesiastical Commissioners, who pay fixed salaries to the prelates.

The official census does not collect church statistics. However, the approximate membership of the Established Church of England and other denominations may be taken as 13,500,000, leaving about 12,500,000 to the nonconformist denominations. Next to the Church of England, the Roman Catholic Church is the most powerful, their numbers in Great Britain being about 2,000,000, and in Ireland 3,960,891. Of the Protestant Dissenters, the most prominent are the so-called Methodists or Wesleyans—including 'the Old and New Connection,' 'Primitive and Free Church Methodists,' 'Bible Christians'—and they may possess about 9000 places of worship, and about 3,500,000 adherents. In Wales, where Calvinistic Methodists form the dominant church, this denomination has 250,365 adherents. The Congregationalists or Independents have 3500 places of worship, and about 1,250,000 adherents in the British dominions. The Baptists have in England and Wales 2000 ministers, 241,764 members, and 325,691 scholars. Of the minor religious bodies, the Unitarians have 355 ministers, 352 chapels, and about 80 mission stations. The Quakers have about 17,000 members. The Moravians have 5550 members, and 6200 scholars. The Catholic Apostolic Churches (Irvingites) have 19 churches. The New Jerusalem Church (Swedenborgians) have 58 societies, with 4207 registered members. The Mormons have 82 churches. The Jews, 50,000 members, and 100 ministers and readers. In 1873, the entire number of sects with registered places of public worship was 131, the number of their places of worship being 19,483; in 1882, 186 and 21,864 respectively.

In Scotland, the Presbyterian Church is established. Its standard of doctrines is the Westminster Confession of Faith. It is a pure democracy—all members being of equal rank and power in the body politic of the church—except when elected to presiding offices, the tenure of which, however, is usually temporary. The church is governed by three inferior church courts, and one supreme ecclesiastical court, in which laity as well as clergy are fairly represented, and have equal deliberative and executive power. In every parish there is the Kirk Session—composed of the parish minister, who is chairman, or 'moderator'—and a variable number of 'elders,' who may be laymen or non-beneficed clergymen, but are usually laymen. They are elected by the male communicants of the church. The session superintends the affairs of the visitation of the sick and poor connected with the church, and keeps up the discipline of the church and parish, interfering in glaring scandals, and inflicting church penalties on offenders. Findings of the session may be appealed against to the court immediately above, called the Presbytery, consisting of the parish ministers and representative lay elders from kirk sessions in the district under jurisdiction of the presbytery. The functions of a presbytery, as regards church government, are not unlike those of a bishop. The next court of appeal from the presbytery is the Synod, composed of a collection of presbyteries in a particular ecclesiastical province; and over the synod there is the supreme church authority in Scotland, the General Assembly, composed of clerical and lay representatives from the various presbyteries, whose authority extends to all questions interesting the church; whose decisions in matters of doctrine, morals, discipline, &c. in everything, in fact, that does not affect civil rights, are not subject to review even by the Queen in council. It is presided over by a moderator, invariably a clergyman; and the civil head of the church—the Sovereign—is represented at its meetings by a Lord High Commissioner. The church is divided into 16 synods and 84 presbyteries. There are 1300 ministers, 1250 churches, and 1800 of what, prior to the Education Act, were known as parish or Established Church schools, with 140,000 scholars. The membership of the church is usually estimated at about half the population of Scotland.

Of nonconformist bodies in Scotland, the Free Church is the most important. Except in two questions of church polity, it differs in no material respect from the Established Church. It consists of 16 synods and 73 presbyteries, ruled by a General Assembly. It has 1084 ministers, 1055 congregations; it pays an equal dividend annually, from a voluntarily subscribed Sustentation Fund, of £160 to each minister; and for the various purposes of the Church it raised, in 1882, £607,680. The United Presbyterian body, between which and the Free Church there exists a treaty of mutual eligibility as regards membership, has 31 presbyteries, 551 churches, 587 ministers, and probably about 174,000 members in Scotland and Ireland, who raise £383,730 for church purposes. The Presbyterian Church has offshoots

in England and Ireland. The Church of Scotland in England has 4 presbyteries, 20 churches, 20 ministers, and 10 military chaplains. The Presbyterian Church of England (comprising a former branch of the Scottish United Presbyterian Church) has 10 presbyteries, 275 churches, 130 ministers, 56,000 members, and 22,000 scholars. In Scotland, the Episcopal Church is in the position of a dissenting body; it has 255 clergymen, and about 75,000 members.

In Ireland, the Established Protestant Church in union with the Church of England, was disestablished and disendowed by act of parliament, 32 and 33 Vict. cap. 42, on January 1, 1871. The Irish Roman Catholic Church numbers 3,951,888 members and adherents; the Protestant Episcopal Church of Ireland, 635,670 adherents; the Irish Presbyterians are in number 485,503; Methodists, 47,669; Independents, 6014; Baptists, 4894; Quakers, 3696; Jews, 453; other persuasions, 19,035. The Roman Catholic Church is under 4 archbishops—Armagh, Cashel, Dublin, and Tuam—and 23 bishops. On the death of the bishop, the clergy of the diocese elect a vicar capitular, who acts as interim bishop; they nominate a person for the office, and postulate or petition the pope to ratify their choice. The bishops of the province also nominate eligible persons to the pope, but the candidate is chosen virtually by the cardinals constituting the Congregation *De Propaganda Fide* at Rome, whose nomination is always ratified by the pope. The emoluments of a bishop come from his own parish, usually the best in the diocese, from marriage licenses, and from the cathedraticum, an annual sum of from £2 to £10 paid by the parish priests, according to the value of their parishes, to keep up episcopal dignity. Parish priests are nominated by the bishops, and are paid by voluntary offerings, mass, baptismal and marriage fees, and Easter and Christmas dues.

EDUCATION.

In spite of the progress made in education since the passing of the Reform Bill of 1832, the ignorance of the masses in England is still deplorable. From a return issued, we find nearly 20 per cent. of the males, and more than 27 per cent. of the females who were married in England and Wales in the year ending September 1872, unable to write their names in the register. This shews improvement, however, since 1841, when the proportions of persons in that ignorant condition were—males, 33 per cent.; females, 49 per cent. The figures also shew the percentage of ignorance greatest in the mining, manufacturing, and agricultural districts, and less in the latter than in the former. In Ireland, the Registrar-general reports in 1872 that 36 per cent. of the men, and 46 per cent. of the women married in 1869, were unable to write their names. In fact, England had, and hardly has still, any definite national system of primary education. The various religious bodies, and private munificence and enterprise, were relied on to supply the country with primary schools. Since 1833, but chiefly since 1846, the government stepped in, but only as an auxiliary or a stimulant to the working of the various agencies carrying on the elementary instruction of the people, and parliament voted an annual grant for educational purposes, the disposal of which was vested in the Committee of the Privy-council for Education. The Committee never took the initiative in promoting education. It only gave grants to those that did, no matter who they were, or what sect they belonged to, provided always that they could shew they were working out satisfactory results, as tested by government inspectors. These grants in aid were (1) for building; (2) for maintaining schools; (3) capitation grants to the teachers of so much per head for each scholar whose proficiency satisfied the school inspectors. In 1870, a step was made towards establishing a national system of primary education, by the passing of Mr Forster's Act (33 Vict. c. 75), which enacted that there should be provided for each school-district a sufficient number of public elementary schools, available for all children residing in that district, for whose elementary education suitable provision is not otherwise (that is, by denominational or adventure schools) made. If new schools are erected to meet the requirements of the district, a thing to be determined by the ratepayers (who signify their desire for increased school accommodation by electing a school-board, under whose management these new public primary schools are placed), the Act provides that all children attending these new public schools, whose parents are unable from poverty to pay for the instruction given, shall be admitted free, and their school-fees paid from local rates. The general expenses connected with managing these schools also must come off local rates. The school-boards have the option of enacting the compulsory education of children between the ages of 5 and 13, of either remitting the fees of indigent children attending the board schools, or, if the parents desire the children to attend denominational schools, of paying their fees for their attendance there—a provision which is made by the 25th clause, and has raised a storm of discontent on the part of the advocates of unsectarian education—or of erecting and opening free schools for the special benefit of indigent children, and supporting them out of the rates. The ratepayers may or may not elect a school-board; that is, they may, if they please, render the Act a dead-letter, and stick to the old haphazard voluntary system; indeed, as a matter of fact, though school-boards have been formed in all the large towns, where they were least needed, comparatively few have been established in the small towns and rural districts, where the influence of the landlords and Established Church is most powerful, and where primary schools were most urgently wanted. The Act is a compromise, in fact, the central ideas of which are two—permissive compulsion and permissive sectarianism. Where its machinery is not adopted, the old system of voluntary schools, with government grants in aid, still prevails.

Scotland has had since 1696 a legalised system of national elementary education. By law, each parish was provided with a primary school at the expense of the landowners or heritors, who had to maintain it, and provide the teacher with certain emoluments, though he was also allowed to charge a small fee for each pupil. These schools were under the management practically of the ministers and presbyteries of the Established Church.

The country outgrew its parochial system of elementary education, and supplementing it there arose large numbers of voluntary, denominational, and private adventure schools, receiving grants in aid from the Privy-council, on the same conditions as primary schools in England. In 1872, the Education (Scotland) Act remodelled the whole system. It swept away clerical ascendency in the parish schools, and in the denominational schools, by making provision for these being transferred to the management of school-boards elected by the ratepayers. It enacted compulsory education for children between the ages of 5 and 13, and enforced the election of a school-board in each parish by the ratepayers, charged with the duty of levying a local rate in support of the public schools and their teachers, of prosecuting and punishing parents who neglected to send their children to school, and with the payment of the expense of educating indigent children whose parents were unable to pay for their instruction. No religious teaching is permitted except after or before the ordinary time laid down for secular instruction, and then its kind and quantity are determined by the school-board. It also set apart 11 borough schools—Aberdeen, Ayr, Dumfries, Edinburgh, Elgin, Glasgow, Haddington, Montrose, Paisley, Perth, and Stirling—to be 'managed by the school-boards accordingly, with a view to promote the higher education of the country.' The teachers are to be paid, appointed, and dismissed at the discretion of the boards, and are to be selected only from men who hold certificates of competence from the Scottish Education Department. Parliamentary grants in aid as formerly are to be continued to boards or national schools that fulfil the required conditions.

Ireland has long had a system of national primary education, only the people do not sufficiently avail themselves of it. The main feature of it is an arrangement by which children of different sects are taught religion at separate times by their respective pastors, the expenses being borne by the government. The schools are under the superintendence of a mixed national board, composed of both Catholics and Protestants; but as in the case of the Scottish Education Board (which lasted for seven years only), it is subject in turn to the central authority of the Privy-council's Committee on Education.

As to higher education, there are in England the universities of Oxford, Cambridge, and Durham; the various colleges affiliated to the university of London; the higher classical schools of Eton, Rugby, Winchester, Harrow, Cheltenham, Marlborough, Merchant Taylors', City of London, Charter-House, Salisbury. In Scotland are the universities of Edinburgh, Glasgow, Aberdeen, and St Andrews, where education is given in a more liberal and less expensive way than in Oxford and Cambridge, and a college at Dundee. In Ireland are Trinity College, Dublin; the Roman Catholic College, Maynooth; and the Royal (formerly Queen's) University, with colleges in Cork, Belfast, and Galway. These latter colleges are purely secular (giving no religious or theological instruction), and are endowed by the state.

The progress of primary education in Great Britain in the years 1864–81 is well shewn in the following tables:

ENGLAND AND WALES, AND ISLE OF MAN, INCLUSIVE OF ROMAN CATHOLIC SCHOOLS IN GREAT BRITAIN.

Years ended 31st August.	Number of Schools inspected.	Number of Children who can be accommodated.	Average number in Attendance.
1864	6,470	1,332,553	862,817
1865	6,867	1,470,473	901,750
1866	7,134	1,510,721	919,922
1867	7,601	1,605,409	978,332
1868	8,051	1,724,569	1,060,082
1869	8,592	1,838,416	1,153,572
1870	8,986	1,950,641	1,255,083
1871	9,521	2,092,984	1,345,802
1881	18,062	4,389,633	2,863,535

SCOTLAND, EXCLUSIVE OF ROMAN CATHOLIC SCHOOLS.

Years ended 31st August.	Number of Schools inspected.	Number of Children who can be accommodated.	Average number of Children in Attendance.
1864	1421	188,904	148,317
1865	1573	207,335	155,995
1866	1619	213,487	162,133
1867	1739	231,898	169,131
1868	1843	246,041	181,698
1869	1745	237,928	179,214
1870	1963	264,594	198,448
1871	1944	264,041	201,392
1881	3074	612,483	409,966

TOTAL FOR GREAT BRITAIN, WITH EXPENDITURE, &C.

Years ended 31st August.	Number of Schools Inspected.	Number of Children who can be accommodated.	Average number of Children in Attendance.	Number present at Inspection.	Expenditure.
1864	7891	1,521,457	1,011,134	1,133,291	£655,036
1865	8438	1,677,808	1,057,745	1,246,055	636,806
1866	8753	1,724,208	1,082,055	1,287,604	649,097
1867	9340	1,837,307	1,147,463	1,394,100	682,201
1868	8894	1,970,610	1,241,780	1,527,655	797,495
1869	10,337	2,076,344	1,332,786	1,639,502	820,755
1870	10,949	2,215,235	1,453,531	1,780,528	912,451
1871	11,465	2,357,025	1,547,195	1,866,006	1,938,624
1881	21,136	5,002,116	3,273,501	3,848,011	6,152,216

From 1839 to 1872, parliament has expended £13,874,487 in Great Britain on primary education. On schools in England connected with the Church of England, there were expended £8,098,788; on British and Foreign Society schools, £1,327,305; on Wesleyan schools, £656,952; on Roman Catholic schools, £538,901; on workhouse schools, £78,323; on inspection and administration,

£1,445,625. As to the results, the following table shews the percentage of children who presented themselves for examination under the various standards from Nos. 1 to 6, fixed by the Education Code in 1871–72 :

	Percentage of Children examined in Standards						Totals.
	1.	2.	3.	4.	5.	6.	
England and Wales :							
Day-schools	64·11	64·54	52·78	56·07	56·99	48·4	60·74
Night-schools	64·41	65·43	62·52	63·2	61·58	65·35	64·07
Scotland :							
Day-schools	87·66	86·95	80·05	68·01	74·56	74·3	81·58
Night-schools	82·9	90·0	84·21	75·0	70·0	69·79	82·15

The percentage of children presented for examination in 1871–72, as given in the foregoing, who failed to wield efficiently the 'knife, fork, and spoon' of education—*i.e.* who failed to pass in reading, writing, and arithmetic—was as follows :

England and Wales.	Day-Schools.	Night-Schools.	Scotland.	Day-Schools.	Night-Schools.
Reading	11·33	8·59	Reading	1·79	·18
Writing	17·68	17·81	Writing	8·16	11·02
Arithmetic	27·79	24·32	Arithmetic	12·3	9·57

The inferences we draw from the above are, (1) that the proficiency of a lamentably large number of scholars is never tested ; (2) that too few attain proficiency enough to come up to the higher Standards 4 to 6 ; (3) that either the teaching must be better, or the pupils cleverer in Scotland than in England ; (4) that the results obtained from the night-schools are more satisfactory than those from the day-schools. It must, however, be remembered that in England the examinations in day-schools were held under the Code of 1871, whilst those in night-schools were held under the Code of 1870 up to the end of February 1871, and thereafter under the Code of 1871 ; but in Scotland the inspections and examinations were all under the Revised Code. The total parliamentary grants for primary schools in Great Britain amounted to £3,102,079 in 1881–82, an increase of about £124,000 on the previous year.

As regards Ireland, the money spent by the Commissioners of National Education in 1881 was £729,868. At the close of 1882, the number of schools was 7648, shewing an increase on the previous year of 58 schools. There were 1,066,259 children enrolled, but the average daily attendance was only 674,290, indicating a decrease of those on the rolls of 16,761, and an increase of 205,733 in daily attendance, as compared with the previous year. The state of education in Ireland is, however, by no means satisfactory as yet. In Ireland, government increases the number of schools, but the people do not seem to care much about taking advantage of them. In some years, notwithstanding, two or three hundred applications have been made for grants in aid to new schools. Of the total number of schools, we find 2620 in Ulster, 1170 in Munster, 1534 in Leinster, 1126 in Connaught, or 6914 in operation at the close of 1871. Of the children on the school-rolls in 1872, 79·98 per cent. were Roman Catholics ; 11·19 per cent. were Presbyterians ; 8·04 per cent. were Protestant Episcopalians, and 0·79 per cent. were of other persuasions.

There is no proper system of national *technical* education in Britain ; but the Science and Art Department, by grants in aid to schools, and capitation grants to teachers who bring their pupils up to a certain standard of proficiency, do a great deal to supplement the want of such a system. Schools of art and design, and mechanics' institutes, and various adventure schools of the kind, have their teachers licensed by the department, subject their students to its examinations, and get its grants in aid. In 1872–73, the expenditure of the department, exclusive of the vote for the Geological Survey, was £209,117, or £17,596 more than in 1871–72. The number of schools at the end of 1881 was 1360, an increase of 412 as compared with the year 1871 ; the number of pupils (61,177) was nearly doubled in the same time. From these schools, 38,837 students went up for the examinations in May 1881 ; besides self-taught students, and pupils of teachers not licensed by the department. In May 1881, the examinations were held at 987 provincial and 111 metropolitan centres. The payments to teachers of proficient students came to £43,519, or 14s. 2d. for each person under instruction. There were 1000 of these schools in England and Wales, 151 in Scotland, 209 in Ireland. The number of persons instructed in art increased from 212,501 in 1871, to 244,134 in 1872. Great progress has, however, been made of late in technical education proper, mainly in connection with the City and Guilds of London Institute of Technical Education. The great difficulty in the way of establishing technical education was, that the masses of the working classes, in the first place, had no desire to be instructed in the scientific principles of their craft ; and in the second, their primary education was so bad, that they could not understand scientific teaching when they got it, and could have no taste for it.

Industrial schools, ragged schools, or reformatories for young criminals, have been instituted for supplying the lowest, or 'City Arab' portion, of our juvenile population with the rudiments of education, and also with food and clothing in cases of great destitution.

ARMY AND NAVY.

A detailed account of these services will be given in MILITARY AND NAVAL ORGANISATION.

FINANCES.

The public revenue for the year 1881–82 was £85,822,281, and the expenditure £85,472,556. The following table gives an analysis of the income and expenditure for the year ending 1873, when there was a surplus of over 5½ millions, an indication of economy on the part of the government, and great prosperity on the part of the country. Where does the revenue come from? Customs duties gave the following net produce—Chicory, £62,667 ; cocoa, £35,413 ; coffee, £202,601 ; currants, £318,059 ; figs, £37,645 ; raisins, £152,579 ; rum, £2,370,514 ; brandy, £2,085,849 ; Geneva, £94,830 ; various spirits, £330,373 ; sugar, unrefined, £2,689,320 ; refined, £556,782 ; molasses, £36,979 ; tea, £3,191,981 ; tobacco and snuff, £7,046,930 ; wine, £1,686,629. How few know that out of every shilling's-worth of cocoa they buy, 1¾d. is paid to government ; of coffee, 2¼d.

currants, 3¾d.; raisins, 2½d.; molasses, 1⅝d.; raw sugar, 2d.; refined sugar, 2¼d.; tea, 4¼d.; whilst the spirit-duty adds 3s. 9d. to every shilling's-worth bought. In the case of tobacco, of every 3d. paid for an ounce, a halfpenny is for the tobacco, and 2½d. for taxes. The excise produces from chicory, £6647; licenses, £1,188,081; malt, £7,544,175; railways, £507,079; spirits, £13,749,542; sugar, £153,893. Stamp-duties, which are prices fixed to stamped papers, on which it is imperative that all legal documents concerning transfer of property, contracts, &c. shall be drawn, yielded £9,998,033. The income-tax is held to be a war-tax, and never regarded as a permanent duty. It is imposed on incomes above a certain amount, now £150, and has varied in amount from 1s. 4d. a pound in the year 1857 to 2d. in 1874. Regarding the Post-office, it may be said that the transfer of the telegraph service of the country to this department of government, effected in 1870, resulted in giving a large net profit on each year's transactions, amply sufficient to pay the interest on the money the state had to invest in buying up the rights and property of the various telegraph companies. The cost of collecting the customs duties is, roughly speaking, about £3, 17s. 1¾d. for every £100 of duty raised. During the period 1858–73, there have been reduced or repealed taxes to the amount of £35,879,871; taxes imposed equal to £15,672,218; shewing a gross reduction of taxation for that period of £20,207,653.

Turning to local taxation for expenditure connected with relief of the poor, police, maintenance of roads, public health, &c. we may subjoin the following table (see next page). Adding local to imperial taxation, we find that the total taxation of Great Britain for 1873 was £102,022,770, or £3, 4s. 1d. per head of the population.

Expenditure.—The chief item of our expenditure is the payment of interest on and management of the National Debt. During the present century it has swallowed up £1,900,000,000 of money. Up to the restoration of Charles II. there was no public debt, for wars were paid for from revenues derived from crown lands allotted to vassals on conditions of feudal service and payments by way of rent. Charles II. abolished these feudal obligations, but exacted nothing in return, so that the landholders became landowners, and compensated the crown by empowering it to tax the people at large by excise duties, &c. Charles II. got into debt to the extent of £500,000, but even then it was called the 'King's Debt,' not the National Debt. With King William 'the Deliverer' came the idea that it was the duty of Britain to keep up the balance of power in Europe, and also the idea of a 'National Debt,' and in 1699 an act was passed allowing a permanent interest of 3 per cent. on it. The wars of the reign of George III. increased the debt from £102,014,018, the amount at his accession, to £834,900,960. The National Debt had been reduced to £763,045,940 on March 31, 1882. This sum is inclusive of unfunded debt and terminable annuities. The total charge for interest and management was £29,665,945 in the same year. Between 1867 and 1882 the debt was reduced by 40 millions.

AGRICULTURE.

The extent to which the soil is cultivated in England is very much misunderstood. Taking the area of the United Kingdom, including the Channel Islands, as being 80 million acres, we find that there are 11,648,245 acres under corn crops; 5,111,944 acres under green crops; 30,058,983 acres under other crops, grass, &c.; 2,412,251 under timber crops—accounting for only about 50 millions of the total acreage of the kingdom. The remaining 30 millions, after making allowance for what is covered by building, bogs, lake, mountain, and waste land, &c. seems, and must surely be, capable, in great part at least, of reclamation and cultivation. Each year since agricultural statistics began to be made up it would appear that the return of cultivated acreage is on the increase. As regards holdings in Great Britain, England seems to be the land of small holdings. Of holdings of ¼ to 1 acre, there are in England and Wales 68,525 acres; in Scotland, 1319; 49,000 of these being held in England by agricultural labourers and working-men. Of holdings of from 1 to 5 acres, there were in England, 93,148; in Wales, 10,041; in Scotland, 21,091. In 1873, in Great Britain, the live-stock was estimated as follows: Cattle, 5,764,549; sheep, 29,427,635; pigs, 2,500,259. The wealth in the shape of profits derived from agricultural enterprise is difficult to estimate. The only indication that can be given of it is the gross amount assessed for income-tax under schedule A. (profits derived from occupation of land, &c.), and in 1880 that came to £69,383,066 in Great Britain and Ireland, shewing an increase of 10 millions in 10 years.

COMMERCE AND INDUSTRY.

The national balance-sheet, indicating the amount of business done by the country with other nations, has never been more satisfactory than in 1872, for in that year more business was done by Great Britain than had ever been done by any other country before. In 1871, the total imports and exports came to £614,590,180. In 1872, they reached the colossal sum of £669,282,458, and of this, £256,267,347 was the value of British manufactured articles exported, as against £223,066,162 in 1871. These figures give an idea of the wonderful wealth, resources, and business talent of the country. It is to be noted too that in 1840 the value of the imports was £62,004,000; in 1872, it was £354,693,624; *i.e.* an increase of 572 per cent., and that in those years the increase in the value of imports per head of the population was from £2, 7s. 6¾d. to £11, 2s. 10d. or nearly fourfold. The value of British produce and manufactures exported in 1840 was £51,308,740; in 1872, it was £256,257,347—an increase of £204,948,607, or 499 per cent.; or, taking the proportion per head of the population, an increase from £1, 8s. 9d. to £8, 1s. Nothing could more clearly demonstrate the wonderful and progressive material prosperity, the growing opulence of Great Britain, than these figures; extending over a period which began with a year when the country was in the deepest distress, and when things that are in the very poorest houses to-day common necessaries of life, were dainty luxuries, rarely indulged in more than once a week—often not once a month—often not from one end of the year to the other. During these 19 years, Britain has had a national traffic amounting to upwards of 8000 millions sterling, and that affords an indication of the vast improvement made in the condition of the people.

Another fact bearing on this matter is, that in 1842–43, the gross amount of income and profits assessed in Great Britain was £251,013,003. In 1870–71, it was £442,188,798. This shews that the national income has in 28 years increased 76·14 per cent. Though British commerce extends all over the world, its dealings on a large scale are with comparatively few countries; half the total import trade being with six countries, viz. United States, France, India, Russia, Germany, and Australia; half the exports going to United States, Germany, India, France, Netherlands, and Australasia. British trade with America and Germany is increasing at the greatest rate.

The chief imports, cotton, corn, sugar, wool, silk manufactures, and tea amount to nearly one-half the value of the total British imports. Two-thirds of the total exports are represented by cotton fabrics, woollens, iron, linen manufactures, coal, machinery. The total imports and exports for 1880 were valued at £697,644,031.

	1870.	1871.	1872.

The progress of textile industry in Britain is illustrated by the fact, that whereas the quantity of raw cotton imported in 1815 was only 99,000,000 pounds, it rose to 891,751,952 pounds in 1855, and to 1,256,984,736 in 1861. Owing to the convulsion in America, it fell the following year to 523,973,296 pounds, and slowly rose to something like its proper quantity in 1866, after the effects of the American war had ceased to operate injuriously. In 1880 it was 14,541,648 cwts. The import of wool has been steadily on the increase. In 1880 it was 463,508,963, of which 226,129,887 pounds are retained for home use. In the cotton, woollen, and worsted trades we find, in 1870, 684,774 persons employed, an increase of 189,067 hands since 1850. In 2483 cotton factories there were, in 1870, 300,480 horse-power in form of steam, 8390 in form of water, and 450,087 hands employed in the trade. There were 125,130 persons employed in 1829 factories of woollen goods in 1870. There were, in 1870, 109,557 persons employed in 630 worsted factories. Minor branches of textile industry employed in 1870 upwards of 60,000 persons, of whom 40,000 were workers in silk, and 22,000 in flax—the rest being engaged in the hosiery and lace trade.

MINES.

The rich mineral wealth of England has done much, as already remarked, to make it so prosperous. There are 30 coal-fields in the United Kingdom of which the Yorkshire one is the largest, having 505 pits in 1880. Stafford had 598; Scotland, 651; Lancashire, 535; Durham and Northumberland, 380; South Wales, 344; Midland group (Derby, Nottingham, Leicester, and Warwick), 335; Gloucester and Somerset, 139. Ireland has a large number of pits, but their output is trifling. As regards output, Durham and Northumberland stand highest, with 34,000,000 tons in 1880. Scotland comes next, with 18,200,000 tons. The total output of the United Kingdom in 1881 was 154,000,000 tons from 3813 collieries. In 1872 there were 393,344 persons employed in the mining trade. Within the last thirty years our exports of coal have increased almost eightfold, as this table shews.

Year.	Exported Amount in Tons.	Value.
1847	2,483,161	£1,087,122
1872	12,712,231	9,858,418
1881	19,587,063	8,785,950

In 1871, the Cornish mines yielded 21,948 tons of iron ore; the Devonshire, 14,125 tons; Somersetshire, 32,884 tons; Gloucestershire, 207,599 tons; Wiltshire, 159,894 tons; Oxfordshire, 28,330 tons; Northamptonshire, 779,314 tons; Lincolnshire, 290,673 tons; Shropshire, 415,972 tons; Warwickshire, 34,075 tons; North Staffordshire, 1,513,080 tons; South Staffordshire, 705,665 tons; Derbyshire, 492,973 tons; Lancashire, 931,048 tons; Cumberlandshire, 1,302,704 tons; York (North Riding), 4,581,901 tons; York (West Riding), 407,997 tons; Northumberland and Durham, 285,297 tons; North Wales, 51,887 tons; South Wales and Monmouthshire, 969,714 tons; Isle of Man, 75 tons: Scotland, 3,000,000 tons: Ireland, 107,734 tons. The total iron ore produced in the United Kingdom came to 18,026,049 tons in 1880, the value being £6,585,806.

Since the discovery of gold in California, Australia, &c. a large amount of bullion has been imported from gold-producing countries to Britain. A certain quantity of it, both gold and silver, seems to be exported again. The value of the bullion and specie imports and exports was as follows:

	1860.	1865.	1870.	1881.
	£	£	£	£
Imports	22,985,196	21,624,201	29,300,980	16,864,403

Imports	7,343,618	12,868,869	22,076,041	..
Exports	..	..	..	5,638,411

In order to conduct this enormous national traffic, we have a large carrying-trade both by land and sea. The land carrying-trade is now chiefly by means of

RAILWAYS.

The first railway was opened in 1825; and from that year to 1850, 6621 miles of railway were laid in Great Britain and Ireland, being 265 miles a year.

TOTAL LENGTH, CAPITAL, PASSENGERS CONVEYED, RECEIPTS, AND WORKING EXPENSES OF RAILWAYS IN THE UNITED KINGDOM.

The number of passengers in 1881 in the United Kingdom was 622,423,000, and the total traffic receipts £63,873,000. In 1872 the passenger returns were—first class, 37,678,538, receipts £4,319,185; second class, 72,459,562, £4,228,201; third class, 312,736,722, £10,318,761.

England and Wales had, in 1883, 12,810 miles of railway; Scotland, 2930 miles; Ireland, 2440 miles. To the total paid-up capital, England and Wales contribute £616,453,000; Scotland, £94,808,000; Ireland, £34,258,000. Of traffic receipts, England got £54,322,000; Scotland, £6,966,000; Ireland, £2,585,000. In an average year, the trains on these various lines travel altogether a total distance equal to more than 7000 times the circumference of the earth, and more than twice the distance of the earth from the sun.

SHIPPING.

The other great branch of the carrying-trade is the mercantile marine. The progress of British shipping since the era of free-trade began is not less remarkable than the progress of the British import and export trade—indeed, it has been a consequence, to some extent, thereof. In 1849, the protective Navigation Laws were repealed, and from that time progress has been very wonderful. In 1872, there were, of sailing-vessels in Great Britain, 19,709, with a tonnage of 4,245,904 tons register, employing 137,101 men. Of steamers, there were 2845, with a tonnage of 1,515,704 tons, employing 66,619 men. Comparing this with the figures for 1849, when the protective Navigation Laws were in force, 1872 shews an increase of 4333 vessels, of 2,665,266 tons in their capacity, and of 51,109 men employed. Further comparing the figures shewing the number of vessels, British and foreign, entering and clearing at ports in the United Kingdom, from and to foreign ports, it is seen that British shipping stands highest. In 1881, the tonnage of vessels entered and cleared at ports in the United Kingdom came to—British, 41,543,259 tons; foreign, 16,406,286 tons; giving an excess of 25,136,973 tons in favour of British shipping. It is also a

curious fact that, whilst the repeal of the Navigation Laws has increased our own shipping-trade, it has not injured the foreign shipping-trade done with us. Comparing 1872 with 1849, the last year of the restrictive laws, there is in the former year an increase in British tonnage represented by 22,228,605 tons, or 444 per cent.; and an increase in foreign tonnage of from 2,949,182 tons in 1849 to 13,781,935, represented by 457 per cent.

MONETARY SYSTEM.

The coin in circulation in Great Britain may be taken at upwards of 75 millions of gold, 13 millions for silver and copper. Taking the last quarter of the year 1872, it seems the average monthly circulation of bank-notes has been—Bank of England, £25,162,000; private and joint-stock banks in England, £4,973,691. In Scotland, the bank-note circulation for the same period was £5,632,112. In Ireland, for the Bank of Ireland, it was £3,254,525; and for joint-stock and private banks it was £4,365,564. The total for the United Kingdom was £43,387,892. In England, the notes are not lower than £5; in Scotland and Ireland they are as low as £1. The Bank of England monopolises the circulation within 65 miles of London. The authorised issue of notes is £15,000,000. The aggregate fixed issues of provincial English banks, originally £8,631,647, have fallen to £6,653,966. In Scotland, the authorised issue is £2,749,271, the average amount of specie held by the banks is £3,500,000, and the actual circulation about £5,500,000, issued by 10 joint-stock banks and upwards of 700 branches. The authorised circulation of the Bank of Ireland is £6,354,494.

Savings-banks.

In the Post-office savings-banks there is a vast amount of capital invested, giving one a fair idea of the wealth of the working-class in the mass. In 1863, in the United Kingdom, it came to £3,376,828, and has gone on steadily increasing by one or two millions each year, till it in 1881 amounted to £36,194,496. Besides these banks, we have others, called trustees' savings-banks, in the United Kingdom; in which we find deposited, in 1863, £40,951,505, but then the deposits decrease until 1867, when they begin to increase but slowly; and even in 1881 they only amounted to £44,140,116. Perhaps the institution of Post-office banks has something to do with this. In 1841, the total deposits in savings-banks were £24,474,689. And the total deposits in Post-office and trustees' savings-banks were, in 1881, £80,334,612, an increase of £55,859,923. The commercial policy initiated by the free-traders has therefore enriched the labouring classes as well as their employers.

THE BRITISH COLONIES AND DEPENDENCIES

embrace about one-third the surface of the globe, and one-fourth its population. The total area of them is 4,500,000 square miles, or 30 times the area of the mother-country. The articles on geography will treat of them in detail; meantime, we may subjoin the following table, giving a brief view of the resources of these portions of the empire:

Name of Country.	Area in Square Miles.	Population.	Revenue.	Public Debt.	Imports and Exports.
			£	£	£
Great Britain and Ireland.....	121,115	31,857,338	76,608,770	732,203,081	669,282,458
Indian Possessions.....	1,558,254	240,000,000	50,110,215	111,542,208	96,676,750
Other Eastern Possessions....	25,268	3,120,297	2,188,164	1,800,000	33,294,748
Australasia.....	2,582,070	2,102,055	9,500,000	39,000,000	64,656,968
North America.....	3,169,375	4,311,044	4,374,163	21,715,283	35,853,601
Africa.....	223,291	898,083	970,765	1,455,000	9,319,209
West Indies.....	12,683	1,010,000	1,068,576	1,000,000	10,616,316
European Possessions	120	155,063	209,098	250,000	15,139,827
Various Settlements.....	96,171	185,542	550,000	650,000	5,314,265
Totals.....	7,788,347	283,639,422	£145,579,751	£909,615,572	£940,154,142

EMIGRATION.

During the years 1840 to 1872, the total number of emigrants from Great Britain has been 6,578,058. Of these, 4,487,497, more than two-thirds, however, have not gone to the colonies, but to a rival country—namely, the United States. From 1840 to 1872, 956,748 emigrants have gone to British America; 958,077 to Australasia; and 175,736 to other places. In 1881 the numbers were, for United States, 176,104; British America, 23,912; Australasia, 22,682; other places, 20,304.

POPULATION AND SOCIAL STATISTICS.

A special part is devoted to this subject, so here we may be brief. The total area of the British Islands is 121,115 square miles, with a population in 1881 of 35,262,762; this includes the army and navy and merchant seamen abroad. The population from 1801 to 1841 is given by estimate. The number of families in 1841 was incorrectly taken. It will be noticed that the figures under the head 'increase' for Ireland 1841–71 indicate a *decrease* of 2,811,370. The census of 1881 shewed the population of England and Wales to be 25,968,286, an increase of 3,256,020 since 1871; Scotland was 3,735,573, an increase of 375,555; and Ireland 5,174,836, a decrease of 237,541: making a total increase in the United Kingdom of about 3½ millions. The census of 1871 shewed an increase of 519,612 inhabited houses in England and Wales; of 18,965 in Scotland; 944 in Channel Islands and Man; but in Ireland a decrease of 33,927. The net increase of inhabited houses for the United Kingdom was 505,620. The population in urban districts, in England and Wales and Scotland, seems to have grown about twice as fast as it has done in the rural districts. Although

POPULATION ENUMERATED IN ENGLAND AND WALES, SCOTLAND AND IRELAND, AT EACH DECENNIAL CENSUS, 1801–71, AND ISLANDS IN THE BRITISH SEAS, IN 1851–71, EXCLUSIVE OF ARMY, NAVY, AND MERCHANT SEAMEN ABROAD.

England and Wales.	Population.			Increase.		Families.		Inhabited Houses.

* Decrease.

there were nearly 5,000,000 of inhabited houses in Great Britain in 1871, only 796,452 were assessed for house-duty; of these, 723,514 were assessed under £100 rent, only 72,938 above that. There were 92,922 assessed at £20, 299,894 under £30, and 561,003 under £50. It seems incredible that in a country of such wealth as this, of 5,000,000 houses, only 796,452 should be taxed as within the £20 rental limit, and it is thought the tax is evaded in many cases by the houses being let or valued at something just within the limit, to evade the tax.

PAUPERISM.

Notwithstanding the flourishing state of the nation, 1 in every 25 of its adult inhabitants is a pauper—a fact worthy of the gravest consideration. During the 33 years of great national prosperity from 1840, the poor-rates of England and Wales came to £283,294,738, of which, in actual relief of the poor, were spent £195,043,694, and for other purposes, £85,467,491. In Scotland, from 1846 to 1872, the poor-rates came to £18,401,879, the expenditure was £18,179,544. In Ireland, from 1840 to 1872, the poor-rates collected were £25,401,482, the expenditure £24,629,598. In England and Wales, £8,007,403; in Scotland, £862,171; in Ireland, £868,820, were spent in relief of the poor by rates in 1872. As regards

CRIME,

the following little table will give a concise view of the leading facts and figures bearing on this subject:

CRIMINAL CONVICTIONS, 1858 TO 1872.

Year.	England and Wales.	Scotland.	Ireland.
1858	13,246	2850	3350
1859	12,470	2563	2735
1860	12,068	2414	2979
1861	13,879	2418	3271
1862	15,312	2693	3796
1863	15,799	2438	3285
1864	14,726	2359	3000
1865	14,740	2355	2661
1866	14,254	2292	2418
1867	14,207	2510	2733
1868	15,033	2490	2394
1869	14,340	2592	2452
1870	12,953	2400	3048
1871	11,946	2184	2257
1872	10,862	2259	2565

There is manifest here a gratifying decrease of crime—comparing the figures not one year with the one before it, but regarding them as a whole. The number of paupers in receipt of relief in the unions and parishes of England and Wales in 1881 was 803,126; in Scotland, 97,787; in Ireland, 109,655. The number of criminal convictions in the same year were respectively 11,353; 1832; and 2698.

MILITARY AND NAVAL ORGANISATION.

THOUGH we are very far from maintaining with Hobbes, that, in a state of nature, every man instinctively wages war against his neighbour, it is clear, from a study of the remains left by primeval man, in the shape of rude weapons, &c. that the Golden Age of peace lies far beyond the dawn of history, far beyond the still grayer dawn of even prehistoric antiquity. The desire on the part of people who have much to get more, and to get it by taking it from those that are weaker than themselves; and the equally strong desire on the part of those who have little of this world's goods, to augment their possessions by despoiling their richer neighbours, at all times in the history of mankind have impelled nations as well as individuals to wage wars, offensive and defensive, against each other. In later times, wars have arisen from other causes than mere lust of material conquest. We have had wars for ideas; and of all wars, the most sanguinary are those waged on behalf of certain social and religious ideas. The wars of the old French Republic—of the Communists at Paris and Carthagena, but ended the other day—and of the Crusades, are specimens of political, social, and religious conflicts. Such wars are not always pure evils. They are often to society what surgical operations are to the human body, painful but powerful remedies for cankering malignant disease—remedies which act by removing the old corrupt growths, and enabling more healthy forms of organisation to take their place. In this light, the wars of the French Revolution, which stamped out the frivolous feudalism and effete civilisation of the 18th century, in spite of all the blood and treasure they cost, are not altogether to be regretted—by us at least, who breathe so freely in the purer, clearer, political atmosphere of the 19th century.

In the early stages of a nation, when few have settled occupations, and war is a matter of muscle and courage, rather than of discipline and science, the armed force naturally consists of all able-bodied men. As civilisation advances, and the division of labour becomes more distinct, the duties of war are delegated to a portion only of the community; at first, taken from other occupations merely when actual warfare requires it; ultimately, as the lines between different pursuits become more marked, and each advances to a science, detached altogether from the businesses of peace, and devoted wholly to war or preparation for it. These stages are represented, the first by a militia, which follows soon after the settlement in a fixed place of a wandering nation; the second, by a standing army, which only appears at an advanced period in a nation's life. In modern times, offensive war is by all civilised nations intrusted to the standing army; but for defensive purposes the older forms still exist, and form the military 'Reserves.'

The tendency of modern civilisation is to substitute armed nations, as in Switzerland, and partially in Germany, for standing armies, such as those of France and Russia. An armed nation will only engage in a popular war, and such an army is not likely to let itself be made the passive instrument of tyranny in the hands of a sovereign. In a national army, the occupation of a soldier may not be an ignoble one. He is not a mere mercenary who makes war for money and loot. He gives up remunerative civil employment, in order to help to protect the community in its peaceful pursuits, and it is but just he should be paid a little more than will keep body and soul together by the people he protects. His pay is but a fraction of the premium due for the insurance of the national life every state effects when it establishes and maintains a national army. A soldier of such an army is not a professional man-slayer. He kills because he is commanded to make war, and the end can only be attained by violence; but he prefers to gain victory without slaughter: on the other hand, he is ready to lay down his life rather than let the enemy overcome the policy of his country.

BRITISH MILITARY SYSTEM.

In Saxon England the war-force was a militia of a local character, each shire, hundred, and tithing being bound to furnish its quota of armed men for the king's service on occasion of national emergency. The strength of this force lay in its admirable archers. Under the Normans the array took a more feudal form, each baron or knight appearing in the field, at the call of his suzerain, with his armed retainers. At this period the strength was principally in the knights and men-at-arms, who, encased in armour, took little heed of the undisciplined footmen, who as spearmen, billmen, and slingers constituted a rabble infantry. Under the Plantagenets, the races had become sufficiently assimilated for the monarchs to gladly add bodies of Saxon archers to their armies. Henry V. appears to have had an army in the modern sense, paid by the crown, and but little dependent on the feudatories. The Wars of the Roses put an end to feudal musters, and thenceforth the wars of England were waged by royal armies. These, however, were not standing armies, for each was disbanded when the occasion ceased for which it had been raised. The jealousy of standing armies manifested by the people, finds legal expression in the 'Bill of Rights' of 1690, which declares that 'the raising or keeping of a standing army in time of peace, unless it be with the consent of parliament, is against law;' and the Act, annually passed, for bringing into force the Army Discipline and

Regulation Act, like the Mutiny Act which it superseded in 1879, declares this formally in one of its first paragraphs. Parliament, in sanctioning the maintenance of such a force, never does so for more than one year—and it can extinguish it by a couple of votes when necessary. Practically, the strength of the army for each year is decided by the government of the day, at a cabinet meeting, held shortly before each annual session of parliament. The cabinet act on data forwarded by the commander-in-chief, and the decision of the ministry is carried out by the War Secretary, who frames 'the army estimates,' or detailed statement of the proposed strength and cost of our military force, for acceptance and sanction by the House of Commons. These estimates are submitted to the House in certain chapters or 'votes,' and discussed and criticised. Then parliament is real ruler of the army in another way. Without its consent, military discipline could not be kept up, or a military code enforced in time of peace. In theory, the army is in direct subservience to the sovereign; but in time of peace, without the special sanction of parliament, the sovereign cannot subject a soldier to the operations of any other law save those applicable to civilians. Therefore parliament furnishes the sovereign with the means of enforcing military discipline independently of the common law, by passing annually the 'Army Discipline and Regulation Act.' This Act superseded in 1879 the time-honoured, annually renewed 'Mutiny Act,' which enabled the crown to enforce the 'Articles of War,' or military code by which the British army is ruled.

The strength of the army varies, of course, each year. The estimates for the year ending March 1880, provide for a force of 7384 commissioned officers; 17,241 non-commissioned officers, trumpeters, and drummers; and 111,000 rank and file—being a total of 135,625, including the depots of regiments in India, and the general and departmental staff. The following statement shews the strength of the different branches of our regular army in 1883-84, the cost of which is defrayed from army grants:

Branches.	Officers.	Non-commissioned Officers, Trumpeters, and Drummers.	Rank and File.
Officers on General and Departmental Staff—			
General Staff	242	163	..
Army Accountants	281	70	..
Chaplains' Department	87	..	..

Staff of Militia, &c.	629	6,453	..
Miscellaneous	160	498	148
Total force, cost of which is defrayed from army grants	7,199	19,423	110,910

The total force of the British army in India is about 61,000 men of all ranks. So far, we have only considered the strength of the regular army; this, however, does not represent the total armed force of Great Britain. From the earliest times, we have had in Britain an army of reserve. In early times we had the 'Fyrd;' then the 'Trained (or Train) Bands;' then the militia, which is the modern form of the two former forces, and which is the ancient constitutional defensive force of the empire. The militia is not bound to serve anywhere out of the three kingdoms. This formed the first line of reserve; and we include in it a mounted militia known as yeomanry, consisting of farmers and country gentlemen, mounted on their own horses, but otherwise armed, and when on duty, paid by the crown. Behind this, we have the second line of reserve—the volunteers, who in 1804 numbered 405,000 strong; and lastly, the *levée en masse*, or general call to arms, which would muster over 3 or 4 millions of able-bodied, but untrained and undisciplined men. The Estimates recognise four classes of reserves or auxiliary forces—militia, yeomanry, volunteers, and enrolled pensioners and army reserve forces. The total number of militia in the Army Estimates for 1883–84, is put down at 142,874, comprising a permanent staff, and including the militia reserves. The militia are turned out for 21 days' training per annum. The yeomanry amount to 14,404, including their permanent staff. The volunteer force numbers, including staff, 247,921. The army reserve (a body of much greater importance since the short service system was introduced) is divided into two classes: in the first class there are 33,500 men; and in the second, 9000 men.

A general idea of our military organisation may be gathered from the following statement: Since 1873, the United Kingdom has been divided into 13 military districts, each under command of a general officer. Under these are sub-districts—in the case of the infantry, 102; in that of the artillery, 12; in that of the cavalry, 2 in number, commanded by colonels—the whole, districts and sub-districts, and their respective commanders,

being under the direct authority of the commander-in-chief. The military force of an infantry sub-district consists of a brigade. It is composed of two line battalions—one of which is generally abroad, the other at home—two militia battalions, the enrolled pensioners and army reserve, the brigade depot, and the local rifle volunteer corps. In an artillery sub-district there are the royal artillery, the militia and volunteer artillery, and the artillery of the army reserve. In a cavalry sub-district, the force consists of the regular cavalry, the yeomanry, volunteer, and reserve cavalry. The colonels commanding these sub-districts are necessarily officers in the regular army, and they are responsible for the efficiency and discipline of all the various forces, regular and auxiliary, in their sub-districts. Thus it will be seen that the auxiliary volunteer forces are no longer out of the pale of our national army organisation, but that regular army, and auxiliary volunteers and reserves, all form one homogeneous defensive force.

As regards the sources from which our soldiery are derived, the following table gives one an idea of the numbers of men contributed to the army by each of the three kingdoms :

Army.	Natives of England.	Natives of Scotland.	Natives of Ireland.
Household Cavalry....	940	172	93
Cavalry of the Line....	11,661	1,091	2,429
Royal Horse Artillery..	4,192	330	899
Royal Artillery.....	18,710	2,020	5,589
Royal Engineers.....	3,024	1,108	630
Foot Guards.....	5,604	604	108
Line Infantry.....	71,262	10,232	38,812
Army Service Corps....	1,827	260	333
Army Hospital Corps..	481	68	199
Total.....	117,701	15,885	49,092

PERSONNEL.

By the personnel of the army, we mean the men belonging to the various combatant and administrative branches of the army.

Infantry.—By the recent changes the 109 regiments of the line, with the Rifle Brigade, have been so reorganised as to form 71 territorial regiments, having linked battalions of line and militia. Since 1881 the old numerical designations have made way for territorial ones, and many of the smaller regiments have ceased to have a separate existence, having become the second battalion of one of the new regiments. Thus the former 94th is now the second battalion of the Connaught Rangers ; the 73d is the second battalion of the Black Watch or Royal Highland Regiment. Some of the old and familiar descriptive (not numerical) names are still retained by the regiments ; thus the East Kent Regiment is also known as the Buffs.

The Foot Guards include the Grenadier, Coldstream, and Scots Fusilier regiments, all celebrated in history, from the days of Marlborough downwards. They are *corps d'élite*, the flower of the British infantry. The men are picked men, of great stature and strength ; the officers are to a great extent members of the nobility, or of the families of very wealthy commoners.

The Colonial Corps consist of the West Indian Regiments and Malta Fencibles. The West Indian regiments are composed of negroes, with white officers and sergeants, and are enrolled for duty in the West Indies and in Africa. Under good leading, they render gallant service. The Malta Fencibles is a corps of artillery, in which officers and men are alike natives.

The infantry are organised into regiments, a man enlisted for one regiment serving throughout his time in that same corps. Officers occasionally exchange from one regiment into another ; but their ordinary service and promotion are in one regiment throughout their career, until they attain the rank of general officer. As regards strength, a regiment is somewhat indefinite, for it may include any number of battalions ; and the number of companies in a battalion may vary from 8 to 14, while the men in a company range from 60 to 100, or even more. Each battalion comprises twelve companies, of which two remain at home to form a depot of instruction for recruits when the regiment is sent abroad. A company is under the command of a captain, who has a lieutenant and a sub-lieutenant, or, as he used to be called, an ensign, to assist him. His men consist of 4 corporals, 1 pioneer, and 60 privates ; while, as an intermediate class—the non-commissioned officers—there are 1 colour-sergeant, 3 sergeants, and 2 drummers. The total strength of a company is therefore 74 officers and men of all ranks, and 12 such companies form a battalion. In command of the whole battalion (which is usually divided into right and left wings) is a lieutenant-colonel, assisted by a major for each wing ; an adjutant, who superintends drill ; a quartermaster, who looks after quarters, clothing, &c. ; a paymaster, who pays the corps ; a surgeon-major, and one or two surgeons, whose functions are obvious. There are also certain non-commissioned officers of the regimental staff, as the sergeant-major, schoolmaster, quartermaster-sergeant, sergeant-instructor of musketry, band-master, drum-major, paymaster-sergeant, armourer-sergeant, hospital-sergeant, orderly-room clerk, band-sergeant, sergeant-master-tailor ; besides musicians and hospital-orderlies. Finally, to complete the corps, there is the colonel, who, however, has no functions to perform, his office being purely a sinecure, and constituting an honourable pension of a thousand a year for a general officer.

For purposes of drill, each *company* is divided into two *subdivisions*, and each subdivision into two *sections*. When the men stand in position, a 'rank' consists of a row of them taken sideways ; a 'file,' of a row taken from front to back. Hence the body of private soldiers are spoken of as rank and file.

The above description shews the organisation of a battalion on its peace-footing, its strength being about 930 men. On war breaking out, nothing is easier than to augment this strength. The whole machinery of officers and non-commissioned officers is ready ; it only remains to add to the privates by new enlistment. The recruits are distributed among the companies, where their small number among the disciplined soldiers renders their inexperience immaterial. A battalion may thus be increased 30 per cent. without seriously diminishing its efficiency.

The 60th Rifles and Rifle Brigade wear dark-green uniforms ; certain Highland regiments are clothed in the costume of their reputed clans,

with tartan and kilt. The other regiments wear scarlet tunics, black shakoes or bear-skins, and black, dark-blue, or white trousers, being distinguished from one another by the colour of the facings—that is, the collars, cuffs, and pocket-lapels. Each regiment and battalion has also two ensigns or colours: one the Queen's colour, consisting of the Union-jack; the other, the regimental ensign, bearing the emblem of the corps, and around it memorials of the different actions in which it has distinguished itself. The arms of the men are the rifle and bayonet; non-commissioned officers use a sword-bayonet; and the sergeant-majors have swords; while officers carry the sword alone, except that in battle they usually arm themselves with revolver-pistols. In dress, the difference, except as regards fineness of material, between officers and men, is as little conspicuous as possible: the officer wears a shoulder-sash of crimson silk; the sergeant also has a shoulder-sash, but of crimson cotton.

Cavalry.—The British cavalry comprises thirty-one regiments: Life Guards, two regiments; Horse Guards, one regiment; Dragoon Guards, seven regiments; Dragoons, three regiments; Lancers, five regiments; Hussars, thirteen regiments.

These are, as regards equipment and stature, divided otherwise into Guards, three regiments; Heavy Cavalry, four; Medium, eleven; Light, thirteen. Like infantry, cavalry is organised in regiments, though the number in each is somewhat smaller. Each regiment comprises eight troops, corresponding to the infantry companies. The ranks are much the same as in the infantry; the lowest grade of officers, however, were, previous to recent reforms, styled cornets. Each regiment has on its staff a riding-master and a veterinary surgeon, for whom no necessity arises in the infantry. Also among the non-commissioned officers, the principal of each troop is not called a colour-sergeant, but a troop-sergeant-major. The private soldiers are not spoken of as rank and file, but commonly as 'troopers.' The drummers of the infantry are represented in the cavalry by trumpeters.

Twelve regiments wear scarlet uniforms, nineteen blue. They are further distinguished by their facings and ornamentation, which is far more abundant than in the infantry. The Life Guards and Horse Guards are adorned, rather than protected, by polished steel cuirasses and helmets. The other regiments wear on their heads black and brass helmets, bear-skin caps, busbies, and leather shakoes; these bear various plumes. The regiments also carry colours, called guidons or pennons, which are smaller than infantry colours.

The arms of cavalry are the sabre for all, varying from 40 to 34 inches in length; a rifled carabine (usually breech-loading) for all troopers except lancers; a rifled pistol in the holster for non-commissioned officers of all cavalry, and for lancer troopers, whose principal weapon is a lance 9 feet 3 inches in length, loaded and sharp at the point. The small pennons on these lances give their gay air to regiments of lancers. Officers carry swords and their own pistols—usually revolvers.

The horses are bought at the different horse-fairs, as four-year-olds of about 15 hands 2 inches height, and at prices not exceeding £35. Two troops of cavalry constitute a squadron, and a regiment may contain any number of squadrons; but the number is not often less than three nor more than four. There are no battalions of cavalry; and if it is desired to augment a regiment, one or more squadrons must be added. In computing the force of cavalry with an army, the calculation is made by squadrons. In battle, the cavalry mode of fighting is by a charge in a deep compact mass of thirty or sixty troopers wide, and many deep. In such a charge the weight of man and horse is an important ingredient, infantry formed in square being alone able to resist heavy cavalry charging in mass. So long as the weight does not impair the speed or overcome the endurance of the horse, there can be no question of the superiority of the heavy trooper, save for the general duties of a campaign, where the light-horse, well mounted, on small hardy animals, and armed with the lance, possess advantages over all other cavalry.

Artillery.—In the British army, the artillery constitutes nominally one vast regiment, known as the 'Royal Regiment of Artillery;' but except as regards the promotion of officers, this unity is only nominal. The regiment is divided into six Horse Brigades, nine Field Brigades, thirteen Garrison Brigades, three Mixed Brigades, one Depot Brigade, and one Coast Brigade, each of which, except the Depot and Coast Brigades, has a colonel-commandant, who is a general officer, holds a sinecure, and corresponds to the colonel of an infantry regiment. The strength of a brigade varies from 600 to 2500 men, according to the duty required.

Horse Artillery has all its officers and men mounted either upon horses or the limbers and ammunition wagons, to enable them to keep pace with cavalry, that being the department to which horse artillery is usually attached in the field.

Field Artillery, as its name implies, is ready to march with an army and operate in the field. It is only required to keep pace with infantry.

Garrison Brigades are trained in precisely the same manner as field brigades, and can be forthwith converted into that formation; but as their duties are confined to the guns of fortresses, or of batteries in a siege, they have no horses attached to their establishment.

The Depot Brigade has its headquarters at Woolwich, and serves as a nursery in which recruits are trained for duty in the other brigades, and to which invalids from foreign service are sent pending recovery.

The Coast Brigade is a sort of veteran establishment, composed of old artillerymen selected for good conduct and long service. The officers are mostly promoted from the ranks of other brigades. The duty is to take charge in small detachments of the minor forts and towers which guard the coast. This is of the nature of a resident service, in which the men are able to have their families with them, and forms an appropriate reward and rest for deserving old soldiers.

The brigades (except the Coast and Depot) are divided into batteries, which form the unit in calculating the force of artillery with an army. Each battery consists usually of six guns—Armstrong, 6-pounder, 9-pounder, or garrison—and has for officers one captain, one second captain, three lieutenants, an assistant-surgeon, and a veterinary surgeon; with men and horses in proportion to

the weight of ordnance. The strength and equipage of a 9-pounder Armstrong battery of field artillery on active service may be adduced as a specimen :

Officers	8	
Non-commissioned officers and men	256	
Artificers	13	
		277
Riding horses	35	
Draught horses	212	
Bât horses (pack animals)	8	
		255
9-pounder Armstrong guns	6	
9-pounder rocket carriage	1	
Ammunition wagons	18	
Spare gun carriage	1	
1 forge wagon, 1 store wagon, 2 general service wagons, 1 store cart	5	
		31

Ammunition.....1272 rounds for guns.
102,960 rounds for small-arms.
100 rockets.
10 sets of artificers' tools.
6 months' materials for repairs.

As the above includes neither the food nor tents for the men or horses, it may be imagined what are the impedimenta of an army, when forty batteries are by no means an extraordinary force of artillery.

In siege works, where very heavy ordnance and mortars are brought into operation, under the collective title of siege-train, a different and temporary organisation of the artillery takes place. In the field, the artillery of the army is collected into divisions, with the horses picketed round, so that it may be put in motion at a minute's notice. This formation is called the Park of Artillery.

Engineers.—The corps of Royal Engineers is an important and the most scientific adjunct of the army. The officers undergo very high training in pure and applied science; the men are only admitted if proficient in some trade of a constructive character, as proved by actual trial. Formerly, the men were styled *Sappers and Miners*, and at a still earlier date *Military Artificers*, the officers only being called Engineers; but in 1857 the term Royal Engineers was extended to the whole corps. Officers and men are highly paid ; and from the experience they obtain in scientific duties, are in high request in colonies and civil life for many important situations. From this cause many leave the corps prematurely. The men embrace the following trades : carpenters, joiners, masons, bricklayers, smiths, wheelers, coopers, painters, plumbers, engine-fitters, miners, printers, harness-makers, surveyors, draftsmen, photographers, tailors. From this it will be seen how various the work is which the corps is called on to perform. In time of peace the engineers are the general artificers of every garrison and camp, in addition to their prime duty of keeping the fortresses in repair. In war-time, if on the march, they form bridges over rivers, render roads practicable, throw up field-works to cover the army; in attacking a place they take the principal part in forming the approaches and batteries. They also construct mines, and in case of assault provide means of crossing the ditch and scaling the walls. In defensive works, they countermine, to prevent the mines of the besiegers from doing mischief, and repair the ramparts as fast as the enemy's fire damages them. The strength of the engineers consists of about 5000 men, of whom the privates are called Sappers. The organisation is in forty companies and two troops of train. Four companies are employed on the Ordnance Survey, six form an instructional depot at Chatham, and the remaining companies are distributed at home and in the colonies. Besides these forty companies, however, there are 260 officers employed in India, who have no men of the corps under them, the non-commissioned officers and men there being native Indians. The functions of the engineer train are to carry the intrenching and other apparatus of the corps, and more especially the train of pontoons for bridging rivers which obstruct the march of an army. The uniform of the corps is a scarlet tunic; blue facings ; Oxford mixture trousers, with scarlet stripe ; fur busby of black sealskin, with white plume and blue bag. In some foreign armies the pontonniers are organised as a distinct body.

Military Train.—This is formed for the purpose of providing armed transport for the army in time of war. It is a corps of mounted infantry, and during peace is maintained in somewhat a skeleton condition. It is, however, capable of unlimited expansion in the field. Its duties are to carry the provisions, the wounded, the tents, and the reserve ammunition. In the Peninsular war the Duke of Wellington found the necessity of organising a transport corps, which was called the Royal Wagon Train ; but we forgot that lesson, and entered the Crimea without any proper transport, until Colonel M'Murdo enrolled the Land Transport Corps, which, two years after, was remodelled into the Military Train.

Occasional Corps.—The necessities of actual warfare generally lead to the formation of temporary, local, or peculiar forces, such as foreign legions of mercenaries; and in the Russian war, the expensive Army Works Corps of navvies, organised by Sir Joseph Paxton, the organisation and status of which was, however, purely civil, its duties being to make railways, and throw up earthworks at spots not actually under fire ; native transport corps, such as the Coolie corps in China, or the corps of Fantee men and women engaged in the late Ashantee war.

Staff.—No matter how gallant, strong, or well disciplined an army may be, it can perform no efficient service unless its operations be directed by a properly organised staff of commanders. For this purpose, from two to four regiments are banded together as a brigade under a brigadier-general or major-general, who has a brigade-major to assist him, in somewhat the capacity of an adjutant ; two or more brigades are associated, with perhaps some batteries of artillery, and companies of engineers and military train, to form a *division*, under a lieutenant-general, whose staff consists of an assistant-adjutant-general and an assistant-quartermaster-general ; two or more divisions, including all arms, are thrown together into a *corps d'armée*, as the command of a general. For his staff he has a deputy-adjutant-general and deputy-quartermaster-general, with their subordinates; and an assistant military secretary. Over all the *corps d'armée* is the commander-in-chief, who may be a general or field-marshal. His staff is brilliant and numerous, having at its head his adjutant-general, quartermaster-general, and military secretary. Besides these officers, every general officer, according to his rank, has one or more young

officers attached to him as aides-de-camp. These are detached from their regiments, and their employment is to convey the orders of their general to the different sections of his command. They form his personal staff, and share his tent.

Staff-officers receive a high rate of pay for staff duty in addition to their other pay as officers of their rank in the army. They wear broad gold shoulder-belts and cocked-hats with lofty white plumes. As all staff-officers are mounted, their plumes render them very conspicuous as they gallop about on the field of battle.

We have now described the organisation of the fighting men of the army, and how they are commanded; but to keep our men up to the fighting mark, they require to be fed, housed, doctored, taught, and—unfortunately—punished; and for each of these services there is a distinct body of officers and men, forming the

Administrative Departments of the Army.

These departments are all now merged into the Control Department, of which there are three divisions—relating to (1) the food, (2) the shelter, (3) the stores of the army. The chief officers of the department are controllers, deputy-controllers, &c.

Food.—The collection of food, its preservation, and punctual distribution to the sections of the army, are the all-important functions of the Commissariat, which is superintended by a commissary-general, deputy, assistants, &c. The formation of magazines of food, and the conveyance of great supplies to the requisite point, in perhaps a devastated country, require a great power of organisation in the superintendent of the commissariat. Attached to this department is the commissariat staff corps, a body of disciplined butchers, bakers, &c. who ply their trades with the army, and furnish the troops with fresh meat and bread.

Shelter.—In times of peace, and when not encamped, the soldiers are lodged in capacious barracks; each of these is in charge of an officer styled a commissary of barracks, who has barrack-sergeants and labourers to assist him in maintaining it in a habitable condition. When the troops are encamped, or in the field, they are housed in tents during the summer, and in huts during the winter. These are under the charge of the quartermaster-general's department, which is responsible for their preservation, cleanliness, and issue in proper numbers to the troops.

Medical Attendance.—Soldiers are liable to disease—first, in a small degree, from wounds received in action; secondly, and more, from the hardships of campaigning; thirdly, and in a proportion far exceeding the other two together, from the results of their own excesses. To counteract disease, and superintend the general sanitary arrangements, the army has a very large staff of medical officers, comprising inspectors, deputy-inspectors-general, surgeons-major, and surgeons. The officers are fairly paid; but the upper ranks are too few to insure rapid promotion, and much of the duty lies in tropical and unhealthy climates. These causes render the Army Medical Department unpopular with the profession. The Purveying Department consists of non-professional officers, who have charge of the food, clothing, and comforts of the sick. The Army Hospital Corps is a body of ward-masters, male nurses, cooks, &c. for service in the military hospitals: they are under the orders of the surgeons. There is likewise a staff of female nurses for the general hospitals, originated by Miss Florence Nightingale. Every regiment has its surgeons, who attend their patients in the regimental hospital, which is a hut or tent set apart for the service. More serious cases are sent to the divisional hospital, where there is a deputy-inspector-general and medical staff. On a still larger scale is the general hospital, established usually in rear of the army, where there is a full staff of officers, nurses, &c. with every appliance that medical skill can suggest, under the direction of an inspector-general.

Stores.—An army requires stores in a variety and to an amount which seem quite incredible to a civilian. It is of prime necessity that these should be duly supervised as to their storage, classification, and issue, for melancholy results have ere now ensued from ill-organised arrangements for the army stores. The Control Department undertakes this duty. It consists of commissaries of stores, their deputies, assistants, &c. in five grades.

Divine Service.—Having provided for the welfare of his body, the state turns its attention to the soldier's spiritual interests. At every military station of importance there is a chaplain, who is a commissioned army officer; where the troops are too few to justify this, they attend a neighbouring church, the incumbent of which is paid according to the space occupied. Army chaplains are not allowed to interfere with the secular instruction of the men. They are of three denominations—namely, Church of England, Roman Catholic, and Presbyterian, all of whom rank equally. Their pay rises, with length of service, from 10s. to 22s. 6d. a day. When a man joins the army, he is required to declare his religion; and he is compelled to attend the ministration of that religion once every Sunday, when practicable. The chaplains also superintend the Sunday schools.

Instruction.—For the instruction of officers there is the Staff College at Sandhurst, through which all officers must pass at two very severe examinations before they are eligible for employment on the staff. The Royal Engineer establishment at Chatham is for instruction of officers and men in their professional duties. The School of Gunnery at Shoeburyness affords practical teaching to the artillery; while the Schools of Musketry at Hythe and Fleetwood do the same for the infantry. For general instruction in drill and discipline of the depots of corps on foreign service, the depots furnish ample time and force. In all corps, gymnasia have been established, to afford the men amusement, and develop their physical powers. At Netley, near Southampton, is a Military Medical School, to impart a military, surgical, and hygienic training to candidates who have already passed as qualified practitioners. The camps at Aldershot and Curragh, while being defensive points at which strong forces are concentrated, are, at the same time, great schools for tactics and manœuvring.

As regards general instruction for the men, each regiment has on its establishment a trained schoolmaster, who gives lessons gratuitously to

all soldiers who choose to attend his classes. There is also a schoolmistress, who teaches the daughters of soldiers, and the sons under eight years of age; their elder sons are taught by the regimental schoolmaster. In addition to ordinary elementary education, the schoolmistress conducts an industrial and an infant school during the afternoon. If the pupils are numerous, she is allowed pupil-teachers and monitresses to assist her. The charge is one penny a month for each soldier's child attending the school; for the child of an officer, half-a-crown must be paid monthly; and contractors and other civilians employed in connection with military works, may send their children to the school of a neighbouring regiment for a fee of 5s. each a month: the school is likewise open to the children of soldiers on foreign service or orphans of soldiers gratuitously, and to the children of pensioners residing near at 3d. a month. It is strictly forbidden that any distinction be made between these classes of children in their treatment in the school.

Punishment.—Implicit obedience and subordination are the only means of maintaining that exact discipline which distinguishes an army from an armed mob; and for securing this, summary powers are necessarily vested in commanding officers. Formerly flogging was inflicted upon slight occasion; latterly, it was had resort to only in time of war. But after much discussion and strong opposition, flogging was finally abolished in 1881, a system of other summary punishments being prescribed instead. The laws of discipline constitute martial law, and are detailed in the Articles of War. These are necessarily severe, and the penalty of death is annexed to numerous crimes which would be but lightly punished under the civil code; but it is usually only under circumstances of actual war that the full punishment is inflicted. In military life the idea of trial by the prisoner's peers has no existence; the court to which all offences are referred is a court-martial composed in nearly every case of his superiors. The powers of a military court-martial depend upon its constitution as a regimental, district, or general court; but the sentence requires confirmation by superior authority.

The punishments usually inflicted are degradation of rank, dismissal (with or without ignominy), loss of good-conduct pay, imprisonment, or extra drill. The imprisonment takes place in a military prison, of which there are several. Time spent in prison is occupied in carrying cannon-balls from one place to another, and then carrying them back again. Added to this, the prisoner is put on rations which would be called starvation in a civil jail; and yet, strange to say, nine prisoners out of ten come out of prison heavier and healthier than they went in.

Rewards.—In the punishments, the military code is severe and rapid; in rewards, it is not remiss in acknowledging merit. For officers, the rewards are brevet promotion, the Order of the Bath, and certain sinecure appointments. For men, there is good-shooting pay; extra pay for being a good swordsman, gunner, or lancer; but the principal reward for steady and continued merit is good-conduct pay, the theory of which is as follows: After two years' service, if a soldier has committed no offence of sufficient magnitude to cause his name to be entered in the Defaulter Book, he is granted an additional penny a day, and a chevron or badge on his arm. After every five years more of immunity from heavy offences, he receives a further penny and badge up to 6d. a day, which he is able to hold with his pension when he retires from the service. By misconduct he forfeits a penny at a time, and can only regain it by a period of renewed merit. For officers and men there are silver medals in commemoration of campaigns, with clasps for the battles in which they have been engaged; and, most honourable distinction of all, there is the Victoria Cross, open to all ranks for conspicuous valour in the field. For officers, this cross is unaccompanied by pension; but for men, it carries a pension of £10 a year for life. Besides the foregoing, there are rewards for meritorious service, which consist of annuities of £100 a year to officers who have served long and well; and annuities of from £5 to £20, or gratuities, accompanied by a medal, for deserving soldiers.

Appointment, Promotion, and Retirement of Officers.

Candidates for commissions in the Artillery and Engineers, now, as formerly, must pass an open competitive examination, for admission as cadets to the Royal Military Academy, Woolwich. After a course of professional study there, they pass a professional examination, and get gazetted to regiments if found duly qualified. After the candidate joins his regiment, promotion is by seniority. In the other branches of the army, admission and promotion up to the rank of lieutenant-colonel was, until lately, by purchase. A very small number of commissions were given to non-commissioned officers of high merit, and to distinguished students at the Cadets' College, Sandhurst. The rest were bought by persons desirous of becoming officers, who, if they were not graduates of universities, or promoted from the ranks for merit, passed a not very stiff examination; and if they were not 'plucked,' were gazetted to their regiment as commissioned officers. After that, promotion was by purchase—the officer buying each step in rank up to the grade of lieutenant-colonel, as vacancies occurred; and if unable to buy it, giving place to the next man below him in rank who could afford to do so. The prices varied with the rank, from £500 to £5000—and even higher, as fancy prices were often exacted. By Royal Warrant, in 1872, this system was abolished, and the Line put, as regards entrance and promotion, on the same footing as the Artillery and Engineers.

An officer may rise in his regiment to be a lieutenant-colonel (or to be a colonel in the Artillery or Engineers), and this is *substantive rank;* but after he has attained the rank of captain regimentally, he may be granted, for distinguished service, army or *brevet* promotion up to the rank of lieutenant-colonel. This does not alter his position in the regiment, but gives him higher rank in the army generally. A lieutenant-colonel must command a battalion or serve on the staff for five years, to become colonel. There is a fixed establishment of general officers; and when a vacancy occurs in it, the senior colonel who has actually served for six years as a field-officer (*i.e.* as major, lieutenant-colonel, or colonel), is promoted to the rank of major-general. He thence reaches the ranks of lieutenant-general and general by seniority as vacancies

occur, unless promoted out of his turn for distinguished service. Field-marshal is an extraordinary rank, rarely conferred, and only as a mark of the sovereign's special favour. The retirement of officers is provided for by 'retired full-pay,' which is a limited establishment attainable after thirty years' good service, and 'retired half-pay,' to which every officer has a right after twenty-five years' service. These periods are reduced if the officer be disabled by ill health or wounds.

Recruiting, Enlistment, Promotion, and Retirement of Soldiers.

The country is divided into a certain number of recruiting districts. From some central place in each, a recruiting agency, consisting of an officer and several non-commissioned officers and men, scour the district for recruits. As military service has always been voluntary in this country, it is difficult to persuade men to enlist, especially in times when wages are good, and food and work plentiful. Hence it has been the unvarying policy of the government of late to increase the inducements to enter the army. This has been done in two ways: 1st, by augmenting the pay; 2d, by shortening the service. By 33 and 34 Vict. c. 67, a recruit can now enlist either for short or long service. If he elects short service, he enlists for twelve years—the first six of which he must pass in the regular army, the other six in the 'army reserve.' After his first six years' service, he may go back to civil life, and live anywhere in the United Kingdom, and follow any trade he chooses. Whilst serving in the reserve he will get fourpence a day, and will be liable to be called out for drill occasionally, but so as to injure as little as possible his general occupation. If, however, he elects to enlist for 'long service,' he may enlist for the whole twelve years in the regular army. At the end of this time, if he has conducted himself well, and gets leave from his commanding officer, he may re-enlist, and complete his twenty-one years' service, so as to entitle him to a pension for life. Great care is taken by the law that men shall not be enlisted on false pretences, or in a state of intoxication. Every recruit is taken before a magistrate, who explains to him the step he is taking. If he does not appear, or on appearing does not assent to be enlisted, no further proceedings are taken. If he signs the declaration and takes the oath, he is enlisted; but by the Army Discipline and Regulation Act of 1879, he may at any time within three months of enlistment, be discharged on payment of ten pounds. Once established in his regiment as a private soldier, the man must look to his own steadiness and courage for promotion. The ranks of corporal and sergeant are earned in the company or troop to which the soldier may be posted; promotion from sergeant to be a staff-sergeant or sergeant-major is made by selection among all the sergeants in the regiment. A deserving sergeant or sergeant-major is usually selected for the commission of quartermaster, and a few sergeants are promoted to be sub-lieutenants. The number so advanced to commissions is not, however, large; and unless the man be still young, and of manners above his class, the boon is questionable. A sergeant promoted to a commission is thrown among men socially his superiors, and probably richer than himself. It will be difficult for him to adapt himself to this change; and, considering that a sub-lieutenant's pay is very low, still more difficult for his wife, should he be married.

The Army, as a Profession, compared with Civil Life.

In comparing the military and civil professions as a means of livelihood, and a mode of passing life, it is unnecessary to consider the liability to violent death. The devotees of any calling furnish a considerable percentage as martyrs to their pursuit. As regards the officers, the rich and aristocratic ones care little for any profit from the service, and enter for the social position, or the chances of honours and distinction. With the poor officer, the service is his means of living; to him it is a lottery. If he be fortunate, he may obtain promotion, distinction, and, in staff employ, no contemptible income; if he be in a regiment where promotion stagnates, his career is wearisome, slow, and ill-paid. Army appointments—indeed, all government appointments open to gentlemen—shew badly by the side of commerce; but they are as good in the earlier stages as the learned professions, and later on, though with less brilliant prizes, they possess more certainty, and carry with them a retiring allowance after the work of life is over. As to pay, the yearly salary of a field-marshal and general-commanding-in-chief is £5999; of a general-commanding-in-chief, £3458; of a general, £2075; of a lieutenant-general, £1383; of a major-general, £691; of a brigadier-general, £520; of a colonel, £415; of an adjutant-general and quartermaster-general, if a general, £1383—if a colonel, £1095; of a deputy-adjutant-general and deputy-quartermaster-general, £691; assistant ditto, £346; deputy-assistant-deputy ditto, £260; assistant at headquarters, £346 or £501. The regimental pay is represented in the following table (see next page):

A private in the Foot Guards gets 1s. a day; in the cavalry, 1s. 2d.; infantry, 1s. A gunner in the artillery (field), 1s. 2½d.; in the horse artillery, 1s. 4d. There is no stoppage for rations now, except in the case of groceries, which cost the soldier about 4d. a day. This rate of pay is very small. Still, it is twice as good as the pay of the French soldier; and whilst the average yearly cost of the English soldier, including pay, clothing, and food, is £78, 18s. 5d. a head, according to Colonel Sykes, that of the German is only £35, 15s.

In the present state of the labour-market, the poor pay offered the soldier is a very serious drawback to recruiting; yet, considering the class from which the army is recruited, and the advantages in the way of gratuitous education, pension, easy work, and good regular living, insured to the soldier, the army, as an occupation, is preferable to most of the occupations the same class of men in civil life would find open to them. The men who offer themselves for military service do not belong to the class of skilled workmen, as a rule. Out of every 1000 recruits, in 1871, there were 637 agricultural and unskilled labourers, only 80 skilled manufacturing artisans, 182 mechanics (smiths, masons, carpenters, &c.), 77 shopmen and clerks, and 7 belonging to professional classes. Neither are the recruits men who, even as unskilled labourers, would be worth much, for one in every three had to be rejected for physical incapacity

by the examining medical officers. They are certainly not, as a class, men of education, for out of every 1000 there were 143 who could neither read nor write, 94 who could only read, and 740 only who could both read and write. The well-behaved soldier has means of earning many extra allowances for doing extra duty, not purely military or combatant, which increase his nominal pay.

MATERIEL.

The materiel of an army comprises everything in connection with it which is neither human, nor a beast of burden, nor a dwelling-place, nor a fortification. The articles thus included are of almost infinite variety—military stores of all kinds, medical stores, camp equipage, food and forage, pontoon train, arms, and ammunition. The very limited space of this article will only allow a short description of the last two items.

Arms.

In all ages the sword appears to have been the principal weapon in hand-to-hand combat, or at least from the time that the club of the mere savage had been set aside. As early as the fourteenth century, fire-arms began to be employed, first as artillery, and very shortly after in the shape of the harquebus as a clumsy hand-gun.

In their earlier stages, cannon went by various names, as *bombard* (parent of mortars), *culverins*, *petronels;* later on, they were reduced to the three denominations—cannon, mortar, howitzer, of which hereafter. Small-arms were at first literally small cannon; the old harquebus being no more than a diminutive gun mounted on a rude stock, rested on a triangle or wall, and fired by a match applied at the touch-hole. Naturally, every effort was made to increase the portability of this weapon; and it passed through various stages—first, the *match-lock* of the fourteenth century, then the percussion-lock of our own day, which produces fire by the blow of a hammer on a copper cap containing detonating powder. This lock was adopted in 1840 by the British government, but it has now been superseded by the needle-gun lock, by which a sharp pin is driven through a detonating cap in the bottom of the cartridge, and thus explodes it. This was introduced with the breech-loading weapons. The smooth-bore musket, known as 'Brown Bess,' continued to be the form until from 1853 to 1856, when its place was supplied in the British service by the Enfield rifle. Meanwhile, as early as the reign of Henry VIII. large pistols had been constructed as a convenient hand-weapon. These were reduced gradually in size, and altered in shape, until the excellence of the present *revolver* was attained.

Adverting, now, to the weapons actually in use in the British army, the *rifle* owes its accuracy to certain grooves or spirals within its barrel, which cause the ball to revolve rapidly on an axis parallel to the axis of the piece, and therefore presumably to keep within very small divergence from the line of aim. The advantage of this revolution has been greatly increased by the adoption of conico-cylindrical balls, instead of the old spherical bullet. Thus provided, the Enfield rifle is tolerably certain at 900 yards, while 'Brown Bess' was considered quite harmless at 100 yards. The next improvement was effected by the invention of Mr Snider, who converted the Enfield rifle into a breech-loading weapon, which, without being comparable as an arm of delicate precision to the French Chassepot, still combines simplicity, durability, economy, and efficiency in a greater degree than any other weapon then used in warfare: 12 to 18 shots per minute can be fired from it. But the weapon now used by our army is the Henry-Martini rifle,

which has a twist in the rifling of 1 turn in 22 inches, and a calibre of ·45 of an inch. The barrel is designed by Mr Alexander Henry of Edinburgh; the breech mechanism by Mr Martini, a naturalised Swiss. The Henry-Martini or Martini-Henry rifle excels the Chassepot by its greater strength and safety of ammunition, higher penetrative power, greater accuracy and longer range, and above all, in increased rapidity of fire. In 1883, arrangements were being made for introducing into the British army improved magazine or repeating rifles. Prussia has superseded the needle-gun by the Mauser, and France has greatly improved the Chassepot.

Cannon comprise the smooth-bore gun, the rifled gun, and the shell gun. The rifled gun at present in the service is made of various calibre, from a 3-pounder for mountain, to a 700-pounder of 35 tons weight. The projectile is an elongated bolt or shell. The smaller guns, up to the 40-pounder, are breech-loading, the breech being secured by a steel vent-piece falling into a slot. Apart from the rifling, the specialty of the gun is its mode of manufacture, to insure the strength necessary to resist the explosion of the heavy charges used. The results of the Armstrong gun, the first of the spiral rifled guns introduced, were very satisfactory, a range of 5¾ miles, with very trifling aberration, having been attained. The arm is, however, somewhat delicate, more especially when made to load at the breech; and it is expensive. A cheaper modification of the Armstrong gun, invented by Mr Fraser, executive officer of the Woolwich Gun Factory, has been adopted. No system of breech-loading has been found out yet sufficiently handy, safe, and durable for the heavier guns.

Mortars are short guns of large calibre in proportion to their length, from which shells are fired with comparatively small charges, at a considerable elevation, in order that they may fall nearly vertically on the object attacked.

Howitzers are cannon of considerable bore, but small thickness of metal; they are adapted for small charges and hollow shot, and therefore are only serviceable at close quarters. In a field of battle, among masses of men, their fire is very destructive.

The cost of artillery is enormous: a 12-inch 600-pounder, 23 tons weight, costs £2627; an 11-inch 500-pounder, 25 tons weight, costs £1893; a 10-inch 400-pounder costs £1305; a 9-inch gun costs £912; and a 7-inch gun £503. Small 9-pounders cost £84 each; still smaller 6-pounders cost £78 each. In fact, comparing our modern artillery with the old cast-iron guns, we find the cost of production increased by about 400 per cent. On the other hand, the power of modern artillery has enormously increased—so much so, that one single projectile thrown from one of the 35-ton Fraser guns (700-pounder) in one of the *Devastation's* turrets, exceeds in weight a whole broadside from one of Nelson's 'old seventy-fours'—not to speak of the 81-ton gun.

Ammunition.

Ammunition includes the powder by which the projective force is produced, and the missiles themselves. Those for modern arms are as follows: For small-arms, the bullet of lead, in shape conico-cylindrical; for the smooth-bore cannon, *round shot*, varying in weight from 6 to 700 lbs. and of cast-iron; *hollow shot* of the same diameters, but less weight; *case*, *canister*, and *grape shot*, which consist of bullets and small iron balls, bound together in clusters, to disperse on being fired, and produce disastrous effects on bodies of men; *chain shot*, formed by two cannon-balls being united by a short chain, and which are destructive to the spars of shipping. For rifled guns, shells or solid shot of an elongated form; exploded by a time-fuse, burning a certain number of seconds, or by a percussion-fuse on striking any object. Solid elongated shot of steel are used against iron-plated ships. For mortars, *shells* are used, which consist of heavy hollow iron spheres, containing a charge of powder with bullets, slugs, and pieces of metal. *Grenades* are small shells of iron or glass, with a fuse, which are thrown by hand among the holders of a ditch or a scaling-party, and produce great confusion at their explosion. *Carcasses* are shells of light specific gravity, which contain combustibles capable of burning for some time, and setting fire to anything on which they fall. A *rocket* is a gun made of so light a material, that on the explosion taking place it shoots itself through the air, breech foremost, to a great distance. Rockets are made as large as 32-pounders, and become terrible weapons, especially against cavalry. *Gunpowder* varies as regards the proportion of its ingredients, but the proportions of the constituents in English government powder are saltpetre, 75; sulphur, 10; and charcoal, 15 parts in the 100. There is no powder in the world equal to that produced in the government mills at Waltham Abbey. The physical characters vary—the size of the grains ranging from the fine pistol powder, the grains of which are retained on sieves with 72 meshes to the inch, up to the 'pebble' powder for big guns, the grains or lumps of which are as large as the top of a man's thumb. *Cartridges* consist of (1) projectile, (2) powder, (3) detonating apparatus to ignite the powder. These are arranged in a case—that of the Boxer cartridge for the Snider rifle being made of brass covered with paper. The detonating apparatus is a percussion-cap, which lies in the 'cap-chamber' at the bottom of the powder, right against a small shouldered brass anvil. Ignition is effected by the cap being struck (by the striker of the rifle) against the anvil, when the flash from the detonating composition of the cap passes through the firehole at the bottom of the cap-chamber to the powder, and explodes it.

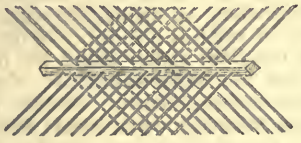
MANUFACTURING DEPARTMENTS.

There are two methods by which the vast supplies of materiel for the army can be procured—by contract with private manufacturers, or by direct manufacture in the government establishments. There is much to be said in favour of either source. It is always desirable to maintain throughout the country a sufficient number of skilled artisans, to complete the orders given on an emergency; and this can only be done by fostering the private trade in such articles. On the other hand, if such articles are manufactured exclusively by the trade, the prices are found to rise progressively, for the authorities have no criterion by which to compute the proper price, and in most warlike implements the numbers in

each branch of trade are too few to insure a healthy competition. To reconcile these difficulties, government purchases stores by contract from the private manufacturers to a greater or less extent according to circumstances, and makes the remainder it may require in its own workshops, as a check upon the prices charged.

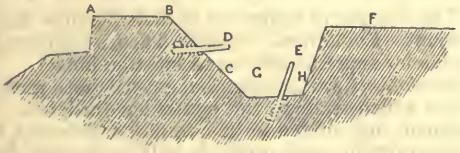
WORKS.

For defensive purposes, the strength of an army or garrison is materially augmented by the interposition of physical obstacles to an enemy's advance. If an army be in the field, it is usual to throw up some sort of breastwork to cover its front or flank, and give the men time to run to arms in the event of an unexpected attack. The simplest of all obstacles is a row of *abattis*, consisting of trees cut down, and laid in a row with their boughs outwards; the boughs may be pointed, to render them more annoying to an assailant. Next would be *chevaux-de-frise*, formed by iron or wooden



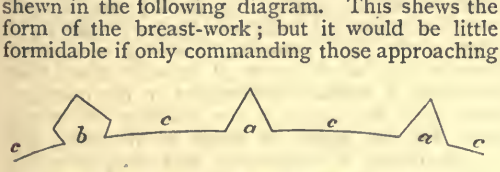
stakes set cross-wise in a strong beam, so that it will always stand, and yet be a difficult object to support.

If time allows more solid works, the simplest is a parapet, formed by digging a ditch and throwing up the earth behind it to form a mound as steep as the nature of the soil will allow. The ground before the ditch should be cut to a gentle slope, called the *glacis*, that an enemy might be fully exposed in approaching. The work can be yet more



ABC, parapet; G, ditch; F, glacis; D, fraise; E, stockade.

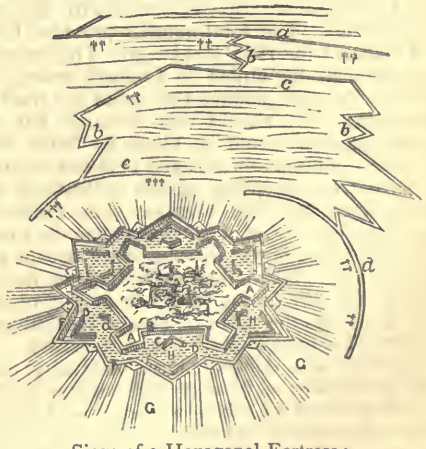
secured by adding stockades and fraises, which are stout beams sunk in the ground, and only surmountable by climbing or battering down by artillery. A section of a simple field-work is shewn in the following diagram. This shews the form of the breast-work; but it would be little formidable if only commanding those approaching



Line of Field-works: *a*, redan; *b*, bastion; *c*, curtain.

immediately in front, which is all that it would do if completely straight. To obviate this, projections are made, called *flanking defences*, within range of each other, when a fire may be opened on the enemy attacking the front of the breast-work. These projections may be simply *redans*, or the more elaborate *bastions*.

Permanent works of fortification are those by which towns and fortresses are defended. They are constructed on the principle of field-works, though of a more solid and formidable construction, having greater height, more perpendicularity, and being faced commonly with masonry or iron plates; outworks are also constructed in front of the main ditch, to constitute more than one line of defence. The circuit of the place to be defended is traced as a polygon, probably of many sides; each side of the polygon becomes a *curtain*, and at each angle is erected a bastion. A massive *rampart* is drawn on these lines, and the *parapet* is formed upon it, with *banquettes* behind for the defenders and guns to stand upon. In front of each curtain, a *redan*, *demi-lune*, or *ravelin* is made, of less elevation than the curtain, so as to be commanded by it, and not to obstruct its fire. A smaller ditch is dug in front of the ravelins, and before that, at a still smaller elevation, is the *covered-way*, which is the outmost defence, and from which the *glacis* slopes down to the country round. In fortifying a place, a skilful engineer takes advantage of all natural eminences, so that it rarely happens that the polygon is a regular one. To prevent shot from bounding along the works in a ricochet fire, and enfilading perhaps a whole battery, earthen mounds called *traverses* are erected at intervals. As a science, fortification was first brought to perfection by Vauban, and his system still continues in vogue with comparatively trifling modifications. The plan of a portion of Vauban's first system is shewn in the accompanying sketch:



Siege of a Hexagonal Fortress:

A, bastions; B, curtains; C, tenailles; D, ravelins; F, covert-way; G, glacis; H, ditch; *a*, first parallel; *b*, approaches; *c*, second parallel; *d*, third parallel, right attack; *e*, third parallel, left attack; ††, breeching batteries.

As the guns of such a work command every point around, it is only possible to approach it by trenches. These are cut zigzag, with great danger to the sappers; and when a sufficiently near point is reached, the trench is carried in a direction parallel to the walls of the place—sand-bags and the excavated earth forming a parapet before it. This line is called a parallel, and batteries are formed along it, with wide places d'armes for the troops to assemble in it. From these batteries the

defences are cannonaded, and if possible breached. Three successive parallels are usually constructed, the last very near the covered-way. From the third the final assault is made. Mines are often run from it under the ditch and ramparts, in the endeavour to blow them up; the besieged also countermine, to destroy the hostile mines and approaches. Terrible battles thus take place underground. The siege of a strong work is a very formidable undertaking; many miles of trenches and mines having frequently to be dug out, and thousands of lives sacrificed during the process.

RESERVE FORCES OF THE UNITED KINGDOM.

Army of Reserve is a small force including men discharged from the army for other cause than misconduct before having earned a pension, and the 'short-service' men who have served six years in the line, and who serve other six in the reserve, and enrolled pensioners, who, as long as they are in receipt of pension and able-bodied, are all liable to serve in this force, and undergo annual training. The number of this force in 1882–83 was 47,000; 23,000 men being in the first class, and 24,000 in the second. Over the pensioners there are, in the various districts, staff-officers, who drill them and pay them.

Militia.—The militia is the old constitutional force of the country. The acts under which it is actually constituted are of late date, the principal being 15 and 16 Vict. cap. 50. It is wholly a territorial force, each county being called upon to contribute a certain power under the command of its lord-lieutenant, as vicegerent of the crown, which by the constitution is vested with the command-in-chief. The total number provided for in the Estimates for 1883 is 143,459. This number is apportioned by Order in Council among the counties. In each county the quota is raised by volunteering; but should this resource fail, the requisite number would be taken by ballot from the whole civil population, aged between eighteen and thirty-five, excepting certain professions and classes which are held exempt. The militia in time of peace are trained for twenty-one days each year, and in time of war may be called out for permanent duty. When thus embodied, or out for training, the pay is the same as in the regular army, as is also the uniform, except that silver is substituted for gold in all the accoutrements.

Yeomanry is a domestic force of cavalry, composed principally of farmers and country gentlemen, all mounted on their own horses. They are armed and partially clothed by government, and paid at a high rate during the annual training, which must not exceed fourteen days. The numbers provided for in the Estimates for 1883 were a permanent staff of 328, and 14,458 yeomen. They are at all times liable to be called out in aid of the civil power, on occasions of riot or disturbance, and to be embodied in the event of invasion.

Volunteers.—When Napoleon threatened England with invasion in 1803, the nation ran to arms, and not less than 463,000 effective men appeared in the ranks. This force diminished when the danger vanished, and disappeared after the peace. In 1859 it was revived; government took the direction of the movement, and appointed an inspecting staff. The result has been, that the institution has taken firm root in the land, and that about 200,000 men of admirable physique and intelligence are fair soldiers and expert marksmen. Parliament grants a capitation rate in aid for every man who proves himself 'efficient.' The bulk of the volunteers is infantry; but there is a large force of artillery, well served; and there are also small numbers of light horse, mounted infantry, and engineers. They select their own officers and uniforms, subject to the approval of the crown. They are not available for preserving internal peace.

CENTRAL ADMINISTRATION.

The headquarters of the army (but not of the reserved forces) is at the *Horse-Guards*, where is the office of the *Commander-in-chief*, with his staff of high officers round him. He is responsible for the discipline of all troops and for their movements. In all other respects the entire military strength of the country is subject to the *Secretary of State for War*, who administers its finances, and is ultimately responsible to parliament for everything in connection with it. This great officer of state is a member of the Cabinet, and sits at the *War Office*, where his immediate assistants are two under-secretaries of state, and an assistant under-secretary. Besides these, the heads of the following departments form part of his office: Fortification and Works, Barracks, Divine Service, Commissariat, Medical, Purveyors, Stores, Ordnance, Surveys, Clothing, Contracts, Militia, Volunteers, Account, and Audit. Such multifarious duties, with the charge of the fourteen millions which the army, &c. annually costs, involve of necessity a large department. The total net charge for the British army for the year ending March 31, 1883, was calculated at £15,458,100.

ACTIVE OPERATIONS OF AN ARMY.

The science of command is divisible into three sections—Evolutions, Strategy, Tactics; although genius for supreme command must be innate.

Evolutions are the rules that govern those movements which strategy and tactics have ordered. A regiment may march in line, in file, in columns, in close order, in open order, in half or quarter distance, in échelon, and in other ways; and the mode of changing from one of these movements to another, or of forming square on the field of battle, belongs to evolutions. If a general, in the heat of battle, suddenly orders a large part of his army to make a new attack in a new spot, he depends on his officers to master the several evolutions that will bring the troops to the right place at the right moment. *Strategy* is a name given to the whole series of considerations that determine a military commander in his management of a war—such as the selection of strong posts for the depots or bases of his army, the establishment of magazines and hospitals, the decision whether to take the offensive by attacking fortresses and commanding roads, or the defensive by insuring a good line of retreat. To excel in strategy is to possess the highest qualities of a commander. *Tactics* denote the management of troops in actual conflict with the enemy. Strategy lays down the plan of a campaign; tactics

fight the battles. How to make different bodies of troops march from different places so as to arrive at a given spot at a given time, is itself a difficult tactical problem, since the general must take into account the nature of each detachment and the sort of ground to be got over. In short, the great object of all strategy with every general should be to make his force, however inferior on the whole, the stronger at the point of actual attack, for, as Frederick II. of Prussia wittily said: 'Providence fights with the big battalions.' To this system, Napoleon, and, on another element, Nelson, owed all their victories; their attack being to double on half the hostile line, and break it before help came from the other half; thus Napoleon well-nigh destroyed in detail the armies of Blücher and Wellington before they had united to crush him at Waterloo.

NAVAL ORGANISATION.

Before the sway of the Western emperors had ceased to be felt, the shores of Britain had been guarded for several years by a British fleet under the usurper Carausius. Alfred the Great, in the endeavour to vanquish the Norse sea-robbers, founded the English navy, consisting of galleys rowed by thirty or forty pair of oars. William the Conqueror gave privileges to the Cinque Ports, on condition of their furnishing a certain number of ships for the national service. Richard I. took a considerable fleet to Palestine. John claimed that all foreigners should strike to the English flag. The navy waxed strong under his successors, until, in 1340, it utterly defeated the French fleet, with 40,000 men on board, at Sluys. The first large British ship was

The Great Harry.

the *Great Harry*, built by Henry VII. who also was the first to maintain a fleet during peace. The modern navy may be said to have been founded by Henry VIII. who established the Admiralty, the Navy Office, the Trinity House, and the dockyards at Deptford, Woolwich, and Portsmouth; besides appointing regular salaries for officers and sailors. His most famous ship was the *Henri Grace de Dieu*. Under Elizabeth, the fleet that encountered the Spanish Armada, provided only in part by the crown, numbered 176 vessels, manned by 15,000 seamen. Under James I. the royal ships, by being built less high and narrow than before, became more efficient. The largest ship in the time of Charles I. was the *Sovereign of the Seas*, of 100 guns, and the first three-decker. Cromwell, who greatly improved the navy, was the first to place naval estimates before parliament, and to obtain a specified annual supply for that service. The royal navy under James II. comprised 173 vessels; increased at the death of Anne to 200, averaging 50 guns each. During the great French war the British navy increased rapidly: in 1793, it comprised 564 ships of various sizes; in 1803, it was 970; but the chief increase had been in small rather than large vessels. In 1820, when peace had succeeded to a long period of hostilities, the total war-ships, built and building, amounted to 127 ships of the line, and 338 under 50 guns. These numbers, in 1839, had decreased to 98 and 294 respectively.

A great epoch in naval warfare was marked by the introduction of steam-navigation. When the British government built the screw-steamer *Rattler*, of 900 tons, in 1843, as an experimental vessel for testing the relative capabilities of the paddle and screw, the latter became the recognised propeller of the service. From the time of the peace in 1815, the efforts of the royal ship-builders have tended to larger and larger vessels. In 1853, the three-deckers culminated in the *Duke of Wellington*, a splendid vessel of 4000 tons, 131 guns, and 1100 men. She was essentially on the same principle as the old line-of-battle ships, with the addition of steam and the screw. In 1859 began that reconstruction of the navy which led to our discarding the old 'wooden walls of England.' The *Warrior* was built, cased in 4½-inch iron plates, and could stand with impunity the fire of the largest naval guns then (1860) known, even though firing at 200-yard ranges. The *Northumberland*, *Agincourt*, and *Minotaur* were then built, each of 6621 tons, 1350 horse-power, 26 enormous guns, and clad in 5½-inch iron plates, with a teak backing of 20 inches, and an iron skin of 1 inch behind all. Some of these vessels were built (as the *Defence*) with the bow projecting under water, so that they might act as rams. But when the 68-pounder was replaced by 6½-ton guns, there came a change; for projectiles from these weapons could go through the *Warrior's* sides at 1200 yards. Then there was built the *Bellerophon*—known to our tars as the 'Billyruffian'—whose armour resisted 12½-ton guns at a range of 800 yards. The *Hercules* was an improvement on the *Bellerophon*, for its side-armour was proof against the 18-ton gun, firing at it within 600 yards. Now, however, a still more wonderful step has been made in bringing naval defensive armour-plating to perfection: our two latest floating monsters, the *Devastation* and *Thunderer*, can approach within 1200 yards of each other with impunity, even though they were battering each other with their 35-ton guns, loaded with 700 lb. shot, each one of which is propelled by a charge of 115 lbs. of gunpowder. The development of guns and that of armour have kept pace with each other, and the common assertion that guns are more powerful than armour now, is a delusion. The power of the old 6½-ton

gun, compared with the old 4½-inch armour in use in its day, is the same as that of the *Devastation's*

Stern view of the *Thunderer.*

35-ton gun, compared with the *Thunderer's* 14-inch armour. And the curious fact is, that though the strength of our fighting iron-clad turret-ships has increased, we have not increased the expense, as might have been anticipated. Ten years ago, our strongest ships, such as the *Minotaur*, were 400 feet long, weighed 10,500 tons or thereabouts, had armour 5½ inches thick, and cost £480,000 each. The new type of fighting ship of the *Devastation* class, with 14-inch armour, is not to be more than 285 feet long, weighs under 10,000 tons, and costs £350,000, or £130,000 less than ships of the old *Minotaur* class. Of the two classes of iron-clads—the old ones with guns mounted on broadsides, *e.g.* the *Warrior*, and the new ones with fewer guns mounted on revolving turrets—*e.g.* *Devastation*—the government have of late favoured the latter.

The *Devastation* is a mastless, sail-less sea-going monitor—made to carry the heaviest possible guns and armour, and the largest possible supply of coals. She is 285 feet long, and 62 feet 3 inches in her broadest part. Her draught forward is 25 feet 9 inches, and aft 26 feet 6 inches. She is 4406 tons burden, and carries four 35-ton 700-pounder guns in two revolving turrets, and is clad in armour of 10, 12, and 14 inch thickness. Her speed is 13 knots an hour. She is propelled by twin screws, with two sets of engines—and she carries 1600 tons of coal—enough to carry her 6000 miles. Her covering-in deck consists of 3-inch iron plating, with two thicknesses of teak planking. On this is built the elliptical breastwork between the turrets, with heavy 10-inch armour-plating, rising 24 feet above water, and with superimposed hurricane-deck, to which openings from the hold are carried with 2-inch iron plating, with two thicknesses of teak planking over all. On it the boats are stowed. Rising above this breastwork there are the two turrets or revolving circular batteries, and here the chief peculiarity of the ship is displayed. In the original American turret-ships—*e.g.* the *Miantonomah*, and *Monadnoc*—the turrets were mounted on a metal base ring, laid on the ship's deck, and were to be fought in these vessels with only two feet of freeboard, very close to the water's edge; so the base of the turret itself, always the weakest part, was freely exposed to the 'plunging' fire of an enemy's frigate with broadside guns. In the *Devastation* this defect is got over by the elliptical breastwork, for it carries a second or hurricane-deck, rising from the hull-deck proper, 24 feet

The *Devastation.*

above the water's edge; and as this breastwork is heavily clad with armour, it protects as well as incloses the bases of the turrets. The turret-guns are also in this way fought at as high an elevation above the water-line as those of the best broadside frigates, giving the *Devastation* an infinitely more sweeping range than any of the old turret-ships—its turret-gun ports being 13 feet 6 inches above the water-line. The two turrets are 24 feet 3 inches in internal diameter, and are built of fine laminal iron plating and teak planking alternately: *viz.* (1) 2⅝-inch plates; (2), six-inch horizontal teak planking, bearing (3) six-inch armour-plates; (4) nine-inch vertical teak planking; and (5) an outside armour-skin of eight-inch iron plating. Each turret carries two Fraser muzzle-loading rifled guns, of 35 tons each.

A still more formidable ship is the *Inflexible*, completed in 1881, 320 feet long, 75 feet in breadth at the water-line, with a displacement or tonnage of 11,800. The central part of the ship is a citadel 12 feet high and 110 feet long, inclosing with its rectangular wall the engines and boilers, the base of the turrets, the loading gear, and the most vulnerable parts of the whole. Its walls are 41 inches thick, consisting partly of armour-plates from 16 to 24 inches thick, partly of strong teak backing between and behind the plates. The turrets are also 12 feet high, each carrying two 81-ton guns, capable of firing 1700-lb. shot with a charge of 450 lbs. of powder. There are two iron masts with brig-rigged sails.

The navy may be divided into five classes: (1) Twelve turret-ships and barbette ships for great naval warfare at home and abroad, in

cluding the *Inflexible*, *Dreadnought*, *Devastation*, *Thunderer*, and others. (2) Ten ships for ocean warfare, but inferior in power to the first class. Most iron-clads can be used as rams, but in four of this class the ramming power is a chief point. The *Polyphemus* is a unique ship, meant for torpedo warfare, and is simply a steel tube, deeply immersed, with no masts, and with a powerful ram below and a *torpedo-port* under it, for discharging Whitehead torpedoes. (3) About twenty rigged ships for cruising (including the *Monarch*, *Hercules*, *Sultan*, &c.), with armour from 5 to 18 inches, and carrying from 9 to 16 guns (mostly from 12 to 18 ton guns). (4) About twenty partly antiquated rigged cruisers, with guns under 12 tons, and armour under 6-inch thickness. The old *Warrior* and *Black Prince* belong to this class. Their defects, as compared with the preceding, are—their unwieldy length, 'unhandiness,' and limited fighting power, rendering them almost useless, save for the protection or destruction of merchant-ships. (5) Eleven small iron-clads for coast defence—thought now to be too antiquated for much service in modern naval warfare. Several swift unarmoured vessels intended to play the part at sea of flying batteries of artillery on land, have been added to the navy, including the *Inconstant*, *Shah*, and *Raleigh*. Swifter still are the steel despatch vessels. Torpedo-boats are a recent addition to our naval defences. This fleet is scattered in squadrons all over the world, each squadron under a flag-officer; and several squadrons are sometimes united under an admiral or vice-admiral.

PERSONNEL OF THE NAVY.

Except in two instances of brief duration, when a Lord High Admiral was appointed, the government of the navy has, since 1688, been vested in the Board of Admiralty, consisting of 'Lords Commissioners for executing the Office of High Admiral.' The First Lord and parliamentary Secretary are members of the government, the former being a cabinet minister. The other lords are Senior Naval Lord, Third Lord, Junior Naval Lord, and Civil Lord. Under them is the permanent administration—and heads of departments, not changing with the government—the Controllor, Directors-general of the medical and engineering departments, Hydrographer, Superintendent of contracts, stores, &c. The First Lord has supreme authority. The Senior Naval Lord directs the movements of the fleet, and is responsible for its discipline. The Third Lord manages the dockyards, and the Junior Lord has charge of the victualling and transports. The officers are Combatant and Civil. The former includes admirals, vice-admirals, rear-admirals, and commodores, who are 'flag-officers,' and always command squadrons. A flag-officer derives his title from bearing a small flag at the mast-head of his ship. For the first three grades this is a St George's Cross—*i.e.* a red cross on a white ground. An admiral bears it at the mainmast head, a vice-admiral at the foremast head, and a rear-admiral at the mizzen. Commodores hoist a broad pennant. Commodore is only a temporary rank, conferred on the senior captain present with a squadron which is operating beyond the command of an admiral, vice-admiral, or rear-admiral. The next permanent grade to that of rear-admiral is captain, who is the commander of an individual ship (larger than a gun-vessel). He commissions his ship by hoisting a pennant at the main. His ship also bears the white or St George's ensign at the peak, whenever it is desired to shew her nationality. In vessels larger than frigates, the captain has a commander under him, who is responsible for the condition of the ship and discipline of the crew. In other vessels, this duty falls to the first-lieutenant. Besides the first-lieutenant there are other lieutenants, according to the size of the ship, who command the watches in turn, take charge of boat expeditions, &c. Junior to the lieutenants are the sub-lieutenants, whose duties are analogous to theirs. Naval cadets are young gentlemen learning their profession. As combatant officers, but specially devoted to navigating the ships, are the 'Navigating Lieutenants.'

The civil branch comprises the secretaries of flag-officers, the medical officers, the engineers, the chaplains, naval instructors and paymasters, who have charge of the money, food, and clothing stores on board. Throughout these ranks, up to captain inclusive, promotion is entirely by selection or patronage. After captain, promotion is by seniority, the senior captain, who as such has been six years at sea in command of a ship, succeeding to a vacancy among the rear-admirals. Examinations have to be passed before appointment as a naval cadet, sub-lieutenant, and lieutenant. There never was any purchase of commissions in the navy. As compared with the army, the denominations carry higher rank; for instance, a captain in the navy ranks with a colonel in the army, a lieutenant of eight years' standing with a major in the sister service.

Intermediate between the commissioned officers and the crew are the *warrant officers*, formerly rather numerous, but now limited to the gunner, boatswain, and carpenter, who all rise from before the mast (which is the technical expression for having been originally a common sailor). The junior engineers are also, on first appointment, warrant officers. The crew consists of petty officers and seamen.

The *petty officers* correspond to the non-commissioned officers in the army, and, besides certain special offices in aid of discipline, are usually the chief men in the several classes of work which the crew are called upon to form. Such are the gunner's mate, boatswain's mate, master-at-arms, ship's schoolmaster, chief stoker, armourer, calker, &c. The crew comprises *able seamen*, who are practised navigators, *ordinary seamen*, and *boys*, who are undergoing a paid apprenticeship to the ocean.

Terms of Service.

The regimental system, which forms so remarkable a feature in army organisation, has no existence in the navy. When a ship is wanted, the Admiralty designates the officers who shall serve in her; the captain hoists his pennant, and his crew is then made up of volunteers, who, either by his reputation, or the nature of the service to which the ship is destined, are desirous of forming her complement. The men engage for the period of the vessel's commission (three to five years), during which they are under martial law, and cannot be absent, except by permission, without

rendering themselves liable to the penalties for desertion. When the ship is paid off, they become free, have a run on shore, spend their money with startling rapidity, and then engage in another vessel. Of late years, however, there has been organised another class of men, called 'continuous service seamen,' who engage for a specified number of years—ten, afterwards renewable—and when their ship is paid off, have a few weeks' leave to visit their friends, then join a depot, and subsequently are drafted into another vessel, as their services may be required. As it is of importance to the Admiralty to obtain as many of these continuous service men as possible, they are paid at higher rates than other sailors. It must, however, be borne in mind, that although never exercised since the great French war ended in 1815, the power of impressment still rests with the crown. All seamen become entitled to pensions after long and faithful service.

Officers are either employed in ships or are on half-pay, the latter being a recognised condition in the navy for all officers for whom the state has no immediate necessity.

In point of pay, that of the officers is extremely low as compared with the remuneration of men of the same class in civil life; but there is honour to be obtained, the life is healthful, and neither the mental nor bodily labour oppressive. The command of a ship is, under existing rules, so expensive, that few officers can venture to undertake it unless they have private means besides their naval pay. As regards the men, the pay is tolerably liberal; though many merchant services and some foreign governments are able to outbid the royal navy. During war, prize-money adds much to the allurements of the service. Unlike the army, the navy is a perpetual establishment, its discipline maintained by a special martial code permanently sanctioned by parliament. Parliament does not, as in the case of the army, vote first the *number* of men for the navy, but merely the *wages* of the number fixed on by the government. The navy expenditure in 1879–80 was £10,586,894; number of men, 58,800; the expenditure in 1883–84 was £11,578,058, while the number of men was as follows:

FLEET.		
Seamen	35,090	
Boys	4,800	
		39,890
Marines afloat	6,200	
Marines ashore	6,200	
		12,400
Total		52,290
COASTGUARD.		
Afloat and Ashore, Officers and Men		4,000
INDIAN SERVICE.		
Officers and Men		960
Grand Total		57,250

These figures include 17 flag-officers, 30 officers superintending dockyards and naval establishments, and 2506 other commissioned officers on active service.

Dockyards.

Although recourse is had, in times of emergency, or for particular constructions, to private shipbuilders, the greater number of war-ships are built, and all are frequently repaired, in the royal dockyards. These consist of vast establishments at Portsmouth, Plymouth, Pembroke, Sheerness, Chatham, Woolwich, Cork, Malta, and the Cape, most of which are fitted with huge docks, basins, slips, and factories for manufacturing all the appliances of the vessels. The steam-engines are, however, always made by private firms, and arms are made in the army factories.

Besides the dockyards, there are victualling yards at Deptford, Gosport, and Plymouth, in which ship-biscuit, salt meat, cocoa, and other articles of food, are prepared and barreled in vast quantities.

Royal Marines.

As an auxiliary to the navy, and under the same government with it, are the Royal Marines, an amphibious and very valuable corps of soldiers for sea-service. Every ship of war has a detachment on board, where they act as sentries, are an armed guard to restrain the sailors in case of insubordination, and, during action, serve as marksmen to annoy the enemy's crews. The officers of the marines have military titles and rank, and for purposes of brevet promotion they join in seniority with the army. In their own corps, promotion is by pure seniority, and the numbers in the higher ranks being small, it is but slow. When on shore, the marines are in divisions at Portsmouth, Plymouth, Woolwich, and Chatham.

Reserve Forces.

The navy has two numerous and valuable reserves: first, the Coast Guard; second, the Royal Naval Reserve. The *Coast Guard* was originally a semi-naval organisation, partly on shore and partly in revenue cruisers, for the suppression of smuggling. Smuggling having almost disappeared, the force has been converted into a defence for our shores. The coasts of the United Kingdom are divided into eleven districts, each under a naval captain, with a block-ship for his castle. Subordinate to him are inspecting officers, in charge of sub-districts, to each of which a gun-boat or cruiser is attached. The men are old seamen of good character, living free in neat little cottages along the shore; they are liable for service in the district block-ship or cruisers whenever required, and in time of war, to service in any of Her Majesty's ships. This force comprises about 4000 men.

The *Naval Reserve* is a species of naval militia, auxiliary to the royal navy. It consists of men who have during the ten years preceding their enlistment served five years at sea, and one at least as able-bodied seamen. Unlike the former Coast Volunteers (a similar force, which has now ceased to exist, but was recruited from men in the coasting trade, or in ships often at home), the men may belong to ships making long voyages, and are liable to be called on for five years' service in case of war. Besides men, this force comprises lieutenants and sub-lieutenants, who must be certificated masters and mates of merchant-vessels. They train for twenty-eight days every year. The act recognises a force of 30,000 men; usually there are about 20,000 in the Naval Reserve, and in a state of high efficiency.

EUROPE.

REFERRING the reader for all that appertains to the general constitution of the globe to the article on PHYSICAL GEOGRAPHY (No. 4), we purpose, in this and several following sheets, to direct attention to the special features of the respective continents—describing the territories of the several states, their natural products, their commercial industry, population, laws, religion, and other topics usually comprehended under the title of POLITICAL GEOGRAPHY.

Constituting but a fragment of the Old or Eastern World, Europe, strictly speaking, is not entitled to be called an independent continent. But though the smallest of the *quarters* into which geographers have divided the globe, it is by far the most important—its inhabitants giving now, as they have long done, the tone and character to human progress. Its limits are usually comprehended within the 36th and 71st degrees of north latitude, and the 10th degree of west and 68th of east longitude; thus placing it almost wholly within the northern temperate zone. Including the islands, which contain about 317,000 square miles, the land superficies of Europe is estimated at rather more than 3,720,000 square miles; its population at nearly 328,000,000. If we count the German Empire as one state only, there are in Europe upwards of 20 states in all. The leading states, usually styled 'the Five Great Powers of Europe,' are Great Britain, Russia, Prussia (representing Germany), France, and Austria; but the vast changes that have taken place on the continent since the close of the Crimean war, have entirely altered their relative importance. Italy also might fairly claim, since its unification, a place among the leading states. Those of a secondary rank are Spain, Sweden, Denmark, Holland, Belgium, Portugal, the Swiss Confederation, and Turkey. It is no longer necessary to assign any rank to the minor states of the German Empire, since, even where not absorbed by Prussia, they have no military independence, and, therefore, no place in European politics. It is to the continental or foreign states that we now confine our description, reserving the component parts of the United Kingdom—England, Scotland, and Ireland—for treatment in the three subsequent numbers.

FRANCE.

France, one of the largest and most important of the European states, is situated between lat. 42° 20′ and 51° 5′ north, and long 8° 15′ east and 4° 54′ west. It is bounded on the north by the English Channel, Strait of Dover, Belgium, the grand duchy of Luxemburg, and the Rhenish provinces of Prussia; on the east, by the German territory of Alsace-Lorraine (annexed in 1871 at the close of the war with France), by Switzerland, and Italy; on the south, by the Mediterranean and by Spain, from which it is separated by the Pyrenees; and on the west, by the Atlantic. The greatest length of the country from north to south is 676 miles, and its greatest breadth from east to west is 494; its area, including Corsica, is a little over 204,000 square miles.

Superficially, France may be described as a flat country, the greater portion consisting of valley-like tracts or open plateaux, with low hilly ranges or swelling eminences between. The principal ranges which diversify the surface are—1. The Vosges, on the north-east, presenting rounded outlines, with gentle slopes, and affording much open pasture; the highest point over 7000 feet. 2. The Jura Mountains, lying south of the Vosges, and forming part of the boundary between France and Switzerland, the extreme height of which is about 6000 feet. 3. The Cevennes, and other portions of the long range which forms, as it were, the western brim of the valley of the Saône and Rhône: the highest points do not exceed 5800 feet. This range may be said to form the great water-shed of France, from which all the large rivers flow in a north-west direction to the Atlantic. 4. The clustering hills of Auvergne, or Central France, remarkable for their crateriform tops and recent volcanic origin, the highest of which reaches an elevation of 6200 feet. The largest and best defined *river-basins* or *valleys* are those of the Saône and Rhône on the east, which may be regarded as one; those of the Adour, Garonne, Lot, and Dordogne on the south and south-west; those of the Loire and Seine in the centre; and those of the Somme and Meuse on the north. The soil of most of these valleys is a fine deep alluvium, with a greater or less admixture of sand. There are large tracts of heath in Bretagne, Anjou, and Maine; and the Atlantic sea-board presents in many places, as in the tract called the Landes, wide expanses covered with sand-dunes.

The great *rivers* exclusively French have all a westerly flow towards the Atlantic; those flowing northward—the Scheldt, Sambre, and Meuse—have only the upper portions of their courses in France; and the Rhône, the sole large river running southward, has also a great portion of its course in another country. Of those flowing westward, the most important are the Seine, the Loire, and the Garonne.

'*Geologically*,' says one authority, 'the whole of France may be considered as one extensive basin, the circumference and centre of which consist of primitive formations, the intermediate space being filled with those of a secondary and tertiary kind.' Taking this statement as a mere proximate outline, we find primary rocks in the Ardennes on the north; in the Vosges, Jura, and Alpine ridges on the east; in the Pyrenees on the south; in Bretagne, Maine, and Normandy on the west; and, centrally, in the hilly ranges of Auvergne. Lying upon these in many places, without the intervention of the transition and older secondary strata, occur the coal-measures, the oolite

limestones and shales, and the chalk; and not unfrequently even the coal-measures are absent, and the oolitic and chalk repose immediately on the upper primaries. The tertiaries generally occupy the great river-drainage of the centre, shewing that at no very distant epoch a large portion of France was a shallow sea or estuary of deposit. The chief *minerals* are—coal, of which it possesses several considerable beds, principally in the east and north, the amount raised, however, being less than one-twelfth of that raised in Great Britain; iron largely from ten or twelve districts; gypsum, or plaster of Paris, in unlimited quantities; and abundance of building-stone of various kinds, granite, freestone, marble, slate, basalt, lava, &c. With the exception of iron, the other metals are of no great commercial importance.

Geographers have divided the *climate* of France into four regions—namely, 1. The most southerly, in which the vine, olive, mulberry, and orange flourish, bounded north and west by a line drawn from Bagnères-de-Luchon, in the Pyrenees, to Die in Drôme; 2. That through which the cultivation of the vine and maize extends, stretching as far north as a line passing from the mouth of the Garonne to the northern extremity of Alsace; 3. That region which terminates with the culture of the vine, near a line drawn from the mouth of the Loire to Mezieres in Ardennes; and 4. The remaining portion of the country, having a climate somewhat allied to that of England, and yielding rich verdant pastures and forest growth. Along the entire western coast the climate is distinguished by a greater degree of humidity than in any other district; the south and east have about a third fewer rainy days than the north and west; winter is often pretty severely felt in the north-east; snow seldom lies in the central and southern regions, yet the Mediterranean districts in particular are exposed at times to the ravages of the burning winds which have passed over the deserts of Africa, and to the destructive north-west wind known as the *mistral*, which often does great injury to the fields near the mouths of the Rhône and Var.

Of grains and vegetables largely cultivated, we may enumerate wheat, rye, oats, maize, millet, buckwheat, kidney-beans, pease, carrot, beet, melons, potatoes, flax, hemp, and tobacco; and madder, saffron, and hops on a smaller scale. Of fruit-trees, the vine, olive, orange, pistachio, fig, apple, pear, plum, peach, apricot, and cherry, with which we may also class the mulberry and caper. Of forest-trees, the oak, beech, maple, ash, chestnut, walnut, birch, poplar, larch, pine, fir, box, cornel, acacia, and cork-tree. The forest-growth of France is said to cover about one-seventh of the entire surface, an amount which is rendered necessary by the use of wood as the chief domestic fuel.

The *wild animals* are fast diminishing from the soil of France; the lynx is rarely seen, even among the higher Alpine regions; but wolves are still numerous in the mountainous districts of the central departments; while the chamois and wild-goat, as well as the marmot, ermine, and hamster, are found among the Pyrenees, Alps, and Vosges. The wild-boar, roebuck, fox, squirrel, polecat, and marten are to be met with in the woods. The red and fallow deer are scarce; hares and rabbits abound, and game generally is plentiful.

The *insects* of any economical importance are the bee, silkworm, gall-nut fly, and the blistering-fly. Respecting the breeds of the *domesticated animals*, if we except the merino sheep and poultry, it may be safely asserted that they have hitherto been inferior to those of Great Britain. A spirit of improvement, however, has of late sprung up. During the half-century, for example, from 1812 to 1862, the number of horned cattle was doubled in France.

The *fisheries* are not on a great scale, in spite of liberal help from the state. The coasts of Normandy and Brittany, however, yield large quantities of pilchards and mackerel. The Bay of Biscay has extensive oyster and mussel beds; while tunnies and anchovies are caught on the shores of the Mediterranean.

The *inhabitants* may now be arranged under four distinct heads or races: 1. The *French* proper, constituting nine-tenths of the population, and consisting of the descendants of the ancient Romanised inhabitants of Gaul, with a considerable admixture of Germanic blood infused at the overthrow of the Roman dominion; with these may be classed the Italians of Corsica; 2. The *Celtic* or Cymric race (Bretons) of Bretagne, who are simply the pure descendants of the ancient Gauls (as the modern Welsh are of the ancient Britons), their position and political fortune securing them against much external influence; 3. The *Basques* of the Low Pyrenees, a people of uncertain origin; and 4. The *Jews*, who are found in all the principal towns. There are thus four distinct languages spoken within the country—French and Italian (both of Latin origin), Celtic, and Basque; independent of several widely differing provincial dialects. In 1881, the population of France was 37,672,048.

The *Roman Catholic faith* is the predominant religion, the adherents of all the other denominations being under 2,000,000. Though it is thus the national religion, it is not exclusively associated with the state; for Catholic and Protestant, Jewish and Mussulman clergy, are paid out of the public revenue. The Roman Catholic Church has about 54,000 clergy of all ranks; while the Protestant ministers number scarce 800, and the rabbis less than 70. Public education is entirely managed by the government. The *facultés*, practically universities, are fifteen in number. There is in every department an *Académie*, or board of education, consisting of a rector and council, of which the bishop or bishops of the department and a Protestant clergyman are members. The direction of the educational matters of the department is in the hands of this board, subject to the control of the Minister of Public Instruction. Nearly every commune has one or more primary schools, the larger communes have also secondary schools, and the more important centres have institutions of a higher grade, called colleges and lyceums, which serve as preparatory to the universities. There is in general a 'normal school' or seminary for training elementary teachers in every department; while the superior Normal School of Paris trains professors for the lyceums. It is allowed on all hands that education has made great progress in France within the last generation; yet there must have been something very unsatisfactory in the methods of instruction, for in 1870-80, there were nearly eight millions of

the French population above 20 years of age who were unable to read or write, as well as 20 per cent. of those under 20 years. Perhaps the cause of this lies to some extent in the hostile attitude of the dominant church to enlightened instruction. Roman Catholic children seldom remain at school after eleven or twelve years of age, and are consequently apt to forget, in after-years, the little they may have been indifferently taught. But the quality of education varies in different parts of the country; in the east and north, it is more general and more effective than in the southern districts.

With respect to *national industry*, France may be regarded more as an agricultural than a manufacturing country. By the law of inheritance, the property of a father is divided equally among his children; and consequently, there is a progressive tendency to more minute divisions and subdivisions of the land. According to the latest official returns, the cultivated land of France, embracing an area of 90,000,000 acres, was divided into 5,550,000 distinct properties. Of these properties, over 5,000,000 were under six acres in extent, and the result is a generally mean condition of rural affairs, and a deficiency of high-class systematic agriculture. The chief agricultural product is bread-corn, chiefly wheat. The next article in importance is wine. Silk and olive-oil are largely produced in the south; and from beet-root are manufactured yearly above 300 million pounds of sugar. Poultry is a more important article of agricultural produce in France than elsewhere. In *manufactures*, France ranks next to Great Britain. The leading articles are silks, woollens, tapestry, shawls, cotton, shoes, gloves, hardware, &c. The French specially excel in articles of ornament and *mode*, wherever skill and taste are required, and the manufacturer must also be an artist. *Ship-building* is carried on at Rochefort, Brest, Cherbourg, &c.; and in engine-building and other heavy machinery, the French are beginning to attain considerable eminence. The *commerce* of France has enormously increased since the peace in 1815; the annual value of her imports and exports together, during the fifteen years from 1867 to 1881, being on an average nearly 240 millions sterling. The number of vessels that entered the harbours of France in 1881 were 35,420, with a tonnage of 11,675,750; departures, 23,373 vessels, tonnage, 7,527,000. The mercantile marine in 1880 consisted of 15,058 vessels, having a tonnage of 919,298; of these, 652 were steamers, with a tonnage of 277,760. The internal communication of the country is carried on by well-kept roads—these being classed into national, departmental, and communal, according as they are upheld by the government, or by the departments and communes to which they belong; by river-navigation, of which there is upwards of 5616 miles; by 2250 miles of canal; and by railways, of which, according to the official report of 1882, about 16,500 miles are in operation. About 10,000 miles more are arranged for.

The *government* of France has repeatedly changed its form since the first great Revolution in the end of the eighteenth century. On September 4, 1870, the Emperor Napoleon III. was declared to be no longer the head of the state, and a republic was proclaimed. At the close of 1872, the supreme power was vested in a National Assembly, with whom rests the nomination of the chief officer of the state, bearing the title of President of the French Republic. He is authorised to execute all laws and ordinances passed by the Assembly. The Assembly consists of two houses—the Chamber of Deputies with 584 members; and the Senate of 300 members. There are nine administrative departments: (1) the Ministry of Justice; (2) of Foreign Affairs; (3) of Finance; (4) of the Interior; (5) of War; (6) of Marine and Colonies; (7) of Public Instruction and Worship; (8) of Agriculture and Commerce; (9) of Public Works. In 1882, the revenue amounted to about 2,856,500,000 francs (£114,000,000), and the expenses to about 3,315,000,000 francs (£132,500,000). In the same year the public debt was about £960,000,000, one half of which was incurred in the dreadful war of 1870. The *army*, according to the government estimates of 1882, is calculated at 498,500 men; the effect of the new law of military service passed by the National Assembly in 1872, being that practically the whole French people are subjected to military drill. The *capital* is Paris, with a population (in 1881) of 2,269,023.

SPAIN AND PORTUGAL.

These two perfectly distinct and independent kingdoms belong to a region so unique in character and situation, that we shall treat them, in regard to their physical geography, as one. This region, commonly known in Britain as 'the Peninsula,' lies at the south-western extremity of the European continent, with which it is connected by an isthmus 230 miles broad, and is situated between lat. 36° and 43° 46′ north, and between long. 3° 20′ east and 9° 30′ west. It is bounded on the north by the Bay of Biscay, and by France, from which it is separated by the Pyrenees; on the east, by the Mediterranean; on the south, by the Mediterranean, the Strait of Gibraltar, and the Atlantic; and on the west, wholly by the Atlantic. The only islands geographically connected are the Balearic—an important group, exhibiting in miniature all the characteristic features of the mainland. The area thus included is computed at 231,577 square miles, of which 195,766 belong to Spain, and 35,811 to Portugal.

In *superficial character*, the Peninsula is decidedly mountainous. The interior may be considered as one vast table-land, from 2000 to 3000 feet above the level of the sea, traversed by numerous mountains, and intersected by rivers. Around this central nucleus extends a narrow belt of maritime low land, sloping gradually towards the sea, and broken into an alternation of hills and valleys, which produce a most agreeable variety of aspect, and present a pleasing contrast to the bleak and barren sameness by which the central region is characterised. The principal mountain chains, all of which run east and west across the Peninsula, are: (1) the Cantabrian Mountains and the Pyrenees, forming the most northern range; (2) the Sierra de Guadarrama; (3) the Sierra de Toledo; (4) Sierra Morena; (5) the Sierra Nevada, running parallel to the shores of the Mediterranean. Between these ranges flow the great rivers of the Peninsula—the Ebro, the Douro, the Tagus, the Guadiana, and the Guadalquivir, all of which, except the first, discharge their waters into the Atlantic, and form channels

of communication with the interior. In this respect the Guadalquivir is the most important, being navigable for vessels of 100 tons to Seville, about 80 miles from its mouth. The principal economic minerals are—granite, marble, serpentine, common limestone, coal, rock-salt, gypsum, alabaster, meerschaum, and several of the precious stones; the metals—iron, lead, silver, mercury, tin, copper, antimony, and cobalt.

The *climate*, as might be expected from the position and physical conformation of the region, is extremely diversified. All along the Mediterranean sea-board, the temperature is mild and equable, seldom sinking below 32°, and generally ranging between 55° and 60° Fahrenheit. Here snow is almost unknown, and verdure is rarely checked, unless during the occasional droughts of summer. On the central plateau, matters are quite reversed; the summer's heat is excessive, and the winter's cold, rendered keener by stormy blasts from the mountains, is equally so. In this region the winter is long, and snow covers the sierras; while the summer is short, and so hot, that verdure is often destroyed. On the northern and western sea-board the summer becomes cooler; and the winds, charged with moisture from the Atlantic, bring rains and other atmospheric diversities.

The *vegetation* of a country so diversified in surface and climate must necessarily present great variety, and thus we find within its limits the banana and palm of the tropics, and the pine of the northern regions. Besides the usual grains and fruits, the vine, olive, sugar-cane, and mulberry are largely cultivated. The *animal kingdom* presents only one or two features worthy of notice. The principal wild animals are—the bear, wolf, fox, herds of wild-boar, lynx, wild-cat, and monkey; the vulture, quail, bustard, flamingo, and some African birds; and of insects economically important, may be mentioned the bee, silkworm, gall-nut fly, and cantharides. The distinguishing features in the domesticated animals are—the horse, of Arab extraction; mules, the finest in the world; and the merino sheep.

The *inhabitants* of the Peninsula—Spaniards and Portuguese being originally one—may be arranged into three races: 1. The *Spaniards* and *Portuguese*, an admixture of Romanised Iberians with Visigoths, who constitute the great bulk of the people, and whose languages, like those of Italy and France, are merely modern forms of Latin, and are hence called Neo-Romanic; 2. The *Basques*, of Navarre and the Basque provinces; and 3. The *Gitanos*, or Gipsies, spread indiscriminately over the country, but preserving intact the individuality and peculiarities of their race. The Spaniards of the south have a considerable admixture of Moorish blood, but the *Moriscoes* proper were finally banished from the land in 1610.

The *religion* of both countries is Roman Catholic. In Spain, the whole population, with the exception of about 34,000 persons, nominally adhere to that faith; but recent political events seem to have proved that large sections of the populace are imbued with notions hostile to all forms of the Christian religion. The *Intransigentes* of Carthagena, Barcelona, and other large cities are in favour of subverting all ecclesiastical, as well as all civil organisations, and even the moderate liberals are probably sceptical in regard to the utility of the church. In 1862 Spain possessed about 40,000 clergy of all ranks, including 9 archbishops and 43 bishops. The Primate of the church is the archbishop of Toledo. *Education* at the close of last century was in a deplorable state. In 1797, less than 400,000 children were at school; but since the government undertook the superintendence of the matter, great progress has been made, and in 1880 more than 1,769,000 were attending school. *Secondary* education is given in Institutions, or middle-class schools, which prepare for the universities, of which there are ten.

Portugal has not more than 500 professed Protestants, mostly foreigners. The clergy number over 3800, and the head of the church is the 'Patriarch' of Lisbon, who is always a cardinal. There are also two archbishops and fourteen bishops. The superintendence of public instruction is under the management of a superior council of education, and is entirely free from the control of the church. The kingdom possesses one university, that of Coimbra, which has 46 professors and lecturers, and about 900 students.

The *industrial pursuits* of the two kingdoms composing the Peninsula are much of the same kind and character. Both are more agricultural than manufacturing or commercial countries; comprehending under the former term all that appertains to grain, fruits, herds, and other produce depending upon the soil. But Spain, during the last twenty years, has made more progress than Portugal, whose agriculture is particularly wretched. In *mining*, of late, considerable activity has been exhibited, principally, however, through the agency of foreign companies, in the quicksilver, lead, and iron departments. In the *arts* and *manufactures*, neither country exhibits much skill or activity. Their commerce, once the greatest in the world, fell off miserably during the 17th and 18th centuries, but is reviving again. During the ten years from 1862 to 1872, their exports to Great Britain doubled themselves. The chief exports of Spain are—wine, quicksilver, lead, wool, raisins, figs, oranges, lemons, and other fruits; olive-oil, barilla, cork-bark, honey, and occasionally wheat—the total value during the years 1877–81 averaging £20,000,000 annually: those of Portugal are wine, oranges, lemons, figs, and other fruits; cork-bark, olive-oil, sumach, wool, goats' skins, and small quantities of tallow, brandy, and other articles, valued in 1880 at nearly £5,500,000.

Railways and *telegraphs* have now been introduced into both countries. In 1880, Spain had 4000 miles of railway, and 25,000 miles of telegraph; Portugal, in 1882, had about 1000 miles of the former, and over 7000 miles of the latter. Neither the *army* nor the *navy* of Spain is in a creditable state, in spite of repeated 'reorganisations.'

The *government of Portugal* is a limited hereditary monarchy, with the succession unrestricted to sex. The parliament consists of a Chamber of Peers and a Chamber of Deputies; the executive, of a responsible cabinet, with seven portfolios. Total population, 4,160,000; annual revenue, £5,000,000; debt (1881) £97,500,000. The capital city is Lisbon, on the Tagus, with a population of 247,000.

The *government of Spain*, since the expulsion

of the Bourbons in 1868, has undergone frequent changes, was for a time a military dictatorship, then a monarchy under a prince of the reigning family of Italy. The old dynasty was restored in the person of the ex-queen's son, Alfonso XII., who died in 1885, and was succeeded by his daughter. The population is under 17,000,000; revenue, £31,000,000; debt (1881) £500,000,000. Capital, Madrid, with a population of 398,000.

SWITZERLAND.

Situated between lat. 45° and 47° 49′ north, and long. 5° 55′ and 10° 30′ east, Switzerland occupies the very centre of the Alpine development, and is consequently the most elevated and irregular of European countries. It is bounded on the north by Germany; on the east, by Austria; on the south, by Italy; and on the west, by France. Its superficies is estimated at 15,991 square miles, of which a large proportion is covered with lakes and glaciers.

The *superficial character* of the country is sufficiently indicated by the mention of its position—a region composed of mountain-ridges, radiating in every direction, with narrow and tortuous river-valleys between. The higher mountain-ridges range from 6000 to 15,700 feet above the sea; their summits, from 9600 feet and upwards, buried in perpetual snow and glaciers, and their sides broken into every imaginable diversity of crag, cliff, ravine, and water-fall, dotted at intervals with clumps of pine and fir. The valleys, on the other hand, are distinguished alike for fertility and beauty, and form a singular contrast with the rugged heights which frown above them. The tract lying between the Alps and the Jura Mountains, and in which all the great lakes, from Constance to Geneva, are situated, may be regarded as the Lowlands of Switzerland.

The *rock formations* in the higher and central districts are strictly primary, flanked by transition and the older secondaries. The equivalents of our own lias and chalks are also found at great heights overlying the older rocks, thus marking the date of the Alpine and Jura elevation; and in the low tract above described, occur alternations of soft greenish sandstones and limestones, the supposed equivalents of the Paris tertiaries. The mineral products are insignificant.

Several important European *rivers*—the Rhine, Rhône, Inn, Ticino, and Doubs—have their sources amid the glaciers of Switzerland, but the Aar is the only river of any navigable importance having its course exclusively within the territory of the Confederation. The *lakes* of Switzerland, either as regards their extent or the beauty and magnificence of their scenery, are unexcelled by any in the world. The principal are—Constance, or the Boden-see, Geneva or Leman, Neuchâtel, Zurich, and Lucerne, on this side the Alps; and portions of Maggiore, Lugano, &c. which lie on the other side of the Alps, chiefly within the confines of Italy.

With respect to *climate*, Switzerland is much colder than its latitude or its position in Europe would appear to warrant. While the mean annual temperature at London is 50·5° Fahrenheit, that at Bern, which is more than four degrees of latitude further south, is 45°; at Zurich, 48°; Geneva, 49·5°; at St Gothard, 30°. Of course, altitude is the prime cause of this deficiency. The plants of nearly all the different zones of Europe are found in Switzerland, from the vine, olive, and mulberry of the sunny valley, up to the herbaceous willow, the lichens, and mosses that struggle up to the confines of eternal snows.

The *inhabitants* are usually ranked under two races—the Germanic and the Celtic: the former comprising the German Swiss of the northern, eastern, and central cantons; the latter, the French and Italian Swiss of the western and southern parts. Of the 2,846,102 inhabitants (1880), 2,030,000 speak German, 608,000 French, and 162,000 Italian; while the language of 38,700 inhabiting the valleys of the Grisons, is derived from Latin, and called Romansch.

The *religious* statistics give the Protestants 1,667,000 of the population; the Roman Catholics, 1,160,369; other Christian sects, 11,000; and Jews, 7370. Some of the cantons (Ticino, Uri, Unterwalden, Valais, Schwytz, Lucerne, &c.) are almost exclusively Catholic; while in others (Bern, Aargau, Basel, and Geneva), Protestantism predominates.

In regard to *education*, Switzerland holds a high place in Europe. In most of the Protestant and mixed cantons, 1 in 5 of the population may be assumed as attending school, and a greater proportion of the public revenue is devoted to schools of various grades than in any European state. The Catholic states are not quite so far up. There are normal schools for teachers in most of the cantons. For higher education there are gymnasia in all the chief towns; and universities at Basel, Zurich, Bern, and Geneva, with 300 professors and teachers, and 1000 students. Several schools in Switzerland are distinguished for combining industrial training with intellectual culture.

The *productive industry* of the country is great. Although more a pastoral than agricultural country, a considerable area is under tillage, yielding excellent crops of wheat, oats, barley, and rye. Maize, beans, lentils, potatoes, turnip, hemp, and flax are also raised. It is in the management of the dairy that the Swiss chiefly excel—cattle, cheese, and butter being articles of export. The vine is cultivated in the valleys; and in some districts are large orchards of apples, pears, and cherries, for the manufacture of liqueurs. In several of the *arts* and *manufactures* the Swiss exhibit great ingenuity and taste; and many branches (watch-making, wood-carving, &c.) are carried on in the cottages of the peasants. Zurich is the chief seat of the silk and cotton manufacture. The chief industrial products for export are silk, cotton, watches, jewellery, and straw-plait. The *railway and telegraph systems* have penetrated even into Switzerland. At the end of 1882, nearly 1600 miles of railway had been laid down; and at the end of 1881, more than 4000 miles of telegraph.

In respect of *government*, Switzerland is a federative republic, composed of 22 cantons, each of which has an internal government of its own. The sovereign power of the confederation is vested in the Federal Assembly, which consists of a national council and a senate or council of state. The first is chosen for three years, by universal suffrage, one member for every 20,000 inhabitants; the senate consists of forty-four members, two from each canton. The Federal

Assembly can alone make war and peace with other countries. It chooses a federal council or ministry of seven members, who conduct the several departments of administration. At the head of this executive board is the president of the confederation, who is chosen yearly in a united sitting of the assembly. Bern, with a population, in 1880, of 44,000, is the federal capital.

The federal army, at the end of 1881, consisted of 115,700 men of all arms; besides these, the *landwehr* of the several cantons can be called out by the federal authority. The federal revenue, in 1882, was 42,000,000 francs; the expenditure, rather less; the debt is almost nominal.

ITALY.

Italy is partly a peninsular and partly an insular country, lying between lat. 36° 35′ and 46° 40′ north, and long. 6° 40′ and 18° 30′ east. It is bounded on the north by Switzerland and Austria, from which it is naturally separated by the Alps; on the east, by the Gulf of Venice; on the south, by the Mediterranean; and on the west, by the Mediterranean and France. Its area, including that of the islands, is computed at 114,290 square miles. The largest and most important of these islands are—Sicily and the Lipari group, Sardinia, and Elba.

Superficially, Italy exhibits much diversity and beauty. Guarded by the Alps, its northern fringe exhibits all the features of the Swiss landscape; but this soon changes into scenery of the most opposite description—namely, the great plain of Lombardy, which extends along the base of these mountains for more than 250 miles, with an average breadth of 50, is flat and low, but fertile and well cultivated, and watered throughout by the Po and its numerous affluents. The only other mountain development is that of the Apennines, which, branching from the Maritime Alps in Genoa, ranges southward like a backbone or spine through the centre of the peninsula, bifurcating at Venosa into two minor ridges—the one forming the heel, the other the fore-foot of the fanciful boot. From the Apennines, which, in Gran Sasso d'Italia ('The Great Rock of Italy'), attain an extreme height of 9520 feet, the country slopes on both sides, intersected by streams and valleys, and terminating near the coast in flattish land, forming the 'Maremma' of Tuscany, the Roman Campagna, the Pontine Marshes, &c.

The principal *rivers* of the country are—the Po, with its numerous Alpine tributaries, flowing through the great plain of Piedmont and Lombardy, and falling by several mouths into the Gulf of Venice; the Adige, also flowing into the Gulf of Venice; the Tiber, with its small affluents, rising in the Apennines, and falling into the Mediterranean, navigable to Rome; and the Arno in Tuscany, navigable to Florence, and connected with the Chiana, one of the tributaries of the Tiber, by means of a canal.

As regards its *geology*, granite, primary schists, and limestones occur in the Alps, in the northern extremity of the Apennines, and in their southern bifurcations. The great central range of the Apennines is said to consist chiefly of Jurassic limestones, occasionally broken through by older strata, flanked on the north by secondary rocks, and on the south, downwards to the Mediterranean, by recent tertiaries, replete with marine remains. Through these tertiary sandstones and marly limestones rise numerous volcanic hills, but lately extinct, or still in operation. This chain of volcanic action may be said to fringe the whole of the Mediterranean sea-board, from the Arno to Sicily—exhibiting numerous dormant craters, and the still active ones of Vesuvius, the Lipari Isles, and Mount Etna. The principal mineral products of the country are—iron, from Elba; the finest statuary marble, from Carrara, in Modena; sulphur, from Sicily; alum and nitre, from near Rome; alabaster, from Tuscany; puzzolana (a hydraulic cement), from Puzzuoli, near Naples; and borax.

The *climate* of Italy has been greatly extolled; but this is true only of certain localities, and under certain seasons. The temperature may be generally mild, the atmosphere of unexampled transparency, and the sky unclouded; but certain tracts—as the Maremma of Tuscany, Campagna di Roma, the Pontine Marshes, &c.—are subject to the fatal scourge of the *malaria*, while the southern shores are occasionally visited by the pestilential and enervating sirocco and simoom.

The *vegetable* productions of Northern Italy differ little from those of Southern France and the valleys of Switzerland, already described; the cultivation of rice, and the more extensive growth of the mulberry, being perhaps the main peculiarities. In Southern Italy, the products, such as the olive, the orange, the lemon, and the sugar-cane, are more analogous to those of the south of Spain—receiving greater diversity from the successive stages of the Apennines, which are clothed in many places with forest-growth to the very summit.

Even in ancient times the *inhabitants* of Italy were not *one* race. The north was Celtic; the region between the Arno and the Tiber, Etruscan; the shores of the southern half of the Peninsula, Greek; but the political predominance of the Latin race through the conquests of Rome, in the course of years obliterated all primitive distinctions, and created a practical unity among the population. The vicissitudes of history have not materially altered this. The Lombard, the Byzantine, the Arab, have left untouched the noble impress of classic antiquity, and the language of Cicero and Virgil in the modern form of Italian still rules from the Alps to the Strait of Messina.

The *Roman Catholic religion* is the national religion, and is professed by nearly the whole nation; the only exceptions being the Protestant Waldenses in Piedmont, the Greeks in the principal commercial towns, and the Jews, who are found chiefly in Rome, Leghorn, and Venice. Yet here (as in Spain) there is intense hostility to the priesthood among the educated and liberal party. Infidelity is wide-spread, and even atheism is not rare. The number of ecclesiastics is extraordinarily great; in May 1869, it was reckoned that the proportion was seven to every thousand of the population, which would give over 180,000, and that was after the law which annihilated ecclesiastical jurisdiction and the privileges of the clergy had been in operation for eight years. The confiscation of monastic property by the new Italian government has been fortunate for the cause of education. The money thus obtained has been

devoted largely to the instruction of the people. Primary schools are nearly universal, schools for training teachers are springing up, and twenty-two universities give a liberal and professional culture. But in 1881, the average number of the people above six years of age who could not read or write was 61 per cent.

The *productive industry* of Italy presents considerable variety. Lombardy is the chief corn-growing state; in Tuscany, the culture of fruit is much attended to; the central parts are mainly pastoral; and in Naples and Sicily, 'the abundance of vegetable productions is more owing to the climate and soil than to the industry of the husbandman.' The culture of silk, the vine, and olive, are important. Fish form an important article of consumption; and the tunny, anchovy, mullet, and other fisheries are conducted upon an extensive scale. The chief manufactures are those of silk fabrics, silk thread, &c. which have their principal seat in Lombardy. The commerce of Italy has largely increased of late. In 1885, the total value of her export trade was given at £47,250,238; that of the imports was a little more. There are over 5500 miles of Italian railway in use. In 1885 the revenue, shewing, contrary to custom, a surplus, was £62,428,506; the debt was over £400,000,000. The war effective of the Italian army amounts to 1,990,000 men, including militia. The *navy* has nearly 120 ships of war, of which over 20 are iron-clads, including several of the most powerful afloat. The population in 1881 amounted to 28,459,628.

Politically, Italy was long divided into a number of independent states, but since 1870, when the troops of Victor Emanuel took possession of the papal territories, it has become a single nation. The government is a limited monarchy, with two Houses, a Senate and a Chamber of Deputies; the latter elected by the people, the former, mainly nominated by the king for life. Rome, the capital, had in 1881 about 273,000 inhabitants.

ROUMANIA, SERVIA, MONTENEGRO.

The three *principalities*, Roumania, Servia, and Montenegro, formerly subject to Turkey, secured the recognition of their independence at the Berlin Congress of 1878; and since 1882, Roumania and Servia are kingdoms.

ROUMANIA, lying between the Danube and the Eastern Carpathians, which separate it from Austria, has an area of 45,000 square miles, and a population in 1880 of above 5,000,000. Both of its main divisions, Moldavia and Walachia, are fairly fertile. The inhabitants are a mixed race, descended partly from Roman colonists, and speak Roumansch, a language largely derived from Latin. The principality is a constitutional monarchy; the creed is that of the Greek Church.

SERVIA, partly highland and partly plain, lies south of the Danube; it has an area of 18,800 square miles, and a population of 1,900,000. The people are of the Slavonic race, and, speaking a pure Slavonic tongue, belong mainly to the Greek faith. The king and his council are responsible to the Senate and Assembly.

MONTENEGRO, chiefly a wild highland, just touches the Adriatic on its western border. The area is near 3550 square miles, and the population is estimated at 250,000. The people are Slavs of the Servian branch, and adhere to the Greek church. The prince is substantially an absolute monarch.

TURKEY IN EUROPE.

Turkey in Europe lies between lat. 39° and 48° north, and long. 16° and 29° east. It is bounded on the north by Austria, Servia, and Roumania; east, by the Black Sea, Sea of Marmora, and the Archipelago; south, by Greece; and west, by the Ionian and Adriatic Seas. Since the Berlin treaty of 1878, when Montenegro, Servia, and Roumania became independent, Turkey in Europe, including Bosnia and Herzegovina (now occupied by Austria), the principality of Bulgaria, and the autonomous province of Eastern Roumelia, has an area of about 130,000 square miles.

The chief mountain-range is the Balkan, the ancient Hæmus. Branching off from the Dinaric Alps, which separate the plains of Hungary from the Adriatic Gulf, it passes eastward to the Black Sea. The greatest known height is 9700 feet. North of the Balkan, Bulgaria, lying in the great valley of the Danube, consists mainly of rich alluvium. The country south of the Balkan is diversified by offsets from that range; and a branch known in ancient times as the Pindus range is sent off southward into Greece. Between these southern offshoots of the Balkan are inclosed valleys and plains, often of great beauty and fertility. The *minerals* of economical importance are marble; iron, copper, lead, and silver ore; magnesia, meerschaum, and whetstones; but mining, unless in Bosnia, is little attended to.

As to *climate*, the flat provinces in the north have a hot and sultry summer; the winter, on the other hand, is severe, and snow lies for fully five months on the mountains. South of the Balkan, the seasons are less marked, and the climate of the valleys is delightful. In Bosnia and the adjoining provinces, the cereals and other cultivated crops can be raised in any quantities on the plains, while the mountain-slopes are clad with forests of oak, elm, and pine. South of the Balkan, the country is covered with forests of the sycamore, plane, carob, box, and cypress; gardens of roses, jasmine, and lilac; vineyards and orchards of nearly all kinds of fruit-trees. In Thessaly—the garden of European Turkey—the olive, vine, fig, pomegranate, walnut, almond, orange, lemon, citron, cotton, tobacco, silk, &c. are reared in perfection.

The *ruling people* of the country are the Ottoman Turks or Osmanlis, an offshoot from the Tatars of Central Asia, who, between 1390 and 1470, conquered that part of the country lying within the confines of Europe. They form, however, but a small minority in the European portion of their empire. Of the 9 million inhabitants, they numbered, in 1880, only about 2 millions, the rest being Slavs, Albanians, Greeks, Armenians, and Jews. They have, however, imposed their Mussulman religion on 3½ millions of the inhabitants, although the adherents of the Greek Church are nearly twice as numerous. There is some *education* of a kind, but it is almost restricted to the reading of the Koran and its commentaries.

Every branch of *industry* is in a backward state in Turkey. *Agriculture* is in a very rude and even declining condition. Were the Turkish farmers and herdsmen secure from plunder and

extortion, the produce of the country might be ten times what it is; still, so great is the fertility, that there is a surplus of corn for exportation. The grains chiefly cultivated are—maize, wheat, rye, barley, oats, and buckwheat; the vine is grown in most of the provinces; and flax, hemp, saffron, cotton, tobacco, madder, &c. chiefly in the south. *Manufactures*, of late years, have been depressed by foreign competition; and the domestic weaving of cotton stuff for family use, and some silks at Constantinople and Salonica, are now almost the only branches of consequence. Commerce is carried on chiefly with Italy, Britain, Austria, Greece, and Russia, and centres in Constantinople.

During the war with Russia in 1877–78, Turkey called into the ranks of its army no less than 752,000 men, including reserves and irregular troops. In 1880, a partial re-organisation of the shattered military system had been carried through; and the Turkish army was estimated to comprise 150,000 available men. The navy has been seriously crippled; it counted in 1880 only some 18 vessels (formerly 80). The financial condition of Turkey has for years been on the verge of utter bankruptcy.

The *government* is an absolute monarchy or despotism, hereditary in the family of Osman, but restricted to males. The sultan, as calif, or successor of the prophet Mohammed, unites the highest spiritual dignity with the supreme secular power. The only limit to his will is the Koran, or Book of Mohammed (see MOHAMMEDANISM), which he is bound by his oath of office to observe; and this is in reality the source of all civil, political, or criminal law. The legislative and executive authority is exercised under the supreme direction of the Sultan by two high dignitaries, the *Sadr-azam*, or Grand Vizier, the head of the temporal government, and the *Sheik-ul-Islam*, or Head of the Church. Both are appointed by the sovereign, the latter with the nominal concurrence of the *Ulema*, a body comprising the clergy and chief functionaries of the law. The *Divan*, or Ministerial Council, has eight portfolios. All offices of state are open to the humblest subjects. Since 1856, religious toleration has been the law of the land. Capital, Constantinople, with a population of perhaps 450,000.

GREECE.

This country, whose ancient history is so intimately associated with much that is refined and noble in human progress, occupies the south-east extremity of Europe, commonly distinguished as the Hellenic Peninsula. It is surrounded by the Mediterranean, except on the north, where it is bounded by Turkey, of which, till 1821, it formed one of the component sections. Its area, with the recent additions, is about 25,000 square miles, of which about three-fifths are cultivable.

The *physical aspect* of the country is decidedly mountainous and rugged; its hills, though seldom rising above 5500 feet (Guiona, the culminating point of Greece, is 8783 feet; Parnassus, 8068 feet; and St Elias—anc. Taÿgetus—in the Morea, 7900 feet), being so abrupt and craggy as to assume an appearance more majestic and imposing than many others of double the altitude. Rising and radiating in every direction, the hills occupy fully three-fifths of the surface, leaving the remainder in narrow defiles, glens, and basin-shaped valleys, which severally formed the sites of the numerous petty states into which ancient Greece was divided. The mineral products are—marble of various colours, porphyry, slate, coal, gypsum, sulphur, alum, asphalt, zinc, lead, iron, gold, silver, copper, manganese, and cobalt; none of which, however, are obtained in important quantities.

Considerable *diversity of climate* is experienced, in consequence of the varied altitude of the country, and the manner in which it is intersected by bays, gulfs, hills, and valleys. No portion reaches the snow-line, but snow annually falls on the higher hills, where it often lies for weeks together. The vegetable and animal products of continental Greece are quite analogous to those of Southern Italy and Turkish Thessaly, already described.

The *dominant people* are the Hellenes or Greeks, who chiefly inhabit the eastern and central parts, and who boast of descent from the Greeks of classic times. Their language is the Romaic, a modernised form of the ancient Greek, to which it bears a much closer resemblance than the Italian does to the Latin. The other inhabitants are Albanians, occupying the greater part of Livadia and part of the Morea; and Walachs, descended from a colony from Walachia. The established or national religion is that of the 'Orthodox Oriental Apostolic,' or Greek Church, having the sovereign for its head, and governed (since 1833) by a holy synod, consisting of five members annually elected by the dignitaries from their own number. The only other ritual observed to any extent is that of the Roman Catholic, and this more especially in the Ionian Islands and the Cyclades. *Educationally*, Greece is still in a backward state, but the government is doing a good deal to improve it. The public schools are of four grades—the *communal*, the *ancient Greek*, the *gymnasium*, and the *university*. In 1880, the educational returns gave 1200 teachers, with 91,000 pupils. Besides the schools already mentioned, there are schools of medicine, and theological, military, and naval academies. The two universities are those of Athens and Corfu. Athens possesses a university, with a numerous staff of professors and a library, and also a Polytechnic School.

The *productive industry* of the country differs little from that of the southern parts of Turkey, already described. The vine and currant-grape are extensively cultivated; the latter, indeed, forms the staple article of export. In 1881, the value of the currant trade with Great Britain amounted to £1,656,000. The other fruits are more the gift of nature than the results of culture. The manufactures are mostly domestic and quite inconsiderable; fishing is largely carried on. The Greeks are remarkable for commercial enterprise; and a great part of the Mediterranean trade is in their hands. Their commercial fleet numbered in 1882, 6790 vessels, of a burden of near 300,000 tons. The *railway system* embraces short lines from Athens to the Piræus and in Thessaly; and others are in progress.

Greece formed a part of the Turkish empire till 1821, when the people revolted, and after a long and severe struggle, succeeded, with the aid of

England, France, and Russia, in achieving their independence. The country was accordingly formed into the new kingdom of Hellas, and Otho, a prince of Bavaria, appointed king. Otho abdicated in 1862, and was succeeded by Prince George of Denmark. The *government* is a constitutional monarchy, the legislature consisting of a senate and chamber of representatives. The administration is corrupt and inefficient, and brigandage is prevalent. During King George's reign, the average duration of ministries is less than a year. The population, according to the census of 1879, amounted to 1,979,423; the revenue is about two millions; debt, 15 millions sterling; army, 30,000 men; navy, 15 vessels (2 iron-clads) manned by 2700 men. Capital, Athens, with a population, in 1884, of 84,000.

AUSTRO-HUNGARY.

The Austro-Hungarian Empire occupies a large portion of Central Europe, and consists of an aggregation of kingdoms, principalities, and duchies, acquired at various times by treaty or by conquest; but though composed of a heterogeneous assemblage of tribes and nations, it lies compactly together, and is situated between lat. 42° and 51° north, and long. 9° 41′ and 26° 30′ east. Its area is estimated at 240,000 square miles.

The *natural features* of the empire exhibit wide and well-marked diversity of hill and plain. Of the former, the principal are—the Alpine development of the Tyrol, which, under the title of the Carnic, Julian, and other ridges, diverges into Illyria and Styria; the eastern and western Carpathians, which encircle the whole of Hungary and Transylvania north of the Danube; and lastly, the Riesengebirge, Erzgebirge, and Böhmerwald ranges, which, inclosing Bohemia, form the boundary with Saxony and Bavaria. In the western or Germanic provinces of the empire, there are a number of fine valleys, watered by such rivers as the Inn, Enns, Moldau, March, Muhr, and Drave; while in Galicia and Hungary expand some of those vast plains which give character to this region of Europe.

The country abounds in *minerals*, and mining has long been practised and encouraged by the government. Gold and silver are mined in Hungary and Transylvania; quicksilver at Idria in Carniola; iron, lead, tin, and copper are abundant; calamine, zinc, cobalt, antimony, bismuth, manganese, and almost every other metal can be procured. There are also abundant supplies of rock-salt, as at Wieliczka; marble, coal, alum, saltpetre, and sulphur.

In point of *climate*, the country is generally divided into three regions. 1. The southern, extending from lat. 42° to 46° north, where are found the fig-tree, olive, mulberry, and myrtle. 2. The middle region, from lat. 46° to 49° north, where the olive is not found, but where maize and vines thrive in favourable situations. 3. The northern zone, extending from lat. 49° to 51° north, where winter is severe, and lasts fully five months; where vines and maize are no longer met with, but wheat, barley, oats, and rye form the usual crops. The forests of Austria are very extensive, forming about a fourth part of the surface, and comprising all the timber-trees known in England.

The *population* of Austria, amounting, in 1880, to 37,900,000, embraces a great variety of peoples distinct in origin and language. The most numerous are the *Slaves*, stated at 16,200,000. They form the bulk of the population of Bohemia, Moravia, Carniola, Dalmatia, Croatia, Slavonia, the Military Frontiers, the north of Hungary and Galicia. The *Germans* number 9,840,000, or one-fifth of the whole. They are more dispersed over the empire than any other race; but they occupy in greater numbers the Duchy of Austria, Salzburg, Tyrol, Styria, Carinthia, and the west of Hungary. The *Roumans*—speaking languages derived from that of ancient Rome—amount to 3½ millions. They consist of the Italians of Istria and Dalmatia; the *Ladins*, occupying some valleys in the Tyrol; and the Vallaks or Walachians of Transylvania, &c. The *Magyars* or Hungarians proper, 6,430,000 in number, are located chiefly in Hungary and Transylvania. Besides these leading races, there are Armenians, Albanians, Gipsies, Jews, whose combined numbers are estimated at 1,350,000.

In respect of *religion*, 24½ millions of the inhabitants (66 per cent.) belong to the dominant church, the Roman Catholic; the Greek and Armenian churches, including those Greeks who acknowledge the supremacy of the pope, 7 millions; the Protestants, 3½ millions; and Jews, 1,600,000. The extensive powers formerly secured to the Roman Catholic clergy by a special concordat (1855) with the pontifical government, were all swept away by the Reichsrath in 1867–68, and at present throughout the empire the law recognises the perfect equality of all religious creeds. In 1880, the Catholic Church in Austria had 11 archbishops, 51 bishops, and more than 30,000 secular priests.

Of late years, since the rapid growth of liberal opinion in Austria, education has made great progress. Naturally, the German provinces stand foremost in this honourable work. Primary education is universal and compulsory, but the variety of languages spoken in the country embarrasses and impedes the operation of the law. Sometimes three or four are required in one school. There are 9 universities—Vienna, Prague, Pesth, Gratz, Innsbrück, Cracow, and 3 minor ones.

Industrially, Austria is more an agricultural and pastoral than a manufacturing country. It furnishes wheat and other bread-corns in abundance; fruits, wine, hops, hemp, flax, tobacco, saffron, and dye-stuffs; hides, horns, wax, honey, silk, and other animal produce. Bohemia and Moravia have long been celebrated for their manufactures in woollens, linens, cottons, leather, glass, hardware, and fire-arms. The *mineral* produce has been already adverted to; and, *commercially*, Trieste is a place of great importance. Austria possesses magnificently constructed roads, leading throughout the chief provinces; has several well-kept canals of considerable length; and in 1872, 7530 miles of railway, and 22,700 miles of telegraph, besides its great navigable rivers, the Maros, Theiss, Drave, Po, and Danube, on the last of which, passengers and goods are conveyed by steam between Ulm and Galatz, and on to Constantinople.

Since 1867, the Austro-Hungarian empire has formed a double state, consisting of a German or 'Cisleithan' (so called from the river Leitha, which runs near the Hungarian border), and a Hungarian or 'Transleithan' monarchy. Each country has

its own parliament, ministers, and government, and is so far self-regulative; but there is also a higher parliament, composed of delegates from both parts of the empire, whose decisions are final on imperial questions, such as foreign diplomacy, war, &c. The form of government is now essentially *constitutional*, and, as far as liberal reforms can give solid unity to a heterogeneous mass of peoples, the thing is being done in Austria.

In 1881, the revenue of the empire, and of Austria and of Hungary, was nearly £90,000,000; and its expenditure, £80,000,000. The debt in the same year amounted to £470,000,000. The *army* in 1882 numbered 268,470 on the peace, and 1,031,700 on the war footing. The *navy* consisted of 50 steamers (13 iron-clads), and 10 sailing-vessels. Pola and Trieste are the two Austrian war-harbours. Capital, Vienna, with 1,103,000 inhabitants (in 1880).

GERMANY.

Germany, so called from the Latin *Germania*, is the English name of the country which the natives call Deutschland, and the French, L'Allemagne. The word is sometimes employed to denote the whole area of the European continent within which the Germanic race and language are dominant. In this broad sense, it includes, besides Germany proper, parts of Austria, Switzerland, and perhaps even of the Netherlands; but using the word here to denote the territory belonging to the new Germanic empire of 1871, it may be said that Germany occupies the central portions of Europe, and extends from 6° to 22° 40′ east longitude; and from 49° 7′ to 55° 50′ north latitude. It is bounded on the north by the Danish peninsula, the German Ocean, and the Baltic; on the east, by Russia and Austria; on the south, by Austria, Italy, and Switzerland; and on the west, by France, Belgium, and the Netherlands. Its area is estimated at 208,000 square miles, and its population, in 1880, at 45,234,000.

With regard to physical configuration, Germany presents two very distinct formations: 1. A range of high table-land, occupying the centre and southern parts of the country, interspersed with numerous ranges and groups of mountains, the most important of which are, the Harz and Teutoburgerwald, in the north; the Taunus and Thuringerwald, in the middle; and the Schwarzwald and Rauhe Alps, in the south; and containing an area, including Alsace and Lorraine, of 110,000 square miles. 2. A vast sandy plain, which extends from the centre of the empire north to the German Ocean, and the boundaries of Jütland, and including Slesvig-Holstein, contains an area of 98,000 square miles. This great plain, stretching from the Russian frontier on the east, to the Netherlands on the west, is varied by two terrace-like elevations. The one stretches from the Vistula into Mecklenburg, at no great distance from the coast of the Baltic, and has a mean elevation of 500 to 600 feet, rising in one point near Danzig to 1020 feet; the other line of elevations begins in Silesia, and terminates in the moorlands of Lüneburg in Hanover, its course being marked by several summits from 500 to 800 feet in height. A large part of this sandy tract is interspersed with deposits of peat; but other parts are moderately fertile, and admit of successful cultivation. In respect of drainage, the surface of Germany belongs to three different basins—(1.) The Danube, from its source in the Black Forest to the borders of Austria, belongs to Germany, and through this channel the waters of the greater part of Bavaria are poured into the Black Sea; thus opening up communication with the East. (2.) The North Sea. (3.) The Baltic. The chief German streams flowing into the North Sea are the Rhine, the Weser, and the Elbe; into the Baltic, the Oder and the Vistula. The most important of the numerous canals which connect together the great river systems of Germany are Ludwig's Canal in Bavaria, which unites the Danube and Main, and thus opens a communication between the Black Sea and German Ocean; the Finow and Friedrich-Wilhelm's Canals in Brandenburg; the Plaue Canal, which connects the Elbe and the Havel; and the Kiel and Eyder Canal, uniting the Baltic and German Ocean. Numerous lakes occur both in the table-land of Southern Germany and in the lowlands of the northern districts, but few of them are of any great size. Germany abounds in swamps and marsh lands, which are especially numerous in the low northern districts. Its mineral springs occur principally in Nassau, Würtemberg, Baden, Bavaria, and Rhenish Prussia. Many of these springs have retained their high reputation from the earliest ages.

The *climate* of Germany is said to be 'less variable than the nature of its mountain-system, and the ranges of latitude within which it lies, would lead us to imagine; and its vegetation resembles in its general character that of England or the north of France.' Germany is rich in mineral products, among which the most important are silver, found in the Harz Mountains; iron in numerous mountain ranges; salt in many parts of the country; coal in Rhenish Prussia and Silesia. Cobalt, arsenic, sulphur, saltpetre, alum, gypsum, bismuth, pumice-stone, tripoli-slate, kaolin, emery, ochre, and vitriol are all among the exports of Germany. The vegetable products comprise a very large proportion of European flora. All the ordinary cereals are extensively cultivated in the north, and largely exported; hemp and flax, madder, woad, and saffron grow well in the central districts, where the vine, the cultivation of which extends in suitable localities as far north as 51°, is brought to great perfection—the best wine-producing districts being the valleys of the Danube, Rhine, Main, Neckar, and Moselle, which are, moreover, noted for the excellence of their fruits and vegetables. Tobacco is grown in sufficient quantities for extensive exportation on the Upper Rhine, Werra, and Oder. The hops of Bavaria have a high reputation, and the chicory grown in that country, and in the district between the Elbe and the Weser, finds its way all over Europe as a substitute for coffee. The most extensive forests are found in Central Germany, and in some parts of Prussia, while the north-western parts of the great plain are deficient in wood, the place of which is in some degree supplied by the abundance of turf yielded by the marshy lands. Germany has long been noted for its good breed of horses, while Saxony, Silesia, and Brandenburg have an equal reputation for their sheep-flocks, and the fine quality of their wool. The rich alluvial flats of Mecklenburg and

Hanover are celebrated for their cattle; the forests abound in swine and small game, while the Bavarian Alps afford shelter to the larger animals, as the chamois, red-deer, wild goat, fox, marten, and wolf; and in all the plains of the north, storks, wild geese, and ducks are abundant. Germany stands next to Great Britain in regard to the care and success with which its agricultural, mining, and other natural capabilities have been cultivated.

The *people* are mainly of Germanic (Deutsch) origin, speaking various dialects of High and Low German; but using the former as a written medium. Other races are—French and Walloons, on the Rhine and in Lorraine; Slaves (including Poles, Wends, and Czechs) in the east; Danes in the north; and a number of Jews in the principal cities. Lutheran and Calvinistic Protestantism, with Roman Catholicism, divide among them the great bulk of the people—the former having 28 millions of adherents; the latter, 16 millions; the rest are Jews, Moravian Brethren, &c. *Education* is more generally diffused in Germany than in any other country of Europe, and is cultivated with an earnest and systematic devotion not met with to an equal extent among other nations. The elementary schools are so general, that none but the wilfully ignorant, or those of imperfect faculties, can be unacquainted with reading, writing, and the first rules of arithmetic. The schools for classical instruction, denominated gymnasiums, pedagogiums, and lyceums, are found in almost every large town, and dispense learning at a very cheap rate. The universities are numerous (twenty-one within the new Germanic empire), and provide the most liberal and various instruction in the higher branches of knowledge.

Industrially, the Germans are a thrifty, plodding people. Their agriculture and husbandry are of a tidy and domestic character. Their *mines* have been long conducted upon correct and scientific principles. The principal *manufactures* are those of linen, in Silesia, Lusatia, and Westphalia; woollen, in Saxony, Rhenish Prussia, Pomerania, and Bavaria; cotton, in Saxony and Rhenish Prussia; toys, in the hilly districts of Saxony, Bavaria, and the Black Forest; glass, in Silesia; porcelain, at Berlin and Meissen; clocks, in the Black Forest; tobacco, at Hamburg and Bremen, &c. Germany exports grain, wood, cattle, horses, wax, wine, beer, woollen, linen, and cotton goods, glass, hardware, &c.; and imports sugar, coffee, tea, rice, cotton, &c. Internal communication is carried on by navigable rivers, canals, and roads. In 1882, there were over 22,000 miles of railway within the Germanic empire, and 45,000 miles of telegraphic lines.

Since 1871, Germany has been an empire, composed of a confederation of German states, but welded together, for national purposes, into one great power, governed by the king of Prussia, who is hereditary German emperor; and represented by two legislative bodies—the *Bundesrath*, or Federal Council, the members of which are annually appointed by the governments of the various states; and the *Reichstag*, or Imperial Diet, the members of which are elected by universal suffrage and ballot for a period of three years. With the consent of these two bodies, the German emperor can declare war, make peace, enter into treaties with foreign nations, and appoint and receive ambassadors. The empire comprises four kingdoms (Prussia, Bavaria, Saxony, and Würtemberg), six grand-duchies, five duchies, seven principalities, three free cities, and the imperial territory of Alsace-Lorraine.

The revenue of the empire, apart from the revenues of the several states which comprise it, was in 1882 nearly £30,000,000, and the debt £18,000,000. The army had then on the peace-footing a strength of 450,000 men, and on the war-footing 1,500,000. The navy, formed under Prussian auspices, has grown rapidly, till in 1882 it comprised 24 iron-clads, 58 other steamers, besides some sailing-vessels. The total imports of Germany in 1877 had a value of £193,350,000, and in 1878, £186,150,000; the exports in 1877, £134,760,000, and in 1878, £145,820,000. Between 1872 and 1879, the annual imports from Great Britain ranged in value from £19,500,000 to £31,618,000, the greatest value being in 1872; the exports to Great Britain ranged in annual value during the same years from £19,230,000 to £26,270,000, the greatest value of exports being in 1877. The mercantile navy of Germany comprised, in 1879, 4804 sea-going ships, of 1,129,129 tons burden—351 of them being steamers, with a tonnage of 179,662 tons.

HOLLAND, OR THE NETHERLANDS.

This is one of the secondary kingdoms of Europe, lying along the south-eastern shores of the German Sea, which, from their uniformly low and level character, are generally known to geographers as the Netherlands. Its area is estimated at 12,650 square miles.

Superficially, the whole country, saving some slight elevations in Gelderland, Utrecht, and Overyssel, forms one unbroken flat, without forests, or, except in the south part, running waters; the land consisting mainly of moor, marsh, and meadow land, traversed by numerous canals, which, while they are absolutely necessary to drain it, and render it fit for cultivation, answer for the most part the purposes of roads—many of them being navigable for large vessels. In many places, the level of the surface actually falls from twenty to forty feet below that of the sea, against which it is protected partly, as in Zealand, Friesland, and Gelderland, by enormous dikes, and partly, as between the Helder and the Hook of Holland, by sandhills or *dunes*, cast up by the ocean upon the shores.

The *climate*, as might be expected from the situation and lowness of the country, as well as from the number of water-courses which intersect its surface, is generally moist and foggy. In winter, Holland experiences a much lower temperature than the opposite coast of England—the river-mouths and canals being covered with ice often for three months together.

The natural *vegetation* is of the scantiest description: there are no forests, and only a few plantations of oak, beech, and elm, clumps of pine on the links or sand-drift, and rows of willow and poplar along the banks of the canals. The principal cultivated plants are—wheat, oats, and barley; buckwheat, and the leguminous crops in smaller quantities; potatoes to a great, and flax, hemp, tobacco to a considerable extent; madder, rape-seed, chicory, mustard, and beet; tulips,

hyacinths, lilies, dahlias, and other garden flowers, for which the country around Haarlem has long been celebrated.

Of the *inhabitants*, about three-fourths are Hollanders or Dutch, speaking that dialect of Low-German which, of all modern Teutonic tongues, has retained most of the primitive characteristics; the Frisians, also a Low-German race, whose speech was anciently spread over almost the whole country, but is now confined to parts of North Friesland; the High-Germans in Luxemburg and Limburg, and Walloons in Limburg. As to *religion*, the majority of the people are Calvinistic Protestants; the minority consisting mainly of Roman Catholics, Lutherans, and Jews. There is, however, no dominant sect in the country: all forms of faith and ritual are alike tolerated; the clergy are indiscriminately maintained by the state; the universities are upheld in the same manner, and these are open to students of all sects, whose theological studies are conducted under professors of their own creed. Education is spreading rapidly throughout the kingdom, through the operation of the Primary Instruction Law of 1857, but even yet it is calculated that in the rural districts one-fourth of the men and one-third of the women can neither read nor write. According to the government returns in 1880, the number of pupils in the public schools amounted to 408,000, and in the private schools to 137,000. There are about 100 secondary schools. A new university has been founded at Amsterdam; and the universities of Leyden, Utrecht, and Groningen, once famous, are again attracting the notice of Europe by the liberality and learning of their professors.

Industrially and *commercially* the Dutch have long been celebrated. The nature of their *agricultural* produce has been already adverted to; and the careful, cleanly style in which they cultivate the soil and manage their dairies, as well as the manner in which they embank and drain their low plots or *polders*, are beyond all praise. The chief *manufactures* are those of woollen, in Leyden and Utrecht; silks, in Utrecht, Haarlem, and Amsterdam; calicoes, shirtings, drills, tablecloths, and dimities, in the town of Overyssel; tobacco-pipes at Gouda; and paper, leather, sugar-refining, painters' colours, and cordage, at various other places. The distilling of gin is extensively conducted at Schiedam. Delft, and Rotterdam; and ship-building at the ports of Rotterdam and Amsterdam. The trade of the Netherlands is chiefly carried on with Germany and Great Britain, and is rapidly increasing year by year. In 1867, its imports were valued at £44,500,000, and its exports at £36,400,000; in 1880, they had risen respectively to over £69,000,000 and £52,000,000.

The *government*, since the establishment of peace in 1815, has been a constitutional hereditary monarchy. The legislative power is vested in the sovereign and the States-general, which consists of two chambers—the first, of thirty-nine members, elected by the provincial assemblies; the second, of a representative for every 45,000 inhabitants, which, in 1881, gave 86 members, all of whom are paid. Population in 1881, 4,114,000; the revenue of late years has averaged about £9,000,000; the expenditure has generally been a little less. In 1882, the national debt was £78,500,000; the army at the same date was 62,000; the navy consisted of 103 steamers, of which 17 were ironclads. Capital, Amsterdam, with (1885) a population of 366,000.

BELGIUM.

Belgium, another of the lesser kingdoms of Europe, is situated between lat. 49° 27′ and 51° 31′ north, and long. 2° 33′ and 6° 5′ east; and is bounded on the north by Holland; east, by Rhenish Prussia, Dutch Limburg, and Luxemburg; south, by France and Germany; and west, by the German Ocean. Area, 11,372 square miles.

Superficially, the northern and western provinces of Belgium, in their flatness, fertility, dikes, and canals, may be regarded as a continuation of Holland—with this difference, that in no part does the surface fall beneath the level of the sea. The south and east provinces have an opposite character; they are generally more thinly peopled, less cultivated, and exhibit an irregular hilly surface, with tracts of marshy land and extensive forests. The country is intersected by numerous streams—the affluents of the navigable rivers Meuse, Sambre, Dender, Scheldt, Lys, &c. The chief mineral products of Liege, Namur, Hainault, and Luxemburg are—coal, iron, lead, copper, and zinc; besides which may be mentioned manganese, calamine, alum, various kinds of stone, slate, marble, whet-hones, and porcelain clay. Of the *mineral springs* arising from these formations, the most celebrated are those of Spa.

The *climate* resembles that of the south-east of England, but is, on the whole, more humid and variable; some districts, moreover, as Flanders, being at certain seasons rendered unhealthy by noxious exhalations from the water-courses and low polder-lands. The *vegetation*, both natural and cultivated, is the same as that of England and the north of France.

Of the *inhabitants*, about two-thirds, inhabiting the northern provinces, are Flemings, an offshoot of the great Teutonic stem, and speaking a language resembling Dutch. The south-eastern provinces are inhabited by Walloons, who are Celts like the French, and speak dialects (Walloon and Picard) of the French language. French is the language of the educated classes. In regard to *religion*, nineteen-twentieths of the people are Roman Catholics. There are not more than 15,000 Protestants, and perhaps about 3000 Jews.

Education is almost entirely in the hands of the Jesuits. The colleges of that order have more pupils than the royal athenæums and other upper and middle class schools; while the Roman Catholic university of Louvain has twice as many students as the two state universities put together. Elementary education is not yet generally diffused, but is growing.

At present, the *industry* of Belgium is happily distributed between agriculture, mining, and manufactures. The Belgian or Flemish system of agriculture is well known over Europe for its minute and careful management; and no people understand better the method of collecting and preparing every species of manure, without which much of their sandy soil would be next to worthless. Half the surface of the country is under tillage. The mines of Belgium are an important source of

wealth. The amount of coal raised annually is about 16,000,000 tons, and the number of men employed is over 100,000. The most important *manufactures* are—woollen cloths, at Verviers, Liege, Ypres; carpets, at Tournay; linens, at Bruges, Courtray, Ghent, Termonde, &c.; cotton goods, at Ghent, Bruges, Courtray, Mechlin, Louvain, Tournay, Mons, and Antwerp; superb lace, at Brussels and Mechlin; ribbons, at Antwerp, Tournay, Ypres; metallurgy, at Charleroi, Liege, Namur, &c.; steam-engines, fire-arms, and machinery, at Liege; hardwares and cutlery in various localities; porcelain, at Brussels, &c.; glass, at Namur, Liege, and Charleroi. The internal communication of the country is carried on by means of the rivers, already noticed, a number of well-kept canals, good macadamised roads, and a partly national system of railways, which in 1882 had a length of 2600 miles.

The *government*, as established in 1831, is a constitutional, hereditary monarchy. The legislative power is exercised collectively by the king, senate, and house of representatives—the members of both of these chambers being elected by all citizens who pay a small amount of direct taxes. The executive is exercised by the sovereign, assisted by responsible ministers. Population, 5,520,000; revenue (in 1882), £12,000,000; debt, £72,000,000; imports (in 1881), £112,000,000, and exports, £98,500,000; army, on the war-footing, 100,000—on peace-footing, 40,000. Capital, Brussels, with a population (including its 8 suburbs) of 395,000.

DENMARK.

This small but ancient kingdom occupies the greater part of that peninsular and insular portion of Europe betwixt the German Ocean and the entrance to the Baltic Sea; and lies between lat. 54° 35′ and 57° 42′ north, and long. 8° 5′ and 12° 45′ east. The Danish dominions consist of the kingdom of Denmark proper, which includes the peninsula of Jütland, with the islands of Sjaeland or Zealand, Funen, Laaland, Falster, Möen, Langland, &c. The area is 14,740 square miles.

Superficially, both the peninsular and insular portions are low and flat; in many places rising little above the sea, and requiring the protection of mounds and dikes; and in no portion exceeding an altitude of 1200 feet. In the north and west of Jütland, large sandy tracts are prevalent, partially covered with bent, heath, and juniper, and utterly unavailable for culture. The soil of the islands is composed of calcareous sand and clay, and is, upon the whole, of average quality.

The *climate*, in consequence of the low-lying nature of the land, and the proximity of the surrounding seas to its most central portions, is, on the whole, much milder than the latitude would indicate. The distinguishing characteristics are humidity and changeableness. All the common grasses, rye, wheat, oats, potatoes, hemp, flax, and rape-seed, are raised; and in several of the islands are large orchard-growths of apples, pears, cherries, and hazel-nuts.

The *people* belong to the Scandinavian branch of the great Teutonic family, and speak a modern form of the old Norse, which is much simpler in structure, and more musical in sound than its venerable parent. Lutheranism is the established *religion* of the state, and according to the census of 1880 was professed by all but 17,000 of the people. Elementary education is widely diffused, attendance at school being obligatory from the age of seven to fourteen. Almost every one can read and write. Besides the university of Copenhagen, there are thirteen gymnasia in Denmark, where classics are taught, and a large number of what the Germans call *real-schulen*. The parish or elementary schools are nearly 3000 in number.

Industrially, Denmark is more an agricultural and pastoral than a manufacturing country. Its commerce consists almost exclusively in barley, wheat and oats, cattle and butter. The total value of the exports in 1880 was £12,650,000. They consist mainly of butter, grain, and cattle; and nearly half go to Great Britain.

The *government* is a hereditary monarchy. The constitution of 1849 gives an elective parliament, or *Rigsdag*, for the whole kingdom, consisting of two houses, a Folkething and a Landsthing, the latter forming a Senate or Upper House. Since 1866, Slesvig and Holstein have ceased to be Danish provinces, and now form part of Prussia. Population (in 1880), 1,969,000; revenue (in 1881), £2,875,000; debt (in 1882) £11,203,000; army, 38,000; navy, 41 vessels, of which 8 were ironclads. Capital, Copenhagen, with 273,000 inhabitants.

SWEDEN.

This country occupies the eastern and more important section of the Scandinavian peninsula, and is situated between lat. 55° 20′ and 69° north, and long. 11° 10′ and 24° east. Its extreme length is about 965 miles, and its average breadth 188: the area is computed at 172,000 square miles.

Physically, the country presents several districts of very different aspect; the whole, however, declining from the Kjölen and Dofrine ranges towards the basin of the Baltic. Starting with these, which have the character of an irregular table-land, about 20 or 25 miles across, and only at intervals studded with mountains of more than 5000 feet high, we find the general elevation between 2000 and 2800 feet, covered with straggling forests of pine and birch. From this tract the country descends by steps or terraces. Throughout the whole of these, the rivers which rise in the mountain-plateau hold on their course, presenting numerous rapids and water-falls; only a few of them, as the Angermans, being navigable during the lower stages of their descent. Such is the superficial character of Nordland. As we travel southward through Svealand, the face of the country becomes flat, or only diversified by the insignificant ridges which inclose the great lakes Wener, Wetter, &c. South of the lakes, the greater part of Gothland presents the same low and sandy character as the opposite coast of Denmark. The most important *mineral products* are—iron (the best in Europe), copper, and lead in abundance; cobalt, zinc, antimony, gold, and silver in minor quantities.

Respecting *climate*, Nordland, part of which lies within the Arctic Circle, has from five to six months of winter; snow and ice then covering the mountains and rivers, and locking up the waters of the Gulf of Bothnia. On the other hand, the summer is sudden and short, but excessively

warm; at midsummer, the sun never falls beneath the horizon north of Tornea; and the crops of oats and barley come to maturity in six or eight weeks. In the central parts, winter lasts only about four months, but is severe enough in most seasons to lock up the Baltic; and in the southern level tracts, the climate is very similar to that of Northern Germany.

The *vegetable productions*, as might be expected from the high latitude and natural poverty of the soil, are by no means abundant. In the forests, pines, firs, alders, and birches are prevalent in the north; these, with oak, elm, and ash in the central districts; and the beech, chestnut, mulberry, &c. only in the south. Apples, pears, and other garden-fruits are grown in Gothland. The cultivated products consist chiefly of rye, barley, oats, wheat, potatoes, peas, hemp and flax, buckwheat, madder, hops, and woad, in the south; but as we proceed northward, most of these disappear, and oats, barley, maslin (a mixture of barley and oats), and potatoes, are alone cultivated—oats ripening so far as 66° north, and a coarse variety of barley even to the limits of the pine-woods in 69° 30′. The principal *wild animals* are—the bear, wolf, wolverine, fox, lynx, badger, otter, squirrel, lemming, and other small rodents; with a few scattered members of the beaver family. Game-birds are everywhere rife, from the partridge to the capercailzie; and aquatic birds appear in great abundance. Seals and porpoises are found in the Baltic, whose waters also furnish plentiful supplies of cod, sole, turbot, pilchard, herring, stremming, mackerel, oysters, &c.; while in the rivers and lakes are sturgeon, salmon, trout, pike, and perch.

The *inhabitants*, with the exception of a few Finns and Laplanders, belong (like the Danes) to the Scandinavian branch of the great Teutonic family, and speak a variety or dialect of the old Norse. The *religion* of the state, and that to which the whole population, with the exception of some 7000, adhere, is the Lutheran, administered by 1 archbishop, 11 bishops, and over 3000 inferior clergy. Education in Sweden is both free and compulsory. In 1881, 97 per cent. of all the children between eight and fifteen attended school. High schools or gymnasia exist in all the provincial capitals; and there are two universities—namely, those of Upsala and Lund.

Industrially, the Swedes are a busy, hardy, clear-headed, and progressive people. The staple exports are timber, bar-iron, and corn; and the staple imports, textile fabrics, coal, colonial merchandise, and machinery. In 1880, the total value of all Swedish exports amounted to £12,500,000, and of all Swedish imports to £16,000,000, an increase of more than 100 per cent. in ten years. The *manufactures* are chiefly domestic, the peasantry supplying themselves, as winter employment, with nearly all the coarse woollens, linens, and cottons they require. There is now a considerable network of railways in Sweden, partly belonging to the state, and partly to private companies.

The *government* is a limited monarchy, hereditary in the male line, and restricted to the Lutheran creed. The legislative power is vested in the king and representative Diet, consisting of two chambers—both elected by the people. The executive is managed by the king and a state council.

Population in 1881, 4,572,000; revenue in 1882, £4,375,000; debt, £12,000,000; army, 184,000; navy, 130 vessels, of which 14 are iron-clads. Capital, Stockholm; pop. (1881) 176,700.

NORWAY.

Norway occupies the western section of the Scandinavian peninsula; extends from lat. 58° to 71° 10′ north, and from long. 5° to 31° east; and is bounded on the west and north by the Northern Ocean; east, by Russian Lapland and Sweden; and south, by the Skagerrack. Its greatest length is upwards of 1100 miles, and average breadth 50; area, 120,000 square miles.

The *general aspect* of the country is bleak, rugged, and sterile; the shores are rocky and precipitous, and, on the west, fenced by numerous small islands, and indented by *fiords*. The interior consists chiefly of the mountain masses of the Kjölen and Dovre-fjeld, rising in the north almost from the water's edge, and in the south spread out in plateaux, or *fielle* (*i.e.* fields), intersected by narrow valleys susceptible of a scanty culture, or by steep ravines, down which impetuous rivers cleave their way by rapids and water-falls. The lowest tracts, and those to which cultivation is chiefly limited, occur round Christiania fiord, and the adjoining shores of the Skagerrack, or to the south and east of the Bay of Trondhjem. The geology of the country is primary, and yields, like the contiguous parts of Sweden, iron, copper, cobalt, zinc, marble, and slate.

The *climate* is milder, but more variable than that of Sweden under the same parallels. The cause is supposed to be the warmth of the Gulf Stream. At Christiania, winter lasts from the middle of September to the middle of May, and summer is short and warm; in Lapland, winter endures from August till May, and for many weeks the sun is invisible (the aurora borealis and stars being the only natural lights); while summer is short and fervid, the sun never sinking beneath the horizon.

The *inhabitants*, with the exception of the Laplanders, are members of the Teutonic race, and immediately descended from the old Scandinavian Norsemen—a dialect of whose language they employ. According to the census of 1865, the whole population, except some 5000, were Lutherans in *religion*. In *educational* matters, Norway occupies a high position: elementary instruction is compulsory between the ages of seven and fourteen, and is provided for partly by stationary parish schools, partly, on account of the scattered state of the population, by ambulatory teachers; and the higher departments by 13 *laerd skole* (learned schools) in the principal towns. The subjects taught in these higher schools are theology, Latin, Greek, Norwegian, German, French, English, mathematics, history, and geography. There is a university at Christiania.

The *industry* of Norway is chiefly limited to her *forests*, which yield excellent timber, bark, and tar; to her *fisheries* of cod, lubfish, herrings, lobsters, salmon, anchovies, &c.; to her *mines* and foundries of iron, copper, and cobalt; and to *shipping*, much of which is employed in the carrying-trade of other countries. *Agriculture* is improving; the manufactures are almost wholly domestic. During the years 1877–81, the average

value (annually) of the imports into Norway was £8,963,000; and of the exports, £5,684,000.

With respect to *government*, Norway was an appanage of the Danish crown until 1814, when, by the convention of Kiel, it was placed under that of Sweden. It still, however, retains its own representative body or *Storthing* (which is essentially democratic); and is, in reality, no more connected with Swedish rule than Hanover was formerly with Britain. The *Storthing*, when assembled, divides itself into *two* houses, the *Lagthing* and the *Odelsthing*. The executive is vested in a council of state at Christiania. Population in 1876, 1,806,900; public revenue (1881–82), £2,313,000; debt, 6 millions; army, 40,000; navy, 37 steamers, of which 4 were iron-clads, carrying 152 guns. Capital, Christiania, with 128,000 inhabitants.

PRUSSIA.

Prussia, the most powerful state in Germany, and, since the wars of 1866 and 1871, one of the most powerful in Europe, occupies the northern half of the imperial territory, from 49° 6′ to 55° 35′ N. lat. and from 6° to 22° 15′ E. long. Its area amounts to 134,380 square miles.

Its *physical aspect, geology, climate, vegetation,* and *animal* productions are identical with those already described under the north and west of Germany.

The *people* of Prussia belong principally to the great Teutonic and Slavonic families—the Germans forming seven-eighths of the whole. The *religion* of the majority (five-eighths) is Protestantism (Lutherans and Calvinists), while rather less than three-eighths are Roman Catholics. These enjoy equal civil rights. The recently formed secession from the Roman Catholic Church, under the title of 'Old Catholics,' is now recognised by the state. 'In no other country is the *system of education* so complete; and in none is the instruction of all classes so carefully provided for. The law imposes upon parents the strict obligation of sending their children to school, unless they can prove that they are giving them a proper education at home; and care is everywhere taken to furnish the poor with the means of complying with this law, by providing their children with the things necessary. Every parish is bound to have an elementary school, and every town one *bürgerschule* ('citizen-school') or more, according to the population. Above these are gymnasia, and in these institutions classical learning is pursued preparatory to admission into the universities, of which there are eight—in the cities of Berlin, Göttingen, Breslau, Halle, Bonn, Königsberg, Greifswalde, and Kiel.' Besides these, there are normal schools for the training of teachers, establishments for instruction in particular arts, and collections of natural history, philosophical apparatus, and public libraries, accessible to any person who chooses to avail himself of their assistance. The whole of this admirable system is upheld partly by the respective towns and provinces, and partly by the state, and partly also by fees; the whole being under the strict and unremitting surveillance of government functionaries.

The *national industries* have been already mentioned under the head of Germany. Prussia is well provided with means of communication in navigable rivers and roads; and in 1882 had 13,000 miles of railway.

The government, until 1847, was an absolute monarchy; since then, a modified constitutionalism has been introduced, though the king still declines to be a mere cipher, and appoints his own ministers, irrespective of parliamentary majorities; and there is therefore always the risk of a collision between him and his parliament. But the vigorous and triumphant *national* policy pursued of late years by the monarch, under the bold and sagacious guidance of Prince Bismarck, has hitherto prevented any quarrel. Both in the *Herrenhaus* ('House of Lords') and the *Abgeordnetenhaus* ('House of Deputies') the majorities are in sympathy with the policy of the king and his ministry. Population (1880), 27,279,000; revenue (1881), £45,500,000; debt, £103,000,000. The army of Prussia is the most important section of the army of the German Empire, and the imperial navy is wholly due to the initiative of Prussia. The Prussian troops number 350,000 in peace, and 900,000 in war. Capital, Berlin, with (1880) a population of 1,122,330.

RUSSIA.

Russia, the largest country in Europe, is bounded on the north by the Arctic Ocean; east, by the Ural Mountains and the Caspian; south, by the Caucasian range and the Black Sea; and west, by Turkey, Austria, Prussia, and the Baltic. The area is estimated at 2,059,000 square miles.

Superficially, the territory may be regarded as one vast plain, with a slight elevation running diagonally across the interior, and forming the great water-shed which diverts the rivers to the Arctic Ocean on the one hand, and to the Caspian and Black Seas on the other. If we except the Uralian Mountains on its eastern border, and a hilly tract in the Crimea, there is no portion of the country which rises more than 1100 feet above the sea, and that only near Valdai in the central plateau. 'The northern section, which sensibly declines,' says a native author, 'towards the White and Frozen Seas, is covered with vast forests, abounds in marshes and lakes, and is but little fit for cultivation. The other, and more southerly portion of the plain includes the whole district along the Volga as far as the sandy steppes or deserts between the Caspian and the Sea of Azov, and constitutes the finest part of Russia; generally, it has a fertile soil, the arable and pasture land preponderating over the woods and marshes.'

The chief economic *minerals* of Russia are—gold, platina, silver, lead, and copper from the Ural; copper and tin in Finland; iron from the central elevation of Valdai, &c.; coal, in Poland, Tula, and Ekaterinoslav, but of little importance; rock-salt and brine-springs in Poland, Taurida, Perm, and other places; lime, alabaster, gypsum, and amber.

The *climate* of Russia is much colder than that of other European countries in the same latitude; and the farther we proceed eastward, the temperature becomes still lower, in consequence of the uncultivated state of the surface, distance from the tempering influences of the ocean, and the frequency of easterly and northerly winds

from the icy regions of the Arctic Ocean. In the northern section, the winter is severe, and lasts from eight to nine months; summer, on the other hand, is short and hot; and there is, generally speaking, neither spring nor autumn. In the central region, winter is also severe, but shorter; there is something like spring and autumn, and summer is still warmer. In the south, winter continues only for about five months; and summer is often fervid and oppressive. The provinces bordering on the Baltic have a wet and variable climate, and this feature extends to the elevated tract which borders the upper basin of the Volga.

The *vegetable* and *animal productions* present less variety than might be expected from a region lying between the 45th and 70th parallels. The most remarkable feature in the former is the vast expanse of forest growth, covering about two-fifths of the entire superficies. Among the cultivated plants, we may notice rye all over the country; barley to 67° north; oats to 62° north; wheat in the fertile tracts along the southern rivers, but also pretty far north; millet along the Don; hemp and flax in the west and centre; tobacco in the Ukraine; cranberries in the marshes of the north, fruit in the south-east; the vine in the Crimea and Caucasian provinces; and variously, potatoes, rape, rhubarb, poppy, &c. The characteristic wild *animals* are—the polar bear, the black and brown bears of the forest, the reindeer, elk, urus, wild-horse of the Ukraine, wolf, blue fox, lynx, beaver, sable, ermine, lemming, &c.; game, but not abundantly; the sturgeon, salmon, trout, carp, pike, mackerel, and a variety of other fishes in the rivers; and the bee, whose honey and wax form valuable products of consumption and export.

The *population* of the country, amounting in 1881 to more than 83,000,000, is composed of a vast variety of races, differing in language, religion, manners. The chief are: the *Slavonic*, including the Russians proper, the Poles, Bulgarians, and Servians; the *Finns* of Finland, Lapland, and Esthonia; the *Lettish* tribes of the Baltic provinces; the Tatars of the Caucasus, Astrakhan, Kazan, the Crimea, &c.; the *Germans* in Riga, Revel, and the Baltic provinces generally; the *Swedes* of Finland; and in lesser numbers, Jews and Greeks, with some French and English traders. The settled inhabitants are ranked in four classes—nobles, clergy (along with whom are classed government officials, artists and professional men generally), merchants, and peasants. Each of these classes either possesses special privileges, or is subject to special obligations; on the other hand, each enjoys, to a certain extent, the right of self-administration in its own affairs. Each apportions its taxes, and chooses some of its own functionaries. In 1861, serfdom was abolished, and 20,000,000 peasants became freemen.

All forms of *religious faith* are tolerated; but that of the orthodox Greek Church, which has 54,000,000 adherents, is the established religion of the empire, and is professed by the Russians, Servians, &c. The Roman Catholic faith is that of the Poles and Lithuanians; the Swedes, Danes, Finns, and most of the Germans are Lutherans; Calvinism reckons but a small number of Poles and Germans; Islamism is the creed of the Tatar tribes. In Russia there are nearly 500 cathedrals, and about 29,000 churches, with 70,000 parish clergy belonging to the established faith. Besides, there are about 550 convents. The emperor is the Head of the Church, and appoints to every office in it, but he does not possess the power to decide questions of doctrine. The ecclesiastical chief is the archbishop of Moscow. *Educationally*, the country is in a very backward state. In 1882, 19 out of every 100 of the inhabitants could read and write. The number of primary schools was only 28,000, and the number of pupils 1,539,975, but this is an immense advance on 1860. In the same year, there were 456 secondary schools for boys, and 384 for girls, and 8 universities.

The *industrial operations* of the country are rapidly increasing. *Agriculture* is in its first stage, and yet, owing to the excellency of the soil and comparatively small home-demand, large supplies are annually exported. Of late years, *manufactures*, under high protective duties, have risen to some consideration, and the country now possesses a number of establishments for the preparation of woollen goods, silk, cotton, linen, and metal wares. The chief seats of these are the governments of Moscow, Novgorod, Vladimir, Saratov, Tula, and St Petersburg. The Russians excel in the manufacture of leather; and from their advantages in respect to raw material, their canvas, strong linens, cordage, felt, mats, potash, soap, candles, caviare, and isinglass are quite as good as those made elsewhere. During the ten years from 1861 to 1871, the trade of Russia with foreign countries more than doubled itself; the imports in 1870—1880, varied from 54 to 91 millions, the exports from 55 to 96 millions. The internal commerce has, of late years, been immensely extended by the introduction of the railway system; and in 1883 nearly 15,000 miles of railway were open for traffic; and in 1882, nearly 60,000 miles of telegraph.

The *government* is an absolute hereditary monarchy; all power emanates from the czar, emperor, or autocrat, whose authority is without limit or control. He is the central point of the administration, the head of the church, as well as of the state, and to his decision, or for his sanction, all important measures must be submitted. His authority is delegated to four great boards, the members of which are of his own appointment; and to these respectively are committed the ordering and execution of all legislative, judicial, civil, religious, financial, and other affairs. Population (1881) of Russia in Europe, 83,000,000, and of the empire, 98,000,000; revenue, £93,000,000; debt, £640,000,000; army, on the peace-footing, 840,000, the war-footing, 2,264,000; navy, 224 vessels, of which 31 are iron-clads. Capital, St Petersburg, with 876,500 inhabitants.

ENGLAND AND WALES.

ENGLAND, comprehending Wales, is bounded on the north by Scotland, from which it is chiefly separated by the Solway Firth, the Cheviot Hills, and the river Tweed; on the east, by the German Ocean; on the south, by the English Channel; on the west, by St George's Channel and the Irish Sea. The space thus included is rather irregular in form, and lies between lat. 50° and 55° 45′ north, and between long. 5° 41′ west and 1° 46′ east. Measuring along the second meridian, from St Alban's Head on the south to Berwick on the north, its length is 362 miles; its breadth, from Land's End to North Foreland, in Kent, 330 miles; from St David's Head, in Pembroke, to Lowestoft, in Suffolk, 300; from Lancaster Bay to Bridlington Bay, in Yorkshire, 110; and from the Solway Firth to Tynemouth, only 64 miles.

SUPERFICIAL FEATURES.

Northern Division.—If we draw a line from the mouth of the Mersey, by the Peak of Derby, to the mouth of the Humber, the country between this line and the Scottish border may be properly called the northern division of England. This district is traversed towards the west coast by the range of hills called the Pennine chain, which, starting from the Cheviots, runs south for about 180 miles, and ends with the Peak of Derby. It forms the water-shed between the east and the west of the north of England. The chief rivers on the west are the Ribble and the Mersey, in Lancashire; on the east, the Tyne, the Wear, the Tees, the Ouse, and the Humber. The Cumberland Hills are an offshoot of this range. To the east of the Pennine chain, from the Tees to Doncaster, a length of 180 miles, lies the fertile *Plain of York.*

Western Division.—A line drawn from the mouth of the Dee, by the eastern border of the English counties of Shropshire, Herefordshire, and Monmouth, to the mouth of the Severn, will mark the natural border of this division of England. It is traversed by the Cambrian range of hills, running, like the Pennine, north and south, and keeping still nearer than it does to the western shore. The summits of Snowdon, Cader Idris, and Plinlimmon mark its course. Snowdon (3557 feet) is the highest mountain in England. It is said that Scotland can be seen from the top. Plinlimmon is the boundary rock between North and South Wales. On the west of the Cambrian range, there is nothing that can be called a river. On the east are the Wye and the Usk, running into the Bristol Channel. The Malvern Hills, dividing Herefordshire from Worcestershire, form a water-shed between the Wye and the Severn, which has its source in Plinlimmon, and also flows into the Bristol Channel. Wales, the whole of which is comprehended in this division, is generally rugged and mountainous like the Scotch Highlands. Its population and dialect are Celtic.

Eastern Division.—It extends from the mouth of the Humber to the mouth of the Thames, comprising four littoral counties and Cambridgeshire; or, at least, it may be fairly held to comprehend the greater part of this county. It is a low plain, the most level part of which is the Fen district, on the west and south of the Wash. A large part of this tract is called the Bedford Level, having been drained at the instance of the Duke of Bedford, in the reign of Charles I. The rivers in this district are inconsiderable, and almost stagnant. The chief ones are the Witham, Welland, Nen, and Great Ouse, flowing into the Wash; and the Yare, with its branches, the Wensum and Waveney, in Norfolk. This is the district of England most advanced in agriculture. Norfolk produces the best barley, and Essex competes with Kent in producing the best wheat in England.

Midland Division.—It extends from Middlesex to Cheshire, embracing both of these counties. It is bounded on the south by the Thames, and in other quarters by the boundary-lines of the other divisions, as already indicated. It is an undulating plain, with an average elevation of from 200 to 400 feet. There is no hill in it 1000 feet high. In Leicestershire, near the centre of the district, is Bardon Hill, 850 above the level of the sea, and not more than 200 above the level of the surrounding country, yet it commands a view of Lincoln Cathedral, the Derbyshire Peak, of the Wrekin near Shrewsbury, and of the Malvern Hills; the whole comprising nearly one quarter of England. The Trent and the Severn are the principal rivers by which this district is drained.

Southern Division.—This comprises all the country south of the Thames and the estuary of the Severn. In Cornwall and Devon, the inland districts are mountainous and rocky. The Downs, North and South, are elevated tracts, covered with turf or short grass, stretching from Devonshire to Sussex. The highest point, 930 feet above the sea, is in Dorsetshire. Between the termination of the Downs and the borders of Kent, lies the Weald, a flat and fertile tract. Gloucestershire is traversed by the Cotswold Hills, which form the water-shed between the Severn and the Thames. A branch of the range, called the Mendip Hills, traverses Somersetshire. Salisbury Plain, which lies chiefly in the south of Wiltshire, is a bare tract of country, with a general elevation of about 500 feet. Its extent is about 20 miles by 15. The peninsula between the Bristol and English Channels is generally a hilly country. Dartmoor, in Devonshire, is a granite table-land, with an area of 100,000 acres, covered in a great part by marsh and peat. The highest summits on this moor are upwards of 2000 feet. The rivers of the southern district are small. The Medway, in Kent, and the Avon—to be distinguished from the Upper Avon at Tewkesbury, and the Lower Avon at Bristol—in Wiltshire, are the most considerable.

The growth of hops in England is almost wholly confined to this district, Worcestershire and Herefordshire being the only counties north of the Thames in which they are cultivated.

GEOLOGY.

The geology of England is best understood by taking the island of Great Britain as a whole; and, for the sake of space, it is more convenient to bring it in under the head of Scotland, in the next sheet.

CLIMATE.

The general characteristics of the English climate, compared with those of the west of Europe, between the forty-fifth and fifty-fifth parallels of latitude, are, its milder winters, cooler summers, greater humidity, and greater variability. But England has a variety of climates, and these change relatively, according to the season of the year. The mean temperature of January in London, and on the south-east coast generally, is 38°, which is 1° below that of Cape Wrath, in the north of Scotland, and the same as that of the Faröe Islands, in 62° N. lat. Going west along the south coast, the winter temperature rises rapidly; the mean of January at Portsmouth being 39°, at the Isle of Wight 40°, at Exeter 42°, at Plymouth 43°, and at Land's End 45°, which is but 2° below that of Nice (47·1°, according to the Scottish Meteorological Society), and 4·5° above that of Pau (40·5° according to the same authority). It is necessary, however, to keep in mind that this high mean temperature of the south-west coast of England, in winter, arises chiefly during the night, and during westerly winds, whose moisture, imbibed from the Atlantic, is condensed into cloud on reaching land, at this season many degrees colder than the sea, and nocturnal radiation is thus impeded. Still, there can be no doubt that the south coasts of Devon and Cornwall possess the best stations in England for those who require a high winter temperature. The advance of temperature is, however, much slower on the west than on the east coast. In March, London and Bristol have both a mean of 43°, Land's End of 46°; and during June, July, and August, the warmest part of Great Britain is embraced in a circle, whose centre is about half-way between London and Bath, with Cambridge for the northern limit. Broadly, we may say that the temperature of Great Britain is determined by longitude from November to March, and by latitude from March to November. The mean July temperature of London is 64°, which is equal to that of Nice and of the French Riviera generally, in May. It falls rapidly going north, being but 60° at York, and 59° at Newcastle. The following table, taken from Sir James Clark's valuable work, shews the mean monthly and annual rainfall at one or two places in England, and also, for the sake of contrast, at one or two places elsewhere:

GOVERNMENT—ADMINISTRATION.

Respecting the political constitution, laws, religion, and education of England, the reader is referred to the article on the CONSTITUTION AND RESOURCES OF THE BRITISH EMPIRE, in which he will find statistics and details, which we do not think it expedient here to repeat.

For administrative purposes England is divided into fifty-two counties, twelve of which are in Wales. The Channel Islands and the Isle of Man are under peculiar jurisdiction.

The table on next page shews the areas of the counties, their population in 1871 and 1881, and the number of their inhabited houses at the former date.

POPULATION.

Ethnology.—The constituent elements of the English population are to be traced in the history of the country. The first inhabitants were Britons, probably a mixed Celtic race, who, during the time of the possession of the country by the Romans, must have become slightly changed by the admixture of that race. Upon a scattered population of Romanised Britons came the great wave of the Saxon invasion in the 5th and 6th centuries. After this, the predominant element of English society was undoubtedly Saxon; the Norman conquest only adding to it a French aristocracy, which had little effect on the bulk of the population. The English therefore, exclusive of the Welsh, who are almost purely British, may be regarded as mainly a Teutonic people; the British element diminishing as we recede from Wales and approach the east coast, where the people are nearly pure Teutonic.

English Character.—It has been said that if a suggestion of action were made to a Frenchman, a Scotchman, and an Englishman, the first would ask if it would bring him glory; the second, if it was reasonable; and the third, if it would 'pay.' Frenchmen and Scotchmen probably value money as much as an Englishman does, but—of course we talk of the general rule—they place less value on lavish expenditure, at least the Scotchman certainly does. It is the

social weight incident to possession and to being supposed to be living prudently as regards money, that a Scotchmen chiefly values; while the mainspring of the Englishman's action is his

intense dread of the world believing him unable to afford to live in pecuniary ease relatively to his social position. The expression which this social dread takes may often be vulgar, yet it is a mighty social force inciting to labour and enterprise. Burke has said of the money-loving Englishman, that 'his desk is his altar, his ledger is his Bible, his business is his religion, and money is his god.' That there is truth in this, can hardly be denied; yet it is this same determination to acquire wealth —this horror of falling behind in the race for gold —which has made England the mart of the world, and sent her people to colonise the globe. Less subtle than the Scotch or the German—troubling itself less with the mysteries of the universe—the English intellect is probably more politically efficient than either; being less prone than the Scotch to fall in early life into the error of supposing that mankind may be efficiently worked on by mere force of reason. A contempt for logic in political arrangements, and a respect for the majority, are, as applied to these, its essential characteristics. A French political party is defeated—it retires in a rage to hatch a revolution. If he cannot change the law, the Englishman obeys and growls. It may be very bad, in his opinion, but he reveres the British constitution, and he has a wholesome horror of revolutions.

A contempt for all expression of emotion—especially of anger or affection—is a noteworthy feature of difference between British and French character. A member of the House of Commons may be as insolent to another member as one man can be to another, if he takes care not to be 'unparliamentary' in his language; but if it is seen that he is indulging temper at the expense of policy, he will never rise into power. Frenchmen kiss each other when they have been parted for a week. An Englishman nods to his brother whom he has not seen for ten years, and says: 'How do you do, Jack?' In Scotland, social grades melt into each other, so that you can hardly say where one begins and another ends. In England, the lines between them are clearly and firmly drawn; and in no other country are the dread of falling, and the desire to rise in the social scale, so intense as in England. In no other country will the member of the lower grade so abase himself to gain admission into the higher. But let us here do the Englishman the justice to say that he is aware of this weakness, which the great English satirist of our time has called 'snobbishness;' that he satirises himself unsparingly; and on this, as on other social points, allows the foreigner to do so, with invincible—on which account, perhaps, provoking—good-temper. The Frenchman and Frenchwoman are kindly to dependents and servants, treating them as part of the family, and as having an interest in its affairs. The Englishman, or rather let us say the English lady, while never rude to her servants, widens the social gulf between them with a haughty and exacting reserve; and lives in a state of chronic surprise that she does not meet with fidelity and personal attachment.

These observations on English character refer to the manifestation of it in the middle and upper classes of society; but the essential elements are probably much the same in all classes. In all, there is the same love of political liberty, with a heartfelt veneration for social rank. Frugality—a distinguishing virtue of Scotch and French character—is certainly not an English virtue in any class; indeed, the average Englishman despises it. An English working-man will spend half-a-crown on his dinner, while the Scotchman with the same wages will dine for sixpence. And in every respect the lower classes in England are more self-indulgent than the Scotch or than the continental. Love of domestic order and cleanliness are eminently virtues of the lower classes of England—an

English village shewing, in these respects, a beauty not to be easily found elsewhere. The peasantry of the south of England are courteous in manner, more so than the peasantry in the north; but those in the north are shrewder, and in intellect more like their Scotch brethren.

If the Englishman is semi-maniacal in pursuit of wealth, it must be conceded that he makes a free and generous use of it when acquired. His fortune made, he does not wish his sons to tread the same path of drudgery over which he has manfully toiled—he gives them a liberal education, sends them to Oxford or Cambridge, and hopes to see them dignitaries of the bar, the church, or the state. In no other country are the minutiæ of social culture held so essential as in England to admission to the society of the well-born and well-educated. An Englishman may be rich, clever, handsome, and generally socially attractive, yet, if he calls a house 'an 'ouse,' or uses a knife when a fork is the proper implement, he may as well try to climb to the moon, as to scale the barrier between him and cultivated society in England. One of the most distinctive characteristics of the Englishman is his fondness for the privity and sanctity of his *home*—a name which has hardly an equivalent in any other language. This feeling finds expression in the following verses of Mrs Hemans:

The stately homes of England,
How beautiful they stand,
Amidst their tall ancestral trees,
O'er all the pleasant land!
The deer across their greensward bound,
Through shade and sunny gleam;
And the swan glides by them with the sound
Of some rejoicing stream.

The merry homes of England,
Around their hearths by night,
What gladsome looks of household love
Meet in the ruddy light!
The blessed homes of England,
How softly on their bowers,
Is laid the holy quietness
That breathes from Sabbath hours!

The cottage homes of England,
By thousands on her plains,
They are smiling o'er the silvery brooks,
And round the hamlet fanes.
Through glowing orchards forth they peep,
Each from its nook of leaves;
And fearless there the lowly sleep,
As the bird beneath their eaves.

The free, fair homes of England,
Long, long, in hut and hall,
May hearts of native proof be reared
To guard each hallowed wall.
And green for ever be the groves,
And bright the flowery sod,
Where first the child's glad spirit loves
Its country and its God.

Increase of Population.—The population of England in the time of the Plantagenet sovereigns is believed to have been little more than two millions. It has been estimated at 5,500,000 in 1696. The progress during the greater part of the eighteenth century was slow; the amount in 1760 is supposed to have been about 6,500,000. In 1801, for the first time, a regular census was taken; and this has been repeated once in ten years ever since, giving the following results:

1801	9,156,171	1841	16,035,198
1811	10,454,529	1851	18,054,170
1821	12,172,664	1861	20,066,224
1831	14,051,986	1871	22,712,266

The increase of the population has been much greater in the towns than in the country; and this tide, setting from the country to the towns, still continues. Thus the sixty-one principal cities of England and Wales, which in 1801 contained rather less than a fourth of the entire population, contained in 1851 above a third of the entire population. In 1851, the whole town and country populations of England were almost exactly equal; in 1861, the town population was not far from being three-fifths of the entire population; while, in 1871, it bore to that of the country the ratio of 62 to 38. In the last of these years, the 103 principal towns contained more inhabitants than the whole of England and Wales together in 1801.

NATIONAL INDUSTRY AND GENERAL WEALTH.

No country in the world probably gives to its people greater natural advantages for the getting of wealth than England does. Its soil and climate give it luxuriant pasturage and abundant harvests; its rivers and harbours, its vast mineral wealth, and compactness of resource, enable it to take the lead in commerce; while the climate incites to labour, by rendering an indolent life—enjoyable perhaps under brighter skies—intolerable. Railways and free-trade, added to these causes, have created a commerce and a wealth such as have never before been known in the world. Referring the reader for further detail to the article CONSTITUTION AND RESOURCES OF THE BRITISH EMPIRE, we here give the following as illustrative of this subject:

Agriculture.—According to parliamentary papers, the total number of returns for separate holdings of agricultural land, exclusive of allotments, obtained in 1873, amounted to 422,655 for England, 57,517 for Wales, and 80,857 for Scotland, and to 561,029 for the whole of Great Britain. 'The total acreage,' says the Report, 'under crops, fallow, and grass, in 1873, divided by the total number of returns obtained, shews that the average extent of land for each holding was 56 acres in England, 46 acres in Wales, 56 acres in Scotland.' In Ireland, it was 26 acres. 'The return,' continues the Report, 'shews that there were, in 1873, as many as 246,000 allotments of land in Great Britain, of which 242,000 were in England, 1700 in Wales, and 2100 in Scotland. . . . The total extent of land let in garden allotments in Great Britain, in 1873, was 59,631 acres, which shews almost exactly an average of one quarter of an acre for each allotment; and the average for England is the same.' By the table No. 1, the total acreage, 'under all kinds of crops, bare fallow, and grass,' in 1873, was, in England, 23,893,558; in Wales, 2,647,080; corn crops (including pease and beans), 7,501,713 and 536,786; green crops, 2,749,318 and 133,232; bare fallow, 649,374 and 34,730; grass, clover, &c. under rotation, 2,678,311 and 360,555; and permanent pasture, 10,237,814 and 1,581,585. The 'acreage of orchards, or of arable or grass land used also for

fruit-trees,' was 143,295 and 3052. The 'acreage of woods, coppices, and plantations,' was 1,325,765 and 126,823. The number of horses was 979,012 and 120,273; of cattle, 4,173,635 and 642,857; of sheep, 19,169,851 and 2,966,862; of pigs, 2,141,417 and 211,174. The total uncultivated area of England (woods being considered cultivated) is 7,378,000; of which 2,745,000 is in the counties of Northumberland, Cumberland, Westmoreland, the North and West Ridings of Yorkshire, and in Devon. The total area of England is 50,933 square miles, or 32,597,398 acres; of Wales, 7378 square miles, or 4,721,823 acres.

Mines.—The total value of coal raised in the United Kingdom, according to evidence laid before a Committee of the House of Commons, was, in 1872, £123,386,758, of which value there was used in the manufacture of iron £38,228,875. The total iron produced in the United Kingdom was, in 1871, 16,334,884 tons—of which Scotland produced 3,000,000; Ireland, 107,734; England, 13,227,150. The total value was £7,670,572. Tin is produced from only two counties, Cornwall and Devon. In 1868, the total value was £901,400; total weight, 9300 tons. Copper comes principally from the same counties. In 1868, the yield of pure metal was 157,335 tons; value, £761,602. The total value of the mineral produce of Great Britain in 1868 was £43,525,524.

Trade.—The value of imports into the United Kingdom was, in 1862, £225,716,976; in 1872, £354,693,624: of exports, in 1862, £166,168,134; in 1872, £314,588,834. The parliamentary returns do not enable us to assign their shares in these vast totals to each division of the United Kingdom, but readers may form an estimate from the fact, that the total amount of custom-duties paid by England, for the year ending 31st December 1872, was £16,095,678; by Scotland, £2,498,805; and by Ireland, £1,944,065; England's proportion relatively to that of Scotland, as 6·44 is to 1; and relatively to that of Ireland, as 8·27 is to 1. Of the English total, £9,785,126 was collected in London, £3,030,843 in Liverpool, and £1,027,769 in Bristol. The total number of trading-vessels belonging to England, at 31st December 1872, was 20,097; the total tonnage, 4,510,556; number of the crew, 193,506. The number belonging to the United Kingdom, at same date, was 25,083; tonnage, 5,681,963; crew, 244,994. Some notion of the enormous increase of one or two of the leading branches of British commerce, in recent years, may be got from the following facts. In 1857, the declared value of cotton yarn exported was £8,700,589; and of cotton manufactures, £30,372,831. In 1871, these values were respectively £15,054,742 and £57,635,570. In 1857, the declared value of woollen yarn was £2,752,386; of woollen and worsted manufactures, £10,706,023; of iron and steel, £15,133,388. In 1871, these values were respectively £6,101,777, £27,184,704, and £26,149,136.

Summary for 1880.—The total acreage of land under crops, bare fallow, and grass throughout the United Kingdom in the year 1880 was 47,586,700 acres (47,646,112 in 1881). The total acreage under wheat was 3,065,895 acres. The total value of the mineral produce of the United Kingdom for 1880 was £74,094,638 (£62,395,000 being for coal). The total value of imports in 1880 was £411,229,565 (in 1881, £397,022,489); the value of exports in 1880 was £286,414,466 (in 1881, £297,082,775). Cotton manufactures were exported to the value of £75,560,000; woollen manufactures, £20,600,000. The total value of real property assessed under the property and income tax in 1880 was £152,553,738 in England and Wales; £19,582,445 in Scotland; and £13,241,587 in Ireland. The railway capital of the United Kingdom in 1881 was £831,127,312.

ENGLISH SCENERY.

English scenery has many features which give it a poetic beauty of its own. We do not refer, in so saying, to the specially noted landscapes of England—to those of Wales or of Cumberland—but to those of the low and fertile midland and southern districts, and of the Plain of York; whether these be green with their dense summer foliage, golden with harvests, ruddy with orchards, or dark and grimy as that of the Black Country itself. 'With unabated bounty,' says Thomas Carlyle, 'the land of England blooms and grows; waving with yellow harvests; thick studded with workshops, industrial implements, with fifteen millions of workers, understood to be the strongest, the cunningest, and the willingest our earth ever had.' Of the Black Country, Mr W. White (*All Round the Wrekin*), writes: 'The name is eminently descriptive, for blackness everywhere prevails; the ground is black, the atmosphere is black, and the underground is honeycombed by mining galleries, stretching in utter blackness for many a league. The scene is marvellous, and to one who beholds it for the first time by night, terrific. Then the roaring furnaces are seen for miles around, pouring forth their fierce throbbing flames like volcanoes; then the hundreds of chimneys of iron-works display their blazing crests or sheafs of fiery tongues; then the dull gleam of heaps of roasting ironstone makes you fancy that the old globe itself is here smouldering away; overhead, dense clouds of smoke reflect a lurid light, rolling fitfully before the wind; while the hissing and rushing of steam, the clang and clatter of machinery, the roaring blasts, and the shock of ponderous hammer-strokes, all intensified by the presence of night, complete an effect which amazes alike the eye and the ear. By day, as the train speeds across, you hear the same noises, and see fires divested of their nightly terrors, yet find it difficult to believe that a scene of so much havoc represents prosperous industry, and one of the most important departments of British trade. Perhaps for the first time you become aware of the omnipotence of coal and iron. You catch glimpses of smoking heaps, of muddy canals, complications of locks, bridges, tramways; boats moving, trains rolling, of coal-pits where the iron arm projects from the little engine-house, working busily up and down, while the whimseys creak as the long rope passes over; of abandoned workings, where office and engine-house are in ruin, and scraps of ragged hedgerow look very miserable, and the tall posts stand up skeleton-like, and fragments of machinery lie about devoured by rust. . . . And amid all this are the cottages of artisans and miners; English homes, whence sun and stars are seen darkly, situate in a region devoid of repose and beauty, which look as if smitten by desolation, notwithstanding that here and there grow patches of wheat and plots of potato. And

so it continues for thirteen miles, all the way from Birmingham to Wolverhampton.' Pursuing his journey, our author continues: 'The country appeared more and more rural as I pursued my north-westerly route; the sound of distant chimes came floating on the breeze, and the very air seemed glad with the music of larks. . . . The view, made up of broad rolling fields, and a glimpse of blue uplands in the distance between the trees, feasts the eye with verdure and good cultivation; and though not at all romantic, holds a charm in its pretty lanes and inviting footpaths, and soothing quietness. . . . Then there were the timbered houses, relics of the olden time, that seem impregnate with domestic histories of the days of the Shropshire worthies — Baxter, Wycherley, and stout old Benbow, or, peradventure, with reminiscences of the civil wars. If outward signs may be trusted, that one with pretty spires to the dormer windows, and with such a wealth of roses, sweet brier, and hollyhocks in the front garden, such magnificent lilies and peonies, is the happiest of all. Another, partly overhung with ivy, has checkered panels, black and white being the prevailing style. . . . Not a mile of the way but shews signs of prosperity, and fertility is manifest by the timber as well as by the crops. . . . Then more sycamores and large oaks, and clumps of walnuts, and more gray gables and thatched roofs; then a lane, along which runs a green strip between the wheel-tracks, where the hedges, furlong after furlong, are a maze of ferns, roses, and honeysuckle; where the oak branches meet overhead, and ivy enwraps the stems; where from time to time a half-concealed pool almost startles you by its sunken shadows, and there seems something mysterious in the bird that darts suddenly from the covert, and flits silently across the sleeping water.'

A noteworthy and harmonious feature of English scenery is the country town, replete with historic association as it often is. 'The narrow declivitous thoroughfare of Water Lane,' says Mr White, describing Shrewsbury, 'shews us where the parliamentary troops were secretly admitted while besieging the town in 1644-45. The Butter Cross suggests an earlier time, for it stands on the place where David of Wales was tortured to death by order of Edward I.; and where certain noble and knightly prisoners, captured at the battle of Shrewsbury, lost their heads. Under the graceful spire of St Alkmunds, or Stalkmuns, as the natives have it, we are reminded of Ethelfleda, who built a church on the spot in the tenth century—of the stately edifice that followed, which the parishioners pulled down in a panic because St Chads fell; in which church, as the chronicler tells, writing in 1533, "This yere upon twelffe daye in Shrousbury, the Dyvyll appearyd in Saint Alkmonds' Churche there, when the preest was at high masse, with great tempeste and darknesse, so that as he passyd through he mountyd up the steeple in the sayde churche, tering the wyers of the clocke, and put the print of his clawes upon the 4th bell, and took one of the pynnacles awaye with hym, and for the tyme stayed all the bells in the churches within the sayde towne that they could neyther toll nor ringe." And so,' continues Mr White, 'while passing hither and thither, our thought flits to and fro among the centuries. The castle grounds, approached by a lofty arched gateway, contain vestiges of our old acquaintance Roger de Montgomery's stronghold, and the keep and round towers built by Edward I. We can imagine its history from the glimpses we have had of the olden time in our wanderings through the country. Near the bridge stand a few houses of the reign of Henry VII. At Ludlow, we saw the lodgings of the two young princes; at Bridgenorth, we were not far from the place where the Duke of Buckingham, riding one day in a discontented mood, met by accident the Lady Margaret, Countess of Richmond, and, as he relates, "communed with her a little concernynge her sonne;" and here we are in the streets through which the Earl of Richmond marched on his way from Milford-Haven, to victory and vengeance at Bosworth Field.' These extracts, we think, convey forcibly and truly a sense of the poetic spirit of English landscape—tame and uninteresting it will doubtless seem to many, who can fully appreciate the awful grandeur of Glencoe. Its peculiar charm—for charm to some it certainly has—lies, it seems to us, in the blending of august historic association—of a sense of the warfare and long-spent fury of bygone ages—with a feeling of the wealth, activity, security, and peace of the present.

ANTIQUITIES, ETC.

Perhaps the earliest objects of antiquity in England are the barrows or *tumuli* with which the Britons, like so many other uncivilised nations, were accustomed to cover the remains of the dead. Several specimens of these still exist, but many more have been destroyed and levelled with the soil. Their construction, contents, and other peculiarities are noticed under ARCHÆOLOGY.

With tumuli may be classed the *dolmen* (Celt. *daul*, a table; *maen*, a stone—table-stone) which consists of a large slab of stone placed flatwise, or in a sloping position, upon two upright ones. These structures were at one time believed to be altars for human sacrifices; but numerous excavations have demonstrated them to be sepulchral monuments. *Cromlechs*, or stone circles, are more complicated. They usually consist of circles of huge stones placed on end, with, in some instances, connected lines or rows of similar stones, the whole forming objects at once rude and imposing. From a once prevalent belief that they were the temples of the Druids, they are often called Druidical circles. The most remarkable Druidical circle is that of *Abury*, six miles from Marlborough, in Wiltshire. While the diameter of the outer circle of stones at Stonehenge is about 100 feet, that of Abury is nearly 1300. The position of 650 stones at Abury has been ascertained, but not above 20 of these are now standing. With a deplorable Vandalism, the rest have been broken up to build the modern village, which stands within the inclosure. The structure of Abury was in some respects peculiar. The whole was surrounded by a huge rampart, and, inside of it, a deep ditch; the slope from the bottom of the ditch to the top of the mound measures even yet, in some places, from 70 to 80 feet. The circular area thus inclosed contains upwards of 28 acres. Around the edge of this area stood a hundred massive unhewn pillars, 27 feet apart, and from 14 to 17 feet high. Within this outer circle were two other smaller circles, standing side by side;

each was composed of a double ring of stones, the outer ring having a diameter of 270 feet, and consisting of 30 stones, the inner ring a diameter of 166 feet, and 12 stones. In the centre of one of the small circles stood a stone upwards of 20 feet high; and in the other, three such pillars with a flat stone on the ground in front of them, which is generally held to have been the altar. From this great inclosure there proceeded two stone avenues with gentle curves, one towards the south-east, the other towards the south-west. They were upwards of a mile long each, with a breadth of 45 feet; one of them, which terminated in a double oval, had 258 stones; the other appeared to terminate in a single stone. Another Druidical circle of great note is that of *Stonehenge*, upon Salisbury Plain, a district also presenting many tumuli and other vestiges of the Britons. The Stonehenge temple, in its perfection, consisted of 140 stones, arranged in two concentric circles, the outermost 108 feet in diameter, with similar stones laid flatwise along the tops of the upright stones. The blocks which remain are from 18 to 20 feet high, and about 7 feet broad. Within the inner circle are two oval ranges, supposed to have formed the cell, and which consist of stones about 30 feet in height.

Roman remains are now rare, and nearly obliterated. The roads formed by this people have, in some instances, been changed into our present comparatively broad and well-formed ways; in other cases, slight traces of their original pavement, which generally consisted of large stones forming a causeway, are to be found. Between Newcastle and Carlisle are the remains of the two walls built respectively by the Emperors Adrian and Severus in 120 and 210, to keep out the northern barbarians: the first being a high mound of earth, and the second a rampart of stone, 68½ miles long, running parallel to the first. All the towns the names of which terminate in *chester* or *cester*, are considered as having been originally Roman stations. Near St Albans are the remains of the walls which once surrounded the Roman town of *Verulamium*, the site of the town itself having long been subjected to the plough. In making excavations in London and other places, remains of Roman buildings—temples, baths, &c.—are frequently brought to light, proving that Roman civilisation had made considerable progress in our island. In Uriconium—the British Pompeii, as it is named—the most important of the excavations extend southward from the wall called in the neighbourhood the 'Old Wall,' which is built of small squared stones, with a layer of red tiles at intervals, in a similar style to that which is found in the Roman city of Silchester. It is on the southern side of the Old Wall that the principal discoveries have been made—discoveries which shew to us the arts and customs of the days of Constantine. We see the pillars of the hypocausts, the marks on the walls of the flue-tiles through which the heat ascended, and even the soot left by the fires. Coins and skeletons have been found, with other evidence indicative of the manner in which the city was destroyed—being supposed to have been burnt by Scandinavian pirates.

Several of the small churches built soon after the introduction of Christianity still exist, and continue to be used as parish churches. The larger churches connected with monastic establishments, and the cathedrals which were the seats of bishops, took their rise at a later period, chiefly during the twelfth and thirteenth centuries. This was a time when an enthusiasm existed for founding and endowing monasteries and churches. To it we are indebted for many superb minsters, the solemn beauty of which continues to be a proud possession of our land. Westminster Abbey, York Minster, and the cathedrals of Winchester, Lincoln, Gloucester, Canterbury, Lichfield, and Salisbury, may be instanced as particularly august specimens of the Gothic style, in which all ecclesiastical structures were then built. There are also many ruinous remains of the great abbeys of the middle ages: those of Tintern, near Monmouth; Glastonbury, near Wells; and Bury St Edmunds, are of famed beauty. A kindred class of structures exist in what are called *crosses*, which consist generally of an elegant tapering Gothic erection with a small shrine below, and were in most instances erected to hallow the spot on which the remains of venerated persons rested on their way to the tomb.

Of the huge castles built by the Norman nobility and by the sovereigns during the first few centuries after the Conquest, many specimens still exist, but few which are not in ruins. Conway and Caernarvon Castles, which, with several others, were raised to overawe the then independent principality of Wales, are noble specimens.

CITIES—TOWNS—PORTS.

The Metropolis.—London, the capital of the British empire, stands on both banks of the Thames, about 60 miles from the sea. The dome of St Paul's is in latitude 51° 30′ 48″ N. and in longitude 5′ 48″ W. The decennial returns of the present century give the progress of the population of London as follows:

1801	864,845	1831	1,474,069
1811	1,009,546	1841	1,870,727
1821	1,225,694	1851	2,362,236

In 1861, it was 2,719,126; in 1871, it had increased to 3,132,599. At the census in April 1881, the figures (revised and corrected) were as follow: City of London, 50,652; Registrar-general's London, 3,816,483; Local Management London, as also School-board London, 3,834,354; Police London, 4,716,009.

For *parliamentary* purposes, London is divided into the City of London and 29 parliamentary boroughs, returning together 62 members to parliament. Before the Act of 1885 there were only nine boroughs besides the City. For *poor-law* purposes, London is divided into forty unions. The 'Metropolitan Buildings Act' of 1855 divides it into 56 districts. The City of London—spoken of by Londoners simply as *the City*—is the heart of the mighty commerce of England's capital—indeed, it may fairly be said to be the centre of the finance operations and trade of the world. The bustle and traffic of its streets are wholly inconceivable by any one who has not seen them. While it is estimated that nearly 700,000 persons enter the City every day, not more than a tenth of this number remain in it over the night, and this proportion is decreasing, from the conversion of dwelling-houses into commercial establishments. It is

divided into 25 wards, each represented by an alderman in the *Common Council*, which consists of 206 members. The Council, of which the Lord Mayor is the chief, forms a kind of parliament for the management of City affairs. Westminster and Southwark are each under local authorities, but only in minor matters. The Mansion House and Guildhall are the chief buildings for the transaction of corporate business; the Bank of England and the Stock Exchange for financial affairs. Nearly all the drainage and sewage of London now enters the Thames about 12 miles below London Bridge. A new system of drains has been introduced of recent years, the expense of which has come to nearly £5,000,000. London is the seat of a bishopric, which comprises about 320 benefices. St Paul's is the cathedral for the diocese. It was built by Sir Christopher Wren (1675–1710), at a cost of £748,000. It is 514 feet long by 286 wide. The cross over the ball above the dome is 356 feet above the pavement. Plans are in progress for an extensive restoration of the interior. *Westminster Abbey* is 530 feet in outer length by 203 in width. The west towers are 225 feet high. It is said to have been founded by Sebert, king of the East Saxons (*circa* 616). It was enlarged by King Edward the Confessor, and rebuilt nearly as we now see it by Henry III. and Edward I. Here the kings and queens of England have been crowned from Edward the Confessor to Queen Victoria, and here many of them are buried; here also are interred many of England's most famous men. Men of world-wide renown in war, literature, and politics, whose span of life was divided by centuries, are here assembled in death. Here lie the conquerors of Agincourt, Blenheim, and Waterloo; here those whose genius has charmed the world, from Shakspeare to Dickens; whose brain has ruled the destiny of nations, from cunning Burleigh and Elizabeth to genial Palmerston. It is quite impossible, within necessary limits, to give even a sketch of the chief buildings and spectacles of London, and merely to make a list of them would be neither useful nor amusing. The stranger who may wish to form an idea of its magnitude and wealth, would do well, after seeing Westminster Abbey and the Houses of Parliament, to walk or drive into the City by the Strand, Temple Bar, and Fleet Street; let him then cross into Oxford Street, and so reach Hyde Park about five o'clock in the afternoon. Having seen the commercial, he will then see the fashionable world of London at full-tide; and certainly, if the sight of splendid equipages, horses and chariots, dress, beauty, and boundless wealth, has any charm for him, he ought to be fully gratified. Covent Garden Market is also well worthy of a visit early in the morning, as conveying an idea of the immense requirements of the great city—surely the greatest and most wonderful which the world has ever seen.

Liverpool, a town in Lancashire, on the north bank of the Mersey, is, taken with Birkenhead, on the opposite side, the most important town in England, next to London, in a maritime point of view. The rise of the port has been very remarkable. In the middle of the 14th century, it was but a village, with a population under 1000. It was not till 1647 that it was made a free port, having down to that date been subject to the Chester officers. Its individuality as a parish was not declared till 1697, when its population was estimated at 5000, its shipping at 80 vessels. In 1700, its first regular dock was built, on the site where the Custom-house stands at the present day. From 1760 to 1800, the population advanced from 25,700 to 77,700; the shipping from 1200 to 5000 vessels; and the amount of dock dues from £2300 to £28,300; nearly two-thirds of the increase taking place during the last 15 years of the period. The progress of the cotton-trade was the chief cause of this rapid improvement. Simultaneously with the mechanical revolution brought about by the inventions of Hargreaves, Arkwright, and others, there came an increased foreign trade, and owing to the opening of the Bridgewater Canal in 1773, inland business was also augmented. The following statement shews how far Liverpool was benefited by the cotton-trade in the end of last century:

Years.	Raw Cotton.		Cotton Manufactures.	Population.	Vessels.	Dock Duties Collected.
	Imported.	Exported.	Exported.			
	lbs.	lbs.	£		No.	£
1781.....	5,198,778	96,788	355,000	35,000	2300	5,000
1791.....	31,447,605	363,442	1,875,000	50,000	4200	10,000
1800.....	43,378,278	4,416,610	6,040,000	77,000	5000	28,000

The rapid growth of Liverpool, and of its trade, will be seen from the following table:

Years.	Population.	Vessels.	Tonnage.	Dock Dues.
1801.....	77,708	5,060	459,719	£28,365
1831.....	205,572	12,537	1,592,436	183,455
1861.....	443,938	21,095	4,977,272	444,417
1871.....	493,346	20,121	6,131,745	562,953

The next table shews the importance of the export trade of Liverpool relative to that of other British ports.

DECLARED REAL VALUE OF EXPORTS AND IMPORTS AT LIVERPOOL IN 1880.

	Exports.	Imports.
Liverpool.....	£84,029,651	£107,460,187
London.....	52,600,929	141,442,907
Hull.....	18,572,005	17,600,430
Grimsby.....	7,236,471	3,906,321
Glasgow.....	11,828,729	12,564,978
All others.....	48,792,661	128,254,742
	£223,060,446	£411,229,565

This gigantic trade has given being to the magnificent system of docks extending five miles along the river, containing 54 docks and basins,

covering an area of over 260 acres, and having nearly 19 miles of quay space. The whole of these docks have, with the exception of the Salthouse, King's, part of the George's, and part of the Queen's, been built since 1812. They were erected chiefly under the superintendence of the late Jesse Hartley, Esq. and are held to be one of the greatest engineering triumphs of the present century. Several of the docks are inclosed by large warehouses; the erection of those round the Albert Dock cost £358,000, and the dock itself £141,000. The architecture of the town has been wonderfully improved within the last 40 years. Liverpool is connected with Birkenhead by railway below the bed of the Mersey. The population of Liverpool, excluding Birkenhead, was, in 1871, 493,405; in 1881, 552,508. Since 1885, Liverpool returns nine members to parliament.

Manchester, a city, municipal and parliamentary borough of Lancashire, and the great centre of the cotton manufacture of the north-west of England, stands on the Irwell, 32 miles east-north-east of Liverpool, and 188 miles north-north-west of London by railway. In 1881 the population of the parliamentary borough was 393,585, whereas in 1871 it was 383,843. In the adjoining borough of Salford, the population in 1881 was 176,235. The Seats Act of 1885 gave Manchester six, and Salford three members of parliament. Water for the supply of Manchester is collected on Blackstone Edge, and conducted from a series of reservoirs through iron pipes nearly 20 miles to the borough. Powers were obtained in 1879 to secure a supply of water from Lake Thirlmere, in Cumberland. The water-works, in which are invested about £3,750,000, and the gas-works, involving about £450,000, belong to the corporation. From the sale of gas, there accrues an annual profit of about £50,000, which is devoted to improving the borough. In 1845–46, 3 parks, of about 30 acres each, were acquired by public subscription; and a fourth, of about 60, has since been acquired by the corporation. Manchester was the first borough to take advantage of the Free Libraries Act, which allows an assessment of a penny per pound on the local rates for parks, libraries, and museums; here also was established the first free lending library in England. The ratable value of municipal Manchester in 1873 was £1,760,000, and of Salford, £484,000. The celebrated Bridgewater Canal connects Manchester with Liverpool, and access is also obtained for heavy barges by the rivers Irwell and Mersey. The chief trade is cotton-spinning. Respecting this branch of industry, an article in the *Daily Advertiser* of September 5, 1739, copied into the *Gentleman's Magazine*, says: 'The manufacture of cotton mixed and plain is arrived at so great perfection within these 20 years, that we not only make enough for our own consumption, but supply our colonies and many of the nations of Europe. The benefits arising from this branch are such as to enable the manufacturers of Manchester alone to lay out above £30,000 a year for many years past on additional buildings. It is computed that 2000 new houses have been built in that industrious town within these 20 years.' 'In a rapidly advancing country,' says Edward Baines, writing in 1835 (*History of the Cotton Manufacture of Great Britain*), 'the great things of our age are insignificant in the eyes of the succeeding age. Thus, the period of 1739, whose prosperity was so much vaunted, is now looked back upon as the mere feeble infancy of the cotton manufacture.' Mr Baines then cites figures shewing the growth of the cotton-trade during last century. From these it appears that, in 1701, the total declared value of British cotton goods exported was £23,253; in 1764, it was £200,353. In 1833, according to Mr Baines, the imports of cotton wool were 303,726,199 lbs., and the declared value of exports, £18,486,400. In 1871, the quantity of raw cotton imported was 15,876,248 cwt., the declared value £55,767,545; the declared value of cotton yarn exported was £15,054,742; and of manufactured cotton, it was £57,635,570. There are now ordinarily employed in the cotton-mills of Manchester about 60,000 persons, who earn about £30,000 a week in wages. There are at least 7000 skilled mechanics constantly engaged in the production of steam-engines, spinning-mules, looms, and other machinery, chiefly for the production of the various textile fabrics, whose wages average about 32s. each per week, and who need some 1500 labourers to assist them. In 1846, John Owens, a Manchester merchant, left £100,000 to found a college for secular instruction. It has now a large staff of professors, magnificent chemical and physical laboratories, and about 800 students. According to the School-board returns of 1873, the number of day scholars in Manchester was 38,500 in actual attendance; and in evening schools and literary institutions, there are from 4000 to 5000 pupils. In Manchester originated the agitation which ended by rendering practical the theories of Adam Smith regarding free-trade. The parish of Manchester covers a large area, reaching to Stockport, Oldham, and Ashton-under-Lyne.

Birmingham, the chief town in Britain for metallic manufactures, and supplying much of the world with hardware, is in the north-west of Warwickshire, with suburbs extending into Staffordshire and Worcestershire, 112 miles north-west of London. Built on the east slope of three undulating hills, on the Rea and the Tame, on a gravelly foundation, overlying clay and new red sandstone, and supplied with plenty of water, it is one of the best drained towns in England. The older part of the town is crowded with workshops and warehouses; but the modern is open and well built. The architecture and general appearance of Birmingham present some striking contrasts. Many of the streets are handsome, but the older parts of the town are mean and squalid. The suburbs would be pleasant but for the atmosphere, which is generally darkened with smoke, belched forth by a forest of tall chimney-stalks, which form one of the main features of the town and neighbouring landscape. The manufacture of guns and articles pertaining to them, and of steel pens, are the chief industrial branches of Birmingham. In visiting the manufactories, one is struck by the extraordinary dexterity of finger which long practice has given to those employed in them. This is, we believe, especially true of the young girls employed in the works. Their tidiness and generally cheerful looks are also noteworthy. You see countless small pasteboard boxes to be filled with so many hooks and eyes. It would seem hardly credible, having regard to the rapidity of the operation, that its result should be accurate, yet we believe that errors are few

and unimportant. The steel for the manufacture of pens is first cut into thin strips, then rolled and re-rolled through a machine, from which it comes out perforated by a double row of blanks—the pieces so cut out forming the pens. The employment is an easy one, and one especially suited for women and girls. The population of Birmingham was in 1690, 4000; in 1801, 60,822; in 1861, 296,076; in 1871, 343,787; in 1881, 400,774. It produces upwards of £5,000,000 yearly. It returns seven members to parliament.

Leeds, the first town in Yorkshire, and fifth in England in point of population, is a parliamentary and municipal borough, returning five members to the House of Commons. It is in the north-west of the West Riding of Yorkshire, in the valley of the Aire. Roundhay Park, one of the most beautiful demesnes in England, two miles from the town, was bought by the corporation in 1872, at a cost of £140,000, and converted into a public recreation-ground. It covers 733 acres, and contains a lake with an area of 33 acres. Leeds is the chief cloth manufacturing town of England. The extent of this and of the other industrial pursuits of the town may be estimated from the following statistics taken in 1871:

Employments.	No of Works.	Persons employed.
Textile fabrics and wearing apparel	1198	26,134
Metals	461	15,272
Leather	78	2,194
Chemicals	27	700
Food, &c.	73	331
Building	440	3,360
Paper	6	565
Tobacco	7	210
Earthenware	41	1,472
Printing	47	848
Miscellaneous	178	1,656

There are 30 churches in Leeds, 5 Roman Catholic and about 60 dissenting places of worship. The chief church is St Peter's, which is in Kirkgate, and was rebuilt in 1838 at a cost of £29,770. It is 180 feet long by 86 feet wide; the tower is 139 feet high, and contains a peal of 13 bells. It is a very noble edifice. The principal windows are of beautiful stained glass. It also contains some fine statues, one of which was erected in memory of those natives of Leeds who fell in the Crimea; the church has a good choir. The most interesting church in the town is St John's, New Briggate, consecrated by Archbishop Neale, 1634 A.D., an almost unique example of a 'Laudian' church, and still retaining the original fittings. The other principal buildings are chiefly of recent erection, and are as follows: The Town-hall is 250 feet long, 200 feet broad, and the tower is 225 feet high. It covers 5600 square yards. The great hall is 161 feet long, 72 feet wide, and 75 feet high. It is richly decorated, and contains one of the largest and most powerful organs in Europe, also statues of Edward Baines and Robert Hall, formerly members for the borough. There is also a colossal statue of the Queen in the vestibule, and of Wellington in the front of the building. Kirkstall Abbey, about three miles from Leeds, was founded between 1147 and 1153 by Henry de Lacie for the Cistercian order of monks. It is a fine old ruin, remarkable for its simple grandeur and unity of design. Adel Church, about four miles from Leeds, is an interesting building, erected 1140. Near it was a Roman station, where several antiquities have been found. The General Infirmary was erected in 1868 from designs by Sir G. G. Scott, at a cost of £100,000, and contains accommodation for 300 in-patients. The Mechanics' Institute, erected in 1867, at a cost of £25,000, contains a lecture-hall accommodating 1700 persons. The Free Library, established in 1870 (under the Free Libraries Act), contains 30,000 volumes. The Grammar-school was built in 1859, at a cost of £13,000; it is built in the shape of a cross in the Gothic style, Decorated period. The Yorkshire College of Science at Leeds is a thriving and well-endowed institution. The borough jail is a large castellated building at Armley. The Corn Exchange, a handsome building of an oval form; the Post-office, formerly the Court-house, near which is a statue of Sir Robert Peel; the Queen's Hotel, recently erected by the Midland Railway Company; the Philosophical Hall, built in the Doric order of architecture, and having a fine museum; the Wesleyan Training College, in the Gothic style, erected in 1868; Turkish Baths (cost £14,000); Beckett's Bank, a fine work by Sir G. G. Scott; &c. There is also a library of 30,000 volumes, founded by Priestley in 1768. The population of Leeds, in 1871, was 259,212; in 1881, 309,119.

Sheffield, an important manufacturing town and parliamentary borough in the West Riding of Yorkshire, and capital of an independent district called Hallamshire, is picturesquely situated on several hills that slope towards the confluence of the rivers Sheaf and Don. It is 162½ miles north-north-west of London, by the Great Northern Railway. The town generally is well built, although, on account of the smoke, its appearance is dingy as contrasted with the surrounding beautiful scenery. The place is of considerable historical interest. Here, in a mansion built by George, the fourth earl, Wolsey lodged before his death at Leicester; and here Mary, Queen of Scots, was imprisoned for twelve or fourteen years in Sheffield Manor-house, about two miles from the town. Of Sheffield Castle nothing now remains. As far back as the time of Chaucer, Sheffield was noted for the manufacture of cutlery; and at the present day, besides cutlery, endless varieties of articles in brass, iron, and steel are produced at the many manufactories with which the town abounds. Among the new branches of trade are electro-plating in gold and silver, and the manufacture of iron plates for the armour-plating of ships of war. The conversion of iron into steel, by both the old and new processes, is one of the largest and most lucrative of the branches of the trade of Sheffield. The river Don, navigable to within 3 miles of the town, and the canal in connection with it, along with several important lines of railway, afford ample means of developing its resources. It possesses many handsome and interesting public buildings. There is the parish church, supposed to have been built in the reign of Henry I.; the Cutlers' Hall; the new Market Hall. The Mark Firth College was opened in 1879. The borough was incorporated in 1843, and returns five members to parliament. The population in 1871, was 239,947; in 1881, 284,508.

York, the capital of Yorkshire, is situated at the junction of the rivers Ouse and Foss, the three Ridings of the county meeting at the same place. It is nearly equidistant from London and Edinburgh. It is the seat of an archbishopric, a

county in itself, and a municipal and parliamentary borough, returning two members to parliament. The government is vested in 12 aldermen and 36 councillors, the chief of whom is the Lord Mayor. The population in 1871 was 43,796; and in 1881, 60,343. York is among the most ancient of British cities. Before the Roman invasion, it was one of the chief towns of the Brigantes, the most numerous and powerful of British tribes. It was constituted a Roman station, under the name of Eboracum, by Agricola, about 79 A.D.; and it very soon became the principal seat of Roman power in the north. Here Hadrian lived, and Severus died. Here, too, died Constantine Chlorus, the father of Constantine the Great. Little is known concerning the city for a century after the Romans had left it, which they did about 409 A.D.; but it suffered much during the long conflict between the Britons and the Picts. It afterwards became the capital of Northumbria. The first metropolitan church in England was built here by Edwin, the Northumbrian king, whom Paulinus baptised; and here also Edgar, the first monarch of all England, held, in the year 966, the Witena-gemót. William the Conqueror was long unable to overcome this stronghold of the north. One Norman garrison of 3000 men was put to the sword in 1069; but William took severe revenge in the following year, when he laid waste the whole country between York and Durham. The first English parliament was held at York in 1160 by Henry II. and for 500 years afterwards, parliaments were occasionally summoned to the ancient city. Under Henry III. the courts of King's Bench and Exchequer sat at York for seven years. During the insurrections consequent upon the dissolution of the monasteries by Henry VIII. York was seized by the insurgents of the 'Pilgrimage of Grace;' and in the immediate neighbourhood, Fairfax, in 1644, conquered Prince Rupert on Marston Moor. In the city are many remains of Roman towers and temples, and of the earliest British churches. One of the most magnificent of the Anglo-Saxon churches was here erected in the 8th century; this was burned, and a new building placed on its site. This, enlarged and changed from time to time, is now known as York Minster. A portion of the original church was disinterred during the excavations which followed the latest burning of the minster in 1829. The present building ranks with the finest specimens of Gothic architecture in the world. It was mainly built in the 13th and 14th centuries. Its length, from base to base of the buttress, is 524 feet, and its extreme breadth 250 feet; being 24 feet longer than St Paul's Cathedral, and 149 feet longer than Westminster Abbey. The magnificent east window is 75 feet high, and 32 feet broad; and contains about 200 compartments, each a yard square, representing scriptural subjects. War and fire have conspired to deform this splendid cathedral. During the Commonwealth, much damage was done by war and wantonness, and many of its old monuments were mutilated or broken. In 1829, it was set on fire by Jonathan Martin, a maniac, and the roof of the choir, 222 feet long, with all the woodwork on each side, was destroyed. While this damage was being repaired, a workman's candle was carelessly left burning one night in 1840, and again a terrible fire broke out, destroying the south-western tower, with its splendid peal of bells, and the roof of the nave. The cost of the repairs exceeded £100,000. Whatever the trade of York may have been in ancient times—and old writers speak of it in glowing terms—it is now small. The making of leathern gloves, combs, glass, &c. occupies many. Of late, the construction of railway carriages has become part of the city industry.

Newcastle-upon-Tyne, the chief town of Northumberland, stands partly on an elevated platform, and partly upon the north bank of the river. The more ancient houses are chiefly built of timber, the upper stories projecting beyond the lower; dormer windows and gable ends appearing in the roof. It has the privileges of a county of itself. Gateshead, on the opposite side of the river, though in a different county, and having a separate jurisdiction, is virtually a part of Newcastle. According to the census of 1881, the population of the latter was 145,359, of Gateshead 65,803; together, 211,162. Gateshead sends one member to parliament, Newcastle two. The Romans had a stationary camp here, called Pons Allii—one of the chain of forts by which the wall of Hadrian was fortified. On the withdrawal of the Romans, the town became the residence of a colony of monks, and the town was called Monkchester. Robert, Duke of Normandy, a son of the Conqueror, hastily built a castle here in the lifetime of his father. Hence the modern name of Newcastle. William Rufus rebuilt his brother's castle, surrounded the town with a wall, and gave the inhabitants peculiar privileges. The present castle, which shews better than any other in England the genius of Norman military architecture, was erected by Henry II. between the years 1172 and 1177. Newcastle having been the rendezvous of the vast armaments which the first three Edwards led into Scotland, it was in their time surrounded with new walls of unusual strength and magnitude. Portions of them yet remain.

Chiefly owing to one man of humble origin, Richard Grainger, Newcastle has, in modern times, received the addition of many streets, squares, and public buildings, which, in point of architectural effect, are scarcely to be excelled by any in the kingdom. An extensive conflagration in 1854 led to more recent improvements. The river is crossed by three bridges—the High-level Bridge, the Redheugh Bridge, and a swing bridge (completed in 1874), one of the largest structures of the kind in the world. The High-level Bridge is one of the engineering triumphs of Robert Stephenson. It consists of six cast-iron arches, supported upon piers of masonry. The length of the viaduct is 1337 feet, and the height of the railway above high-water mark, 112. Below the railway, this gigantic structure carries a carriage-way for ordinary traffic, by which the precipitous streets on both sides of the river are avoided. All the railways entering the town terminate in a large station near its centre. Upwards of 250 passenger trains arrive and depart daily. The trade of Newcastle consists chiefly in coal and in those articles which great heat is required to produce. Its coal-trade began in the reign of Henry III. The trade is not now confined to Newcastle, but is spread over the greater part of the sea-board of Northumberland, and the whole of Durham. Upwards of thirty millions of tons of coal were

raised in the northern coal-field in 1872, giving direct employment to about 80,000 persons. Until recently, very little iron was smelted on the Tyne, but since the discovery of the Cleveland ironstone, the manufacture has increased prodigiously. The make in 1872 was about 800,000 tons. On the Tyne the yearly produce of steel is 3000 tons. Large quantities of lead from the mines of Alston Moor and Weardale are brought to Newcastle for shipment. Here, too, the silver is extracted, and the lead is rolled into sheets and pipes, or converted into shot, litharge, red and white lead. Copper, too, to the value of £200,000 is annually got from the copper pyrites used at the chemical works of the Tyne. At Newcastle, locomotive and engineering establishments are found upon a great scale. The ordnance works of Sir William Armstrong at Elswick, a western suburb, are well known.

Bristol is an important maritime city in the west of England (long. 2° 35′ 28″ W., lat. 51° 27′ 6″ N.), upon the rivers Frome and Avon, partly in Gloucestershire, and partly in Somersetshire. It is joined to the former for ecclesiastical and military purposes, but otherwise it is a city and county in itself. The population of Bristol proper was, in 1871, 62,662, and of the suburban districts, 141,378; total, 204,040, steadily increasing; total in municipal boundary, (1881) 206,876. It returns four members to the House of Commons. It has extensive manufactures of shoes, of chocolate, and of soap. The town ranks fourth amongst English sea-ports in respect of the customs-duties received. There were entered in 1880, 9412 vessels, of 1,083,886 tons; cleared, 9408 vessels of 1,215,082 tons. In 1872, the total entrances were 9103 vessels, and 1,025,264 tons. The clearances outward for the same year shew 4618 vessels, and 538,209 tons. The custom-duties on imports produced £1,026,516. The chief trade is with Canada and the United States, West Indies, and South America, Portugal, the Mediterranean, Russia, Mauritius, Turkey, France, and west coast of Africa. The annual value of exports is about £400,000. The old part of Bristol consists almost wholly of shops, warehouses, and other commercial buildings. The streets are, with few exceptions, narrow and irregular, but great improvements have recently been effected. The modern portions of Bristol are almost wholly suburban; Clifton, Cotham, and Redland are the principal ones. They consist of handsome residences, in squares, terraces, crescents, and detached villas. At Clifton there is a remarkable suspension-bridge over the Avon, 702 feet in span, and 245 feet above high-water. These suburbs of Bristol, with their breezy down, fertile and prettily wooded neighbourhood, are very attractive as places of summer residence; but in winter or spring they are, for the most part, unsheltered from the high and cold winds which often prevail during these seasons over the district. When they blow, the residents call the weather they produce *Channel* weather; thus apparently attributing the obnoxious character of the wind to the influence of the Bristol Channel.

The first records of the history of Bristol speak of it under the ancient British name of Caer-oder. It became a stronghold of the Romans, on whose departure it was again occupied by the Britons. In 584 they were driven out by the Saxons, who gave it the name of Brightstowe or Bricstowe, making it a thriving place of trade—aboriginal slaves being a principal item in the commerce. It was sacked by the Danes. During the civil wars it was alternately taken by the Royalists and by the Parliamentarians; by the latter, the castle and fortifications were raised. It afterwards became the principal port for trade with the West Indies, carrying on a flourishing business in negro slaves. In 1793, the 'Bridge Riots' occurred. In 1804 the docks were begun, and in 1809 they were opened to shipping. In 1831, the 'Reform Bill Riots' resulted in the destruction of the Bishop's Palace, Custom-house, and other public buildings, besides a number of private residences. The bill, by the addition of Clifton, &c. gave the city its present municipal boundaries. Among the names of note identified with the history of Bristol are those of William of Worcester, Sebastian Cabot the navigator (said to have anticipated the discovery of America by Columbus), Chatterton the poet, Lawrence and Baily, artists, Robert Hall, Hannah More, and Sydney Smith.

Oxford, an ancient and famous city, and seat of learning, the chief town in the county of Oxford, is situated on the north-east bank of the Isis, a tributary of the Thames, a little above the point where it is met by the Cherwell. Both streams are crossed by numerous bridges. Latitude of the city, 51° 45′ 55″ N., long. 1° 15′ 29″ W., 55 miles from London. Population in 1881, 40,837. Oxford is on an undulating site, is surrounded by rich and wooded meadows, and presents to the eye of the visitor, on approaching it, a scene of great architectural magnificence, spires, and towers, and domes rising as thickly as chimney-stalks in the manufacturing towns of Lancashire or Yorkshire. The western half of the town is the most uninteresting; and it is unfortunate that the railway stations are placed here, as travellers on arriving are thus first introduced to the meanest parts of the city. The county courts and jail, and the remains of the castle from which the Empress Maud escaped, will be observed in passing. There is one good street in this part—namely, Beaumont Street, built on the site of the ancient Beaumont Palace, where Richard I. was born. At the end of this street is Worcester College. In St Aldate's Street is Christ Church College, the entrance tower of which contains the great bell, 'Tom of Oxford,' weighing upwards of 17,000 lbs. The other colleges and important buildings connected with the university lie back from the principal streets. Though there is nothing remarkable about their architecture, regarded individually, yet the number of the structures, and variety of their style, form an imposing and effective whole; the effect being greatly strengthened by the interspersion of gardens, meadows, and venerable trees. Christ Church is celebrated for its magnificent hall, picture-gallery, and library, as well as for its extensive grounds; its chapel, the cathedral church of Oxford, is Norman in style. It is smaller, and less beautiful, than many other English cathedrals. Merton College is situated a little to the south of the High Street. It retains the original chapel, and part of the other buildings erected by Walter de Merton in the 13th century. Magdalen College retains its celebrated cloister and tower of the 15th century, and the buildings there are more ample than

those of any other college in Oxford. Oriel College, a comparatively modern structure, is very picturesque. New College ranks among the noblest buildings in the city—'the chapel, the hall, the cloisters, the groined gateways, and some original doors and windows, remain in their exterior at least as they came from the hand of their master architect,' William of Wykeham, 500 years ago. Queen's College is Grecian in its style of architecture. It has a spacious and handsome chapel, and good library. Trinity College is also Grecian in its style of architecture. University College is a mixture of Gothic and Italian. Exeter College has a splendid frontage to the west, and its chapel (built 1857–58), in the Gothic style, is the finest modern building in the city. It has also an excellent hall and a beautiful library. Balliol College has a remarkably fine chapel, built a few years ago. The chief buildings connected with the university, besides the Bodleian and the Ashmolean Museum, are—the Radcliffe Library, a circular structure, adorned with Corinthian columns, and surmounted by a dome; the Radcliffe Observatory, crowned by an octagonal tower, in imitation of the Temple of the Winds at Athens; the University Printing-office; and the Taylor Institution, founded 'for the teaching the European languages,' an exceedingly handsome and extensive range of buildings. The Botanic Gardens are not far from the Cherwell, and nearly opposite Magdalen College. Oxford is a municipal and parliamentary borough, but its magistrates have no authority over the university. The city sends, since 1885, only one member; the university sends two members to parliament. Oxford, by the Saxons called Oxnaford, and in Domesday Book, Oxeneford—probably from its having been originally a ford for the passage of oxen—is of great antiquity. The date of its origin is unknown, but as early as the eighth century, there was a nunnery established there; and in 802, an Act of Confirmation by Pope Martin II. describes it as an ancient seat of learning. It is said to have been a residence of King Alfred, and also of Canute, who held several parliaments within its walls. The townsmen closed their gates against William the Conqueror, who stormed the town in 1067, and gave it to one of his followers, Robert D'Oyley, who built a castle there, to overawe the disaffected Saxons, some ruins of which are still to be seen. The paction which ended the strife between Henry II. and Stephen was drawn up at Oxford. In the reign of Edward III. the preaching of Wicliffe excited great commotion among the students, and threatened the dissolution of the university. In the reign of 'Bloody Mary,' Oxford saw the martyrdoms of Ridley, Latimer, and Cranmer. During the great civil war of the 17th century, it was for a while the headquarters of the royalist forces, and was conspicuous for its adherence to Charles I. Since that period, it—at least its university—has been characterised by an extreme devotion to 'the church' and the 'king.' The university is erroneously said to have been founded by King Alfred; but it is certain that, from very early times, students resorted to Oxford to attend lectures there delivered by learned men, and that they lived in the houses of the townspeople. Sometimes the students combined so as to secure the services of a common teacher, with whom they lived in a large tenement called an inn, hostel, or hall. The residence of the students with the townspeople gradually ceased; and by Queen Elizabeth's time, it had become obligatory on the undergraduates to reside in some college or hall, for their first twelve terms at least. But now undergraduates may in most colleges live in lodgings from the beginning of their course. The colleges were founded at various periods from the end of the 13th century to the beginning of the 18th. Fourteen out of the nineteen were founded before the Reformation. Under a statute passed in 1868, any man may now become a member of the university without becoming a member of a college or hall, provided he satisfies certain disciplinary requirements; for which purpose, those unattached students are under the control of a Board of Delegates, but no special provision is made for their instruction. In Worcester College and the halls, there is still a class of fellow-commoners who pay more than the ordinary fees and enjoy certain privileges. They consist mainly of men above the usual age of undergraduates, who wish to have the intellectual advantages of the university without being subject to the common routine of discipline. All other formal distinctions between wealth, or position, and poverty, are almost wholly abolished. Special privileges are no longer given to peers; nor is any regard now had to the poverty of candidates, as it was formerly in the case of certain scholarships. The cost of tuition varies at different colleges, but an average of £65 may be given as paid by the undergraduate during his whole career. This payment is at some colleges distributed over three, at others, over four years. Private tuition has grown to be an institution in Oxford, though not formally recognised. Many of the ablest young men, after taking their degree, remain in Oxford a year or two, taking private pupils. Private tutors usually charge £10 a term for three hours a week. There are four terms in each year. With regard to the expenses of Oxford, it is impossible to be definite. They vary at different colleges, not only indirectly, from the tone of the society, but even directly, from the charges made for necessaries. A man should be exceedingly comfortable at Oxford with £200 a year; with £150, he can do, with economy. Many young men could not with prudence be exposed to the difficulty of living in Oxford on less than the latter sum. There have, indeed, been instances of men passing creditably through the university course on £100 a year; and returns procured by the delegates for unattached students, cover their board, lodging, and tuition for about £45 a year. The *necessary* expenses do not exceed that sum. The habits of the young men cause a great part of the expense.

Cambridge, the chief town of the county so named, takes its name from the river Cam, anciently called the Granta. By the Saxons, Cambridge appears to have been known as Grantabrygge. The population of the municipal borough in 1881 was 35,363; that of the parliamentary borough, 40,878. The town sends one and the university two members to parliament. The town is not generally pretty or picturesque; but the gardens at the back of the college, by the Cam, are exceedingly beautiful in summer. The history

of the university may be said to begin early in the 12th century—about which time it began to be the resort of students, who attended lectures delivered by learned monks. When Alfred of Beverley was a student there—namely, 1129 A.D.—there were no public halls or hostels, but each one lived in his own hired lodgings. The first regular society of students was that of Peterhouse, founded in 1257. These societies gradually increased; the hostels in which the students lived together, under a principal, being generally named after some saint or adjoining church. It was between the latter part of the 13th and the close of the 16th century, that these foundations, which now constitute the university, were endowed. Hugh de Balsham has the honour of being the first benefactor in this way. Michael House was founded by Hervey de Stanton, in 1324; and King's Hall, by Edward III. in 1332. These were both merged into Trinity College under Henry VIII. in 1546. Clare Hall, as it used to be called, one of the earliest colleges in Cambridge, was founded by the Countess of Clare in 1326. King's College was founded by Henry VI.; and his queen, Margaret, began the foundation of Queen's College, which was added to by Elizabeth Woodville, queen of Edward IV. Lady Margaret, Countess of Richmond and Derby, mother of Henry VII. founded Christ College, and St John's, in the beginning of the 16th century, and also the Divinity professorship named after her. Henry VIII. appropriated part of the spoils of the monasteries to the foundation of Trinity College; and Queen Mary augmented the endowment. The five Regius professorships were endowed by Henry VIII.

In 1643, Cromwell took possession of the town, and the most eminent royalists were expelled from the university. From that time no new college was added, until the founding of Downing College in 1800. The present university statutes were confirmed by Queen Victoria, by Order in Council of 31st July 1858. The governing body is the Senate, and the building where they meet is called the Senate House. All university laws are approved by an elected body called the Council, before they are submitted to the Senate. The executive powers are intrusted to a Chancellor, High Steward, Vice-chancellor, and Assessor. There are four classes of students—*Fellow-commoners* and *Noblemen*, *Pensioners*, *Sizars*, and the more distinguished students, who are elected *Scholars* on the foundation of their college. The first class are so called from their dining at the Fellows' table. They wear silk or embroidered gowns, and pay heavier fees. The Pensioners are the great body of students who are not on the foundation, and who pay for their own commons—namely, dinners in hall, &c. and for their chambers. The Sizars are the poorer students, who are admitted at lower charges than the Pensioners, but wear the same dress, and are no longer subject to the performance of menial offices, as they once were. The Scholars are elected by examination from the Pensioners and Sizars; they are on the foundation of the college, have rooms and commons free, and other emoluments. The Fellows are subsequently elected from the Scholars and the students who have distinguished themselves in the Tripos examinations. Vacancies are, as a rule, filled up from members of the college, but many fellowships are open to the competition of the whole university. The usual age of admission is from 17 to 20. The great prizes of the university are the Fellowships, of which there are about 360 open to all candidates, without restriction; but conditions of tenure as to marriage and holy orders vary at different colleges. Their value varies from £100 to £300 per annum, and many of the Senior Fellowships are over £500 a year. The office of Tutor is one of great honour and emolument. The Chancellor gives annually two gold medals to the two *commencing* bachelors, who, having taken a *senior optime's* degree in mathematics, shew themselves the greatest proficients in classical learning. The members of parliament for the university give annually four prizes for the best dissertations in Latin prose. There are numerous other university distinctions, for an accurate account of which the *Cambridge Calendar* should be consulted.

Winchester, a famous historical city, the chief town of Hampshire, is situated in the middle of the county, on the right bank of the Itchin, 67 miles south-west of London by railway. Population in 1881, 17,780. The Castle Hill is the site of the old castle built in the 13th century by Henry III. and of a magnificent hall, of which the only remaining portion is used as the county court. About a mile from the town is the famous hospital of St Cross, founded in 1136 by Henry de Blois, bishop of Winchester, for thirteen poor men 'decayed and past their strength.' It was at one time munificently endowed, but its sources of income have, in course of time, been narrowed. Its ancient charters and grants were destroyed in the 13th century. The city cross in the High Street, dating from the 15th century, is very beautiful in design. The college of Winchester, called originally 'Seinte Marie College of Wynchestre,' now St Mary's or Winchester College, was founded by William of Wykeham, bishop of Winchester, in 1387, and the buildings were finished in 1393. The charter of the school, which is in existence, was granted by Richard II. in 1396, and confirmed by all the subsequent sovereigns, Mary excepted, down to Charles II. The endowment at present amounts to about £15,500 a year. The pupils of the school are of two classes, foundation scholars and commoners. The scholars are elected between 12 and 15 years of age by competitive examination; the average annual number of vacancies being 12, and the number of candidates 100. The scholars are well boarded, lodged, and educated at the expense of the foundation; having to pay for incidental charges only £21 a year. Many of the quaint old customs of the school are still retained. The average number of commoners has of late been about 300. They generally enter between 12 and 15 years of age, and stay 3 or 4 years. Those who are not on the foundation are boarded in the houses of the masters, at a total cost of about £112, including expense of tuition, pocket-money, and cost of travelling. Winchester possesses 70 scholarships tenable at school for foundationers, and 8 exhibitions for commoners; also 4 exhibitions yearly of £50 for 4 years, tenable after leaving, and 6 scholarships annually at New College, Oxford. *Fagging* is permitted to the 18 chief boys, who are called 'Prefects.' The monitorial system was first established in this college. The cathedral is

520 feet long, which is longer than any other English cathedral, except those of Ely, 560 feet, and Canterbury, 525 feet. Its breadth at the transepts is 208 feet; the length of the nave is 351 feet; its height 86 feet; and the low central Norman tower is 150 feet high. The exterior is somewhat disappointing; but the interior is magnificent, and contains many objects of great interest. There is the tomb of William Rufus; the golden shrine of St Swithin—which famous saint was bishop of Winchester—the tomb of Edmund, the son of King Alfred; and the tomb of Izaak Walton.

The noteworthy architectural styles are: Early Norman in the crypt and transepts; Early English in the eastern aisles and chapels behind the presbytery; and Perpendicular in the nave, which for beauty and grandeur is only rivalled by York. Besides the cathedral, there are some churches of interest in the Transition, Norman, and Perpendicular styles.

Canterbury, the seat of the metropolitan see of all England, is situated on the river Stour. It is 81 miles from London by the South-eastern Railway, and about 60 by the London, Chatham, and Dover. Population in 1881, 21,704. The glory of Canterbury is its *cathedral*. When St Augustine became archbishop of Canterbury, 597 A.D. he consecrated, under the name Christ's Church, a church said to have been formerly used by Roman Christians. Cuthbert, the eleventh archbishop, 740 A.D. added a church to the east of this. Among those who helped to repair, enlarge, and rebuild it, were Archbishops Odo (940 A.D.), Lanfranc (1070), and Anselm (1093). In 1174 the choir was destroyed by fire, and to rebuild it, a number of French and English artificers were summoned. Among the former was William of Sens, and to him, a man of real genius, the work was intrusted. The church was rich in relics: Plegemund had brought hither the body of the martyr Blasius from Rome; there were the relics of St Wilfred, St Dunstan, and St Elfege; the murder of Thomas Becket had recently added a still more popular name to the list of martyrs. The offerings at these shrines, especially the last, contributed to defray the expenses of the work. William of Sens did not, however, live to see its completion. He was succeeded by another William, an Englishman, and to him we owe the completion of the existing unique and beautiful choir, terminated by the corona or circular chapel called Becket's Crown. Gervasius, a monk, who witnessed the fire of 1174, tells us that the parts of Lanfranc's church which remained in his time were the nave, the central and western towers, the western transepts, and their eastern chapels. In the 14th century, the nave and transepts were transformed into the Perpendicular style of that period. The central tower, called the Angel Steeple, was carried up (1486–1504) to about double its original height, also in the Perpendicular style; it is 234 feet high, and 35 feet in diameter. The north-west tower was taken down in 1834; it was 113 feet high, and divided into five stories. The Norman plinth still remains on each side of the nave in the side aisles, and portions of Norman ashlaring may be seen about the transepts, outside the west wall, and on the east piers of the great tower. The indiscriminate use of the 'Round' or 'Norman,' and the 'Pointed' or 'Early English' arch, is also a striking feature in the eastern part of the building. The Lady Chapel, now called the Dean's Chapel, stands on the north side of the church, and was built in 1468; the roof is a fan-vault. The north transept is called the Martyrdom, for here took place the murder of Becket, on Tuesday, December 29, 1170. Fifty years later, his remains were translated from the crypt to a shrine in the newly erected Trinity Chapel, eastward of the choir. About the year 1500, the yearly offerings at this shrine amounted to £4000; but they had then declined much in value. A mosaic pavement still remains in front of the place where the shrine stood, and the stone steps which lead up to it are worn by the knees of countless pilgrims; but the shrine itself was demolished in 1538, and the bones of the saint burned, by order of Henry VIII. In 1643, the building was further 'purified,' as it was called, by order of parliament. Still many interesting monuments remain—such as the tombs of Stephen Langton; that which is commonly, but wrongly, supposed to be the tomb of Archbishop Theobald; with those of the Black Prince, of Henry IV. of Archbishops Maphan, Peckham, Chicheley, Courtenay, Sudbury, Stratford, Kemp, Bourchier, Warham, and of Cardinal Pole. The exterior length of the cathedral is 545 feet, by 156 in breadth at the eastern transept. The crypt is of greater extent and loftier than any other in England.

The archbishop of Canterbury is primate of all England, metropolitan, and first peer of the realm. He ranks next to royalty, and crowns the sovereign. His ecclesiastical province includes all England except the six northern counties. Among his privileges, he can confer degrees in divinity, law, music, and medicine. His seats are at Lambeth and Addington Park. He is patron of 149 livings, and has an income of £15,000 a year.

Brighton, originally Brighthelmstone, is a town and watering-place on the east coast of Sussex, fifty and a half miles south of London. The writings of Dr Russel, a physician of George II.'s time, first drew public attention to Brighton as an eligible watering-place; and the discovery of a chalybeate spring in the neighbourhood increased its popularity. The real discoverer of Brighton was, however, George, Prince of Wales, in 1782. His subsequent yearly visits attracted crowds of visitors from the world of fashion. The settled population in 1881 was 107,546. Near the centre of the town is the Pavilion, or Marine Palace, a fantastic oriental structure with domes, minarets, and pinnacles, and Moorish stables, begun for the Prince of Wales in 1784, and finished in 1827. It is now the property of the corporation of Brighton, and with its beautiful pleasure-ground of above seven acres is given for public recreation. It is in the Steyne, an open space between the east and west parts of the town. The Marine Parade extends about a mile along the margin of the cliff. Westward, there is a similar promenade in front of the more modern part of the town. A rational attraction has recently been added to the place, by the acquisition of an Aquarium—the largest in England, and probably in the world.

Portsmouth, the chief naval arsenal of Great Britain, and an important sea-port, in the south of Hampshire, stands on the south-west shore of Portsea Island, at the entrance to Portsmouth

harbour, and opposite the town of Gosport, with which it communicates by means of a steam bridge. It is seventy-four miles south-west of London by the London and South-western Railway. The population of the borough with its suburbs, was, in 1881, 127,989. The fortress is considered the strongest in Britain. Formidable batteries defend the harbour, and bastioned ramparts inclose the town. Portsea, about a mile to the north, is similarly fortified, the line of its land-defences being distinct from that of Portsmouth. The 12 docks vary from 22 to 36 feet deep. One of the building-slips, roofed and covered in, is so large that three or four vessels can be in process of construction under it at the same time. The Wood Mills contain a number of ingenious block-making machines, the invention of Sir Isambard Brunel, in which rough timber, introduced at one end, is cut, squared, drilled, bored, and turned into the required shape. About 150,000 blocks are made annually, and the machines require the attendance of only four men. Portsmouth harbour, about 420 yards wide at its entrance, expands into a spacious basin, extending inland for about four miles. The breadth along the northern shore is three miles. Large war-vessels can enter and lie at anchor in all states of the tide. The position of this harbour is highly favourable. It is situated in the middle of the Channel, close to the magnificent anchorage of Spithead, where 1000 ships of the line can lie without inconvenience, and it is under the shelter of the Isle of Wight. In 1880, 1903 vessels, of 185,943 tons, entered; and 2020, of 206,729, left the port.

This port only began to be considered valuable in the reign of Henry VIII. Its defences were strengthened by Elizabeth, and afterwards more thoroughly by William III. In a house that still remains in the High Street, then an inn called the *Spotted Dog*, the Duke of Buckingham, the 'Steenie' of King James, was assassinated by John Felton, in 1628. And in Portsmouth harbour, on August 29, 1782, when its commander, Admiral Kempenfeldt, was writing in his cabin, the *Royal George* sank with 800 men on board.

Eight hundred of the brave,
Whose courage well was tried,
Had made the vessel heel,
And laid her on her side.

A land-breeze shook the shrouds,
And she was overset;
Down went the *Royal George*
With all her crew complete. . . .

It was not in the battle—
No tempest gave the shock—
She sprang no fatal leak—
She ran upon no rock.

His sword was in its sheath,
His fingers held the pen,
When Kempenfeldt went down
With twice four hundred men.

Plymouth is an English sea-port and market-town, and a parliamentary and municipal borough in the south-west of Devonshire, 246 miles west-south-west of London. It stands in the bight of Plymouth Sound, between the estuaries of the Plym and Tamar. To the west of it is Stonehouse, a township and coast-guard station; and still further west is Devonport, the great naval and military station. Plymouth proper and Stonehouse having become united by a continuous line of houses, they, along with Devonport, are now generally considered as one town. Devonport is walled, fortified, and surrounded by a moat. Mill Bay and Sutton Pool are two small inlets of the Sound, in which lie all the merchant-vessels bound for Plymouth proper. Between these inlets and running along the shore is the eminence or high plateau of land called the Hoe. From this ridge it is said that the Spanish Armada was first seen from England. It commands a magnificent view by land and sea. On its eastern end stands the citadel, a fortress equipped with 150 guns, commanding the entrance to the Cutwater—the lower estuary of the Plym—and of Sutton Pool. Mill Bay, on the west, is so deep that vessels of 3000 tons can lie at the pier at low-water. There are the important Great Western Docks, covering an area of 14 acres, and having a depth of 22 feet, constructed about the years 1855–58. Close to these docks, and connected with them by a tramline, are the termini of the South Devon, Tavistock, and Cornwall railways. In the year 1880, 3401 vessels of 653,437 tons entered the port. Commerce is carried on to a considerable extent with the Cape of Good Hope, the West Indies, and the Mediterranean. The coasting-trade is also important, and the fisheries are productive. The population in 1881 was 76,080.

Plymouth, described by Leland as being in the reign of Henry II. a 'mene thing, an inhabitation of fishers,' was called by the Saxons Tameorworth—town on the Tamar; and it was not till the reign of Henry VI. that it received the name of Plymouth. During the 14th and 15th centuries, it was frequently attacked and set on fire by the French; and in 1512 an act was passed for the strengthening of its defences. Now, the whole shores of the Sound are well defended by cannon; and a cordon of inland forts has been of late years constructed, at immense cost, surrounding the three towns, at a distance of from two to three miles. Plymouth Sound claims to be the most beautiful estuary on the English coast. It is two and a half miles wide, and extends inland for three miles. It penetrates into the country by the harbours of Hamoaze and Cutwater, the estuaries of the Tamar and Plym respectively. On its west side is Cawsand Bay. The shores, which present many beautiful views, rise in hills of from 100 to 400 feet high, and are dotted over with woods and with villages, and bound by coasts which are generally rocky and abrupt. Mount Edgecombe Park, the beautiful seat of the Earl of Mount Edgecombe, occupies the west shore of the Sound. At the mouth of the Tamar is the small island of St Nicholas, or Drake's Island, a pyramidal rock, strongly fortified. The Sound is open to the south-west, from which direction strong winds frequently blow, bringing in violent surges from the Atlantic. To protect the shipping in the harbour, a massive stone breakwater, 1700 yards long, was completed in 1841 at a cost of about £1,500,000. On a sunken rock, just inside the breakwater, and at its centre, a strong stone fort has of recent years been erected; and an extensive series of stone batteries has been built at Bovisand and Picklecomb on the mainland, on both sides of the entrance to the harbour.

SCOTLAND.

SCOTLAND occupies the northern, the smaller, and less fertile portion of the island of Great Britain. It lies between lat. 54°38′ and 58° 40′ north, and between long. 1° 46′ and 6° 14′ west, or, including the Hebrides, 8° 35′ west. It is bounded on the west and north by the Atlantic; on the east by the German Ocean; and on the south by England, the Solway Firth, and part of the Irish Sea. Its coast-line presents the most fantastic irregularities: here jutting into the ocean in high narrow peninsulas, there receding far inland, in lake-like gulfs, and again suddenly starting seaward, and breaking into a number of bold rocky headlands. Its greatest length, from the Mull of Galloway on the south to Dunnet Head on the north, is about 280 miles; its breadth is variable, being about 146 miles between Buchan Ness, in Aberdeenshire, and the extreme point of Ross-shire on the west, but diminishing to little more than 30 miles between the Firths of Forth and Clyde. The entire surface, including the islands, is estimated at 30,902 square miles. By the census of 1871, the population of Scotland was 3,360,018; in 1881, it was 3,735,573, shewing an increase of 11·18 per cent., the highest rate of increase since 1831.

SUPERFICIAL FEATURES.

Superficially, the country may be described as mountainous and rugged—its central and southern districts, however, exhibit less of this character; hence the common distinction of *Highlands* and *Lowlands*. A line drawn from Aberdeen to Glasgow may be regarded as the boundary between the two regions—the former a country full of romantic scenery, savage precipitous mountains, lakes, dreary moorlands, rushing streams, deep glens, and wild hanging woods; the latter being less elevated and irregular, but still presenting several considerable mountain-ranges. A more correct division, perhaps, would be into northern, central, and southern regions. The boundaries between these regions are formed by two great natural depressions. The first runs from the Sound of Mull, on the west coast, in a north-east direction to the Moray Firth at Fort George, and is called Glenmore or the Great Glen. It forms the line of the Caledonian Canal (see page 250). The other depression runs across the island between the Firths of Forth and Clyde. The region lying north and west of Glenmore may be considered as a high table-land, at a general elevation of 500 to 1500 feet, with a number of rocks and summits rising from it, the highest of which are Ben More Assynt (3273), Ben Wyvis (3429), and Ben Attow (3383 feet). This division of Scotland is little but a wild, barren, rocky desert. The level portions, which are less than one-twentieth of the whole, lie chiefly around the Cromarty Firth, on the east coast, and in the county of Caithness, the greater part of which is an undulating plain.

The central region, comprised between the two depressions, is traversed by the chain of the Grampian Mountains, which begins on the east coast immediately south of the river Dee at Aberdeen, and runs to the south extremity of Glenmore, on the west coast. The highest summits are Ben Nevis (4406), at the west end of the range, and Ben Muicdhui (4296), near the sources of the Dee. The third or southern division of Scotland also contains a system of mountains or highlands, but of a different character from the northern highlands, the hills being mostly of a rounded form, and in great part covered with green vegetation. The most elevated part of this region is that which forms the water-shed between the waters of the Clyde and Tweed on one side, and those that fall into the Solway Firth on the other. The Lowthers, near the sources of the Clyde, rise in two summits to 2377 and 2403 feet. Broad Law, in Upper Tweeddale, is 2723 feet. This elevation is continued eastward in the Cheviot Hills, dividing England and Scotland. Another eastern prolongation of this southern highlands is the Lammermuirs, which terminate in St Abb's Head.

There are no great *plains* in Scotland. There are, however, a number of considerable valleys, known as carses, straths, haughs, and dales, intermediate between the mountain-ranges; and these form, as it were, the granaries of the country.

GEOLOGICAL STRUCTURE.

The following sketch embraces England as well as Scotland, it being more convenient, in regard to geological structure, to treat the island as a whole. The geology of Great Britain is of peculiar importance. The rocks of the earth's crust having been first systematically studied and expounded here, British geologists have given to the world the names whereby the various strata are known, and British rocks form the typical series of the earth's strata. The whole recognised series of stratified deposits occur in Britain, one or two only being more fully developed elsewhere. In the following sketch of their distribution, we shall begin with the lowest and oldest. The *base rocks* occur in the Outer Hebrides, in Tiree and Coll, and along the western shores of Sutherland and Ross. The predominant rock is crystalline gneiss. Resting on the convoluted edges of this old gneiss, on the mainland, and forming the basement rocks in Cumberland, Anglesea, and North Wales, we have the *Cambrian series* of deposits. In Scotland, these rocks are brownish-red sandstones and conglomerates; in England and Wales, they are composed of sandstones, gritstones, and slates. They contain very few fossils. The *Silurian measures* occupy a large portion of the country, extending over the greater part of Wales, the north of Lancashire, Westmoreland, most of the Lowlands of Scotland, and almost all the Highlands north and west of a line drawn between

Stonehaven and Helensburgh. They consist of shales, limestone, graywacke, &c. but the series is greatly metamorphosed; the lower strata being converted into quartzose flagstones and quartz rock, the upper into chlorite and mica-slate, and quartzose and gneissose rocks. Immense tracts of the lower Silurian beds have hitherto proved devoid of fossils; in other districts, the calcareous rocks are almost entirely composed of the remains of marine invertebrate animals, while the shales abound in zoophytes and crustacea. The *Old Red Sandstone Strata*, consisting of conglomerates, coarse and fine-grained sandstones, and dark-coloured schists, with the characteristic fossils of ganoid and placoid fish, frequently overlie the Silurians. Nearly all Caithness, and the seaward portions of Sutherland, Ross, Cromarty, Inverness, Nairn, and Moray, belong to these strata, which also appear in many parts of the east and south-east of Scotland, in South Wales, Devon, and Cornwall, where the predominant rocks are slates, sandstones, and limestones, and the fossils, coral and shell-fish. The strata of the *Carboniferous period* may be said to occupy a broad but broken tract, extending, in England, from the Bristol Channel to the base of the Cheviots; and in Scotland, filling the great trough between the Silurian measures on the south, and the Old Red Sandstone on the north. Besides coal, the whole of the Carboniferous series contain immense stores of argillaceous carbonate of iron, from the ore of which is produced the great bulk of iron used in the country. The *Permian strata*, consisting of magnesian limestone and sandstone coloured with oxide of iron, occupy a considerable area in the centre and north of England. Two small tracts of highly fossiliferous *Lias* occur, the one in Glamorgan, the other in Shropshire; and small patches exist in Scotland, at Brora in Sutherland, and in the islands of Skye, Eigg, and Mull. Far more extensive and important, however, are the *Oolite measures*, which form a belt nearly 30 miles broad, from Yorkshire to Dorsetshire, curving round by way of Lincolnshire. The best building material in England is obtained from these strata, which are composed of limestones, sandstones, and shales. The fresh-water *Wealden series*, with their abundant remains of reptiles, fishes, shells, and insects, occur in Kent and Sussex, in the Isle of Wight, and in Devon; the fossiliferous beds of the *Cretaceous period*, consisting chiefly of chalk, with intercalated sands and clays, lie east of the *oolite* strata, and parallel to them, and have a historical celebrity in the 'cliffs of Dover,' whose *white*-gleaming heights are supposed by some to have originated the name *Albion*, which our island once bore. *Eocene strata*, composed of clays, sands, and marls, occur in various parts of the south and south-east of England; *Pliocene deposits* of shelly sand and marl in Suffolk; and the still more recent Pleistocene deposits of fresh-water sand and gravel on the coast from Norfolk to Kent.

CLIMATE.

It is impossible to contrast the climates of England and Scotland generally without misleading, because, for several months in the year, longitude, and not latitude, is the agent which mainly affects the various climates of Great Britain. Thus, the annual mean temperature of Greenwich is 3·4° higher than that of Edinburgh; but to know this fact alone is worse than valueless, because July is, on an average, 5° warmer in and near London, while January has the same temperature in both places. From charts prepared by Mr A. Buchan (*Scot. Meteorological Society Journal*, Nos. 28, 29), based generally on the observations of the thirteen years 1857–69, it appears that the lowest line of mean temperature at the level of the sea which touches Great Britain in January, the coldest month, is 37°; but this only embraces the tract from Kinnaird Head to Aberdeen. The line of 38°, again, starting from the Faröe Islands, enters Scotland by the Moray Firth, runs west by Perth, Greenock, Glasgow, and Dumfries, traversing England by Carlisle, Derby, and the Naze; 39° starting from the Shetland Islands, passes through the Hebrides, the Mull of Kintyre, and Galloway. Hence January in the south-east of England is 1° colder than in the Shetland Islands and on the whole west coast of Scotland, and as cold as in the Faröe Islands in 62° N. lat. In the Hebrides, again, and in the south-west of Scotland, the January temperature corresponds with that of Dublin, Bristol, and Portsmouth. February makes but a slight alteration, relatively, in the temperature of Great Britain. In March, latitude begins to supersede longitude as the determining agent. An Edinburgh March is about equal to that of York, and 2° below that of London. April in London is 3° warmer than in Edinburgh. It may here be observed that seasons differ less from one another in mean temperature on the west coast of Great Britain, generally, than they do on the east coast; and that while the winters of the west are warmer, its summer is cooler. But this difference in favour of the west in winter, as compared with the east and inland places, arises chiefly during the night. This fact, Mr Buchan attributes to the great predominance, in winter, of south-west winds, 'which,' he says, 'arrive on our western shores bringing the high temperature of the ocean they have just crossed. At the same time, being cooled by coming in contact with the surface of the earth, at this season many degrees cooler than the Atlantic, their superabundant vapour is condensed into clouds, which partially screen the west coast from those intense colds produced by nocturnal radiation. On the other hand, the south-west winds are rapidly cooled as they proceed northwards, and being drained of much of their moisture, the skies are clearer, and thus less obstruction is offered to radiation.'

From this we infer, that during the prevalence of north and north-east winds, the higher temperature of the west coast will be lost, and these winds are just as prevalent in spring on the one coast as on the other. The point is one which deserves the attention of medical men, and those whose health depends on climate.

The coast of Argyllshire, as might have been expected, has a very high winter temperature. The number of frosty nights which occur there in January, is rather fewer than in May in Upper Deeside, where the Scotch winters are coldest. At Easdale in Argyllshire, in January 1862, the temperature never fell to 32°; and during seven years, 1857–64, twelve nights of frost were the

maximum in January; whilst in Braemar, for the same period, there were never fewer than fourteen nights of frost in January, and in that month, in 1860, there were twenty-five. But it is to be feared that the winter climate of Scotland, indeed of all Great Britain, presents but a choice of two evils—cold or damp. The east coast is dry and cold; the west is damp and comparatively mild; where dryness and warmth are both required, southern latitudes—and far south too—must be sought. The questionable superiority of the English as compared with the Scotch climate in winter and early spring, becomes unquestionable as the season advances. In spring, at least during the intervals when the northerly and easterly winds suspend their fury, the southern half of England is very much warmer than Scotland generally; moreover, its skies are brighter, and its sun more powerful—facts of importance to the ripening of crops. The superiority of south over north goes on increasing till July, when the mean temperature of London is 64°, that of Edinburgh 59°. At Cambridge this superiority begins to diminish, and may be said to disappear at Newcastle. The southern advantage is maintained during September and October, but is lost in November, during which month the 'isothermal' of 43° runs through Wigtownshire, Birmingham, and Oxford. Very curious fluctuations, however, occur in the relative summer temperatures of England—by which is meant England south of Cambridge—and those of the Lowlands of Scotland. Thus, in 1857, the mean summer temperature of England was 64·3°, while in Scotland it was only 56·9°; England being thus warmer by 7·4°; and the English July of that year was 10° warmer than the Scotch. In the following year, however, the southern summer was but 1·8° above the northern; and in July of that year the means were respectively 57·6° and 57·3°, or practically the same. From data such as these, it is found that while the summers of Scotland are less warm than those of England, they are less fluctuating. Hence, in cold, backward seasons, the damage sustained by crops may be expected to be proportionally greater in England than in Scotland. The Scotch climate, it appears, is on the whole better suited for the cultivation of turnips than that of England, though it is not so in every respect. The greater rainfall during July and August in Scotland is advantageous to the root, but its autumnal growth continues longer in the south.

The *Journal of the Scottish Meteorological Society*, No. 31, gives a map shewing the annual rainfall at 290 places in Scotland, on an average of fifty-seven years—viz. from 1815 to 1871. It shews a great variety in the climates of Scotland as regards rainfall. At Edinburgh, the annual fall is little over 24 inches, while at Glencroe it is 128·50 inches on an average of 6½ years. The whole of the west coast of Scotland, from the Firth of Clyde to the extreme north-west, including the Hebrides, is wet as compared with the east coast, and with England generally. Towards Glasgow the rainfall begins to diminish; being 62 inches at Greenock and Gourock, while at Glasgow it is but 43. Higher up the valley of the Clyde, it diminishes still further; falling to 28 inches near Uddingston; 'thus presenting,' says Mr Buchan (*Journal*, No. 31, p. 179), 'an almost exact counterpart of the rainfall of the more level parts of Fifeshire, and many other eastern districts.' For a summer residence it is desirable to choose a place whose mean summer temperature does not exceed 60°; the returns of the Registrar-general shewing that above this point there is an increase in the mortality rates, chiefly from diarrhœa and similar complaints. Deeside, Mr Buchan considers to possess one of the healthiest summer climates of our island. He also especially adverts favourably to Upper Strathearn, Innerleithen, and Moffat.

The plants and animals of the country are, generally speaking, specifically the same as those of England, but have a somewhat more boreal character, as might be expected from the higher latitude and altitude of the land. The common cultivated grains are grown profitably, and to great extent, in the Lowlands; but oats, and a coarse variety of barley (bigg), are the only cereals grown in the Highlands and islands. The stag, roe, and wild-cat are thoroughly *ferœ naturœ* on the northern hills; game-birds—as the partridge, grouse, ptarmigan, woodcock, blackcock—are peculiarly abundant in the same localities. Scotland possesses fewer species of fresh-water fish, but has the salmon and trout in greater abundance than England, and also many of the marine animals, cetacea, herring, cod, and other white fish. Pilchard and white-bait are scarcely known on the Scotch coast.

PEOPLE—POPULATION.

The population of Scotland is readily divisible into two great sections—the Lowlanders or Scotch proper, and the Highlanders or Celts. The former, like the English, are of the Teutonic race, but consist of an admixture of Picts, Saxons, Danes, and Scandinavians. They occupy the whole of the Lowlands and the eastern coast-fringe of the Highlands, speaking a variety or dialect of the English language. They are described generally as a tall, large-boned, and muscular race, with features less round and soft than the modern English, and with a larger and more elongated cranium. The Highlanders, on the other hand, are mainly of Celtic origin; and though their language is gradually giving way to that of the Lowlanders, in other respects they retain all the peculiarities of that race.

The Scottish character exhibits a considerable share of both energy and perseverance. It may safely be said that a country with so many physical disadvantages could never have been brought into such a condition as respects rural husbandry, nor, with all the advantage of the English connection, been made so prosperous a seat of both manufactures and commerce, if the people had not been gifted in a high degree with those qualities. A disposition to a frugal and careful use of means is also conspicuous in the Scotch. The poorest poor, at least in rural districts, are in few instances of such improvident habits as to lead to that destitution of furniture, clothing, and tolerable house-accommodation, which meets the eye almost everywhere in Ireland. Caution, foresight, and reflection may be said to enter largely into the Scottish character. Under the influence of these qualities, they are slow, and sometimes cold in speech, and are therefore

apt to appear deficient in frankness and generosity. They are not, however, really so. That *perfervidum ingenium*, or fiery genius, attributed to them by Buchanan, is still a deep-seated characteristic of the people. On subjects which they regard as important, they sometimes manifest this excitability in a very striking manner; as, for instance, in their almost universal rising against Charles I. in defence of their favourite modes of worship and ecclesiastical polity. They cherish more than most people a feeling of attachment for their native country, and even for the particular district and spot of their birth; for their remote as well as immediate kindred, and for everything which reminds them of what is honourable in the doings of those who went before them. A strong sense of religion is a conspicuous feature in the Scottish national character; free, however, from all regard to external things connected with it. It may at the same time be remarked, that their religion is more doctrinal than venerative or sentimental—a peculiarity which may be traced in the plainness of their forms of worship, as either its cause or its effect. There is a considerable tendency in the Scottish intellect to argumentative reasoning, and this shews itself in the service in their churches as well as in their philosophical literature. The domestic virtues flourish in much the same degree in Scotland as in England; but the humbler classes in North Britain are not nearly so cleanly as the lower English. For centuries, the adventurous disposition of the Scotch has been remarkable. An immense number of young persons every year leave their native country to push their fortune in the busier English cities, in public employment in India, in the colonies, or in other parts of the world. These persons have generally a tolerable education in proportion to their rank and prospects; and being found possessed of steadiness, fidelity, and perseverance, they rarely fail to improve their circumstances. We are here reminded of the advantage which Scotland has long enjoyed in the possession of a universally diffused means of elementary instruction. This, though in some respects over-estimated, has at least insured that nearly every person reared in Scotland has some tincture of literature.

Under the Education Act of 1872, parents are now obliged to send their children to school, under penalty of fine or imprisonment in case of failure. This act further provides that every public school subject to inspection, and in receipt of public money, shall be open to children of all religious denominations. The jurisdiction of presbyteries and church courts in Scotch schools is by this act abolished, and transferred to the parochial school-boards; these being amenable to the chief Board, resident in Edinburgh.

GOVERNMENT—ADMINISTRATION.

The *government* of the country, since the Union in 1707, has been identical in its leading features with that of England. Scotland, however, has her own laws and forms of procedure, which in many respects differ from those of England. For administrative purposes, Scotland is divided into 33 shires or sheriffdoms, comprising about 1000 parishes.

Counties.	Area in Stat. Acres.	Inhabited Houses, 1871.	Population 1871.	Population 1881.
Aberdeen	1,251,451	34,589	244,603	267,990
Argyll	2,056,402	13,497	75,679	76,468

NATIONAL INDUSTRY.

Agriculture.—Nowhere, perhaps, have labour and skill effected so much, in spite of an ungenial climate and naturally sterile soil. One great advantage of Scotland over England is in the system of fixed leases, generally for nineteen years. The Scottish farmers have shewn themselves above those prejudices in favour of use and wont which usually characterise their class, and have been ever ready to adopt the suggestions of science and experience. They have accordingly taken the lead in most modern agricultural improvements—drainage, artificial manures, lighter implements, &c. The effects appear in the immensely increased value of the real property of the kingdom.

According to the agricultural returns for Scotland of 1884, out of the total area of 19,063,231 acres, there were under wheat, 68,716; barley, 230,554; oats, 1,045,895; beans and pease, 23,441; rye, 7334; potatoes, 163,847; turnips, 484,998. The total number of horses was 187,803; of cattle, 1,136,604; and of sheep, 6,983,293.

The following shews the valued rental of the chief counties of Scotland between 1664–95, and in 1882–83:

1664-95.	1882-83.	
Aberdeen...£19,418	£825,408	exclusive of railways.
Berwick.....14,864	368,719	"
Dumbarton... 2,777	399,156	"
Dumfries.....13,220	498,857	"
Edinburgh...15,921	603,544	"
Fife.....30,201	687,931	exclusive of railways and waterworks.
Forfar.....14,287	658,143	inclusive of railways, valued at £62,241.
Haddington..14,072	279,861	exclusive of railways.
Inverness..... 6,099	329,808	exclusive of railways and canals.
Kirkcudbright 9,549	362,675	exclusive of railways and royal burghs.
Lanark.....13,436	2,144,453	inclusive of railways and canals.

	1664-95.	1882-83.	
Perth	£28,330	£888,135	exclusive of railways and waterworks.
Roxburgh	26,222	419,704	inclusive of railways.
Stirling	9,042	415,479	exclusive of railways and canals.
Sutherland	2,266	97,809	supposed to be exclusive of railways, but not stated.
Wigtown	5,634	264,381	

From a parliamentary return published in April 1874, it was shewn that there were then in Scotland 131,530 owners of lands and heritages; that the estimated extent of their property is 18,946,694 acres, the gross annual value of which is £18,698,804.

Mining—Coal.—The first mention of coal in Scotland (*The Industries of Scotland*, by David Bremner; Edinburgh: A. & C. Black, 1869) is found in a charter granted in 1291 to the abbot and convent of Dunfermline, giving them the privilege of digging coal in the lands of Pittencrief; but the first workers are supposed to have been the monks of Newbattle Abbey. In the account of Scotland given by Eneas Sylvius, who visited it in the 14th century, it is stated that the poor people who begged at the church doors received for alms 'pieces of stone, with which they went away quite contented. This species of stone,' he adds, 'whether with sulphur, or whatever inflammable substance it may be impregnated, they burn in place of wood.' A description of Scotland written in the beginning of the 16th century, says: 'There are black stones also digged out of the ground, which are very good for firing, and such is their intolerable heat, that they resolve and melt iron, and therefore are very profitable for smiths, and such artificers as deal with other metals.' Popular prejudice, and want of proper apparatus for digging and raising, prevented coal from being generally used as fuel in Scotland until towards the close of the 16th century, when it is recorded that 'the use of coal beginneth to grow from the forge into the kitchen and halle.' The lot of the early miners in Scotland had its inevitable hardship made worse by a system of bondage, or serfdom, which prevailed. On entering a coal-mine, the workers became bound to labour in it during their whole life, and in case of sale or alienation of the colliery, the right to their services passed to the purchaser without special agreement. The sons of the collier could not follow any occupation but that of their father, and could only work in the mine to which they were born. This slavery was abolished by act of parliament on May 23, 1775. Up to 1843, women and children were employed in the coal-mines of Scotland. It appeared, on investigation by a parliamentary commission, that children as young as eight were employed in Scotland—in England, even as young as four. The women and children were employed to carry the coal on their backs to the pit's mouth; the weight carried on each journey being sometimes as much as 4½ cwt. The Report says: 'The whole of these places, it appears, are in a most deplorable state as to ventilation. The evidence of their sufferings, as given by the young people and the old colliers themselves, is absolutely hideous.' The act of parliament of 1842 prohibits the employment of boys under ten in coal-mines, and prohibits the employment of women. Times are changed with coal-miners, the rate of their wages having of late years been higher than that of almost any other class of workmen. The chief coal-fields in Scotland are those of Mid-Lothian, Fife, Lanark, Stirling, and Ayrshire.

Iron.—Though the existence of ironstone in the Scotch coal-measures was known many years previously, no attempt was made to turn it to account till 1760, when the Carron Ironworks were established. From this time till 1788, the quantity of iron produced in Scotland did not exceed 1500 tons a year; but during the succeeding eight years, a number of new furnaces were erected in the counties of Lanark, Fife, and Ayr. In 1796, the number of blast-furnaces was 17, and the quantity of iron made that year was 18,640 tons. Thirty-three years afterwards, the production was 29,000 tons; and in 1836 the invention of the hot-blast process raised it to 75,000 tons. In 1845, owing chiefly to railways, the quantity had increased to 475,000. In 1882, it was 1,126,000.

Ship-building.—Before the application of steam-power to navigation, the ship-building trade of the Clyde had reached considerable importance. Up to 1830 not more than 5000 tons of steam-shipping had been built on the Clyde. A great advance was made about the year 1840 by the formation of the celebrated Cunard Company, most of whose members were citizens of Glasgow. The total number of ships built in Scotland in 1884 was 358, with a tonnage of 221,635; of these, 70 vessels of 50,900 tons were built for foreigners. At Glasgow, in 1882, there were built 291 vessels, with a burden of 391,934 tons; 37 of these were sailing-vessels, 172 were screw-steamers, and 60 were built of steel.

Fisheries.—The herring-fishery of 1880 was the greatest ever known on the coast of Scotland before 1884. In 1884, the number of barrels cured was 1,697,077; barrels 'branded,' 653,425; exported, 1,185,220; while £10,890 were paid as brand-fees. The value of the fisheries of Scotland in 1884 was as follows:

Cured Fish—			
Herrings		£2,121,346	
Cod, ling, and hake		149,407	
" " " dried and pickled		8,861	
			£2,279,614
Fish sold fresh—			
(White-fish)			
Haddocks	£300,712		
Herrings	150,720		
Cod, ling, and hake	97,443		
Tusk and saithe	10,481		
Whitings	32,808		
Sprats	5,232		
Mackerel	5,286		
Turbot	9,368		
Halibut	17,624		
Flounders	47,723		
Skate	14,171		
Soles, &c	24,727		
			£716,295
(Shell-fish)			
Lobsters	£29,942		
Crabs	23,799		
Mussels	16,062		
Oysters, &c	11,136		
			£80,939
Salmon			250,000
		Total	£3,326,848

Manufactures.—The Border towns, Hawick and Galashiels, are the chief seats of the woollen manufactures of Scotland. About the year 1830, we are told (see Bremner, p. 155), a Border firm sent a quantity of 'tweels' to London; in the invoice the word was written indistinctly, and was read 'tweeds' by the consignee, who, in ordering a new supply, adopted what he considered to be a happy designation, Sir W. Scott having then made the

Scottish Border and the Tweed famous all over the world. In a business note-book of 1829, the total turnover of the tweed-makers is estimated at £26,000. 'It is only,' says Mr Bremner, 'by comparing these modest figures with the present overturn of upwards of £2,000,000, that one can gain anything like an adequate conception of the extent and rapidity of the development of the tweed manufacture.' There are woollen manufactures in Ayr, Kilmarnock, Stirling, Aberdeen, Inverness, and several other towns in Scotland. Dundee and the Forfarshire towns are the principal seats of the linen and jute manufactures.

The following are the statistics of textile factories in Scotland for 1885:

	Factories.	Spindles.	Power-looms.	Persons employed.
Cotton	147	1,149,514	29,689	37,167
Woollen	274	621,206	7,958	27,546
Shoddy	1	..	..	12
Worsted	24	83,811	1,432	5,479
Flax	152	243,273	21,626	39,086
Hemp	28	19,047	480	3,383
Jute	105	235,429	10,856	36,269
Hair	9	..	..	608
Silk	10	16,824	238	861
Lace	13	..	..	965
Hosiery	12	..	..	889
Elastic	1	..	..	14
Total	776	2,369,104	72,279	152,279

Of persons employed as above, at same date, the proportion was 30 per cent. of males, and 70 per cent. of females. Besides these textile factories, paper-making is engaged in on a large scale in Mid-Lothian; the distillation of mineral oil for shale forms an important industry in Mid-Lothian and Linlithgowshire and other parts of Scotland, more than £2,000,000 of capital being invested in this business. There were 122 distilleries in 1884, and over 200 breweries. Greenock is the chief centre for sugar refining; and printing and publishing are largely carried on in Edinburgh, many books published in London and elsewhere being printed here.

Commerce.—The total declared values of exports of British and Irish manufacture, from the three chief ports of Scotland, England, and Ireland, for 1880, were as follows: Glasgow, £11,828,729; Leith, £2,819,111; Greenock, £423,092; London, £52,600,929; Liverpool, £84,029,651; Hull, £18,572,005; Cork, £25,816; Belfast, £544,286; Dublin, £105,288. Since the disastrous year 1857, Scotland has been in the highest degree commercially prosperous. Taking the six banks having their head office in Edinburgh, it has been found that the market value of their united capital, originally £6,600,000 (see COMMERCE—MONEY—BANKS), has risen from £10,730,000 in 1857 to £28,880,000 in 1883. The value of capital invested in insurance companies has probably risen in an equal, if not greater degree. The amount insured in the Standard Life Assurance Company is upwards of 18 millions, and its accumulated fund is upwards of 4 millions sterling. The Scottish Widows' Fund (Mutual) Society, has more than 19 millions of insurances, and an accumulated capital of 5½ millions. The following table shews the estimated annual amount of revenue expected to be derived from taxation in England and Scotland, respectively, at the period of the Union in 1706 (Minutes of Conference, Record Commission, v. 11, App. p. 192–196); also the amount of revenue derived from England and Scotland, during the year ending March 31, 1866, with percentage of increase in each country in 1866 over amounts estimated in 1706:

	England.	Proportion per cent. of whole revenue.	Scotland.	Proportion per cent. of whole revenue.
Gross annual revenue expected to be derived from Customs, Inland Revenue, and Post-office, in 1706, on average of three years ending Michaelmas, 1705	£5,664,038	97·4	£151,500	2·6
The same actually received for year ending March 31, 1866	49,818,029	85·5	8,441,677	14·5
Increase in 1866; also percentage of that increase over amount estimated in 1706	44,153,991	779·5	8,290,177	5490·0

That is, for every £1 of imperial taxation paid by England in 1706, England paid £7·79 in 1866; while during the same period the proportion paid by Scotland advanced from £1 to £54·9.

At the union of the kingdoms, 45 of the 658 members of the House of Commons were allotted to Scotland, while Ireland had 100. In 1832, Scotland obtained 53, Ireland 105. In 1868, the total number of members remaining still unaltered, the share of Scotland was increased to 60. At that date, had the number of members been in proportion to population, Scotland would have had 69, Ireland 122, England 467; if in proportion to payments to revenue, Scotland 86, Ireland 64, and England 508. In 1885, the total number of members was increased to 670, of whom 495 fell to England and Wales, 72 to Scotland, and 103 to Ireland.

In 1871, the population of Scotland was 3,360,018. The amount of revenue contributed by Scotland to the imperial exchequer, for the year ending March 31, 1872, was £8,513,087; or £2, 10s. 8d. per head. By the census of 1871, the population of England and Wales was 22,704,108; and the total revenue contributed by England and Wales, for the year ending March 31, 1872, was £59,184,597; or £2, 12s. 1d. per head. The amount of income and property tax contributed by England and Wales, for the same year, was £7,719,170; or 6s. 9½d. per head. The amount contributed by Scotland for the same year was £826,213; or 4s. 11d. per head. The total sums voted for the Civil services for the year beginning April 1, 1872, for Scotland, was £594,075; the total sums chargeable on the Consolidated Fund for Scotland, for the year ending March 31, 1872, and not included in the annual estimates, was £138,312: total, £732,387. For Ireland, these sums were: Civil services, £2,485,566; Consolidated Fund services, £222,646: total, £2,708,212. The revenue derived from Ireland was £7,010,630; from Scotland, as above, £8,513,087.

REMARKABLE SCENERY—NATURAL CURIOSITIES.

The comparatively irregular surface of Scotland, or, as a geologist would remark, its being more generally formed of the primitive and early rocks, has caused the existence of much picturesque and romantic scenery, the attractions of which have been greatly heightened by the works of the native poets and novelists, particularly Sir Walter Scott. The Highlands may be said to form one wide tract of such scenery, though some parts are considerably more beautiful than others. The finer scenery in Scotland generally lies along the basins of lakes or the vales of rivers.

Stirling, Callander, and the Trossachs.—From Edinburgh to Stirling is a two hours' journey by rail. Here the tourist ought to halt. 'The country round Stirling,' says Alexander Smith, 'is interesting from its natural beauty, no less than from its historical associations. Many battles were fought in the seeing of its castle towers. Stirling Bridge, Carron, Bannockburn, Sauchieburn, Sheriffmuir, Falkirk—those battle-fields lie in the immediate vicinity. From the field of Bannockburn you obtain the finest view of Stirling. The Ochils are around you. Yonder sleeps the Abbey Crag, where, on a summer day, Wight Wallace sat. You behold the houses climbing up, smoke feathered, and the wonderful rock in which the grace of the lily and the strength of the hills are mingled; and on which the castle sits as proudly as ever did rose on its stem. Eastward from the castle ramparts stretches a great plain, bounded on either side by mountains; and before you the vast fertility dies into distance, flat as the ocean when winds are asleep. It is through this plain that the Forth has drawn her glittering coils—a silvery entanglement of loops and links—a watery labyrinth. Look in the opposite direction, and the aspect of the country has entirely changed. It undulates like a rolling sea. Heights swell up into the blackness of pines, then sink away into valleys of fertile green. At your feet the Bridge of Allan sleeps in azure smoke . . . Beyond are the classic woods of Keir, and ten miles further, what see you? A multitude of blue mountains climbing the heavens. The heart leaps up to greet them—the ramparts of a land of romance, from the mouths of whose glens broke of old the foray of the freebooter; and, with a chief in front, with banner and pibroch in the wind, the terror of the Highland war. Stirling, like a huge brooch, clasps Highlands and Lowlands together.' Stirling to Callander is about half an hour's journey by rail. 'Callander,' says the same writer, 'sits like a watcher at the opening of the glens, and is a rendezvous of tourists. To the right is the pass of Leny, well worthy of a visit. You ascend a steep path, birch trees on right and left; the stream comes brawling down, sleeping for a moment in black pools beloved by anglers, and then hastening on in foam and fury to meet her sister in the vale of Menteith below. When you have climbed the pass, you enter on a green, treeless waste, and soon approach Loch Lubnaig, with the great shadow of a hill blackening across it. The loch is perhaps cheerful enough when the sun is shining on it, but the sun in that melancholy region is but seldom seen. Leaving Callander, you cross the waters of the Leny, and walk into the country made immortal by the *Lady of the Lake.* Every step you take is in the footsteps of Apollo, and speech at once becomes song. There is Coilantogle Ford; Loch Vennachar, yonder, is glittering in windy sunshine to the bounding hills. Passing the lake, you come on a spot where the hillside drops suddenly down on the road. On this hillside Vich-Alpine's warriors started out at the whistle of their chief; and if you travelled on the coach, the driver would repeat half the poem, with curious variations, and point out the identical rock against which Fitz-James leaned . . . At a turn of the road, Loch Achray is before you. Beyond expression beautiful is that smiling lake, mirroring the hills, whether bare and green, or plumaged with woods from base to crest. At every step the scenery grows wilder. Loch Achray disappears. High in upper air tower the summits of Ben-Aan and Ben-Venue. You pass through the gorge of the Trossachs, whose rocky walls, born in earthquake and fiery deluge, the fanciful summer has been dressing these 1000 years; clothing their feet with drooping ferns and rods of foxglove bells, blackening their breasts with pines, feathering their pinnacles with airy birches, that dance in the breeze like plumage on a warrior's helm. The wind here becomes a musician. Echo sits babbling beneath the rock. The gorge, too, is but the prelude to a finer charm; for before you are aware, doubling her beauty with surprise, there breaks on the right the silver sheet of Loch Katrine, with a dozen woody islands, sleeping peacefully on their shadows.'

The view of the lake, on approaching it on the east, is rather confined; but from the top of the rocky and woody mount above, the prospect is more extensive, and of that singular beauty which Scott in his *Lady of the Lake* has described:

> Gleaming with the setting sun,
> One burnished sheet of living gold,
> Loch Katrine lay beneath him rolled,
> In all her length far-winding lay,
> With promontory, creek, and bay,
> And islands that, empurpled bright,
> Floated amid the livelier light,
> And mountains that like giants stand,
> To sentinel enchanted land.
> High on the south, huge Ben-venue
> Down on the lake its masses threw—
> Crags, knolls, and mounds, confusedly hurled,
> The fragments of an earlier world;
> A wildering forest feathered o'er
> His ruined sides and summit hoar;
> While on the north, through middle air,
> Ben-an heaved high his forehead bare.

Loch Earn.—The route from Edinburgh to Loch Earn is the same as to the Trossachs, as far as Callander, the roads diverging about a mile beyond that village. There is now a railway from Callander to Loch Earn Head, but the tourist will probably prefer to drive or walk, the road being a picturesque one by the margin of Loch Lubnaig; a loch which, despite of the high authority from whom we have been quoting, we think an exceedingly beautiful one. The scenery at the head of Loch Earn is very tame. In spring and autumn there is tolerable fishing in the lake, and boats are to be had at moderate charges. The streams in the neighbourhood are, as well as the loch, open to the public, and abound in small trout. As you

approach St Fillans, at the foot of the lake, the character of the scenery entirely changes. From tame, it becomes as picturesque as any in Scotland. Gracefully wooded knolls bend over rocks festooned with fern, and carpeted with many coloured mosses. Over all, sometimes in gentle slopes, at others in abrupt precipices, rise the Highland hills; in the distance, dark blue; in the foreground, glowing with innumerable tints—from tender green to richest purple.

Middle Perthshire.

Dunkeld.—This small town, so celebrated for the fine scenery in its neighbourhood, is situated on the north bank of the Tay, at the distance of 15 miles from Perth, and 24 from Kenmore. Nestling beneath steep and woody mountains, with a noble river running in front, across which there is an elegant bridge, the first view of Dunkeld, in approaching it from the south, is very striking. The village consists of two small streets, in which are two excellent hotels. At Dunkeld, attention is called to the venerable remains of a cathedral, and the Duke of Athole's mansion, Dunkeld House; but our present business is with the natural scenery. Most of this is in the pleasure-grounds connected with the mansion.

Craig-y-Barns, a lofty hill, wooded to the top, which rises behind the house, is a resort of tourists for the sake of the magnificent view which it commands. They are also conducted by guides to the scenery of the *Bran*, which joins the Tay on its opposite bank near the village of Inver—the birthplace and usual residence, it may be mentioned, of the late Neil Gow, so famous wherever Scottish music is known, at once for his performance on the violin and his excellent compositions. 'About a mile higher up the Bran is the *Rumbling Bridge*, thrown across a chasm, about fifteen feet wide. The bed of the river, for several hundred feet above the arch, is copiously charged with massive fragments of rock, over which the river foams and roars like the waters at Ivy Bridge in Devonshire. Approaching the bridge, it precipitates itself with great fury through the chasm, casting a thick cloud of spray or vapour high above the bridge, and agitating by its fury even the prodigious masses which form the surrounding rocks. Few objects will more amply repay the traveller for his trouble of visiting them, than the woody precipices, the long, winding, shady groves, the ruins and cataracts of Dunkeld.' In the angle formed by the junction of the Bran and Tay rises *Craig Vinean*, a broad shadowy mass of firs, reared against the sky. A neighbouring eminence obtains the name of the *King's Seat*, in consequence of King William the Lion having been in the habit of stationing himself upon it, in order to shoot at the droves of deer which his attendants caused to pass through the adjacent hollows.

Aberfeldy, Kenmore, and Killin.—Aberfeldy, a village not in itself remarkable, is celebrated for the fine cataract, formed by a small tributary of the Tay, in its neighbourhood, and near the House of Moness. The tourist is conducted by a guide along the thickly wooded banks of this rivulet, till, about a mile from the village, he reaches the first of the celebrated water-falls of Moness. A little sub-tributary rill here pours, in a series of cascades, down the side of the glen, amidst a natural scene of the greatest beauty. A little farther up the main dell, the rivulet pours along a steep natural staircase, of a hundred feet in perpendicular descent, the sides of which rise abruptly and ruggedly, clothed with the most beautiful natural plants. This scene is described by Burns in one of his well-known songs:

> The braes ascend like lofty wa's,
> The foaming stream deep-roaring fa's,
> O'erhung wi' fragrant spreading shaws,
> The birks of Aberfeldy.
>
> The hoary cliffs are crowned wi' flowers;
> White o'er the linn the burnie pours,
> And, rising, weets wi' misty showers
> The birks of Aberfeldy.

A ride of six miles along the Tay brings the traveller to *Kenmore*—a village of famed beauty, situated at the east end of Loch Tay, at the place where the river issues from that sheet of water. This is one of the chief stages or *points* in the tour of Perthshire, and it is provided, accordingly, with a good inn. Lofty hills ascend on each side; on one hand there is a noble lake; on the other, towards Aberfeldy, stretch the splendid grounds around Taymouth Castle, the seat of the Earl of Breadalbane.

Loch Tay is a fine sheet of water, 15 miles in length, lying between two ranges of hills. In the centre of the north-west side rises *Ben Lawers*, to the height of (with its cairn) 4004 feet. An island near Kenmore formerly contained a priory of Augustines, founded by Alexander I. in the year 1122. Here his queen, Sybilla, daughter of Henry I. of England, was buried. Loch Tay is remarkable, like some other Scottish lakes, for having been on several occasions greatly agitated at the moment of the occurrence of earthquakes in distant parts of the world. It is from 15 to 100 fathoms deep. There is a road on each side to Killin, the distance being sixteen miles. Both abound alike in fine scenery, though, by pursuing that along the south side, a view will be obtained of the lofty Ben Lawers, which will scarcely be seen so well on the opposite side. The mixture of wood, rock, and cultivated field which the traveller finds skirting Loch Tay, will please him with its happy effect. A steamer plies upon the loch at stated intervals; the sail from one end to the other occupies 1 hour 40 minutes.

Killin, a straggling little village, situated in the low vale at the head of the loch, is celebrated for the varied beauty of its scenery. Here two rivers, the Dochart and the Lochy, come down out of different glens, and join their waters with each other and with the lake. The vale of the latter is peculiarly beautiful; that of the Dochart extending up to Tyndrum, upon the great west road, is stern and wild. On arriving at the town, the Dochart breaks over a strange expanse of table-rock in a thousand little cascades; so that the traveller, who crosses a bridge just at the place, is bewildered, as he looks around, with the flashing and sparkling water which everywhere meets his eye. A branch line connects the village with the Callander and Oban Railway.

Dumbartonshire.

A tract of beautiful scenery extends through this county, from the banks of the Clyde along those of the Leven, and including Loch Lomond,

the largest, and probably most beautiful of our British lakes.

At the starting-point, in an angle formed by the confluence of the Leven and Clyde, is a basaltic mass, shooting up to the height of 560 feet above an alluvial plain. This affords a site for the celebrated *Dumbarton Castle*, a romantic fortress, noted in Scottish history, and one of four kept in repair in terms of the Act of Union. Passing the town of Dumbarton, the tourist proceeds upwards along the vale of the Leven, a scene of singular beauty, filled with thriving villages and with villas. The road, at the distance of two miles from the town, passes the old mansion-house of Dalquharn, in which, in the year 1721, the author of *Roderick Random* first saw the light. Archibald Smollett, the father of the novelist, was the fourth son of Sir James Smollett of Bonhill, and having married against his father's will, was residing here, in possession of one of the farms of the family property, at the time of the birth of his illustrious child. The road leads to *Balloch* (at the foot of the lake), a small village and inn at the southern extremity of Loch Lomond, and 4¼ miles from Dumbarton.

Loch Lomond measures 22 miles in length from north to south; its breadth, where greatest, at the southern extremity, is 5 miles, from which it gradually grows narrower between the inclosing hills, till it terminates in a mountain streamlet. The whole aqueous surface covers 17,420 English acres, and it is studded by above thirty isles, mostly at the southern extremity. Its greatest depth is 630 feet, and its height above the sea, 23 feet. In ancient times, Loch Lomond was famed for three wonders —'waves without winds, fish without fins, and a floating island.' The first phenomenon is attributed to a peculiar atmospheric effect, not easily described, but which has also been observed on the Cumberland lakes; vipers swimming from island to island account for the second; the floating island is supposed to have been a detached fragment of moss, or a matted mass of aquatic plants, which ultimately fixed itself near the west side of Inch Conagan.

Luss, a delightful little village, on a promontory which juts into the lake, is much resorted to in summer, on account of its being a convenient station for tourists in search of the picturesque. One of the finest points for enjoying the scenery of Loch Lomond and the environs of Luss, is Stronehill, to the north of the village. At this point, about one-third of the way up a lofty hill, the whole breadth of the lake is spanned by the eye, including

> All the fairy crowds
> Of islands which together lie,
> As quietly as spots of sky
> Among the evening clouds.

At *Inveruglas*, 3½ miles beyond Luss, there is a ferry to Rowardennan Inn, the usual starting-point for those who desire to ascend to the top of *Ben Lomond*. This mountain, situated in the county of Stirling, is 3192 feet above the level of the lake, which is 23 above the level of the sea. At Rowardennan, when looking northward, it almost completely fills up the view. It is formed in three great stages, each rising above the other; these, again, are divided into a number of lesser swelling knolls, some of which are covered with heath and crags, while others are verdant and smooth. The distance from the inn to the top of the mountain is six miles of a continued ascent, which in general requires about three hours. From the summit, a varied and most extensive prospect opens upon the eye in every direction. The lake, lately contemplated with so much pleasure, now appears a small pool, and its islands as so many specks upon its surface. The coasts of Ireland and the Isle of Man are, when the atmosphere is clear, within the boundary of the view. To the east are seen the counties of Stirling and the Lothians, with the windings of the Forth and the castles of Stirling and Edinburgh. The prospect to the north is marked by grandeur alone. Immense mountains, piled, as it were, above each other, and extending from the borders of Stirlingshire to the western ocean, with the indentations of the coast on one side, and the lakes of Perthshire on the other, form altogether a scene which may be conceived, but which cannot be properly described.

Firth of Clyde—Argyllshire.

This is a tract of scenery much admired and visited, on account of its presenting a fine combination of inland seas, with islands of varied surface, and chains of rugged mountains.

The Clyde expands into an estuary a little way below Dumbarton. There, while the comparatively low hills of Renfrewshire, with the thriving towns of Port-Glasgow and Greenock, are seen on the left, attention is called on the right to the towering alps of Argyllshire. This mountainous region is penetrated by several inlets of the sea, one of which, named Loch Long, is twenty-four miles long. Another, named the Holy Loch, is shorter, but surrounded by equally picturesque ground. A little below is Dunoon, a favourite summer resort of the inhabitants of Glasgow.

Separated from this rugged district by only a narrow strait is the island of *Bute*, remarkable for the amenity of its climate, on which account it is much resorted to by persons affected with pulmonary ailments. It measures fourteen miles in length by about four in breadth, and contains some beautiful strips of level territory. The town of Rothesay, a watering-station, occupies a fine situation on the north-east side of the island. Here are the ruins of a palace which formed the ordinary residence of the earliest sovereigns of the House of Stuart. The *Kyles of Bute*, as the strait above mentioned is named, is remarkable for the fine vistas of alpine scenery which it opens up to the view of the tourist.

To the south of Bute lies the island of *Arran*, 22 miles long, and which entirely consists of a range of rocky mountains, the serrated outline of which, as seen from the neighbouring seas and shores, is extremely grand. The loftiest summit, Goat-fell—called by the natives *Goath-bhein*, the Hill of Storms—is 2866 feet high. Arran bears great value in the eyes of the geologist, on account of its presenting, within a narrow space, an epitome of the whole geological structure of Scotland. Its pathless glens and picturesque hills commend it equally to visitors who do not inquire into the mysteries of stratification and volcanic agency. The whole island, excepting a few small farms, belongs to the Duke of Hamilton, whose ancestor, James, first Lord Hamilton, obtained it from the crown on his marrying Mary, the

eldest daughter of James II. in the year 1474. A road sweeping round the east shore of the island leads to Brodick Bay, at the bottom of which there is a beautiful tract of low and sloping ground, ornamented with some fine wood, containing a hamlet, which forms a favourite resort for sea-bathing. On the adjacent height, amidst old woods, is the ancient château of Brodick. From this place a road strikes across the island, and opens up some magnificent scenery. Two or three miles to the southward of Brodick, the shore forms the more spacious recess of Lamlash Bay, at the bottom of which is a village of the same name, while it is landlocked in front by Holy Island, a small isle which formerly contained a monastery. Lamlash Bay is of great importance to the navigation of the Clyde and Irish Channel, as a harbour of safety.

Loch Fyne, a long narrow estuary, having the ridgy promontory of Kintyre on the one side and the district of Cowal on the other, opens up much fine scenery. In sailing up the loch, the first remarkable place is Tarbert, a fishing village, situated at the bottom of a beautiful small bay, with a ruined fortalice of the Argyll family perched on a rock by its side. Farther up the loch is Inveraray. Between Inveraray and the inn of Tarbet, on Loch Lomond, a road opens up a splendid tract of mountain scenery, the most striking being comprehended in the valley of Glencroe. Another road, proceeding in a northerly direction, leads to Loch Awe, an inland lake possessing many fine features, and upon which stands the ruined castle of Kilchurn, once the chief stronghold of the Breadalbane family. The loch is overhung by Ben Cruachan, a mountain 3689 feet in height, on the skirts of which King Robert Bruce gained a victory over his powerful enemy, the Lord of Lorn.

The northern portion of Argyllshire, where it is bounded by the Western Ocean and its many inlets, contains much fine scenery. In a sheltered situation on the west coast stands the neat and cheerful town of Oban, a point of rendezvous for the numerous steamers permeating these seas, and a kind of entrepôt for the rural produce of the wide district around it. In front is the isle of Kerrera, where Alexander II. died in the course of an expedition to the Western Islands. On the coast, a little to the north of Oban, is Dunolly Castle; and a little way farther north is Dunstaffnage, an ancient seat of the Caledonian kings. The Callander and Oban Railway connects this Highland town with the southern railway systems.

Loch Linnhe, opening between Lorn and Morven, and the commencement of the chain of salt and fresh water lakes formed into the Caledonian Canal, presents on both sides scenery of a most romantic character—a mixture of bold rocky forelands, on many of which are perched the eyrie-like fortresses of the rude chiefs of the olden time, and green smiling hollows, within bays, with many pleasant modern residences. The long island of Lismore, in the mouth of this estuary, was the ancient appanage of the bishops of Argyll, and temporarily the site of a college for Catholic priests, after the French seminaries were closed by the Revolution. Opposite to its upper extremity, Loch Creran, a sub-estuary, branches off into the land of Lorn, opening up much beautiful scenery. On the south shore of Loch Linnhe, to the north of the opening of Loch Creran, is the district of Appin, previous to 1765 the property of a race of Stewarts, descended from a natural son of the last Lord Lorn, and for four centuries conspicuous in Highland history. From Ballahulish Ferry, on Loch Leven, noted for its great quarry of slate, the road from Fort-William to Glasgow runs for a number of miles nearly east through the wild vale of Glencoe, emerging at the solitary inn of King's House, in the desolate district of Rannoch.

Glencoe is a narrow strip of rugged territory, along which hurries the wild stream of Cona, celebrated by Ossian, who is said to have been born on its banks. 'Anything,' says Charles Dickens, 'so bleak, and wild, and mighty in its loneliness, as the whole country, it is impossible to conceive. Glencoe itself is perfectly terrible. . . . Through the whole glen, which is ten miles long, torrents were boiling and foaming, and sending up in every direction spray like smoke of great fires. They were rushing down every hill and mountain side, and tearing like devils across the path, and down into the depths of the rocks. Some of the hills looked as if they were full of silver, and had cracked in a hundred places—others as if they were frightened, and had broken out into a deadly sweat. In others there was no compromise or division of streams, but one great torrent came roaring down with a deafening noise, and a rushing of water that was quite appalling.' 'Even,' adds Dickens' biographer, 'where he expected to find Nature in her most desolate grandeur, in the dreary waste of an American prairie, his imagination went back with a higher satisfaction to Glencoe.'

Inverness-shire—The Great Glen.

Between Loch Linnhe on the west coast, and a point on the Moray Firth near Inverness, there is a remarkable natural phenomenon, in the form of a glen or hollow, passing in a perfectly straight line for 60 miles through a mountainous region, and the bottom of which is nowhere more than 90 feet above the level of the sea. It is called by the Highlanders *Glen-more-nan-Albin* (the Great Glen of Scotland). A chain of lakes extending along this extraordinary hollow suggested the formation of a canal which should admit of navigation between the seas on the two sides of the island, and save the dangerous passage round by the Pentland Firth; and this, under the name of the *Caledonian Canal*, was formed between 1803 and 1822, under the care of Mr Telford, at an expense of £800,000.

The canal commences at Clachnaharry, in the outskirts of the town of Inverness, and, after six miles, enters the first of the chain of lakes, *Loch Ness*, a grand piece of water, nearly 23 miles long, amidst stupendous and sterile mountains. The waters of Loch Ness never freeze, but they are often agitated simultaneously with the occurrence of earthquakes in distant parts of the world. On an elevated rock projected into the north-west margin of Loch Ness, are situated the remains of Urquhart Castle, consisting of a great square keep and several exterior walls of defence. It was besieged in 1303 by the officers of Edward I. and with great difficulty taken; it afterwards was a royal fortress; and finally, in 1509, it became the property of Grant of Grant, ancestor of

the Earl of Seafield, to whom it now belongs. Glen Urquhart, which recedes behind Urquhart Castle, is a beautiful Highland vale. The conspicuous mountain, *Mealfourvounie* (Hill of the Cold Tarn), which is 2284 feet in height, here begins to raise its huge bulk above the banks of the loch. Mealfourvounie stands so prominently above the neighbouring hills, that it is not only singled out by the eye at Inverness, but is the first landmark seen on entering the Moray Firth, at the distance of a hundred miles.

The road along the south side of Loch Ness, though it presents numberless fine views, is enlivened by few traces of man's presence. The paucity of houses gives a sort of distinction to the inn named General's Hut, nearly 18 miles from Inverness, originally the residence of General Wade, while superintending the formation of his roads. Little more than a mile farther on, a recess or chasm in the hill by the side of the lake contains the celebrated *Fall of Foyers*.

A few miles farther on, *Glenmoriston*, a valley full of romantic scenery, opens upon the north-west bank of Loch Ness. At the distance of thirty-two miles from Inverness, the traveller comes on *Fort-Augustus*, situated in a pleasant opening amongst the hills, at the termination of Loch Ness. It was erected in 1730, as an addition to the means previously existing for the control of the turbulent children of the mountains. Its purposes being long since accomplished, it has for many years been only occupied by a few artillerymen. From Fort-Augustus, the cut of the canal is resumed, and several locks are ascended; five miles bring it to *Loch Oich*, the smallest of the chain of lakes. The scenery is here finer than at any other part of the Great Glen.

The next and last loch is *Loch Lochy*, the hills environing which are the most wild and stupendous of all in the glen. The summit-level of the canal is between Loch Oich and Loch Lochy, being 90 feet above the ordinary high-water mark at Fort-William, and 94 above that at Inverness —a difference to be accounted for by the pressure of the Atlantic on the west shores of Scotland. The canal, after leaving this loch, descends in a precipitous series of locks, called *Neptune's Staircase*, into Loch Eil, a continuation of Loch Linnhe, the arm of the sea formerly mentioned.

At this point, the glen is more spacious than anywhere else; it is, however, the spaciousness of a moor. The River Lochy, which issues from the lake of the same name, pours its voluminous and impetuous flood towards Loch Eil on the left; and beyond it Ben Nevis is seen to rear his enormous head, with the vale of Glen Nevis withdrawing from his mighty side into the solitudes of Lochaber. At the distance of little more than a mile is the town of Fort-William, so called from a fortress of the same name, built for the repression of Highland turbulence, and now nearly disused.

A cluster of glens to the south of the Great Glen is remarkable for a natural phenomenon, usually called the Parallel Roads of *Glenroy*, such being the name of the vale in which the wonder is most conspicuously marked. It consists of a set of terraces, in most places three in number, extending along both sides of these vales for many miles, the uppermost 82 feet above the second, which, again, is 212 feet above the first. The common people represent these terraces as roads formed at the command of Fingal, an early hero, for his convenience in hunting; but they are in reality ancient beaches of inland seas—phenomena with which modern geologists are familar.

Western Islands.

The Western Islands are generally bleak and rugged in surface, and occupied by a very poor class of tenantry. It is not possible here to present a particular description of any except the isle of *Staffa*, so remarkable for its basaltic structure. It is about 1½ mile in circumference, and bears no human habitation, its only useful tenants being a small herd of black-cattle. At the point of greatest elevation, towards the south-west, this island is 144 feet high. On the north-east it presents a face of somewhat less height, composed of basaltic columns, and penetrated by several caves of various sizes, into which the sea occasionally breaks with the report of thunder. This face, according to Dr Macculloch, is formed of three distinct beds of rock, of unequal thickness, inclined towards the east in an angle of about 9 degrees: the lowest is a rude trap tufa: the middle one is divided into columns placed vertically to the planes of the lowest bed; and the uppermost is an irregular mixture of small columns and shapeless rock—the whole being partially covered by a fine verdure. The central columnar part having in some places given way, is the occasion of the numerous caves by which the island seems perforated.

At the north-east point of the island, the dipping of the rocks is so low as to afford a safe landing-place at any time of the tide. Proceeding thence, the visitor is conducted along the north-east face, and is introduced to the *Clam-shell* (Scallop) *Cave*, where a curious confusion in the columnar structure is observable. The columns on one side are bent, so as to form a series of ribs, not unlike the inside view of the timbers of a ship; while the opposite wall is formed by the ends of columns, bearing a general resemblance to the surface of a honeycomb. This cave is 30 feet in height, and 16 or 18 in breadth at the entrance; its length being 130 feet, and the breadth contracting to the termination. Next occurs the noted rock, *Buachaille* —the Herdsman—a conoidal pile of columns, about 30 feet high, lying on a bed of curved horizontal ones, visible only at low-water. There is here an extensive surface, resembling that of the Giant's Causeway, and composed of the broken ends of pillars once continuous to the top of the cliff. The colonnade is now for some distance upright and very grand, till the visitor reaches the *Uaimh Binn* (Musical Cave), usually called *Fingal's Cave*, by far the most impressive and interesting object in the island. It opens from the sea with a breadth of 42 feet, a height of 66 feet above the water at mean tide, the pillar on one side being 36 feet high, and that on the other 18. The depth of the recess is 227 feet, and the breadth at the inner termination 22. The sides within are columnar throughout; the columns being broken and grouped in many different ways, so as to catch a variety of direct and reflected tints, mixed with secondary shadows and deep invisible recesses. As the sea never ebbs entirely

out, the only floor of this beautiful cave is the fine green water, reflecting from its white bottom tints which vary and harmonise with the darker tones of the rock, and often throwing on the columns flickering lights, which its undulations catch from the rays of the sun without.

The lowlands of Scotland are overspread with a network of railways little less dense than that of England, and from Edinburgh or Glasgow, by Stirling and Perth, the counties of Aberdeen, Banff, Elgin, Nairn, Inverness, Ross, and Sutherland are accessible by railway. From the town of Inverness, by Dingwall in Ross-shire, the line runs to Strome Ferry on the west coast. From the Ferry, boats communicate with the isle of Skye, famed for the alpine grandeur of its scenery. From Perth there are two lines running north, the one by the east coast to Aberdeen; the other traverses the centre of Scotland, by Blair Atholl, from which place those who are in quest of scenery may do well to walk or drive to Braemar and Ballater. From Ballater there is a railway to Aberdeen. From Glasgow there is ample steamboat communication with the Western Highlands and the Hebrides. Natural scenery and science have thus, in combination, done much to compensate the Highlands of Scotland for their barren soil and ungenial climate; the former by rendering them attractive, the latter by making them accessible to tourists—of whom, and of sportsmen, each month of August brings its fertilising cloud, which dissolves, so to speak, over the land in a golden shower.

ANTIQUITIES, ETC.

There are in Scotland, and particularly in the district between the Firth of Tay and Moray Firth, numerous mounds, upright slab-stones, and carved stones, which are supposed to have been raised as monuments over slain warriors, by the early inhabitants of the country, or by the Danes or other northern nations who occasionally invaded it in remote times. The most remarkable examples of mounds are two at Dunipace on the Carron, in Stirlingshire, and one at Fettercairn, in Kincardineshire. A distinct class of mounds, called *moot* or *moat hills*, are common in the south-western and several other districts. They are generally of a square form, with a flat top. It is believed that they served as places for the administration of justice in rude ages. Such is the opinion of the antiquary, who regards these mounds as *artificial*, and raised for a specific purpose; but to the geologist, acquainted with the phenomena of raised beaches, moraines, and denudations, they appear, what in most instances they really are, substantial *natural* accumulations, which may have been employed by our early ancestors as above described, but which assuredly were never erected by them. For a geological account of the mounds of Dunipace, the reader is referred to an article in *Chambers's Edinburgh Journal*, No. 144, New Series.

Of the carved stones, a remarkable example exists at Forres. It contains figures of men and animals in various compartments. There is another very entire and curious specimen at Aberlemno, in Forfarshire. These carved stones are mostly confined to the north-east part of Scotland. They are undoubtedly sepulchral monuments; but the character of the sculptures is unique, nothing resembling them being known in any part of the world.

In the north of Scotland, and in Orkney, there are some surviving examples of a very remarkable class of early buildings, to which the common people now give the name of *Picts' Houses*, as supposing them to have been built by the Picts. They are generally round buildings, of no great height, with round vaulted tops, altogether built of courses of dressed stone without mortar, and containing for the most part one central chamber, and several long narrow recesses in the thickness of the wall. Circular mounds, the remains of British and Danish camps, are common on the tops of the Scottish hills, having probably been the places to which the early people retired with their flocks in times of danger. On several hills, particularly in Perthshire and Inverness-shire, there are remains of walls, presenting appearances as if the stony materials had been artificially vitrified. It is not yet ascertained whether these *vitrified forts*, as they are called, were works of our Caledonian ancestors, or the effect of accident, though the former is the more likely supposition.

The weapons used by the aboriginal people are often found, consisting of stone axes, arrow-heads of flint, &c. Necklaces, bracelets, and other ornaments used by them, barbarous in style, but generally of gold, are also often found. In various districts, so-called Druidical circles still exist in a tolerably entire state, but none on so large or regular a scale as those of Stonehenge and Abury. There are remains of roads and camps formed by the Romans in their hesitating and imperfect attempts to subdue North Britain; and of the wall built under the Emperor Antoninus, between the Firths of Forth and Clyde, with forts at regular intervals, it is still possible to discern a few traces.

The next class of antique objects are the remains of the Gothic fanes, reared on account of religion during the period when the Romish Church was triumphant. These are everywhere very numerous, but in few cases tolerably entire. Excepting two cathedrals, those of Glasgow and Kirkwall (in Orkney), all of that class of structures are in ruins. The abbeys, priories, and other conventual and collegiate establishments, are in every instance gone to decay. Melrose Abbey, the Cathedral of Elgin, and the Collegiate Church of Roslin, are the most beautiful of these ruinous buildings.

Numerous specimens of the towers and castles occupied by men of note in the middle ages still exist, though mostly in a decayed state. Those which indicate the greatest strength and consequence are—*Lochmaben Castle*, the residence of the Bruces, Lords of Annandale; *Hermitage* (Roxburghshire), which belonged to a powerful noble named Lord Soulis; *Douglas*, the residence of the Earls of Douglas; *Turnberry* (Ayrshire), the residence of the Earls of Carrick; *Bothwell*, another stronghold of the Douglases; *Tantallon* (Haddingtonshire), the residence of the Earls of Angus, a branch of the Douglas family; *Dunnottar* (Kincardineshire), the seat of the Earls Marischal; and *Doune* (Perthshire), the stronghold of Robert, Earl of Fife, brother of Robert III. and governor of Scotland. Four places of strength—*Edinburgh*, *Stirling*, *Dumbarton*, and

Blackness Castles—are still kept in repair at the public expense, and serve as barracks for foot-soldiers.

CHIEF CITIES, TOWNS, PORTS, ETC.

Edinburgh, the capital, is situated in the county of the same name, on a cluster of eminences, distant between 1½ and 3 miles from the Firth of Forth. The city is composed of two principal parts—the Old and New Towns: the former being built on a long narrow eminence gently rising towards the west, where it terminates in a lofty and abrupt rock, on which the castle is situated; while the latter occupies lower ground towards the north. The town is universally built of a fair sandstone, which retains its original colour in the newer parts of the town, and in the best public buildings, and forms one of the most striking features of Edinburgh. The New Town is laid out on a regular plan of rectangular streets and squares, exhibiting in general much architectural elegance. Between the Old and New Towns, and between various sections of the New Town itself, as well as in the centres of the principal squares, there are gardens laid out in the modern style, forming delightful places of recreation. It is chiefly owing to the unequal ground on which Edinburgh is situated, the massive elegance and regularity of its buildings, the intermixture of ornamental pleasure-ground, and the picturesque hills immediately adjacent, whence distant and extensive prospects are commanded, that this city makes so great an impression on most strangers.

Formerly the seat of the government of the country, Edinburgh is still that of the supreme law-courts and of a flourishing university. It is also to a great extent a city of residence, not only for persons connected with the country, but for strangers desirous of enjoying a society of moderate habits, and the benefits of education for their children. Its leading classes are thus composed of legal practitioners, learned persons, and families in independent circumstances. It is only in a small degree a manufacturing town, the principal trade being the brewing of ale (for which the town is celebrated). The leading periodical publications are *Blackwood's Magazine* and *Chambers's Journal*. The *Edinburgh Review* is now published in London. The leading daily paper is the *Scotsman*, a journal of Liberal principles. There are besides several medical, philosophical, and legal journals. The Register Houses in Princes Street contain the historical and legal records of the country. A striking feature in the city and its neighbourhood is the number of its schools and educational institutions. Among the most famous of the latter are George Heriot's and Donaldson's Hospitals. The latter is a palatial building, as also Fettes College. The city is now the centre of the Scottish railway traffic, having lines and telegraphs communicating with all parts of the island. Tramways are laid in the main streets, and a suburban railway connects the principal suburbs.

Amongst the remarkable objects in the city, the most striking is the Castle, a large fortress romantically situated on the summit of a mass of igneous rock, between 200 and 300 feet in perpendicular height. It contains, besides various batteries and other fortifications, a modern barrack, in which a foot-regiment is usually quartered. In a well-protected room are shewn the crown, sceptre, mace, and sword which formed the regalia of the Scottish line of princes. An apartment is also shewn in which Queen Mary was delivered of her son James VI. The Courts of Law are situated in the centre of the Old Town, and are composed of a great hall, formerly the meeting-place of the Scottish Parliament, rooms for the two divisions of the civil court and for the lords-ordinary, a room for the High Court of Justiciary (supreme criminal court), and other accommodations. The extensive libraries belonging respectively to the Advocates (barristers) and Writers to the Signet (solicitors) are adjacent. Holyrood-house, the palace of the Scottish kings, is situated at the lower extremity of the principal street of the Old Town. The oldest part is a mass of building erected by James V. containing the presence-chamber, bedroom, and other apartments used by Queen Mary, with some of the original furniture; as also a gallery, furnished with (generally imaginary) portraits of the kings of Scotland. The apartments of the queen are to be regarded with no ordinary interest, both as furnishing a curious and faithful memorial of the domestic accommodations of a princess of the sixteenth century, and as the scene of the murder of David Riccio. Another part of the building, erected in the reign of Charles II. contains the apartments used by George IV. for his levée in 1822, and a suite of rooms which furnished accommodation to Charles X. of France and his family during the years 1831–33. Closely adjoining to the palace are the ruins of a Gothic church, originally that of the Abbey of Holyrood, and latterly a chapel-royal.

The College is a large modern quadrangular building, in the southern quarter of the city. It contains class-rooms for the professors, and a library of splendid proportions. The university is distinguished as a school of medicine, for which new buildings have been erected in Teviot Row. The Infirmary, Museum of Science and Art, Heriot-Watt College, and Free Library (in progress 1888) are the other chief buildings in the south side.

'Every true Scotsman,' says Alexander Smith, 'believes Edinburgh to be the most picturesque city in the world. . . . The finest view from the interior is obtained from the corner of St Andrew's Street (South) looking west. Straight before you, the Mound crosses the valley, bearing the white Academy buildings; beyond, the castle lifts, from grassy slopes and billows of summer foliage, its weather-stained towers and fortifications, the Half-moon Battery giving the folds of its standard to the wind. Living in Edinburgh, there abides, above all things, a sense of its beauty—hill, crag, castle, rock, blue stretch of sea, the picturesque ridge of the Old Town, the squares and terraces of the New—these things once seen are not to be forgotten. The quick life of to-day sounding around the relics of antiquity, and overshadowed by the august traditions of a kingdom, make residence in Edinburgh more impressive than residence in any other British city. . . . What a poem is that Princes Street! The puppets of the busy, many-coloured hour move about on its pavement; while across the ravine, time has piled up the Old Town, ridge on ridge, gray as a rocky coast washed and worn by the foam of

centuries; peaked and jagged by gable and roof; windowed from basement to cope; the whole surmounted by St Giles' airy crown. The New is there looking at the Old. Two times are brought face to face, and are yet separated by a thousand years. Wonderful on winter nights, when the gully is filled with darkness, and out of it rises, against the sombre blue, and the frosty stars, that mass and bulwark of gloom, pierced and quivering with innumerable lights. . . . Finer still, to place one's self near the Burns Monument, and look towards the castle. It is more astonishing than an Eastern dream. A city rises up before you, painted by fire on night. High in air, a bridge of lights leaps the chasm; a few emerald lamps, like glow-worms, are moving silently about in the railway station below; a solitary crimson one is at rest. That ridged and chimneyed bulk of blackness, with splendour bursting out at every pore, is the wonderful Old Town, where Scottish history mainly transacted itself; while opposite, the modern Princes Street is blazing throughout its length. . . . From George Street, which crowns the ridge, the eye is led down sweeping streets of stately architecture, to the villas and woods that fill the lower ground and fringe the shore; to the bright azure belt of the Forth, with its smoking steamer or its creeping sail; beyond, to the shores of Fife, soft, blue, and flecked with fleeting shadows, in the keen, clear light of spring, dark purple in the summer heat, tarnished gold in the autumn haze; and farther away still, just distinguishable on the pale sky, the crest of some distant peak, carrying the imagination into the illimitable world. Residence in Edinburgh is an education in itself. Its beauty refines one, like being in love. Nothing can stale its infinite variety. From a historical and picturesque point of view, the Old Town is the most interesting part of Edinburgh, and the great street running from the castle to Holyrood—the Lawnmarket, High Street, and Canongate—is the most interesting part of the Old Town. In that street, the houses preserve their ancient appearance; they climb heavenward, story upon story, with outside stairs and wooden panellings, all strangely peaked and gabled. With the exception of the inhabitants, who exist amidst squalor, and filth, and evil smells, undeniably modern, everything in this long street breathes of the antique world. If you penetrate the narrow wynds, that run at right angles from it, you see traces of ancient gardens. Occasionally the original names are retained, and they touch the visitor pathetically, like the scent of long withered flowers. Old armorial bearings may yet be traced above the doorways. Two centuries ago, fair eyes looked down from yonder window, now in possession of a drunken Irishwoman. If we but knew it, every crazy tenement has its tragic story; every crumbling wall could its tale unfold. The Canongate is Scottish history fossilised. What ghosts of kings and queens walk there! What strifes of steel-clad nobles! What wretches borne along in the sight of peopled windows to the grim embrace of the "Maiden!" What hurrying of burgesses to man the walls at the approach of the Southron! What lamentations over disastrous battle-days! James rode up this street on his way to Flodden. Montrose was dragged up hither on a hurdle. . . . Jenny Geddes flung her stool at the priest in yonder church. John Knox came up here to his house, after his interview with Mary at Holyrood—grim and stern, unmelted by the tears of a queen. . . . The Canongate once seen is never to be forgotten: nobles, grave senators, jovial lawyers once had their abode here. In the low-roofed rooms, half-way to the stars, philosophers talked, wits coruscated, and gallant young fellows, sowing wild-oats in the middle of last century, wore rapiers and lace ruffles, and drunk claret jovially out of silver stoups. In every room a minuet has been walked, while chairmen and linkmen clustered on the pavement beneath. But the Canongate has fallen from its high estate—whisky has supplanted claret. Nobility has fled and squalor taken possession. Wild, naked children swarm round every door-step. Ruffians lounge about the mouths of the wynds. Female faces worthy of the *Inferno* look down from broken windows. Riots are frequent; and drunken mothers reel past, scolding white atomies of children that nestle wailing in their bosoms—little wretches to whom death were the greatest boon; and when evening falls, and the lamps are lit, there is a sudden hubbub and crowd of people, and presently, from its midst, emerge a couple of policemen and a barrow, with a poor, half-clad, tipsy woman, from the sister island, crouching upon it, her hair hanging loose about her face, her hands quivering with impotent rage, and her tongue wild with curses; attended by small boys, who bait her with taunts and nicknames, and who appreciate the comic element which so strangely underlies the horrible sight.' Many of these foul closes and 'wynds,' here so vividly painted, have of recent years been swept away, under powers given to the town council by the City Improvement Act. The population of Edinburgh and Leith was, in 1811, 101,492; in 1881, it was 295,487. Edinburgh City (since 1885) returns four members to parliament; the university, with that of St Andrews, returns another.

Leith, the seaport of Edinburgh, is situated at the mouth of the Water of Leith, a polluted and unwholesome stream, which has been improved, but by no means made perfect, by the expensive drainage scheme of 1864. The harbour of Leith, which has frequently been improved, now admits vessels of 2000 tons. In 1863, the Leith Dock Commissioners obtained a grant of £223,000 for construction of new works. These include a great reclamation embankment on the east sands; a wet dock of nearly eleven acres, with entrance basin of about two acres, and lock of 350 by 60 feet. The embankment is about 350 long, inclosing 36 acres. The new dock was opened in 1881. The customs revenue for 1880 was £290,570.

St Andrews.—Few places in Scotland are of greater historical interest than St Andrews. It was constituted a royal burgh by David I. Part of the wall built by Prior John Hepburn in 1516 still remains. From the top of one of its towers, St Regulus, there is a fine view of the Bell Rock, bay, city, and county, with the ruins of the once formidable castle of Cardinal Beaton, the scene of his cruelties and murder. There is also to be seen a specimen of the bottle-shaped dungeon, a sight to make one shudder at the ingenuity of human cruelty. The university was founded in 1411. Madras College was founded and endowed by the late Dr Bell in 1832. St Andrews is the

stronghold of the game of golf, which may be called the national pastime of Scotland.

Dundee, a royal burgh in Forfarshire, on the shores of the Firth of Tay, is the third town in Scotland in point of population and wealth, and the second as regards trade. It is the chief seat of the linen and jute manufactures in Great Britain. In 1745, the port dues were under £1200. Since 1815, when the harbour was placed under new management, the increase of trade has been enormous. For the year ending May 1861, the revenue of the port was £25,329; for the year 1881, the customs revenue was £158,489. The tonnage which entered the port in 1835 was 259,736; in 1881, it was 474,699. The most extensive factory in Dundee is that of Messrs Baxter Brothers & Co. The buildings cover a superficial area of twelve acres. In the spinning department there are 22,000 spindles, with the requisite preparing machines; and in the weaving-room there are 1200 power-looms. Twenty-two steam-engines, having an aggregate of 750 horse-power, are employed. The number of persons employed is about 4500, a large percentage being females. Jute was introduced into Dundee in the year 1824. In 1838, the consumption was 1136 tons; it is now fully 130,000 tons. In 1801, the population of Dundee was 31,058; in 1881, it was 140,239. In 1863, a beautiful park was given to the town and endowed by Sir David Baxter, Bart. The total cost has been £50,000. An admirably equipped University College was established here in 1882, having a principal and four other professors. The Morgan Hospital is an important educational institution. The fund—obtained by the trustees after a lawsuit as to the validity of the will—is £73,000. Dundee returns two members to parliament.

Aberdeen, a city and capital of the county, is pleasantly situated on a slope rising gently from the sea. The chief street, Union Street, is very handsome. About the middle of it, a bridge of one arch spans a ravine, which divides the Old from the New Town. In 1692 the whole shipping of Aberdeen consisted of two galliots, of 30 tons each. About this time, however, its trade began to make progress. In 1788, the number of vessels registered was 169, and the tonnage 11,820. In 1872, there were registered 218, of which the tonnage was 100,279. In 1880, the revenue of the customs was £92.599. Since 1810, when the improvement of the harbour was begun, great sums have been spent upon it. The newest undertakings regarding it are the new breakwater and division of the river; the first turf of which work was cut by Lord Provost Leslie on 22d December 1869. The granite is the great trade of Aberdeen, the annual quantity now quarried being about 55,000 tons. It is estimated to increase at the rate of 500 tons a year. The university is divided into two colleges, King's and Marischal. King's was founded by bull of Pope Alexander VI. dated Rome, February 10, 1494. The charter still exists. Marischal was founded and endowed in 1593 by George, Earl Marischal of Scotland. The old building was taken down, and a new one erected between 1837 and 1841, at a cost of £21,240, of which £15,000 was paid by government, the balance being raised by subscription. The population of Aberdeen was, in 1811, 34,640; in 1881, 105,189.

Inverness is generally regarded as the capital of the Scotch Highlands. It is situated on the river Ness, near its junction with the sea. The neighbourhood is extremely picturesque, with several scenes and objects of traditionary and historical interest. Here Macbeth had a castle, which Boethius, and afterwards Shakspeare, assign as the scene of Duncan's murder. The castle, says the latter,

> Hath a pleasant seat; the air
> Nimbly and sweetly recommends itself
> Unto our gentle senses.

The remains of a fort built by Cromwell are to be seen. Five miles from the town, lies the fatal field of Culloden.

Perth, the capital of the county, is beautifully situated on the Tay, with a fine view of the Grampian Hills. Ginghams and shawls are manufactured in considerable quantities in Perth; there are also flax-spinning mills, bleaching-fields, iron-foundries, and tanneries. In December 1871, there were 45 vessels belonging to the port, with a tonnage of 4357. The customs revenue, for the year ending March 1880, was £24,215. A much-admired statue of the Prince-consort, by Brodie of Edinburgh, was erected in 1864, and inaugurated by the Queen on 30th August of the same year. The population of Perth in 1881 was 28,980. It returns one member to parliament.

Glasgow, the most populous city in Scotland, occupies a highly advantageous situation on the banks of the Clyde, in Lanarkshire, a few miles from the place where the river expands into an estuary, 42 miles from Edinburgh, 397 from London, and 196 from Dublin. The public buildings are in general handsome, and in most instances disposed in such a manner as to be seen to advantage. The more ancient part of the city extends along the line of the High Street, between the Cathedral and the river; the more modern and elegant part stretches towards the north-west. On the left bank of the river, and connected by three bridges, is situated the populous barony of Gorbals, bearing the same reference to Glasgow which Southwark bears to London. Westward from the lowest of the bridges, both sides of the river are formed into quays, which, owing to recent operations for deepening the channel, are now approached by vessels drawing from 15 to 18 feet water, and of 1000 tons burden and upwards. As late as 1820, no vessel drawing above 8½ feet could ascend the Clyde. The quay on the north bank is denominated the *Broomielaw;* there is an extent of quay of about 1½ miles on both sides of the river.

Glasgow took its rise as a dependency of the cathedral of the bishops (latterly, archbishops) of the see bearing its name. It was not, however, till long after the Reformation that it became a seat of considerable population. About the middle of the eighteenth century, it had acquired a considerable share of the import colonial trade, which it still retains; but during the last hundred years, it has chiefly been distinguished as a seat of manufactures. The weaving of lawns, cambrics, and similar articles commenced in Glasgow in 1725. The advantages enjoyed by the city for the importation of cotton in time gave a greater impulse to that species of manufacture. Besides the old park in the east end, or 'Green,' as it is called, Glasgow has of late years acquired three others—one of 40 acres, in the west end, named

Kelvingrove Park, at a cost of £89,000; another of 100 acres, to the south, named Queen's Park, at a cost of about £60,000. Both of these were designed and laid out by Sir Joseph Paxton. The third, the Alexandra, 85 acres, is in the north-eastern part of the city. It has cost about £40,000. Glasgow is paved with granite, and is one of the best-paved cities in Europe. The Loch Katrine water-works, begun in 1856, by Mr Bateman, C.E. were completed in three years. The aqueduct from the lake to the reservoir, 8 miles from Glasgow, is 26 miles long. During half of that distance, the water is conveyed through tunnels. There are four miles of iron piping carried across valleys, and for the rest of the way there are open cuttings and bridges. The cost of the aqueduct averaged £18,000 per mile. The total cost of the works has rather exceeded one million and a half sterling. Over 32 millions of gallons are brought into the town daily. This gives 52 gallons per head to the population. The works are capable of supplying 50 millions of gallons per day. The City Improvement Trust was created in 1866, to acquire decayed buildings and parts of the town where houses were bad or deficient. A tax was imposed for this purpose. The Trust has already acquired £1,100,000 worth of property. The iron trade has grown to be of vast magnitude in Glasgow. In the immediate neighbourhood, in 1880 there were 97 iron furnaces, producing upwards of 3000 tons of pig-iron per day. In 1879, the total manufacture was 932,000 tons; the shipment, in 1880, was 259,425 tons. In shipbuilding, Glasgow holds a high position. The aggregate launched during 1882, a year of exceptional activity, was 291 vessels of 391,934 tons. The commercial progress of Glasgow is indicated by the following table:

Year ending	Duty collected at the Port.
Jan. 5, 1801	£469 13 6
" 1820	11,000 6 9
" 1830	59,013 17 3
" 1840	468,974 12 2
" 1855	668,556 9 4
Mar. 31, 1870	1,072,718 11 6
" 1881	1,036,616 0 0

The Cathedral or High Church ornaments the north-east end of the city. It was founded by John Achaius, bishop of Glasgow in the reign of David I.; a stone over the door tells us that it was dedicated in 1197, St Mungo being the tutelar saint. The new university buildings were begun in 1867; when finished, the total cost will, it is expected, be about £400,000. Towards this, the citizens have subscribed £120,000. The style of building is that of the early part of the 14th century as applied to colleges. There is a large infirmary in connection with the university. In 1811, the population of Glasgow was 103,224. By the census of 1881, it was 674,095. By the same, the population of Manchester (with Salford), 517,741, and of Liverpool, 552,425. After 1868, Glasgow sent three members to parliament; after 1885, seven. The university, in conjunction with that of Aberdeen, returns another.

Paisley.—The country around Glasgow, particularly towards the south, abounds in busy towns and villages, of the former of which the most remarkable is Paisley, situated in Renfrewshire, on the banks of the small river Cart, seven miles from the city above described. It originated from an abbey founded in 1160 by Walter, the first of the Stuarts, and of which considerable remains still exist. Paisley is a noted seat of the manufacture of shawls, and also of cotton thread, gauzes, and velvets. There are also brass-foundries, bleaching-works, and a silk-throwing mill. The population in 1881 was 55,638.

Greenock, in the early part of the 18th century, was a small fishing village. It is now the first seaport in Scotland, possessing commodious harbours, extending 5455 feet from east to west. The Albert Harbour, opened in 1866, cost £200,000. The Princes Pier, extending along the Clyde westward, cost £70,000. It has direct communication with the Greenock and Ayrshire Railway. The new Garvel Park graving-dock, one of the largest docks of the kind in the kingdom, was formally opened by the chief magistrate on 1st April 1874. The works cost upwards of £60,000. The principal trade of Greenock is with the East and West Indies, the United States, and British America. It is a very flourishing town. The population in 1881 was 66,704. It returns one member to parliament.

Dumfries is prettily situated on the Nith, which is navigable to small vessels nearly as far as the town. The population in 1881 was 17,092. Dumfries has some weaving-mills and small manufactures; and is an entrepôt for transmission of cattle to English markets. It derives some importance from being the chief town of a considerable district. In St Michael's churchyard are laid the remains of Robert Burns.

The Border.—Though the scenery of the Scottish Border cannot be compared with that of the Highlands, it is in many parts extremely picturesque; and there are few lands so famed in song and story. 'Many of the Border ballads,' says a poet, 'are so real and life-like, so full of character and humour, that we feel as if the singer had himself wielded a sword in combat, or ridden into England to lift a prey. . . . All that far-off, lawless, and generous life is unroofed to us in these ballads. We wander amid the ruins of a past society, as we would amid the ruins of Pompeii.' Entering from England by Ford, Twizel Castle, and Coldstream, we pass through the country traversed by James on his way to Flodden, and we think of *The Flowers of the Forest*—

I 've heard them lilting at the ewes milking,
Lasses a-lilting before the dawn of day;
But now there's a moaning on ilka green loaning,
For the Flowers of the Forest are a' wede away.

The first town on the Scotch side on the Tweed, after Coldstream, is Kelso, where there is a fine ruin of an abbey of David I. and the ruin of the old fortress of Roxburgh Castle, the scene of the Black Douglas's famous exploit. Eight or nine miles farther up, we come to Dryburgh, within whose abbey Sir Walter Scott is buried—

'Mong mouldering ruins low he lies,

and from his grave you hear meet music—the wail of his beloved Tweed. Five or six miles farther up, stands Melrose, with its famed Abbey, where lie the heart of Bruce, Alexander II. of Scotland, Earl Douglas who fell at Otterburn, and William, 'the dark knight of Liddesdale.' Abbotsford is about two miles from Melrose. It now belongs to the Hon. Mrs Constable Maxwell Scott, great-grand-daughter of Sir Walter Scott, and grand-daughter of J. Gibson Lockhart, his biographer.

IRELAND.

IRELAND is bounded on the south, west, and north by the Atlantic, and on the east by a strait—called, at different places, the North Channel, the Irish Sea, and St George's Channel—which separates it from Great Britain. The strait is about 47 miles wide between St David's Head, in Wales, and Carnsore Point, in Ireland; about 55 between Holyhead and Dublin; and 13 between Fair Head and the Mull of Kintyre, in Scotland. Ireland has a coast-line of not less than 2200 miles. It lies between lat. 51° 26′ and 55° 21′ north, and between long. 5° 20′ and 10° 26′ west. The island, according to Dr Clyde (*School Geography*, by James Clyde, LL.D.) 'consists of a central plain inclosed by mountainous districts, except at the bays of Dublin and Galway, where it reaches the shore in a considerable extent of coast-line. This central plain would very nearly coincide with a four-sided figure, having for its four corners the towns of Wicklow, Galway, Sligo, and Dundalk. It occupies one-fourth of the entire surface of the island, and is so low that the highest point between Dublin and Galway is only 320 feet above the level of the sea. The principal ranges in the mountainous districts separating the central plain from the sea, are the Mourne Mountains, in County Down; the mountains of Antrim, connected with which are the basaltic columns known as the Giants' Causeway; Mount Nephin and Croagh Patrick, in Mayo; Macgillicuddy Reeks, in Kerry, the highest peak of which, Carran Tual (3410 feet), is the highest mountain in Ireland; the Slievh Bloom Mountains, on the borders of King's County and Queen's County; the Knockmele-down Mountains, between Tipperary and Waterford; and the Wicklow Mountains. The central plain nearly inclosed by these mountains is one immense deposit of limestone, overlaid to a great extent by bog. Tullamore, in Queen's County, is the centre of the bog region.'

The largest of these morasses is the Bog of Allen, which stretches in a vast plain across the centre of the island, or over a large portion of Kildare, Carlow, King's and Queen's Counties—having a summit elevation of 280 feet, in which the Boyne and some lesser rivers take their rise. Along the banks of the river Inny—which, rising in Lough Iron, in County Westmeath, crosses Longford, and falls into the Shannon—are large tracts of deep, wet bog, only exceeded in dreariness by that which for miles skirts the Shannon in its course through Longford, Roscommon, and King's County. These bogs consist of turf or peat in various degrees of condensation—from a pulpy or fibrous mass, to a compact mass that admits of being cut into any form. They rest on a substratum of clay and limestone gravel, are from 15 to 40 feet in depth, and are composed chiefly of aquatic vegetables, which have grown on the sites where they are now entombed. Notwithstanding the quantity of water contained in these extensive bogs, there arises from them no miasma injurious to health. This is attributable to the large portion of tannin they contain, which possesses so strong an antiseptic quality, that bodies plunged into a deep bog remain undecayed, the flesh becoming like that of an Egyptian mummy. It sometimes happens that a bog, overcharged with water during a rainy season, breaks through the obstruction which the drained and more solid part affords, and, rushing forward, overflows large portions of good land.

'The central plain,' continues Dr Clyde, 'is drained chiefly by the Shannon, which is the largest river in the British Islands, and the only considerable one on the western shore of Ireland; it is navigable to Lough Allen, a distance of 240 miles. Other rivers draining the central plain are—the Erne, which, like the Shannon, traverses several lakes in its course; the Liffey, navigable only to Dublin; and the Boyne, navigable to Navan, a distance of 25 miles. Most of the rivers belonging to the mountainous regions are small; the more considerable are in the south of Ireland, the Slaney, the Barrow, the Blackwater, and the Lee, forming respectively the harbours of Wexford, Waterford, Youghal, and Cork. The river Bann is the outlet of Lough Neagh, the largest lake in the British Islands; its waters petrify, but its scenery is uninteresting, as the shores are low and flat. On the other hand, the three lakes of Killarney, at the base of Macgillicuddy Reeks, in Kerry, compete with those of Cumberland and Scotland in beauty. The Devil's Punch Bowl, in the same neighbourhood, is a mountain hollow, so called because mist is almost always floating above it.'

GEOLOGY.

A great series of grits and slates of Cambrian age occur in the south-east of Ireland; the upper portion contains a few fossils of zoophytes and worms. Lower *Silurian strata* rest unconformably on the Cambrian rocks in the same district. Detached portions of Upper Silurian measures occur on the western side of the island, in Kerry, Galway, and Mayo.

Between the Silurian and Old Red Sandstone is an enormous thickness (11,000 feet) of sandstone grit and shale in Kerry and Cork. These strata are almost wholly unfossiliferous.

Old Red Sandstone strata, consisting of red and yellow sandstone and slate, cover a large tract of the south of Ireland, stretching almost continuously from the extreme west of Cork and Kerry into Waterford and Kilkenny, being stopped by the Silurian rocks of Wexford and Carlow.

The *Carboniferous Limestone* is extensively developed in Ireland, occupying the whole of the centre of the country, except in those places already alluded to, where the older rocks appear on the surface. This great tract is an extensive plain covered with drift, and with peat-moss and

freshwater marl, in which are found the remains of *Megaceros Hibernicus* and *Bos longifrons*. In Kerry, Cork, and Waterford, the strata are very much contorted, the coal-seams are changed into anthracite, and so squeezed and crushed as to be got only in small dice-like fragments. Further north, the strata are nearly horizontal, but the coal-fields are limited, and the seams are generally of inconsiderable thickness. They occur chiefly in Tipperary, Kilkenny, Tyrone, and Antrim.

CLIMATE.

The *climate* of Ireland is remarkable for its mildness and humidity—results arising, in the first place, from its being surrounded by the Atlantic, from which no portion of its interior is distant more than 50 miles; and in the second, from the comparatively small elevation which the generality of its land attains. This mildness is proved by the fact, that even in the northern county of Donegal, the arbutus, laurustinus, agapanthus, and fuchsia grow healthily in the open air, and myrtles so luxuriantly as to cover the walls of houses up to the second story. Its humidity, though great, differs considerably in different districts; at Cork, for instance, the average annual fall is said to be 40 inches; at Dublin, it is only 30 inches. The average over the whole island is estimated at 36 inches. Owing to its mildness and humidity, the climate is especially favourable to vegetation, the land being clothed in an almost perpetual greenness.

Considerable variety of climate, at least as regards temperature, is found in Ireland, and, as in Great Britain, the temperature of one district changes relatively to that of another, according to the season of the year. We give the following on the authority of the *Journal of the Scottish Meteorological Society* (Nos. 28, 29, art. 'Temperature of the British Islands,' with thirteen charts). In January, the coldest month of the year in Ireland, as in Great Britain, the coldest part of Ireland lies between the 53d and 54th parallel of latitude, at a distance of about 30 miles from each coast. The mean temperature of the month is here 39°, which is equal to that of the warmest part of the mainland of Scotland, and slightly above that of London for the same month. The mean January temperature of 40° takes an eccentric course from Malin Head, in the extreme north, running south at a distance of 20 or 30 miles from the coast to about Limerick in the south-west; thence it passes east, through Dublin and Belfast. The warmest part of Ireland, in January, February, and March, is the corner lying south of a line drawn from the head of Dingle Bay by Killarney to Cork, where the mean January temperature is 42° to 43°, about 1° below that of the warmest part of England, and 2·5° above that of Pau, in the south of France (40·5°). As the season advances, latitude becomes the determining element in Irish as in British climates; by April the isothermals, or lines of equal temperature, run almost in parallels north and south; the corner from Dingle Bay to Wexford being the warmest part of Ireland in spring and summer. Here April has the same temperature as England south of London, 49° to 50°. In July, the warmest part of England is 2° warmer than this part of Ireland, whose mean temperature is then 62°; the corner north of Londonderry and Belfast being then the coldest part of Ireland, with a mean temperature of 58° to 59°; the same as Edinburgh, and 5° to 6° below that of London.

BOTANY AND ZOOLOGY.

The native *Flora* and *Fauna* of Ireland generally resemble those of the neighbouring island; the cultivated plants and domesticated animals are identical. There are, however, some species peculiar to the island, of which the following are the most remarkable: The strawberry-tree, found at Killarney, particularly beautiful from its abundance of red fruit; the Irish rose, found near Belfast; the Irish furze, found sparingly in Down, distinguished from common furze by its upright mode of growth and softer texture; the Irish or Florencourt yew, of upright growth and dark-green foliage, resembling that of the cypress; the Irish menziesia, whose large purple heath-like bells decorate the wild districts of Galway; the Corsican and other species of heaths, found also in Spain and the islands of the Mediterranean; and carrageen or Irish moss, a sea-weed of some commercial importance.

At present, Ireland is not a well-wooded country—a defect which is fast being remedied by extensive plantations; but we have historical evidence, as well as the indubitable records of her bogs, that at no very remote period large tracts were covered with a gigantic growth of the ordinary forest-trees. Morrison (1596) and Davis (1605) mention the forests in which the poor Irish took refuge; and all the scenery of Spenser's *Faëry Queen* is drawn from the river Bandon, which he celebrates as the 'pleasant Bandon wood y-crowned,' as it is to this day. Boate, in his *Natural History* (1652), mentions the great extent of wood then standing. The violent transfers of property that were constantly occurring for many years subsequently to this date, would, of course, produce recklessness and improvidence, and the holders of land would naturally seek to make the most of it by cutting down the woods, while there was little inducement to plant. There are still, however, in a few favoured spots, some remains of the ancient oak and ash woods, as at Killarney, at Glengariff near Bantry, in Connemara, in some spots of the county of Wicklow, and in Donegal, near the beautiful Lough Van, where a few red deer are still to be seen.

With respect to the animal kingdom, the elk has passed away, leaving its skeleton and antlers in the bogs as memorials of its gigantic size; the wolf has disappeared since the time of the Commonwealth; the wolf-dog is still to be met with, though rarely; the red deer frequents the wild mountain districts of Kerry; the eagle inhabits the western coast of Connaught; the Irish falcon of our ancestors is, we believe, extinct; and the gillaroo and dorchar trouts are limited to Lough Neagh. Of the domesticated animals, though these are now generally cross-breeds, Ireland possesses some varieties regarded as peculiar—namely, the Irish black horse, the Kerry and old Irish breeds of the ox, a worthless wiry-woolled sheep, and a long-legged narrow-bodied pig. In consequence, it is presumed, of the humidity of

the soil and climate, the adder and snake are unknown, as is also the mole.

PEOPLE—POPULATION.

The Irish people are, in the main, a branch of the Celtic race, though the Celts were probably not the first settlers in the island; the earlier occupants belonging (as in Britain, before the arrival of the Celtic Britons) to a non-Aryan stock, often called Euskarian or Ivernian. The peasantry throughout nearly the whole country are of Celtic or mixed Celtic and Euskarian blood, and in many parts they still speak the old Irish language. But in the north, a great number of the humbler, as well as middle classes are descended from comparatively recent settlers of Scottish descent. Families of English blood are comparatively rare amongst the labouring class in Ireland; but a large portion of the upper and middle classes are of Saxon descent.

Character.—Irish character is in some respects like the French. As the French are, the Irish are led by impulse and by the humour of the hour. They are more vain, or at least act more from vanity, caring less to conceal the fact of its being the mainspring of action, than the English and the Scotch do. They wholly lack the prudence and the perseverance which are so especially the virtues of the latter people. They are intelligent, witty, hospitable, light-hearted, and, unlike the English and the Scotch, usually content to remain in the social position and circumstances in which they are born. The feature in the character of the Irish, to which the misfortunes of Ireland are apparently to be attributed, is their disregard of law. In Great Britain, popular sympathy is almost always on the side of the law; in Ireland, it is nearly always against the law. How far this and the other defects of national character have arisen from political circumstance, or how far the misfortunes of the people have been owing to these defects, are questions to be studied in the history of the country. See art. HISTORY OF GREAT BRITAIN AND IRELAND.

We take the following from an able chapter in a *Memoir of Thomas Drummond, Under-secretary to the Lord-lieutenant of Ireland*, by John F. M'Lennan, M.A., advocate. 'There are in Ireland,' says Mr M'Lennan, 'as it were, two nations interfused, yet distinct, with separate traditions, and differing in blood, temperament, and religion. The larger represents the tribes which occupied the country before the Conquest; the smaller represents the conquerors. Their relations have always been hostile. The growth of the society which they compose has consequently been abnormal; its growing pains, acute and prolonged beyond parallel. They have not yet ceased; they are constantly producing feverishness and delirium. The history of Ireland is mainly that of the larger of the two nations—the nation of the tribes. In the time of Henry II. this consisted, according to the computation of Sir William Petty, of not more than 300,000 souls, divided into a few tribes, and subdivided into a great number of clans or septs. . . . The number of clans was prodigious. The clan-feuds were incessant; the tribal wars were almost incessant. Antipathies founded on wrongs, real or imaginary, divided the clans; antipathies founded on real or assumed differences of race divided the tribes. There were everywhere hereditary hatreds of unknown origin. The clans even contained within themselves the elements of discord, and fell into factions. . . . Property was held in common; the succession of sons to fathers had not been introduced. The tribes had been resolved into clans of different stocks; but the clans had not yet, properly speaking, been resolved into families. The tie of milk was superior to the tie of blood; children belonged to the sept rather than to the family. They were rarely or ever reared by their own mothers—"the potent men selling," says Sir John Davis, "the meaner sort buying, the alterage of their children." At the period here treated of, Irish civilisation was in some other respects considerable. Christianity was established, and missionaries from Ireland were carrying the new light into places still in the darkness of paganism. In 1154, Pope Adrian IV. as "king of all islands," granted the lordship of Ireland to Henry II. of England, for the purpose of "broadening the borders of the church." Henry's conquest was little more than nominal, and the four centuries which followed were centuries of constant feud and slaughter between the invaded and the invaders. The law of England was "by law" established, but practically there was no law but the will of the stronger. By the time of Henry VII. the English rule in Ireland was verging on extinction. From a report made in the reign of Henry VIII. it appears that "the English order, tongue, and habit" were used, and English laws obeyed, within a district of not more than twenty miles in compass; sixty "regions" of Ireland were under the dominion of Irish chieftains; and thirty "regions" under the authority of chiefs of Anglo-Norman descent—the Irish rebels—who owned neither the laws nor the government of England. The real struggle between England and Ireland began with the Reformation under Henry VIII. and ended with the fall of Tyrone, a native chief, in the reign of Elizabeth, leaving Ireland,' says Mr M'Lennan, 'a waste of blood and ashes. Love of plunder,' he continues, 'had now found a powerful auxiliary in zeal for the Reformed religion. . . . The English army acted, indeed, as if its mission were not to conquer, but to destroy the people. Its route was everywhere marked by slaughter, famine, and desolation. "The soldiers in the camp," says an English chronicler, "were so hot upon the spur, and so eager upon the vile rebels, that they spared neither man, woman, nor child, but *all* were committed to the sword." The natives, when they crowded into castles, were burnt or slain in the mass. Their cattle were carried off, and their crops cut down; and those whom the sword spared, hunger destroyed. Catholic priests were forbidden to exercise their spiritual functions, and were hanged or burned if they did so. One of the first acts of James I. was a jail delivery, from which he excluded "murderers and papists." Plague and famine raged over the unhappy land. According to an eye-witness, whole counties were cleared of their inhabitants. A man might travel twenty or thirty miles and not see a living creature, either man, beast, or bird: where survivors were found, they were either old men and women, or children. "I have seen these miserable creatures," says Colonel

Lawrence, "plucking stinking carrion out of a ditch, black and rotten, and been credibly informed that they digged corpses out of the grave to eat." By twenty-four acts,' says Mr M'Lennan, 'passed between the seventh year of his (William III.) reign and the 29th of George II. the penal code (i.e. against the Catholics) reached the fulness of its hideousness. The papist was withdrawn from the charge and education of his family; he could educate his children neither at home nor abroad. Popish schools were prohibited, and special disabilities attached to papists bred abroad. A premium was set on the breach of filial duty and family affections. . . . The exercise of his religion was forbidden; its chapels were shut up; its priests banished and hanged if they returned home.' The breaking out of the American war extorted some concession to Ireland from the British government; and the French Revolution extorted further concession. In 1792, the Catholics were granted the right of education, admitted to the bar, and allowed to intermarry with Protestants. This, which may fairly be called the beginning of justice to Ireland, was followed by the political enfranchisement of the Catholic population in 1793, by the Union in 1800, and by the completion of Catholic emancipation in 1829; but all came too late to restore tranquillity to the distracted and unhappy country. In 1832 its condition was fearful. The Association that had carried Catholic emancipation was looking forward to repeal of the Union; and Catholic and Protestant fanaticism were alike in a blaze. The condition of the people was deplorable. The landlords were for the most part tyrants or absentees, or both, by means of 'middlemen' between them and the tenants. Most of the estates were in Chancery, and had been there for about half a century. There were the old difficulties regarding the land. The peasantry were sunk in destitution and squalor. There were ever new political combinations, such as 'Ribbonism,' forming among them, to secure their interests by outrage and disorder. There were the difficulties of tithe collection. There was O'Connell agitating; and there was the opposition agitation of the Orange Society, with its secret meetings and armed members. 'Agrarian crimes, faction fights,' says Mr M'Lennan, 'occasional insurrections, perpetual agitations in connection with land, politics, or religion, were the symptoms of the universal discontent and inquietude.' Happily, in our own day, we have seen the voluntary completion by England of those measures of justice to Ireland which in former times were only partly conceded to political necessity. That these measures should be at once fully successful, is, of course, not to be expected. The effect of centuries of oppression and misgovernment cannot be expected to disappear the instant that the cause is withdrawn—the sea, long vexed by tempest, continues to rage for some time after the winds have ceased. But there is every reason to hope that a new and a happier era has at length dawned on Ireland; and that the next generation may see her people prosperous and contented, as they are generous and brave.

No one, probably, had ever a keener appreciation of Irish character—its drollery, its wit and humour amid rags and disorder, its swagger under poverty and debt, its generosity, and its ferocity—than Thackeray. 'What a history,' he writes in his *Irish Sketch-book*, 'of poverty, and barbarity and crime, and even kindness, was that by which we passed! What a chapter might a philosopher write on them! Look yonder, at those two hundred ragged fellow-subjects of yours—they are kind, good, pious, brutal, starving. If the priest tells them, there is scarce any penance they will not perform; there is scarcely any pitch of misery which they have not been known to endure, nor any degree of generosity of which they are not capable; but if a man comes among these people, and can afford to take land over their heads, or if he invents a machine which can work more economically than their labour, they will shoot the man down without mercy, murder him, or put him to horrible tortures, and glory almost in what they do. . . . They are as fond of their mother and children as we are; their gratitude for small kindnesses shewn to them is extraordinary; they are Christians as we are; but interfere with their interests, and they will murder you without pity. It is not revenge so much which these poor fellows take, as a brutal justice of their own.' As descriptive of the disorderly habits of the lower classes of the Irish, take the following: 'But of all the wonderful things to be seen in Skibbereen, Dan's pantry is the most wonderful; every article within is a make-shift, and has been ingeniously perverted from its original destination. Here lie bread, blacking, fresh butter, tallow-candles, dirty knives—all in the same cigar-box with snuff, milk, cold bacon, brown sugar, broken tea-cups, and bits of soap. No pen can describe that establishment, no English imagination could have conceived it!' On the other hand, he continues: 'I have met more gentlemen here (*i.e.* in Ireland) than in any place I ever saw—gentlemen of high and low ranks; that is to say, men shrewd and delicate of perception, observant of society, entering into the feelings of others, and anxious to set them at ease or to gratify them; of course exaggerating their professions of kindness, and in so far insincere; but the very exaggeration seems to be a proof of a kindly nature, and I wish in England we were a little more complimentary.'

The following was the population of Ireland, according to the census returns at decennial periods, from 1821: (1821) 6,801,827; (1831) 7,767,401; (1841) 8,196,597; (1851) 6,574,278; (1861) 5,798,967; (1871) 5,412,377; (1881) 5,159,839. Between 1841 and 1851, the population decreased 19·79 per cent.; from 1851 to 1861, 11·79 per cent.; from 1861 to 1871, 6·83 per cent.; from 1871 to 1881, 4·7 per cent.

Emigration.—In the decennial period ending with 1881, 622,686 Irish-born persons emigrated from Ireland; and in the ten years from April 1, 1861, to March 31, 1871, 819,903 Irish-born persons emigrated from different ports in the United Kingdom. 'To emigration,' says the Census Report quoted by the above authority, 'may chiefly be attributed the decrease of the population during a period when the country was remarkably free from any outbreak of pestilence, scarcity of food, or of the other social calamities which have occasionally retarded the growth of population in this and other countries. It must also be remembered that some of the remote effects of the disastrous period of famine, pestilence, and panic, which commenced with the

potato blight of 1845-46, had extended over the first few years of the decade upon which it is now our province to report. Assuming that the increase of population by births over deaths was at the rate of ·92 per cent. per annum, as stated in former Census Reports emanating from this country, the population of Ireland would—had no disturbing cause intervened—have been about 6,297,275. It is therefore probable that the decrease of the population may be accounted for by the very great emigration, as stated above. It is here worthy of remark, that at the time of taking the census in 1851, there were no less than 250,611 paupers in the Irish workhouses, and 47,014 persons in hospital, of whom 4545 were not workhouse inmates—that in 1861 the numbers in workhouses, healthy and sick, were only 50,010; while there were but 48,989 persons in the Irish workhouses the day before the census was taken in 1871.'

The Act for the registration of Births and Deaths in Ireland (26 Vict. c. 11) came into operation of January 1, 1864. The number of marriages in 1870 afforded a ratio of 1 in 188, or ·532 of the population—1 in every 153 Protestants, and 1 in every 202 Roman Catholics. The marriages in 1871 give a ratio of 1 in 186, or ·537 per cent. of population—1 in 158 Protestants, and 1 in 196 Roman Catholics. The marriages in 1881 give a percentage of ·560 Protestants, and ·379 Roman Catholics.

NATIONAL INDUSTRY AND COMMERCE.

Agriculture.—For the following we are indebted mainly to Thom's *Irish Almanac.* 'Ireland,' says this authority, 'was almost exclusively a pasturing country until the middle of last century. That the soil of Ireland is, however, eminently fitted for tillage, appears from the evidence of every intelligent person qualified to give a sound opinion who has visited the country. . . . "In the elements of natural fertility," says Mr M'Combie, M.P. for Aberdeenshire, "only the richer parts of England, and very exceptional parts of Scotland, approach to it."

'Notwithstanding this great fertility of soil, political, social, and moral forces, the strength of which cannot be known until some time after they have ceased to be in action, have heretofore kept the land in a very imperfect state of cultivation. "Under the treatment the soil of Ireland receives, great part of the soil of Scotland would long ago have ceased to produce any crops at all—would have relapsed into sterility. It is only the natural richness of the soil of Ireland which has averted a like result. But rich as it is, and capable so far of recovering fertility, if only let out into grass, it stands to reason that the finer elements are in course of being gradually withdrawn from the soil. Skilful farmers remark that its meadows—beautiful as is their close carpet of green—do not fatten stock proportionately to their apparent richness. Nor is Irish milk equal to that drawn from the more highly manured, though less verdant fields of Scotland." Another competent observer from Scotland says: "The tillage lands of the south of Ireland, though not so rich as the pasture-lands in Tipperary, Limerick, and the Meaths, are also of great fertility. I join heartily in the eulogium pronounced by Arthur Young and other judges on the richness of the soils of Ireland, though they have been sadly deteriorated by bad farming, since that distinguished agriculturist wrote on them. The overcropping to which the small holdings have been subjected, amounting often to nine or ten crops of oats in succession, is enough to reduce to sterility any soil of ordinary fertility. The average rent of the tillage lands is about 15s. per statute acre. In Ulster the farming is better, and the rents are about 9s. higher than those paid for land of the same quality in the south."—(*Land Culture and Land Tenure in Ireland.* By Peter Maclagan, Esq. M.P.)

'Notwithstanding the bad cultivation of the smaller and other holdings held by tenants at will, it must not be supposed that there are not many exceptions and some improvements. "A journey of some thousand miles through the various counties of Ireland, has made it impossible for the writer to doubt that in the last thirty years there has been generally throughout the country a great development of all the elements of national prosperity—wealth has increased, and the condition of the labouring classes has materially improved."—(*Ireland in* 1839 *and* 1869. By H. S. Thompson, Esq. late President of the Royal Agricultural Society of England.) But this increase of prosperity is very much of foreign origin; *i.e.* it has arisen mainly from the attraction of remunerative employment in the United States of North America, Great Britain, and elsewhere, which has greatly diminished the number of the population, and by the largely increased value of stock, &c. caused by the unlimited demand in the markets of Great Britain, and facilities for reaching those markets.' There can be little doubt, however, that the legislation of recent years has already done, and will continue to do, material benefit to Ireland. The passing of the Landlord and Tenant Act of 1870, unquestionably marked an epoch in the history of Ireland. It may be too much to say that this Act has produced general content; but it has diminished dissatisfaction, and has opened the way to the ultimate solution of the whole questions involved in the term *tenant-right*, which denotes the various claims of right which tenants maintain against their landlords—such as the right of occupancy not subject to removal, and the right to occupy at a rent not subject to increase on the ground of improvements; it being said to be inequitable to make them pay rent for what they have themselves produced. In Ulster and in the north of Ireland generally, the equity of these claims had long been recognised and acted on. In the south of Ireland, on the other hand, tenant-right had never been conceded by the proprietors, while the right of occupancy not subject to removal had *de facto* been enjoyed by the tenants. The non-settlement of the question was long the subject of bitter controversy, and undoubtedly its evil condition was the root of much of the national misery. Owing to the old tenure of land, as tribal or clan property, the people of the south of Ireland never received into their minds the notion of 'contracting' with any one as the 'owner' of the land. They had the traditional feeling of being themselves the owners; and so much was this feeling a source of agrarian disturbance, that few Irish 'landed proprietors' ever ventured fully to exercise their rights of property; and nothing was more

common in the south than to find that the land had been in the occupancy of the same families from time immemorial, without lease or contract of any kind. The discontent in Ireland continued unabated till the imperial government interfered, and settled the question, in so far as practicable, by the passing of the Act of 1870 above referred to. The Land Act of 1881 was still more favourable to tenant-farmers. It established land courts throughout the country for fixing 'judicial' rents, to remain unaltered for fifteen years at a time; limited the possibility of evictions to the non-fulfilment of certain conditions; recognised the tenant's right to sell his tenancy; and made provision for advancing money to tenants wishing to buy their holdings.

In 1884 the number of separate holdings in Ireland was 565,254, being 2471 less than in the previous year. The following table shews the number of holdings, and the entire extent of land under each class of landholders, and the division of land, from the returns in 1872:

Classes.	Number of Holdings in each class.	Area.	Average extent of Holdings in each class.	Proportion per cent. of Holdings in each class.	Total Extent under Crops.	Grass.	Fallow, or uncropped Arable Land.	Woods and Plantations.	Bog, Waste Water, Roads and Fens.
		Acres.	A. R. P.		Acres.	Acres.	Acres.	Acres.	Acres.

TOTAL VALUE OF PRINCIPAL CROPS.

1863	£29,474,583
1864	31,415,922
1865	29,687,703
1870	34,961,042
1883	31,127,837
1884	28,544,794

Live-stock.—Number and value of horses, cattle, sheep, and pigs in Ireland in 1872: 532,146 horses, value, £4,831,368; 4,142,400 cattle, £35,623,882; 4,482,053 sheep, £8,292,571; 1,042,244 pigs, £2,990,614. Total value of cattle, sheep, and pigs in 1885, £63,512,277.

Fisheries.—In her fisheries, Ireland possesses a mine of almost inexhaustible wealth, but, strange to say, it is almost wholly neglected.

NUMBER OF VESSELS AND BOATS, MEN AND BOYS, EMPLOYED IN THE DEEP-SEA AND COAST FISHING FROM 1880 TO 1884.

Year.	Vessels and Boats.	Men and Boys.	Value of Fish exported to England.			
			Salmon.	Herrings.	Mackerel.	Cod.
1880	6459	24,548	£473,596	£246,038	£85,525	£171,303
1881	6458	24,528	511,237	230,466	87,632	163,095
1882	6089	22,391	308,306	140,114	64,353	113,374
1883	5866	21,814	521,443	170,376	93,253	140,883
1884	5759	21,696	440,578	153,266	87,538	138,711

Under the Act 26 and 27 Vict. c. 114 (1863), special Commissioners for Irish Salmon-fisheries were appointed. In their first Report, they say: 'We do not think we exaggerate the value of the salmon-fisheries when we estimate them as being worth over £400,000 a year.' For the development of this branch of industry, they earnestly recommend government loans to the fishermen for the repair and purchase of boats and gear, without which assistance, they say, 'fishing industry will nearly expire on half the coast.'

The herring-fishery is prosecuted chiefly on the east coast of Ireland, by a fleet of about 2000 vessels, from Cornwall, Scotland, and the Irish coast. The success of the fishings fluctuates from year to year. Thus, in 1877, a value of over £350,000 was realised by the herring-fishery at 10 stations; in 1879, it was under £124,000; and in 1881, only £63,850. The total value of salmon, herrings, mackerel, and cod exported to England in 1884, amounted to £820,093. The oyster-fisheries are declining. Nearly everywhere there has been over-dredging; and lately an attempt has been made to stock the used-up beds with French oysters.

Manufactures.—Ireland is not, and never has been, a *manufacturing* country. Its unsettled, turbulent state, and the general dependence of the population on land, have hitherto formed insuperable obstacles to the formation of great manufacturing establishments in most parts of the country; whilst the want of coal, capital, and skilful

workmen, and the great ascendency of England and Scotland in all departments of manufacture, will, there is reason to think, hinder Ireland from ever attaining eminence in this department. Linen may be regarded as the staple manufacture, of which Belfast and the surrounding districts of Ulster are the chief seats.

The exports of linen yarns and manufactures from Ireland to Great Britain were, in 1864, £10,327,000 in value. The woollen manufacture was nearly extinguished at the revolution of 1688, but it revived some time afterwards. There seems to have been a decrease in the number of factories from 1839 to 1850, since which time the trade has revived, and many of the discontinued factories have been reoccupied. The total number of factories is 47, but in only two of these—in the counties of Cork and Dublin—is the number of hands employed over 100. The total number of persons employed in 1868 was 1374. The quantity of flax grown in Ireland, annually, on the average of the seven years ending 1864, was 30,985 tons. The number of acres sown in 1863 was 214,099; in 1872 the number had fallen to 121,864; in 1885 it was 108,149 acres. The position of Ireland as a manufacturing country will be seen from the following table, which shews the number of textile factories, and the persons employed in 1885.

	Factories.	Persons employed.
Cotton	7	1,248
Woollen	141	3,136
Worsted	4	202
Flax	166	61,749
Hemp	2	670
Jute	4	961
Hair	6	192
	330	68,158

Of the persons employed in these factories, 31 per cent. were males, and 69 per cent. females. A great source of employment for females in the north of Ireland is now the working of patterns on muslin with the needle. Belfast is the centre of this manufacture, which employs about 300,000 persons, chiefly females. About 40 firms are engaged in the trade, some being Irish houses, and others agents for Scotch firms. The gross value of the manufactured goods amounts to about £1,400,000.

Distillation.—In 1829, there were 80 distilleries in Ireland, and the number of gallons entered for home consumption in that year was 9,212,223 gallons, the duty being 2s. 10d. per gallon. In 1836, the number of gallons entered for home consumption had risen to 12,248,772, the number of distilleries being in that year 90, the duty 2s. 4d. With some oscillation, the tendency has been from this period to an annual decrease in the quantity of spirits consumed in Ireland. In 1842, the home consumption was 5,290,650, the duty being 2s. 8d. to 3s. 8d. In 1854, again, the figures rise to 8,440,734, the duty being 3s. 4d. to 4s.; but by 1864, again, they have fallen to 4,845,100, the duty being 10s.; in 1881, they are 5,184,953, the duty being 10s. per gallon. The force of these figures is, of course, to be considered in connection with population returns.

Trade and Shipping.—The exportation of the agricultural produce of the country has always been the principal branch of Irish commerce. Great Britain is by far the best and most extensive market for all kinds of the produce of Ireland. Much the greater part of the export trade is carried on by the cross Channel navigation, chiefly to Liverpool, Bristol, and Glasgow; the staple articles being black-cattle, sheep, swine, salted provisions, grain, flour, butter, eggs, and linen. The trade with the colonies and foreign countries is comparatively inconsiderable. The cessation of the collection of the duties on the cross Channel trade, which took place in 1825, has taken away the means of estimating the amounts of imports and exports to and from Great Britain since that period. The total 'Declared real value of British and Irish produce exported direct to foreign countries from Ireland,' from 1866 to 1883, was as follows: (1866) £194,204; (1867) £283,266; (1868) £350,766; (1870) £213,685; (1883) £863,877.

From Dublin, Belfast, and Cork, these values were as follows:

Years.	Dublin.	Belfast.	Cork.
	£	£	£
1866	27,835	18,382	110,703
1867	39,751	7,374	156,644
1868	50,844	7,056	160,202
1882	116,400	725,079	11,795
1883	77,827	777,787	8,263
1884	106,541	640,793	....

Total Foreign Colonial and Coasting Trade.—Number and tonnage of sailing and steam vessels entered inwards and cleared outwards at ports of Ireland, in the coasting, colonial, and foreign trades (distinguishing British from foreign vessels), in the year 1881: Entered inwards—British, 31,129 vessels, 6,445,849 tons; Foreign, 632 vessels, 307,591 tons. Cleared outwards—British, 29,997 vessels, 6,319,155 tons; Foreign, 589 vessels, 295,350 tons.

TOTAL VALUE OF IMPORTS INTO IRELAND FROM FOREIGN COUNTRIES AND BRITISH POSSESSIONS ABROAD, AND EXPORTS FROM IRELAND TO FOREIGN COUNTRIES AND BRITISH POSSESSIONS ABROAD, 1868–1870.

GOVERNMENT—ADMINISTRATION.

For civil and other purposes, the island is divided into 4 provinces—Ulster, Leinster, Munster, and Connaught—which are subdivided into 32 counties, and these, again, into baronies, hundreds, and other minor sections. The following table shews the population of the counties and provinces of Ireland, according to the census of 1881 :

Leinster—	
Carlow	46,508
Dublin	418,152
Kildare	76,102
Kilkenny	99,064
King's	72,668
Longford	60,790
Louth	78,228
Meath	86,301
Queen's	72,598
Westmeath	71,513
Wexford	123,587
Wicklow	73,679
Total	1,279,190
Munster—	
Clare	141,210
Cork	492,810
Kerry	200,448
Limerick	177,203
Tipperary	199,004
Waterford	113,235
Total	1,323,910
Ulster—	
Antrim	423,171
Armagh	162,823
Cavan	129,008
Donegal	205,443
Down	269,927
Fermanagh	84,633
Londonderry	164,714
Monaghan	102,590
Tyrone	197,233
Total	1,739,542
Connaught—	
Galway	241,662
Leitrim	89,795
Mayo	243,030
Roscommon	131,755
Sligo	110,955
Total	817,197
Leinster	1,279,190
Munster	1,323,910
Ulster	1,739,542
Connaught	817,197
Total	5,159,839

The government of the country, since the Union in 1801, has been incorporated with that of Great Britain. It is represented in the imperial parliament by 28 members of the House of Lords, and 103 of the House of Commons. The executive government is invested in a Lord-lieutenant, assisted by a Privy-council and chief-secretary. The mass of the Irish people have long been bitterly discontented with the administration of the country, and through the majority of their representatives in parliament have demanded 'Home Rule'—local autonomy under a national Irish parliament, meeting in Dublin. In 1885, Mr Gladstone's government intimated their readiness to grant this concession, and introduced a bill giving to Ireland Home Rule in a very wide sense; followed by a bill buying up the rights of Irish landlords in the soil.

Religion.—The dominant religion in Ireland is the Roman Catholic. Up to 1869, the Established Church was a branch of the Church of England. But by act of parliament, passed in that year (32 and 33 Vict. c. 42), the Episcopal Church was disestablished in Ireland. Immediately on the passing of the act, in accordance with its 11th and 12th clauses, the Irish Church Temporalities Commissioners took over all the property which the late Ecclesiastical Commissioners had under their control, and issued forms of claim to be filled up by every clergyman, or other person entitled to receive a continuance of income, or compensation, under the terms of the act. The 19th section of the act provides for the reorganisation of the church; in accordance with which, a clerical synod met in Dublin, on 14th September 1869, to consult on the representation of the clergy in a future general convention of bishops, clergy, and laity. This 'National Synod of the Church of Ireland,' consisting of the provincial synods of Armagh and Tuam, and of Dublin and Cashel, met in St Patrick's Cathedral, Dublin, and closed its session on 16th September. It was resolved 'that this synod deems it its duty to place upon record a declaration that it is now called upon not to originate a constitution for a new communion, but to repair a sudden breach in one of the most ancient churches of Christendom.' A meeting of laymen was subsequently held in Dublin, with a view to passing regulations as to the representation of the laity in the general synod of the church. It was resolved that, in the opinion of the meeting, 'the clerical and lay representatives should sit and discuss all questions together in the general synod, with the right to vote by orders, if demanded by three of either order present at the meeting.' A resolution was also carried, affirming the expediency of fixing the number of lay representatives in the general synod in the proportion of two to one of the clergy. On the second day of the meeting, it was resolved 'that the dioceses should be divided into three groups, and allotted a representation as follows: Down, 71; Armagh, 72; Dublin, 59; Derry, 36; Kilmore, 34; Cork, 38; Ossory, 36; Tuam, 19; Meath, 23; Killaloe, 19; Limerick, 19; Cashel, 20—total, 446.' It was also resolved that 'no test be required of the electors in any parish, district, or congregation, except the declaration that they are residents in the parish, or members of the congregation, and members of the Church of Ireland, and twenty-one years of age.' The general convention assembled to legislate on church matters on 15th February 1870. It was resolved that 'no question shall be decided except by a majority of the bishops present, and a majority of the clerical and lay representatives present, whether voting conjointly or separately, provided always, that when any motion has been

carried by a majority of each of the other orders present, and voting, it shall pass, unless seven at least of the existing bishops be present, and shall concur in a dissentient vote.' The mode of election of bishops and ministers was decided by this meeting of general convention. The accounts of the Church Temporalities Commissioners for the year 1871, and for the period from 26th July 1869 (the commencement of the commission) to 31st December 1871, shew that the expenditure has exceeded the available funds to so great an extent, that at the close of the account, the advances made by the Commissioners for the Reduction of the National Debt amount to £3,000,000; and a further sum of £1,543,454, 1s. stands as commutation money on credit to the representative church body; leaving, after deduction of money assets, a net liability, at 31st December 1871, of £3,938,462, 4s. 6d. standing as a charge against the proceeds to be hereafter derived from the sale of church property. The amount of commutation money paid (including bonus where payable) in respect of claims investigated up to February 1873, is as follows:

Archbishops, bishops, and incumbents	£5,561,877 16 1
Curates	1,724,710 7 5
Nonconformist ministers	613,821 14 5
Diocesan schoolmasters, clerks, sextons, &c.	359,264 1 10
Total	£8,259,673 19 9

The Roman Catholic hierarchy consists of four archbishops and twenty-four bishops. The clergy are supported solely by the voluntary contributions of their congregations, paid mostly by fees for marriages, baptisms, and other religious ceremonies. The bishops are nominated by the pope, the parochial clergy by the bishops. The number of priests in Ireland, in 1853, was 2291—of whom 1222 were educated at Maynooth College—in 1881, there were 3155. The curates of the parish priests form more than half of the whole clerical strength, and scattered through the cities and towns are 70 or 80 communities of priests of various religious orders and rules, called *Regulars*, who minister in their own churches, and, though without parochial jurisdiction, greatly aid the secular clergy. All the places of public worship are built from funds collected or bequeathed for the purpose. There are numerous monasteries and convents; the latter are supported partly by sums, usually from £300 to £500, paid by those who take vows in them, and partly by fees paid for the education of children. Various communities of monks and nuns devote themselves to the gratuitous education of the poor. Candidates for clerical ordination, formerly obliged to go to continental colleges for education, are now educated at home. The principal college is the Royal College of St Patrick, Maynooth. Formerly, it had a grant of £26,000 a year from the consolidated fund; this has been commuted for a payment of £372,331.

The Presbyterians are mostly in Ulster. The General Assembly is the supreme Presbyterian ecclesiastical court in Ireland, as in Scotland. The *Remonstrant Synod of Ulster* was formed in May 1830, by the separation of seventeen ministers, with their congregations, from the general synod of Ulster. The *Reformed Presbyterian Synod of Ireland* is unconnected with the General Assembly.

Education.—The university of Dublin is a college incorporated by charter or letters-patent 34 Eliz. (1591). The corporation at present consists of a provost, 7 senior fellows, 26 junior fellows, and 70 scholars. The course of general instruction extends over four years, the principal studies of each year being successively mathematics, logic, natural history, philosophy, astronomy, and ethics. A medical school has been long attached to the university, to which has been lately added a school of civil engineering; and degrees and licences in surgery and civil engineering are granted by the university senate, on the completion of the prescribed courses. The college has a fine library of about 160,000 volumes and 1700 MSS. The number of printed volumes is increased by about 1500 annually, partly purchased, and partly obtained under the Copyright Act.—*Queen's Colleges.* Under the Act for establishing new colleges in Ireland, charters were, in 1849, granted to three colleges, called Queen's College, Belfast; Queen's College, Cork; and Queen's College, Galway; and statutes issued for their government. New charters, amending the former ones, passed the Great Seal in 1863. Candidates for the degree of Bachelor in Arts attend the Queen's Colleges for three sessions, and undergo two examinations in the Queen's University. They have also to pass the college entrance examination, and college examinations held at the close of each session.—*Queen's University.* In 1850, the Queen founded a university, to be called 'The Queen's University in Ireland,' to which these three colleges were subordinate. The Queen's University was superseded in 1880 by a new foundation, the *Royal University.*—*The Royal College of Science for Ireland* was established under the authority of the Science and Art Department, London, in August 1867, in place of the Museum of Irish Industry, Stephen's Green, which then ceased to exist.—*Maynooth College* was founded in 1795 by an Act of the Irish parliament. The ordinary course of study extends over eight years. After its completion, students are considered fit for the duties of the sacred ministry; and those who have taken the highest honours during their course are selected for the Dunboyne establishment—founded by the late Lord Dunboyne, and of the value of £460 a year—on which they continue their studies for three additional years. The number of students that completed their education at Maynooth College from 1845 to 1861 inclusive, was 875. The Dunboyne establishment, temporarily closed in 1872, was soon re-opened. —*Roman Catholic University.* The synod of the Roman Catholic prelates which was held at Thurles in 1850, resolved to establish a university, and appointed a committee to make arrangements. The synodal meeting held in Dublin in May 1854, formally established the university. The schools were opened on November 3, 1854. The university has no endowment or settled property, and depends wholly for its maintenance on voluntary contribution. Collections are made annually on the 3d Sunday of November. The receipts up to December 1, 1881, were £250,000. In accordance with a resolution of the Roman Catholic prelates, at their meeting in October 1873, a considerable number of Roman Catholic colleges throughout Ireland have been affiliated to the university, and their students admitted to certain of its privileges.

—*General Assembly's Theological College*, Belfast. The majority of Irish Presbyterian ministers are educated in this institution. Previous to the passing of the Irish Church Act in 1869, six professors were maintained by a parliamentary grant of £1750 a year, leaving £250 for expenses of management. On the passing of the act, government granted £43,976 as compensation for withdrawal of the annuity; and the interest of this sum, with the interest of £5000 raised by subscription, with the fees of the students, constitute the annual income of the college.—*The Magee College, Londonderry*, was opened on October 10, 1865. It was endowed in 1846 with £20,000, by Mrs Magee, widow of the late Rev. William Magee, Presbyterian minister of Lurgan. The Irish Society have granted an annual endowment of £250 to the chair of Natural Philosophy and Mathematics, and £250 for five years towards the general expenses of the college. The Rev. Richard Dill, who died in 1858, bequeathed £5000 to establish two Professorships, and £1000 for two Bursaries; also his books and the rest of his property, worth about £5000 more. No religious test is prescribed to students either on entering or on graduating; but the professors are required by the General Assembly to sign the Westminster Confession of Faith.—*The College of St Columba*, near Dublin, was founded for the purpose of establishing, under the management of a collegiate body, a system of instruction preparatory for the university.

National Schools.—In 1831, grants of public money were made for the education of the poor, and intrusted, under the Lord-lieutenant, to 'the Commissioners of National Education.' In 1845, the Commissioners were incorporated, under the title of 'The Commissioners of National Education in Ireland,' and adequate powers conferred on them. The principles on which they act are: that the schools shall be open to Christians of all sects; that no pupil shall be required to attend any religious exercise, or to receive any religious instruction, which his parents or guardians do not approve of; and that sufficient opportunity shall be given to the pupils of each religious persuasion to receive separately, at appointed times, such religious instruction as their parents or guardians think proper. The following table exhibits the growth of the system since 1833:

Years.	No. of Schools.	No. of Pupils.	Parliamentary Grant.
1833.....	789	107,042	£25,000
1843.....	2912	355,320	50,000
1853.....	5023	550,631	182,073
1863.....	6163	840,569	306,016
1873.....	7160	974,696	542,222
1881.....	7648	1,066,259	729,868

Number of pupils of each religious denomination on the rolls of the National Schools on 31st December 1881: Protestant Episcopal Church of Ireland, 101,401 (9·5 per cent.); Roman Catholic 841,184 (78·9 per cent.); Presbyterian, 113,242 (10·6 per cent.); other persuasions, 10,432 (1 per cent.).

ANTIQUITIES, ETC.

Tumuli or cairns, dolmens and cromlechs, are common to Ireland, with the neighbouring island and other parts of the world (see the No. on ARCHÆOLOGY). One of the most remarkable 'chambered' cairns known is that at New Grange, on the banks of the Boyne, near Drogheda, in Ireland. It is 400 paces in circumference, and about 80 feet high, and is supposed to contain 180,000 tons of stones. In 1699, it was described by Edward Llhwyd, the Welsh antiquary, as 'a mount or barrow, of very considerable height, encompassed with vast stones, pitched on end, round the bottom of it, and having another, lesser, standing on the top.' This last pillar has disappeared; of the outer ring of pillars, ten still remain, placed at about ten yards one from another. 'The cairn,' says Mr Wakeman in his *Archæologia Hibernica* (Dublin, 1848), 'in its present ruinous condition, presents the appearance of a grassy hill partially wooded; but, upon examination, the coating of earth is found to be altogether superficial, and in several places the stones, of which the hill is entirely composed, are laid bare. The opening [which is nearly square, and lined by large flags] was accidentally discovered about the year 1699. The gallery, of which it is the external entrance, communicates with a [dome-roofed] chamber or cave nearly in the centre of the mound. This gallery, which measures in length about 50 feet, is, at its entrance, 4 feet high; in breadth about 3 feet. Towards the interior, its size gradually increases; and its height, where it forms the chamber, is 18 feet. The chamber is cruciform, the head and arms of the cross being formed by three recesses—each containing a basin of granite. The sides of these recesses are composed of immense blocks of stone, several of which bear a great variety of carving, supposed by some to be symbolical. The majority of these carvings must have been executed before the stones had been placed in their present positions. The length of the passage and chamber from north to south is 75 feet, and the breadth of the chamber from east to west 20 feet. Of the urns or basins in the recesses, that to the east is the most remarkable. It is formed of a block of granite, and appears to have been set upon, or rather, within, another of somewhat larger dimensions.' The Irish antiquaries believe that the chambered cairn of New Grange—'the Cave of Achadh Aldai,' as it was called, from Aldai, the ancestor of the Tuatha De Danaan kings—was opened and rifled by the Norsemen in 862. About a mile from it, on either side, are other two cairns of nearly equal size, named Knowth and Dowth. The latter was opened in 1847, and found to contain a gallery, a cruciform chamber, a basin or sarcophagus, and carved stones, all of the same type as those of New Grange.

Amongst the earliest and peculiar antiquities of Ireland, are the low *Stone-roofed Buildings*, with high wedge-shaped roofs: of these, a few still exist at Kells, Kildare, Ardmore, and Killaloe. The most remarkable relics of the olden times of Ireland are the lofty *Round Towers*, of which, perfect and imperfect, 118 have been enumerated in various parts of the kingdom. They are built with a wonderful uniformity of plan. They are all circular, of small diameter, and great altitude. Of the excellence of the masonry, a proof was given by the Tower of Mahera, which, in consequence of having been undermined, was blown down, and lay, at length and entire upon the ground, like a huge gun, without breaking to pieces, so

wonderfully hard and binding was the cement with which it had been constructed. Various theories have been offered as to the purpose for which these mysterious buildings were erected; the only clear point seems to be, that they are religious edifices erected during the earlier centuries of Christianity in the island. They vary in height from 35 to 120 feet; the internal diameter from 10 to 16 feet, and the outer circumference from 46 to 56 feet. Their tapering shape forms one of the most marked characteristics.

Ecclesiastical Antiquities.—Under this head rank those buildings which may be considered as the most ancient, after the pagan remains, and which bear a peculiar character, differing from that of any extant elsewhere. Of these but few are now in existence. The stone-roofed church of St Doulagh's, near Dublin, belongs to the earliest date; its plan and style are equally uncommon. The latter seems to have been a rude approach to the oldest Norman; it is low, and of great strength; the church, divided by a low-browed arch, seems to have had a small choir and a somewhat larger nave. There are also, strangely disposed, at various heights, small chambers, apparently for the residence of the clergy. A part of the building is used as the parish church; and the old tower has borne the addition of a belfry, so excellent was the mason-work. The beautiful and curious ruin at Cashel, called *Cormac's Chapel*, is Norman in character, and was probably the cathedral of that diocese previous to the English invasion. It is considered to have been built in the tenth century by Cormac, who was both king and archbishop. He died about 990 A.D. It is to be observed that both here and at St Doulagh's are crypts placed *over* the churches—a peculiarity known in Ireland only; the crypts in all other countries being underneath. Ireland cannot boast of any ecclesiastical buildings of great richness or beauty; but there are some of respectable appearance. The two cathedrals of the capital, St Patrick's (recently restored by private munificence) and Christ-Church (presently being restored), are at least elegant in the interior. The large cathedral of Galway, and that of Limerick, are both handsome buildings, as is the cathedral of Kilkenny. These are all in good order, and in daily use. There are numberless ruins of monasteries, abbeys, knights' preceptories, and churches.

Military Antiquities.—The traveller in Ireland must be struck with the vast number of small castles which stud the whole country. They chiefly bear date about the reign of Elizabeth, by whose orders they were raised, as strongholds to overawe the wild Irish. They are usually high and square, with towers at each corner. Besides these fortalices, there are ruins of very large castles, so customarily attributed to King John as to shew that they were built in the early times; of these, the extensive ruin at Trim, in the county of Meath, affords a fair example, as being one of the largest, and often formerly the residence of the viceroy or chief-governor. Parliaments were held within its walls, and money minted there, and sent into circulation. A few of the ancient castles belonging to the old nobility still continue to be inhabited, as *Malahide*, belonging to Lord Talbot de Malahide; and *Howth*, the Earl of Howth's, both in the county of Dublin; *Shanes Castle*, the residence of Earl O'Neil; *Portumna Castle*, on the Shannon, that of Lord Clanricarde; and *Kilkenny Castle*, the seat of the Marquis of Ormond.

THE PROVINCES—LEINSTER.

This is the largest province of Ireland, and contains the twelve counties of *Louth*, *Meath*, *Dublin*, *Wicklow*, *Wexford*, *Carlow*, *Kilkenny*, *Kildare*, *Queen's County*, *King's County*, *Westmeath*, and *Longford*, the whole forming a large tract of country on the east side of the island, and having Dublin at a central point on the coast. The scenery of Leinster is much varied. The county most remarkable for picturesque beauty is that of Wicklow, a short way south of Dublin; the hills, glens, and valleys are here rich in natural wood, and, bounded by an extensive prospect of the ocean, can hardly be exceeded in beauty. The principal points of attraction for tourists are Lough Bray; a woody ravine called the Dargle; and the Vale of Avoca, which is one continuous piece of silvan pleasure-ground. Wexford, still farther south, may also, to a considerable extent, be described as a picturesque and fertile county; and though the county of Meath is for the most part flat and tame, except along the banks of the Boyne and Blackwater, it can boast there of some spots of redeeming beauty; and in a large portion of the county, the quantity of wood and the rich hedgerows give an English character to the landscape. Westmeath is remarkable for expansive lakes, and for the dry gravelly hills which give variety to its surface. The Queen's County, though a good deal disfigured by bog, yet boasts, at Abbeleix and Dunmore, of a great stretch of magnificent natural oak-wood. The remaining part of Leinster cannot be considered interesting or peculiar in its general features.

Leinster may be considered as much superior to the other provinces with respect to agriculture; and some parts of Carlow, Kildare, and Wexford, are cultivated in a manner approaching in skill to that of the agricultural districts of England and Scotland.

The counties of Wicklow and Wexford contain an industrious and thriving population; and because industrious, the people are able to pay, from soils not superior to those of other districts, rents which would be intolerable in other parts of Ireland. The Wicklow peasantry are reckoned the finest in the world, and are proverbial for their handsome features and fine Roman profiles, and still more so as being a respectful, quiet, and well-conducted people. The county of Meath is remarkably fertile. Leinster may altogether be pronounced a prosperous part of the country.

Chief Towns.

The chief towns in Leinster are *Dublin*, *Kilkenny*, *Drogheda*, *Wexford*, *Maryborough*, *Mullingar*, *Carlow*, *Birr* or *Parsonstown*, and *Trim*.

Dublin, the principal town in Leinster, and the capital of Ireland, is situated at the margin of a beautiful bay, on a generally flat piece of country, through which flows the river Liffey, and is therefore conveniently placed for commerce and the accommodation of a large population. In external

aspect, it is essentially an English town, being built of brick in a neat and regular manner, but abounding in a class of elegant public structures of stone, which resemble the more substantial embellishments of Paris and other continental cities. The river, flowing from west to east, divides the city into two nearly equal portions, and is a striking feature in the general plan. The aristocratic parts of Dublin are the south-east and the north-east, containing many beautiful squares, streets, and terraces. The centre and north-west are the commercial quarters of the town. The south-west division, part of which is called the 'Liberties'—once the seat of the silk-trade—is the most foul and degraded quarter; there the streets are narrow, crooked, and irregular. The city is surrounded by a 'Circular Road,' nearly nine miles long, forming a favourite walk and drive of the inhabitants. In the newer parts of Dublin the streets run at right angles to one another, and are remarkable for their breadth and for the uniformity of their architecture, which is, however, not monotonous. The most imposing one is Sackville Street. It is 120 feet broad, and nearly 700 yards long. At its north end stands the Rotunda, with Rutland Square; in its centre the beautiful Ionic portico of the General Post-office and Nelson's Monument, upwards of 130 feet high; on the south, it is terminated by Carlisle Bridge, and a wedge-like block of handsome houses formed by the converging sides of Westmoreland and D'Olier Streets. The squares of Dublin are numerous and well kept, and especially spacious. Stephen's Green, the largest, is about 20 acres in area, and about a mile in circuit. The environs of Dublin are especially beautiful. Rathmines, a southern suburb, has become a large town, and is the favourite residence of the wealthier part of the community. Glasnevin, on the north, was the favourite residence of Addison, Steele, Parnell, Swift, Sheridan, and many other celebrated men. In its cemetery are buried Curran, O'Connell, and Tom Steele. The Phœnix Park is a magnificent area of nearly 2000 acres, in some parts level, in others with broken ground, with many trees and much brushwood, which shelter immense herds of deer. It affords ample scope for military reviews, and is much used for recreation-ground by all classes. Dublin, as a whole, with its magnificent bay, splendid park, massive public buildings, wide streets, spacious and well-kept squares, clean and elegant quays, and beautiful environs, is one of the handsomest and most pleasing capitals of Europe. The residence of the Lord-lieutenant brings to the city many of the Irish aristocracy and county families; thus preserving to the town the character of a capital. The population was, in 1871, 267,717; in 1881, 249,602 (parliamentary, 273,282). The university of Dublin was founded in 1591–92. Its position is that of a college with university powers. Its income was very limited and precarious, till James I. endowed it with certain estates in the province of Ulster, and with a yearly pension of £388, 15s. from the public purse. Scholarships, tenable for five years, are open to competition; some being given for classical, others for scientific, proficiency. The various emoluments of a scholar, arising from salary, remission of fees, rooms, commons, &c. amount to about £50 a year. There are also minor scholarships for the encouragement of the study of divinity and of the Irish language; others are connected with the royal and endowed schools. In 1859, fourteen studentships were founded, worth £100 a year each, tenable for seven years, to encourage graduates in the pursuit of some special study, on which they may afterwards be called to teach, should they become fellows and lecturers. Two are given every year, and are open to persons of all religious denominations. The provost and senior fellows are the electors, There are four grades of students. 1. Noblemen, sons of noblemen, and baronets, who have certain special privileges; the first two being allowed the degree of B.A. *per specialem gratiam.* 2. Fellow-commoners, who obtain degree with one examination less than pensioners, and who dine at the fellows' table. 3. Pensioners, who form the great body of the students. 4. Sizars, who have rooms and commons free. The sizars are limited to thirty. They are elected by competitive examination, and hold their sizarship, worth about £37 a year, for four years. Each rank has a dress peculiar to itself. For entrance and first half-year, the fees are — noblemen, £60; fellow-commoner, £30; pensioner, £15; sizar, £5, 1s. 3d. Other half-years, £33, 12s.; £16, 16s.; and £8, 8s.—the sizars being exempt. This does not include rooms and commons. The university of Dublin is well equipped for educational purposes. The teaching staff is numerous; the tutorial and professional elements being more largely combined in it than in any other British university. The names of Swift and Goldsmith, Sheridan, Curran, and Burke, with a host of others famed in literature and politics, shed a lustre on the university, of Dublin.

Kilkenny, the capital of the county of the same name—and forming, with a rural district of 26 square miles, a county of a city—situated on the river Nore, was formerly a town of great consequence, as its ancient castle, the ruins of its embattled walls, and churches, testify. At one time, it carried on a considerable trade in the manufacture of woollen cloths and blankets; but these branches have in a great degree fallen off, and the business is now confined to the retail of necessaries for its inhabitants, and the sale of the agricultural produce of the district. The city contains several good streets, which are respectably inhabited, both by private families and tradesmen; but the suburbs are miserable. The most conspicuous ornament of the city is the fine baronial castle of the Marquis of Ormond, full of historical associations, rising boldly over the Nore. The Cathedral of St Canice, built in 1202, is not excelled by any of the ancient ecclesiastical buildings in the kingdom, except St Patrick's and Christ-Church in Dublin. The town possesses a number of respectable schools, and various asylums and other beneficiary institutions. Near the town, there is a marble quarry of considerable local importance. The population in 1871 was 15,609, and in 1881, 15,278.

MUNSTER.

Munster contains six counties—*Clare*, *Cork*, *Kerry*, *Limerick*, *Tipperary*, and *Waterford*—and may be considered as that part of Ireland in which the national character and the national habits of all kinds are maintained in their greatest purity. The

province contains many tracts of beautiful scenery, and one in particular which is allowed to be unequalled in the kingdom—the celebrated lake-district at Killarney.

The *lakes of Killarney* are in the mountainous county of Kerry. They are annually visited by travellers from all parts of the island, as well as from neighbouring countries. There are three of them, of unequal size, and of varied, though generally mountainous scenery. Lough Lane, or the Lower Lake, by far the largest of the three, is skirted on one side by the level and well-cultivated country surrounding the pleasant village of Killarney; on the other side rise the Glena and Tomies Mountains. In this lake there are a number of wooded islands, one of which contains the ruins of an abbey, and another the remains of an ancient castle. On the shore, towards the east, is the beautiful ruin of Muckross Abbey. Divided from the Lower Lake by the fine wooded promontory of Muckross, but accessible by two channels of level water, is the Middle Lake, called also Turk Lake, from the name of the mountain at whose foot it reposes. These two sheets of water are beautified by their wooded islands; by irregular promontories and slopes, also generally wooded, which surround them; and by the mountains towering over them in sterile grandeur, down whose sides streams are flashing in foaming cascades. The Upper Lake, the third of the series, is three miles apart from the middle one, on a higher level, and totally embosomed amidst the hills. A stream descending from the one to the other can be passed in a boat; and at a particular place on the passage, it is common for tourists to have a bugle played, in order to enjoy the oft-repeating echoes which it awakes in the neighbouring hills. The Upper Lake, having the wooded heights of Dericunighy on one side, the round-headed Purple Mountains on the other, and at the head, the bare many-coloured ridge of Macgillicuddy Reeks, while the surface is broken by a variety of silvan islets, presents a landscape of enchanting loveliness. In connection with the lakes, there is a narrow rugged vale named Dunloe, which is usually taken in by a tourist in a survey of this fine scenery.

Amongst other beautiful places in Munster are —Glengarriff, a rugged and most picturesque vale near the head of Bantry Bay; the banks of the Blackwater, between Lismore and Youghal; the river Lee, below Cork, and the fine natural harbour (*the Cove of Cork*) in which it terminates; and the lofty iron-bound coasts of Clare, amidst which are some scenes of uncommon grandeur.

The soil in the southern parts of Limerick and Tipperary is perhaps not inferior in fertility to any portion of Europe. The Corkass lands of the former, and the Golden Vale of the latter, are celebrated for their extraordinary richness. These districts are chiefly appropriated to the feeding of black-cattle. Wheat is cultivated throughout the limestone districts of Tipperary, Clare, and Limerick, while dairy-farming is followed in the mountain districts of Kerry and Waterford. The potato-culture necessary to supply the wants of an over-dense population, is pursued throughout the whole province; and it is a deplorable fact, that a large portion of that population have no other food during the greater part of the year. Cork is the great butter-country of Munster.

Chief Towns.

The leading towns of Munster are *Cork*, *Limerick*, and *Waterford*. The name *Cork* is derived from the Irish word *Corcah*, which signifies a marsh. This city, the third in importance in Ireland, stands on the river Lee, 11 miles inland from the entrance of the river into Cork Harbour. The river divides at the city into several branches, and forms an island, on which part of the city stands. The Lee is navigable to about a mile above the city. The harbour commissioners have spent above £300,000 within the last 25 years on the improvement of the navigation. The extent of the quays is now above four miles, and ships of 600 tons reach them. The harbour, noted for its size and safety, is a basin of ten miles square, formed by the estuary of the Lee. It could contain the whole British navy, and has been the main source of the rise and progress of the city. The entrance is by a channel two miles by one, defended by batteries on Spike, Hawlbowline, and Rocky Islands, which are occupied by convict and ordnance depôts, artillery barracks, and a powder-magazine. On the shores of the estuary are the towns of Passage and Queenstown, formerly Cove of Cork. In 1880, 2880 vessels, with a total tonnage of 728,556, entered the port; and 2526, of 649,722, cleared. The exports are valued at several millions sterling yearly. The population in 1871 was 100,518 within the parliamentary limits, and in 1881, 104,496. Nine-tenths of them are Roman Catholics. Cork grew up round an abbey, founded in the year 600 by St Finbar. The Danes in the 9th century built the city walls. Dermod Maccarthy, king of Cork, surrendered it to Henry II. in 1172. Cromwell besieged and took it in 1649; and it was taken by Marlborough in 1688. In Cork, William Penn, the founder of Pennsylvania, became a Quaker, with several of the soldiers of the republican garrison.

Speaking of Cork, Thackeray says: 'I have said something in praise of the manners of the Cork ladies; with regard to the gentlemen, a stranger too must remark the extraordinary degree of literary taste and talent amongst them, and the wit and vivacity of their conversation. . . . The Cork citizens are the most book-loving men I ever met. The town has sent to England a number of literary men of reputation too, and is not a little proud of their fame. . . . I think, in walking the streets and looking at the ragged urchins crowding there, every Englishman must remark that the superiority of intelligence is here, and not with us. I never saw such a collection of bright-eyed, wild, clever, eager faces.'

Limerick, the chief city of the west of Ireland, is situated on the Shannon, near the place where that noble river expands into an estuary. It consists of the Old and New Town, respectively situated on the north and south sides of the river, which is crossed by five bridges, one of them—the Wellesley Bridge—a magnificent structure. The division of the New Town or Irish-town, called Newtown Perry, is considered one of the most elegant towns in Ireland; but the Old Town is confined, dirty, decayed, and inhabited by a very miserable population. Limerick has a handsome cathedral of some antiquity, situated in the old part of the city, five Episcopal churches, meeting-houses belonging to the Presbyterians,

Independents, and the Society of Friends, with five Roman Catholic chapels, three friaries, and one nunnery. There are the usual public civic buildings, some of them handsome edifices. The charitable institutions are numerous.

The manufacture of linen, which had nearly expired, has revived; that of gloves has long been important, as well as that of lace and of fish-hooks. Distilling, brewing, tanning, and ship-building are other branches of Limerick industry. The population in 1871 was 49,980; and in 1881 it was 48,670, of whom 45,000 were Roman Catholics.

Waterford, the chief town of the county bearing its name, and a large seaport, is situated on the Suir, several miles from its junction with the sea. Vessels of 800 tons can discharge at the quays, one of the finest ranges in the United Kingdom. The population in 1871 was 29,250; in 1881, 29,181, of whom 26,000 were Roman Catholics.

ULSTER.

The most northerly province is Ulster, containing the counties of *Antrim*, *Armagh*, *Cavan*, *Donegal*, *Down*, *Fermanagh*, *Derry*, *Monaghan*, and *Tyrone*. The province of Ulster is hilly. The scenery is in general picturesque, especially in the vicinity of its chief towns, Derry, Belfast, and Armagh. In the county of Antrim, the country from Glenarm to Bengore Head presents a succession of striking and romantic views. The most remarkable feature of this scenery is the peculiar conformation of the basaltic columns with which it abounds, and of which the arrangement is strikingly displayed in Fair Head and the *Giants' Causeway*. Bengore, one of the promontories of the Causeway, lies about seven miles west of the little town of Ballycastle: though generally described as a single headland, it is composed of many small capes and bays, each bearing its own proper name, and of these capes the most nearly perfect is *Pleaskin*. The summit of Pleaskin is covered with a thin grassy sod, which lies upon the rock, the surface of which is cracked and shivered. About ten or twelve feet from the top, the rock begins to assume a columnar character, and standing perpendicularly to the horizon, presents the appearance of a magnificent colonnade, supported on a foundation of rock nearly sixty feet in height. About eight miles from Pleaskin is *Fair Head*, the easternmost head of the Causeway, which presents a huge mass of columnar stones, of coarse texture, but many of them more than 200 feet in height. Some of these gigantic stones seem to have fallen from the top, and now present to the eye of the spectator the appearance of groups of artificial ruins. The part which may more properly be called the *Giants' Causeway* is a kind of quay projecting from the base of a steep promontory some hundred feet into the sea: it is composed of the heads of pillars of basalt, which are placed in close contact with each other, forming a sort of polygonal pavement, somewhat like the appearance of a solid honeycomb. The pillars are jointed, and their articulation curiously exact, the convex termination of one joint always fitting with precision into a concave socket in the next.

The soil of Ulster varies much. In the counties of Armagh, Down, Antrim, Derry, and Monaghan, it passes from a deep rich fertile clay to a dry sandy or gravelly loam; while in Donegal, Tyrone, Fermanagh, and Cavan, a great proportion of it is cold, wet, and spongy. Tillage is, in general, in an improved state throughout this province; and though the old Irish plough and the slide-car are still occasionally used in the remoter parts, many of the modern implements of husbandry have been introduced, especially in Down and Londonderry. The corn-crops most general are oats, bere, barley, and a small proportion of wheat. Barley is in Derry said to pay the summer's rent, and flax the winter's. Potatoes are largely planted by rich and poor, and gentlemen-farmers cultivate turnips and mangel-wurzel. Lime and peat are the most usual ingredients of the manure employed in the inland districts; while in the maritime counties, sea-sand, sea-weed of different sorts, and various kinds of shells pulverised, are used in addition. From the wetness of the soil, in some of the northern parts of Monaghan, the manure is usually carried to the fields in baskets called *bardocks*, which are slung over asses' backs, or the shoulders of the poor women.

Whatever were the manufactures of Ireland before the time of James I. they were swept away in the long series of wars between government and the local chieftains in the days of the Tudors; and the Scottish settlers in the north of Ireland, and those English whom Boyle, Earl of Cork, brought into Munster, may be considered the introducers of nearly all the manufactures that now exist in Ireland. During the reigns of Charles I. and II. much attention was paid to them; and the exertions of Lord Strafford, Sir William Temple, and the Duke of Ormond, caused the establishment of the linen trade to be attributed successively to each. The Duke of Ormond not only procured several acts for its encouragement, but sent Irishmen to Flanders to be instructed in the details of the flax manufacture; he also established a linen-factory both at Chapelziod, near Dublin, and at Carrick-on-Suir. In the reign of William III. the linen business rose to still greater importance, from the compact between the English and Irish merchants to discourage the woollen and promote the linen trade; for which purpose they contrived to get an act passed, levying additional duty on Irish woollen goods, from a jealous fear that the prosperity of the Irish woollen trade was inconsistent with the welfare of that of England. Another impetus was given to the linen trade by the emigration of the French manufacturers, after the Edict of Nantes, of whom a large number took refuge in Ireland; and Mr Louis Cromelin, a leading manufacturer, obtained a patent for improving and carrying it on, and his efforts were crowned with considerable success. In the ninth year of Queen Anne, a Board of linen and hempen manufactures was established, and linen allowed to be exported duty free. In the 8th of George I. a grant was given to build a linen hall, and another to encourage the growth of flax and hemp. Previous to 1778, bleached linen was sold in the fairs, the manufacturer being the bleacher; but when the manufacture extended, bleaching became a separate business. Considerable sums had been from time to time voted by parliament for its support; and during the eighteenth century, the trade continued to advance, until the check it received during the American war. On the re-establishment of peace, it revived, and though deprived of all artificial props, in the form of

bounties, is now a flourishing department of industry. Belfast is the great centre to which the linens, not only of Ulster, but also of the weaving districts in the west of Ireland, are sent for sale. The province of Ulster was also the seat of the first cotton-manufactory introduced into Ireland, and Belfast continues to take the lead in that branch of industry.

Speaking of Ulster generally, it may be said the lower classes have more self-respect, more industry, more desire for advancement in life, than in other parts of Ireland. In fact, they are a better educated, and therefore a more improving people. As may be expected, their taste for comfort operates in the economy of their houses and farms; and except in the mountainous districts above alluded to, where old habits still maintain their ground, the Ulster peasantry may be considered as a respectable class in society. The river-fisheries, though less productive than under better management they might have been, yet form in several parts of Ulster a lucrative property. The lakes and rivers abound with trout, pike, perch, eels, and char; and on the Bann, the Foyle, and the Ballyshannon in Donegal, are established very successful salmon-fisheries.

Chief Towns.

The chief towns in Ulster are *Belfast* and *Antrim*, in the county of Antrim; *Londonderry* or *Derry* and *Coleraine*, in the county of Londonderry; *Donegal*, in the county of the same name; *Strabane*, in Tyrone; *Armagh*, in Armagh; and *Newry*, *Lisburn*, and *Downpatrick*, in the counties of Antrim or Down. Without reference to counties, Belfast, Lisburn, Newry, Armagh, and some places of smaller note, may be said to form a cluster of towns chiefly devoted to the linen manufacture, and all occupied by a population who, for generations, have been noted for their industry and peaceful habits.

Belfast is the principal town and seaport in this province, and the second in importance in Ireland. It is advantageously situated on the west side of the Lagan, where that river swells into an estuary called Belfast Lough; distance from Dublin 85 miles. The ground on which the town stands is flat, while the beautiful and fertile environs on the western side of the vale are bounded by a picturesque range of mountains. The general aspect of Belfast is indicative of activity and prosperity; while there is less dirt and smoke than in most of the English commercial towns. Many of the streets, especially in the White Linen Hall quarter, are well built and spacious. The manufactories are mostly on the rising ground on the north and west of the town. Belfast is the chief seat of the trade and manufactures of Ireland, and is second to Dublin as an Irish port. The staple manufactures are linen and cotton. The linen manufacture dates from 1637. Cotton-spinning by machinery dates from 1777, and linen-spinning by machinery from 1806. The other chief branches of industry are linen and cotton weaving, bleaching, dyeing, calico-printing, and iron-founding. There are many flour and oil mills, chemical works, breweries, alabaster and barilla mills, and saw-mills; there are ship-building yards, and manufactories of rope and sail-cloth. The iron ship-building yard on Queen's Island employs upwards of 2000 men. The inland trade is carried on by the Lagan, by the Ulster Canal, and by three railways. The harbour is undergoing extensive improvements which, when completed, will make Belfast one of the first-class ports of the United Kingdom. Before the recent improvements, there were only two tidal docks; between 1866 and 1872, five new docks and a tidal basin, with about 25 acres of water-area, have been opened. On these, £370,000 have been expended, making the total assets of the commissioners £940,000. The imports of Belfast may be valued at £13,000,000 a year; the exports, at about £12,000,000. In 1880, 9583 vessels, of an aggregate tonnage of 1,804,930 tons, entered the port; and 9338 of 1,859,384 tons, cleared. The most important branch of commerce is the Channel trade. Population in 1821, 37,000; in 1851, 103,000; in 1871, 174,394; in 1881, 208,122; of whom about 70,000 were Roman Catholics. It returns four members to parliament. It was destroyed by Edward Bruce in the 14th century. It has been an important town from early in the 17th century. It received its charter in 1611. In the great civil war the inhabitants first joined the parliament, but afterwards became royalists.

Londonderry ranks next to Belfast, being a seaport of considerable importance. It is situated on the west bank of the Foyle, four miles above the point where that river spreads into Lough Foyle; and is distant 146 miles from Dublin. The original town, built by Sir Henry Dowera about 1603-4, was burned by Sir Cahir O'Dogherty in 1608; and the present city may be considered as deriving its origin from the London plantation, which was the immediate result of that catastrophe. The walls of Derry are described by Pynnar as 'excellently made and neatly wrought; the circuit thereof about 284 perches, and in every place the wall being 24 feet high and 6 in thickness;' and after a lapse of more than two centuries, these fortifications retain their original form and character. The north-west bastion was demolished in 1824, to make room for a market; and in 1826, the central western bastion was modified for the reception of the pillar erected in memory of the Rev. George Walker, governor of the city during the famous siege in 1689; but the guns used during the siege are still preserved in their original places. The total number of cannon remaining in the city and suburbs is about fifty; and in the court-house yard stands *Roaring Meg*, so called from the loudness of her report during the siege. This cannon is 4 feet 6 inches round at the thickest part, and 11 feet long, and is thus inscribed: 'FISHMONGERS, LONDON, 1642.'

The chief of the ecclesiastical buildings is the Cathedral, built by the corporation of London in 1633. This event is recorded in a tablet, which was originally placed over the door of the porch of the old cathedral, but is now over that of the belfry, bearing the following couplet:

> If stones could speak, then London's praise should sound,
> Who built this church and city from the ground.
> A.D. 1633.

There are a dozen other churches in the town, of which six belong to the Presbyterians. The salmon-fishery of Lough Foyle is very productive.

An extensive emigration goes on from this port. The population in 1881 was 29,162, of whom about 15,000 were Roman Catholics.

The city of *Armagh*, situated in an inland part of the country, is of considerable local importance. It is placed in the midst of a rich and beautiful district, the face of which is singularly varied by detached hills, some of which are more than 1000 feet in height. This character of country stretches from Lough Neagh in the north to the north-western part of the county of Meath in the south, and is well watered by lakes and streams, and, generally speaking, richly furnished with wood. The city stands on a hill, which is crowned by the old cathedral, around which the town has gradually arisen. The cathedral has been re-edified, at an expense exceeding £30,000, in the pointed Gothic style, for the most part in very good taste; the organ is a remarkably fine one, and the choir excellent. There is water-carriage from both Belfast and Newry by lake and canal, to within four miles of the city; and the Ulster Railway now connects it with Belfast. In 1841, the population was 10,245; in 1871, 8952; in 1881, 10,070, of whom 5000 were Roman Catholics. Near Armagh stands the Observatory, built and endowed by Primate Robinson, whose munificence greatly contributed to the advance of science and improvement of the whole diocese.

CONNAUGHT.

Connaught, the smallest of the four provinces, contains but five counties, those of *Leitrim*, *Roscommon*, *Mayo*, *Sligo*, and *Galway*. There are in this province large tracts of mountainous and sterile land, especially in the western parts of the counties of Galway and Mayo. The peninsula formed by the western part of the first of these counties is named *Connemara*, and is famed for its scenery, which somewhat resembles that of Argyllshire. Connemara contains a small, scattered, and primitive population, usually full of superstitious and old feudal feelings.

From the high grounds near Westport is obtained a view of Clew Bay, a magnificent sheet of almost inclosed water, full of islands, and bounded by lofty mountains; among which the most conspicuous is Croagh Patrick, which is regarded with superstitious feelings by the peasantry, as the spot where their tutelary saint was accustomed to preach.

Amidst the great tracts of wild ground in Connaught, there are a few other spots of an unusually attractive character. The scenery round Lough Allen, out of which the Shannon flows, is extremely pretty, as is also that near Boyle, at the foot of the Curlew Mountains. At Lough Gill, near Sligo, a lake bearing a strong resemblance to the Upper Lake of Killarney, and the little Bay of Ardnaglass, into which falls the cataract of Ballysedare, are scenes of peculiar beauty. Much of the surface of Galway is flat, shewing, for twenty miles together, a succession of narrow limestone rocks, like parapet-walls of three feet high, placed in parallel lines to each other, at distances of from three to ten feet: the intermediate spaces, though apparently but a waste of rock and stone, supply the finest sheep-pasture in the kingdom.

The agricultural capabilities of the province are great compared with what has yet been made of them; but a considerable change in the proprietary and occupants is infusing a new spirit, and great improvement may be looked for. The culture of flax is on the increase.

There are few manufactures of any kind in the province; and the condition of the peasantry in general is that of poverty. Fishing affords occupation to a considerable number of the population. In some years, the sun-fish, or basking shark, are abundant off the shores of Galway, and much excellent oil is produced; but this fish is so capricious, that the fishery cannot be looked to with any certainty.

Chief Towns.

Galway, reckoned the capital of the west, is situated in a valley lying between the bay which bears its name and Lough Corrib. The town is of considerable antiquity, and consists of streets and lanes huddled together without any regard to comfort or convenience. The whole resembles a Spanish town, the result probably of its early intercourse with Spain; and a small open space near the quay retains the name of *Spanish Parade*. The ecclesiastical buildings are the parish church of St Nicholas, founded in 1320, Presbyterian and Methodist meeting-houses, and three Roman Catholic chapels. There are three monasteries and five nunneries. At the head of the educational institutions may be mentioned Queen's College, opened in 1849. In 1851, communication with Dublin was opened by railway.

The chief manufacture of Galway is flour. There are three foundries, an extensive paper-mill, and several breweries and distilleries in the town. Salmon and sea-fish are abundant. The Bay of Galway, protected by the Arran Isles from the swell of the Atlantic, offers great advantages for foreign trade. The harbour has been much improved; and there is a floating dock of five acres. The exports are agricultural produce, wool, and marble. In 1856, there were fourteen vessels belonging to the port, with a tonnage of 1129. The population, which in 1841 was 32,511, had diminished in 1851 to 20,686. In 1881, it was 19,170, of whom 18,000 were Roman Catholics.

Across the country in a northern direction, and also situated at the head of a bay bearing its name, stands *Sligo*, a town of a much smaller population than Galway, but more important as respects its commerce. There are several handsome public buildings; and the suburbs are beautiful and picturesque. The manufacture of linen is carried on; as also of flour, meal, whisky, and beer. The salmon-fishery is very productive. The vessels belonging to the port in 1856 were 35, with a tonnage of 4352. The population in 1841 was 14,318; in 1881, 10,670. Nine Irish boroughs send sixteen members to parliament.

ASIA.

ASIA—the most extensive, the most diversified, and, so far as the early history of mankind is concerned, the most interesting of the great divisions of the globe—is situated between lat. 1° 28′ and 78° north, and long. 26° and 190° east. It thus occupies the greater portion of the Eastern Hemisphere, and is bounded on the north by the Arctic Ocean; east, by the Pacific; south, by the Indian Ocean; and west, by Africa and Europe—being separated from the former by the Red Sea and the Isthmus of Suez; and from the latter, by the Mediterranean, Black Sea, Caucasus chain, Caspian Sea, and the Ural Mountains. The region thus inclosed lies compactly together, the only irregularities in its bounding outline being that succession of peninsular projections and intervening gulfs which give character to its eastern and southern sea-board. Its greatest length, along the 40th parallel, is 5500 miles; the greatest breadth, from Cape Romania, in the Malayan Peninsula, to North-east Cape, along the 104th meridian, 5300 miles; its area is estimated at upwards of 16,000,000 square miles, or above four times that of Europe.

SUPERFICIAL FEATURES, ETC.

The most striking feature in the surface of Asia is the great table-land of Tibet, which rises between India and Mongolia, like a mountain with a flattened top, spreading out over a space equal to two or three European countries, Tibet has an elevation of 15,000 feet—that of the summit of Mont Blanc—and it is the most extensive, and in every way the most remarkable of the table-lands which exist on the surface of the globe. On the south, its upturned edge forms the Himalaya Mountains, which look down upon the plains of India; on the north, it terminates in the Kuen Lun. Beyond this chain it sinks to a lower table-land—that of Mongolia—which runs north-eastward from Western Tibet to the upper basin of the Amour River, at an elevation of less than 4000 feet. Round these two central table-lands of Tibet and Mongolia, the mountains and other highlands of Asia may be grouped. Eastward, the highlands of Tibet are continued by those of Southern China, which, furrowed and hollowed into great valleys by the rivers which traverse them, have lost the form of a plateau, and assumed that of a mountainous country. Between China and India, there projects, from Eastern Tibet, the highland of Indo-China, which, as it proceeds southwards, splits into a series of mountain chains, running like so many fingers from the back of a hand, and inclosing between them the valleys of Burmah, Siam, Cambodia, and Tonquin. Towards the north-west, the edge of the great Tibetan table-land is continued by the Pamir table-land, a lofty elevation without abrupt descent on either side, described by the people of Central Asia as 'the roof of the world.' It is

connected on the south-west by the Hindu Kush with another table-land, that of Iran, which extends from the Indus to the Greek Archipelago, with an elevation of 6000 feet in Afghanistan, 4000 in Persia, 5000 in Armenia, and from 2000 to 4000 in Asia Minor. Two detached table-lands, above the elevation of 1000 feet, fill the interior of Arabia and Southern India. The mountain-chains of Asia generally run along the edges of the plateaus. The Himalaya include the loftiest mountains of the globe—Mount Everest, 29,000 feet; Kunchinginga, 28,156 feet; and Dhawaligiri, 26,680.

The plains of Asia—by which we mean that part of the surface of the continent lying at an elevation of less than 500 feet above the sea—form a vast expanse in North-western Asia, stretching from the edge of the Iranian table-land, through Northern Siberia, to the Arctic Ocean and Behring Strait. This great plain sinks on the shores of the Caspian to a level below that of the ocean. The other plains of Asia, which lie south and east of the table-lands, are much less extensive, but, lying under a warmer climate, they are of infinitely greater importance. The great plain of China includes the deltas of Yang-tze-kiang, the Hoang-ho, and the Pei-ho; the Indo-Gangetic plain, those of the Ganges, Indus, and Brahmaputra; the Assyrian or Babylonian plain, that of the Tigris and Euphrates.

The *seas*, *bays*, and *gulfs* which indent and intersect the surface of Asia are in noway so remarkable as those which give character to Europe.

The *islands* more immediately connected with Asia are the Liakhov group, in the Arctic Ocean; the Aleutians, in the Sea of Kamtchatka; the islands of Japan; Saghalien, Formosa, Hainan, and Chusan, off the coast of China; Ceylon, the Andaman and Nicobar Isles, in the Indian Ocean; and Cyprus, in the Levant. (The large islands of Sumatra, Java, Borneo, Celebes, &c. generally known as the East India Islands, are treated in the following number.)

The *lakes* or *inland seas* of Asia constitute one of its peculiar features, most of these being salt or brackish, having no visible outlet, and being in some instances considerably beneath the general level of the ocean. The largest of these is the Caspian, having a length of 760 miles, with an average breadth of 200, receiving the rivers Volga and Ural, but with no outlet; its waters brackish, and of unknown depth, and its surface-level 84 feet beneath that of the Black Sea.

Of the *rivers* which water the continent, a large number are of the first-class. In Eastern Asia, we find the Amour, Hoang-ho, Yang-tze-kiang, and Hong-kiang, all of which are slow-flowing rivers, and navigable for a long way into the interior. India without the Ganges is watered by the Camboja, Meinam, and Irrawadi; and Hindustan by the Brahmaputra, Ganges, and Indus. The Ganges, though subject to annual inundations, and to a very rapid and dangerous tidal bore, is one of the most valuable rivers in the world, being, with most of its tributaries, navigable to the very basis of the mountains. The same, however, cannot be said of the Indus, which, though of ample volume, has an obstructive and shifting delta, which renders it of little avail, unless to small steamers. In Western Asia are the Tigris and Euphrates—the latter, navigable for flat-bottomed steamers so high as Bir.

CLIMATE, ETC.

In Northern Asia, no mountain chain prevents the entrance of the polar winds, and, in consequence, they sweep southwards over the plains of Siberia and Turkestan. In Southern and South-eastern Asia, the monsoons (see METEOROLOGY) explain the cause and course of the winds. They enable us also to explain the distribution of rain in Asia. The great mountains which fringe the table-land condense the vapours brought from the Pacific and Indian Oceans, and thus China, Indo-China, Eastern India, the coasts of the Indian peninsula, and the southern sea-board of Arabia, are well watered by periodical rains. North of the table-land and its fringe of mountains there is a fall of periodical rains, which, although scanty, redeems from sterility the countries on which it falls. In the interior of the continent and within the plateaux, on the other hand, rain is scarcely known. Thus, the Altaï, the Himalaya, and the Chinese highlands make Tibet and Mongolia the most arid countries of the globe. The great Desert of Gobi, the deserts of Persia, of Syria, Arabia, and Western India, may all be explained by the fact, that the winds which come to them from the ocean have been robbed of their vapour by the mountain ranges. In Southern India, the Western Ghauts receive the vapours of the south-west monsoon; the Eastern Ghauts, those of the north-east monsoon, and both are well watered. But the winds which pass into the interior have become dry, and hence the aridity of the table-land of the Deccan, and the necessity of irrigation to make it fertile. The fact is, that aridity is the chief feature of all the countries lying between the Red Sea and Northern China. They can be rendered fertile when cultivated by a peaceful and industrious population, intelligent enough to construct and keep in repair reservoirs and irrigation canals; but they become utterly desert when war or bad government interferes with the combinations and arrangements necessary for this purpose. Hence, there are no countries the prosperity of which is so completely dependent, as those of Western and Central Asia, on peace and good government.

Asia is traversed by all the zones of climate into which the surface of the globe has been divided by meteorologists and botanists. Northern Siberia, to a line just south of the Arctic circle, has a temperature of from 5° on the north to 30° Fahr. on the south. It is the country of the Tundras—frozen marshes which fill the lower basins of the Siberian streams. The cold temperate zone succeeds—stretching from the last area to a line running from the Gulf of Finland to the northern shore of the Sea of Okhotsk. It has a temperature of from 30° to 40° Fahr. and is the zone to which Norway and Finland belong. There occur within it tracts of arable soil, in which the hardier grains, oats, barley, and rye, potatoes and turnips, can be cultivated in sheltered situations. The next, the temperate zone, from 40° to 60° Fahr. extends southwards to a line which runs from the Black Sea to the north of Corea, and the Strait of Sangar, which separates the southern from the northern islands of Japan. It has the climate of

England; and in it deciduous trees, meadow-grasses, and the European cereals are cultivated with success. It includes on the east the Desert of Gobi, and on the west the parched steppes of Northern Turkestan. The warm temperate zone from 60° to 70° Fahr. lies south of the Caucasus and the Desert of Gobi. It includes Northern Arabia, the south of Persia, and the Punjab and Northern China. It is the climate of Spain and Italy, of the orange and fig, the vine and the tea-plant. In it the grains usually cultivated are rice and millet. It occupies on the west the arid region of Asia, including the Syrian, Persian, and Bactrian and Indian deserts; but on the east, it receives copious showers. Its driest districts are traversed by great rivers. Tibet, which is in the latitude of Cairo, is thrown by its high elevation into the colder zones. The tropical belt—temperature from 72° to 82°—in Asia occupies a comparatively limited space. It includes the Arabian sea-board, the greater part of India, the Indo-Chinese peninsula, and that part of China which lies south of the Nan-ling chain. It is the zone of the palm, the banana, and the sugar-cane. Within this belt, forests of flowering trees, infinite in their variety, and interlaced with lianas and parasitic plants in all places where the atmosphere is moist, overshadow the soil with an almost impenetrable covering of vegetation. Central, Northern, and Western Asia are, in short, characterised by deserts and scanty meadows, the forests being confined to Southern Siberia, and the mountain-ranges exposed to the southern winds. In the promontories of South-eastern Asia, on the other hand, is displayed all the tropical luxuriance of vegetation which characterises Central America.

With this distribution of the zones of climate and of vegetation is connected that of animal life. In Northern Siberia, where there is almost perpetual ice and snow, and little more than a scanty vegetation of lichens and mosses, the reindeer finds its proper food, and supports whole tribes of men. In Central Asia, the horse and the ox are the chief domestic animals of the Tatar population. The Bactrian camel enables them to cross the inhospitable deserts of Mongolia and Turkestan. Farther to the south, it is replaced by the Arabian camel, in the Persian and Syrian deserts. In India, the buffalo and the elephant are the characteristic beasts of burden. In the tropical woods of South-eastern Asia, reptiles and beasts of prey become dangerous enemies to man. The reports given of the destruction of human life by snake-bites and tigers in Indo-China, have been pronounced exaggerated; but the statistics annually collected in India confirm the most startling of them. An official notice gives the number of persons killed in British India in 1881 at the frightful total of 18,670; while 2757 were slain by wild animals. In the same year, 43,609 head of cattle were reported killed by snakes and wild animals; while 254,968 snakes and 15,274 wild animals were destroyed, 103,000 rupees being paid by government for their destruction. In Madras province, 1195 were killed by snakes and wild animals in 1882—920 by snakes, 206 by tigers, 28 by panthers and leopards. In 1873, a single tigress caused the destruction of thirteen villages, and threw 256 square miles of country out of cultivation. In the Central Provinces, in three years the deaths of 946 persons had been ascertained to have been caused by tigers. It is scarcely possible to believe that Mr Markham is not talking ironically when he enumerates among the difficulties in the way of getting rid of these 'gigantic cats,' that their wholesale destruction is objected to by Englishmen in India, as that of a kind of game which affords excellent sport when shot with the rifle; and by the native population, on the ground, that the 'man-eating tiger' is a kind of incarnate divinity, and that it would be dangerous to offend it!

In the number devoted to ANTHROPOLOGY, enough has been said of the distribution of man in Asia; while the rise and course of the chief streams of civilisation have been traced in the HISTORY OF ANCIENT NATIONS. It may be well, however, to remind the reader of the events occurring in the twelfth century which were destined to influence the whole continent. The Mongols who dwelt on the border of the Great Eastern Desert, under the lead of Genghis Khan, then penetrated into Siberia, attacked and took possession of China on the east, and Turkestan and Persia on the west. The sons of Genghis continued his conquests, destroying the califate of Bagdad, and advancing into India. His grandson, Kublai Khan, ruled over the greatest empire that ever existed, extending as it did from the Baltic to the Pacific, and from the Arctic zone to the Indian Ocean. It was in the reign of the Great Khan that Marco Polo, the Venetian, travelled through Asia, and recorded his observation in a wonderful narrative, which has been of inestimable value in guiding and stimulating geographical research, and which, as recently done into English by Colonel Yule, is one of the most readable and fascinating of books. Towards the end of the 14th century little remained of the empire of the Great Khan. A new conqueror then made his appearance—Timur the Tatar, or Tamerlane, who, after invading Persia, Egypt, and India, made Samarcand the seat of his empire, and a chief centre of Mohammedan piety or learning, the position it has ever since retained in the Mohammedan East, a fact which it is important to remember in connection with the recent conquests of Russia. The empire of Timur was soon broken up; but his descendant, Baber, in the early part of the 16th century, still ruled at Samarcand over countries extending south and westward to the Indus. Baber invaded India in 1525, and taking Delhi and Agra, founded the empire of the Great Moguls. The modern history of the continent is that of the English conquest of India, the Russian conquest of Siberia and Turkestan, and the growth of English commerce in China and Japan. Before we refer to these subjects, it is desirable to describe separately the different countries into which Asia is divided.

GREAT DIVISIONS OF ASIA.

A line running through the steppes north of the Caspian and Aral Seas, and along the northern edge of the Desert of Gobi and Shamo to the north of Corea and the Japanese islands, divides Asia into northern and southern parts. Southern Asia is, in turn, divided into a western and eastern section by the mountains of Eastern

Afghanistan, and the western Desert of Gobi; and the eastern section is again subdivided, in a more conventional manner, by the chain of the Himalaya, into the Chinese and the Indian countries. The great divisions of Asia, with an estimate of their populations, are as follows: 1. Northern Asia, 8 millions; 2. Chinese region, 375 millions; 3. Indian region, 260 millions; 4. Western Asia, 47 millions.

NORTHERN ASIA.

The Siberian countries, as has already been seen, are traversed by a mountainous tract, which bounds the great Mongol desert on the north. It includes the Altaï and the Yablonoi Mountains. These sink on the north to the great plain which is drained by the rivers Obi, Yenisei, Lena, and Kolima, descending to the frozen plains of the Arctic Sea. Siberia is not an unproductive country; it abounds in mineral wealth, the great mining districts being those of Barnaul, in the Altaï, and Nerchinsk, in the Yablonoi Mountains. The middle valley of the Yenisei is the most favoured agricultural district; and there, rye, oats, and wheat are successfully cultivated. The countries recently annexed in Manchuria, on the banks of the Amour, have a warmer climate, and when colonised, will probably become the most productive of the Russian settlements in Northern Asia. The Siberian rivers are admirably suited to inland navigation, and have been connected along their upper courses by canals, so that it is possible to convey the products of the middle Yenisei to the confines of European Russia and the peninsula beyond the Lena. A great highway also traverses Siberia, along which Chinese products are brought from Katchta, 150 miles south of Lake Baikal, to Moscow. The length of the road between these places is 4452 miles. Politically, Siberia forms a province of the Russian empire. Its towns are unimportant. The largest is Irkutsk (pop. 28,000), on the Angara, north-west of Lake Baikal. Tomsk (pop. 21,000) depends on the mines. Although Siberia formed part of the empire of Genghis Khan, Europeans were ignorant of its existence as late as the end of the 16th century. In the year 1580, a Cossack, an absconded criminal, named Yermak, at the head of a crowd of wild adventurers, crossed the Ural, and conquered Western Siberia. In 1584, he was drowned in the Irtish; but the Russians continued their conquests. They founded Tomsk in 1604, and Irkutsk in 1661. To their conquests in Turkestan, we shall refer below.

WESTERN ASIA.

This region lies west of the Indus and the Desert of Gobi, and south of the Siberian steppes. It is Asia Proper, the Asia of history, and the ancient abode of the Arabian and Persian races. We have seen that it is covered from east to west by the lofty table-land of Iran; bounded on the north by the plains of Turkestan; on the south, by those of the Tigris and Euphrates. Arabia, south of the latter, forms an independent table-land. The whole region is characterised by its arid climate, the hills by which it is traversed shutting out all the winds which might bring rains to the parched soil. Its lofty summits, however, are reached by vapour-laden clouds; and two river-systems, that of the Oxus and Jaxartes, on the north, and the Tigris and Euphrates, on the south, of the Iranian table-land, were made the means, in ancient times, of irrigating countries which supported a vast population.

Three races inhabit Western Asia—the Aryans, chiefly Persians, the central table-land; the Semites, chiefly Arabs, Arabia, and the southern plain; and the Mongol Turks, the plain of Turkestan. The contest between these three races has lasted since history began. The most powerful governments of Western Asia are now those of Turkey and Persia, representing rival Mohammedan sects, the Sunnites and Shiites, who are bitterly hostile to each other; and they, like all eastern states, are constantly weakened by the interminable strife and feuds which, on the death of a monarch, are sure to break out among the members of his family, owing to varied and ill-understood rules of succession.

Western Asia lies between the two most populous regions of the globe, Europe and South-eastern Asia. In all ages, great commercial routes have existed between them. One passed from the Black Sea across Northern Persia into India. The traffic on this line has been interfered with by Turkish banditti in Northern Persia, and by Afghan civil wars farther east. It has been also, and more seriously, interfered with by steam-navigation in the Red Sea and Persian Gulf. There is still, however, a great necessity for a direct route overland from Europe to India. A network of railways connects all parts of Europe, and a similar system has just been completed for India. The importance of connecting the two is evident. Various schemes are suggested. One is to connect the Mediterranean with the Upper Euphrates, and to make that river and the Persian Gulf the line of a railway to India. Another is to connect Constantinople with Angora, Sivas, Diarbekir, Mosul, and Kermanshah; and to cross Persia by Ispahan and Kerman to Bender-Abbas, thence proceeding along the coast to Kurrachee. One reason for promoting this scheme is, that it would continue Turkish lines already in process of construction. A third scheme is proposed by M. de Lesseps. It would connect Orenburg with Samarcand, Balkh, Cabul, and Peshawur, on the Indian frontier. The proposal seems wild, but not more so than American undertakings recently completed. That any of these lines would confer incalculable benefits on the countries through which they pass, it is impossible to doubt. Western Asia may be divided as follows:

	Population.
Turkestan	10,000,000
Afghanistan	4,000,000
Beloochistan	2,000,000
Persia	5,000,000
Armenia (with Caucasia)	6,000,000
Asia Minor	11,000,000
Syria and Mesopotamia	3,000,000
Arabia	6,000,000
Total	47,000,000

Turkestan was said, till recently, to be bounded on the east by the Bolor Mountains; but a better knowledge of the geography of these countries has shewn that no such chain exists. In Europe, mountains and uplands form the boundaries between states; but it is different in Central Asia, where the best cultivated tracts often lie along the mountain-ridges, and wastes surround

the hollows they inclose. Turkestan is, for this reason, bounded rather by the Gobi Desert, than the 'roof of the world,' or Pamir steppe, which, in recent maps, takes the place of the Bolor chain. The country consists of the mountain-system which ramifies north-east and west from the Pamir table-land, and the low plains to which these highlands sink on all sides. Two races occupy Turkestan—the Tajiks, or Aryan and Persian speaking native population, who are agriculturists and inhabitants of towns; and the Turks, chiefly nomads, but to whom the ruling caste belongs. They are Mongol in race and language, and under their rule the independent states or khanates into which the country has been divided, have been the scene of perpetual strife and anarchy. The Russians, in those parts of Turkestan which they have annexed, have found the subject population, the Tajiks, industrious and frugal, remarkably intelligent, and, like the Japanese, anxious to adopt European habits, and to become acquainted with the arts and sciences of Europe.

The advance of the Russians in Northern Turkestan promises to confer inestimable benefits on the country. In 1864 they took possession of Tashkand, forming part of Fergana, long famous for its beauty and fertility. A religious war against the Russians followed the conquest, and they added to their territory in 1868 Samarcand, the old capital of Tamerlane and Baber—venerated all over the East, and especially in India, as a holy city, only second to Mecca. The possession of Tashkand and Samarcand enabled Russia to control two of the chief Turkish khanates. One remained, that of Khiva, at the mouth of the Oxus, surrounded by deserts, and, in consequence, deemed inaccessible. But in 1873 it too was conquered, and a treaty was concluded with the khan. The Russians have more recently subjected Merv and other districts belonging to the most savage people of the East—the Turkomans, who inhabit the northern frontier of Persia, and who have converted the once beautiful Khorassan into a desert, and destroyed all security for life and property in Northern Persia.

The chief cities of Turkestan are Tashkand (pop. 90,000), and Samarcand (pop. 20,000), both Russian. The other towns are small.

Eastern Turkestan, or Kashgaria, which lies east of the Pamir table-land, has only recently become known to us from the works of Mr Shaw and Dr G. Henderson. Shut up between the Thian Shan and Kuen Lun Mountains and the Desert of Gobi, geographers did not suspect that in this part of Asia there existed a well-cultivated, well-governed country, with three millions of inhabitants. Although the inhabitants now speak Turkish, they are said to shew many Aryan characteristics; and in the upper valley of the Pamir table-land, recent travellers have discovered what they believe to be pure Aryan tribes. East Turkestan contains cities of 100,000 inhabitants, the chief of which are Kashgar and Yarkand. In 1853 a rebellion broke out in Kashgar, which ended in throwing off the Chinese yoke; and Kashgaria was an independent Mohammedan state till the death in 1877 of Yakoob Beg, its first native prince. On the accession of his son, the Chinese authorities reasserted themselves; and in 1879 the little state was again a Chinese province.

Afghanistan forms the north-eastern part of the table-land of Iran already described. Its chief slope lies towards the Persian desert, and it is drained by the river Helmund, which falls into the Lake of Seistan. In the north, the country is traversed by ridges of hills, but to the south-east it is more level. Everywhere the soil is arid; but the tracts lying along the streams are cultivated, and considerable crops of rice, maize, sugar, cotton, and tobacco are produced. The Tajiks, who form about one-third of the population, are agricultural labourers in a state of serfdom. The Afghans, who form nearly another third, are the ruling race. They are a tall, vigorous, and handsome people. The remaining third of the population is chiefly composed of Mongols, including the Hazareh and Eimak—Mongols proper, and the Turkoman tribe of Kuzzilbashes, who act as domestic servants and soldiers. The Tajiks speak Persian, the Afghans Pushtu, which, although an Aryan language, is more akin to the languages of India than of Iran. The chief towns of Afghanistan owe their importance to their military position. They are Candahar (pop. 50,000), Cabul (50,000), and Herat (100,000). The city last named, and the country surrounding it, are inhabited by a Persian population, who differ, however, from the Persians of Western Iran in professing the Sunnee rather than the Shiite Mohammedanism. The Afghans made their first prominent appearance in the history of the East, on the death of Nadir Shah, when Persia became finally dismembered. It was then that Ahmed Khan Duranee seized Candahar, and founded the dynasty, the Duranees, who have since retained the throne. The law of succession in Afghanistan is, that the Ameer shall select his successor from his generally numerous family; and the consequence has been an interminable strife on the death of every monarch, and such a record of fratricidal crime and warfare as no other chapter of history presents. The war with Britain in 1879–80 could hardly be expected to improve the state of affairs.

Beloochistan, south of Afghanistan, and east of Persia, sinks to the low tracts adjoining the Indus and the Indian Ocean. The climate of the highlands is cold for the latitude; that of the plains, tropical and arid. The inhabitants are chiefly pastoral, and there are no important towns. Two races occupy the country—the Belooches, who speak a Persian dialect, in the west; and the Brahoes, who speak an Indian tongue, on the east. The former are a powerful, bold, military race, living in tents, and chiefly pastoral. The latter are a people of smaller stature, but patient and laborious. They are agriculturists and mechanics. The chief town is Kelat (pop. 12,000). The history of Beloochistan as an independent state is quite modern, and the country has been alternately considered as forming part of India and of Persia. England has endeavoured, by granting a subsidy to the Khan of Kelat, to enable him to establish a powerful government in Beloochistan, which may be made responsible for the conduct of the petty chiefs along our frontier.

Persia forms the middle part of the Iranian table-land. It has an elevation of from 2000 to 3000 feet above the sea-level. On the north it is bounded by the Elburz chain, continued eastward

at a lower elevation by the hills of Khorassan. The western part of the country is traversed by a series of mountains, running north-west and south-east, and inclosing numerous valleys which can be rendered exceedingly fertile by cultivation. In these districts, the grains and fruits of Southern Europe are cultivated. The central region of Persia forms a depression with a desert surface in which the streams from the surrounding hill-countries disappear. It contains, however, a few depressions which form fertile oases. The northern slope of the Elburz Mountains sloping to the Caspian, forms on the margin of that sea a country of wonderful fertility. The forests of Central America are not more luxuriant than Mazanderan and Ghilan, the two Caspian provinces of Persia. They produce rice, sugar, and all the products of the tropics, and more especially silk, which forms one of the chief exports of Persia. Persia has an importance in history much out of proportion with its present population. There is no doubt that in antiquity, and during the middle ages, while irrigation-works still fertilised great tracts of country, Persia supported a great population. A native estimate fixed the population at 200,000,000; and the French traveller, Chardin, in the 17th century, thought 40,000,000 not too high a figure. It is only within a few years that careful estimates made on the spot have reduced the current estimate to 7,653,600, 1,900,000 nomads, 1,900,000 peasants, and the rest townspeople. The same estimate states the population of the chief cities to be as follows: Tabriz, the commercial capital, 120,000; Teheran, 100,000; Meshed, 60,000; and Ispahan, 60,000. The population of Persia has been long diminishing, a fact no doubt chiefly due to the invasion of the Turkish races, and long continuance of misrule and extortion by the provincial governors, the neglect of irrigation works, and the consequent recurrence of famines, in a dry country where successful cultivation depends on an artificial supply of water.

The history of Persia in modern times is chiefly that of the struggle between the native and the invading races, the periods of prosperity generally coinciding with the success of the former. Thus the country flourished under the Sassanian kings from the 3d to the 7th century. The Arab, Mongol, and Turkish invasions followed. Early in the 16th century, the Sofi dynasty restored the prosperity of Persia. Shah Abbas the Great, who drove the Turks out of Khorassan, extended toleration to the Armenian Christians, whom he induced to settle in the country; constructed important public works, irrigation canals, and roads, and did all he could to encourage agriculture and trade. He established a splendid capital at Ispahan. Nadir Shah (1736–1747), a Turkish adventurer, put an end to the Sofi dynasty. After his death, Persia became really split into a number of independent states until 1795, when another adventurer, a Turkoman of the Kajar race, founded the present dynasty. During this century, Persia has been weakened by wars with Russia. In October 1856, the Persians took possession of Herat, which they were compelled to restore, after a war with England. They have since been engaged in disputes with the Afghans and Belooches, settled by English arbitration, and in the old struggle with the Turkomans, which the advance of the Russians now bids fair to terminate—if it be decided that the exigences of European policy do not absolutely require that there should be an artificial desert between the English and Russian possessions in the East.

Armenia and the Caucasian countries lie between Persia and Asia Minor, bounded on the north by the Caucasus, or rather by the steppe beyond, and on the south by the plains of the Euphrates. Armenia Proper forms part of the great Iranian plateau. It has an elevation of from 5000 to 6000 feet, and is a bare, treeless country, with a cold climate. Georgia is warmer, and the soil is in many places very fertile. Under Russian protection, German colonists have founded settlements in various parts of the country, and good roads have been formed. A railway is now being constructed which will connect the Black Sea and the Caspian. The Armenians are Christians of the Armenian Church; the Georgians belong to the Greek Church. Mohammedanism prevails in the Caucasus. The chief town in Armenia is Erzeroum (pop. 40,000); and in Georgia, Tiflis (pop. 60,000). Since the beginning of this century, the Caucasus, Georgia, and part of Armenia have been annexed to Russia, with great advantage to the native populations.

Asia Minor forms the western extremity of the table-land of Iran. It sinks, as it proceeds westward, from an elevation of 4000 to 1000 feet above the level of the sea, and finally subsides into low and fertile valleys drained by the rivers falling into the Ægean Sea. In the interior of the peninsula, there are desolate plains and wastes, which never can be cultivated; but there are also vast tracts of fine agricultural soil, covered with the remains of old and splendid cities, shewing that the country was at one period the abode of a numerous, a prosperous, and highly civilised people. The chief inhabitants of the interior of the table-land are now wandering Turks and Kurds. The Greek population is chiefly confined to the sea-coast. We know little of the peoples inhabiting Asia Minor before the Greeks, but it seems probable that the discoveries made in the plain of Troy by Dr Schliemann will establish the fact, that it has been occupied in succession by races which had made considerable progress in civilisation, long before its colonisation by the Greeks. It was during the Roman epoch that Asia Minor seems to have reached its highest prosperity. It was then that great roads were constructed throughout the country, that agriculture and trade flourished, and that the great and beautiful cities, to the ruins of which we have just referred, sprang up over the whole country. The religious controversies which broke out in the 5th century, and which led to so much strife in the Eastern empire, were the chief cause of the weakness which opened the way for Turkish invasion. After the Crimean war, when the Turks were less carefully watched than they had been by Russia and the other European powers, the last relic of the independent Christian communities in Asia Minor, Zeitun, was destroyed—the inhabitants being massacred in a manner which recalls the worst atrocities of Cawnpore.

Syria and Mesopotamia may be held to include all the countries lying between Armenia and Arabia, Persia and the Mediterranean Sea. Syria

is traversed from north to south by two mountain-chains, inclosing a valley, which, in the south, where it is occupied by the Dead Sea, sinks below the level of the Mediterranean. Like the rest of Western Asia, it suffers from aridity. In some places, however, where the streams have been employed for irrigation, as in the country round Damascus, it becomes amazingly fertile. The inhabitants of Syria speak Arabic, but are not Arabs; they resemble more the inhabitants of South-eastern Europe. Neither are they all Mohammedans. They are hopelessly divided by their religious creeds. The Druses of the Lebanon have a religion of their own. In 1860 their sanguinary conflicts with the Maronites, Christians who now acknowledge the supremacy of the pope, were put an end to by a French expedition. The Mohammedan population is partly Shiite, and partly Sunnite, and is split by minor distinctions, which also appear to be causes of strife. At Aleppo (pop. 70,000) there are large manufactories of silk and cotton. The city has been for a time falling off in population, due to an earthquake in 1822, and more recently to the growing competition of the West in the markets of Asia. Damascus (pop. 150,000), the capital of Syria, is less prosperous than it was, it never having recovered from the injury done to its trade in 1860, when the fanatical Mohammedan mob rose and massacred the Christian population. Beyrout (pop. 60,000) is the seaport of Damascus, and the chief seat of European commerce with Syria.

Palestine, although forming only a small, and one of the least fertile provinces of Syria, claims special notice as the scene of events which have influenced the whole course of human history. It consists of (1) The deep valley of the Jordan, in which lie the Sea of Galilee, 120 feet above, and the Dead Sea, 653 feet below, the Mediterranean; (2) The hills and table-lands of Gilead and Moab, which bound this valley on the east; (3) The table-land of Judæa, Samaria, and Galilee, with a mean elevation of 1000 feet, bounding the valley of the Jordan on the west; and (4) The plain of Sharon, which lies between the last-mentioned table-land and the sea. The geography and history of Palestine are probably better known to most Englishmen than those of any country except their own; however, the pleasure-excursions which the enterprising Mr Thomas Cook now conducts through the chief scenes of sacred history, give his pilgrims a very different impression of the Syrian landscape from that obtained from the works of the old Italian painters, and the engravings from them, which still find a place in our illustrated Bibles. The tourists return probably better pleased than when they went with the fogs and leaden skies of England, and above all, impressed with that want of water everywhere which now characterises the Promised Land. Yet they see traces of ancient cultivation. They see that the country must at one time have been highly productive, and supported a teeming population, for even in those places where it is now most desolate, are the vast remains of terraces, constructed to collect the rains and fertilise the soil, and of cities, which seem to have crowned every eminence. Jerusalem (population probably 20,000) stands on the highland of Judæa, in a rocky country, at an elevation of 2660 feet above the sea. One-half of the population is Mohammedan; one-third, Christian; and what remains, Jewish. Its only industry is the manufacture of beads and crucifixes and other objects, sold to pilgrims, of whom more than 10,000 annually visit the holy places in and around the city.

Assyria was the name once given to the country lying west of the Zagros Mountains, and drained by the Upper Tigris and its eastern tributaries. It corresponds pretty nearly with the modern Kurdistan. In the east, the mountainous districts are well watered and productive; but westward, the plains are alternately a garden and a wilderness, the heat of summer completely drying up the vegetation. The Kurds are a rude people, speaking an Indo-Germanic language, but indulging to a great extent in the predatory habits of the Turks and Arabs. Mossul (pop. 30,000) is the seat of a Syrian Christian patriarch, and was anciently the metropolis of the Mesopotamian Christians, of whom there are still said to be 10,000 in the city. It is needless to say that the ancient prosperity of Assyria is attested by wonderful ruins of reservoirs and canals for irrigation, and of splendid and populous cities, of which Nineveh was the chief.

Babylonia is the name given to that part of the plain of the Tigris and Euphrates south of the point where the rivers first approach each other. It is a low alluvial plain, and forms for the most part an unproductive and unhealthy wilderness; but in early times it had, under a skilful system of irrigation, the very highest fertility. In antiquity, the country was, in fact, traversed in all directions by great canals, which have been described by the Greek historians. The soil is now only cultivated near the villages, but where it is irrigated, its fertility is unbounded. The depredation of wandering Kurds and Arabs, and Turkish misgovernment, give no hope of any improvement in its cultivation. The capital is Bagdad (pop. 65,000). It has manufactures of silk, cotton, and leather. Bassorah (pop. 60,000), on the Shat-el-Arab, the name given to the Tigris and Euphrates after their union, is the port for Indian commerce. According to Sir Henry Rawlinson, recent researches carry back the historical period of Babylon to about 5000 years B.C. (see HISTORY OF ANCIENT NATIONS). Now that the extension of the cultivated surface of the globe has become the chief necessity of the rapidly increasing population of Europe and India, it is not impossible that modern statesmen and capitalists may consider if it would not be possible to recultivate an area which could supply with food and clothing the inhabitants of a whole series of cities which, in ancient Babylonia, seem to have rivalled the capital in size and splendour. Asia Minor, Syria, and Mesopotamia form part of the Turkish empire, as immediate possessions of the sultan.

Arabia lies south of the Syrian countries. It forms, as has been already stated, a lofty table-land, nowhere sinking to less than 1000 feet, and surrounded on the west and south by lofty mountain-chains and terraces. The southern slopes are, at certain seasons, well watered, especially in parts of Yemen on the west, and Oman on the east. Between these countries lies Dahma, or the great sandy desert which spreads over one-third of the table-land. Farther north is the

highland of Nedjed, in which rain falls at certain seasons and fertilises the soil. This district is bounded on the north by the Syrian Desert. The Nedjed was, until recently, when it was visited by Mr Palgrave, supposed to be as sterile as the coasts of the Red Sea. This has been found to be a mistake. It is a fertile and well-cultivated country, inhabited by a numerous population of settled inhabitants. It is the seat of the empire of the Wahabis, described as a sect of warlike Mohammedan Quakers, who do not recognise the claims of the Turks to any suzerainty over Arabia. Their chief city is Riad (pop. 40,000), and their territory includes a large number of towns with populations of from 10,000 to 30,000 inhabitants. The Turks exercise a nominal sovereignty over Yemen and the Hedjaz. The former is a fertile country, which seems at a remote period to have been better cultivated than now, by means of reservoirs and irrigation canals. It produces coffee, which has a high reputation. Its capital is Sana (pop. 40,000); and its chief port is Mocha (pop. 7000). Aden (pop. 20,000), the great English packet-station on the route between Suez and India, stands on a peninsula of the Yemen coast. The Hedjaz is chiefly important as the country in which is situated Mecca (settled pop. 45,000), the birthplace of Mohammed, and the seat of the Kaabah, an inclosure which contains the famous black stone which all pilgrims must kiss. Upwards of 100,000 men still assemble annually at Mecca from all parts of the Mohammedan East. The state of Oman, in Eastern Arabia, is populous. Its chief town is the seaport of Muscat (pop. 60,000). The ruler is the Imaum, who has a considerable navy, and, till recently, exercised great power on the shores of Persia and Beloochistan, and the east coast of Africa.

INDIA.

In dividing Asia into its great regions, we used the name India to describe the countries which lie south of the great mountain-wall of the Himalaya, and the mountains which continue it eastwards into Southern China. It consists of the two great promontories of Hindustan and Indo-China, and the Malay Islands. For an account of the last, we refer to AFRICA—OCEANIA.

HINDUSTAN.

It is often said that no country is so completely isolated from the rest of the world as Hindustan, by great natural barriers; but perhaps the statement has been exaggerated, for in the East it is difficult to say whether Bhotan and Assam belong properly to it or to Tibet or Indo-China; and in the west, Beloochistan is as much Indian as it is West Asian. We have already briefly referred to the great natural features of Hindustan. South of the Himalaya is an elevated terrace, which slopes towards the low plain of the Ganges. To it belong the hill-countries of Nepaul, and Bhotan, and Assam, which are separated from the low plain on the west by the great pestilential swamp or forest of the Terai, and on the east by the forests which clothe the Garrow Hills. The Vindhyan Mountains bound on the north the long and narrow valley of the Nerbudda, which falls into the Gulf of Cambay. The table-land of the Deccan lies south of them. It forms an undulating table-land, 2000 feet above the level of the sea. The Western Ghauts bound it on the west, leaving between them and the sea a narrow plain 30 or 40 miles in width. They are 2000 feet high in the north; but in the south, at the Neilgherries, have an elevation of 9000 feet. The Eastern Ghauts have a lower elevation, and are situated at a greater distance from the sea. The table-land of Malwah, 2000 feet above the level of the sea, extends from the Deccan towards the Aravilli Hills. Farther north, extends the plain of India. The Thur, or Indian Desert, separates the basin of the Indus from that of the Ganges, and the Upper from the Lower Indus. North of it lies the Punjab; south of it, Sinde, separated from Gujerat by the Runn of Cutch. The basin of the Ganges is divided into two parts at a point east of Benares, where the plain is contracted by a ridge running eastward from the plateau of the Deccan. West of this line, the plain is described as that of Hindustan proper; east of it, is that of Bengal.

The soil of India is fertile in almost all these districts where it is well watered. The Deccan, like other table-lands, does not support great forests; but its soil and climate are favourable to the growth of cotton and the grain plants. The great plains of the Indus and Ganges, where watered, are very productive, and it has been found possible by irrigation to increase their fertility to a wonderful extent, and, accordingly, the greatest efforts are now being made by the government to encourage the formation of irrigation canals, especially on the Indus and Western Ganges, and the plateau of the Deccan. The consequence has been, to avert to a great extent the recurrence of those famines which from time immemorial at intervals depopulated India.

Hindustan is rather a continent than a country, in the European sense of the term, and its inhabitants are in every stage of civilisation. In the most inaccessible districts, protected by dense forests, tribes linger in the first stages of human progress; but generally the natives are agriculturists, remarkable for their contented, sober, and industrious habits. A description of the lower classes in Bengal probably gives a tolerably correct impression of the general condition of the Indian population. It is stated that, in Bengal, the ordinary habitations of the people are built of mud, or of brushwood plastered over with mud. The frames consist of bamboos tied together, and the roofs are constructed of two sloping sides, which meet at the top in a ridge. There is no window or aperture except the doorway. Each hut is concealed by thick vegetation, to keep off the sun, and each has a patch of ground in which vegetables are cultivated. These, rice, and occasionally fish, supply the ordinary food. The only dress of the men consists of a turban, and a cloth fastened round the waist, and reaching to the knees. The dress of the women is more elaborate and elegant, and even the poorest of them have armlets of silver or brass. Of course, this description does not apply to all the people of India, or to the landlords of Bengal, who are often enormously rich. The position of the peasantry in different districts of India has been very much influenced by the systems of tenure of the land which prevail in them. These may be classed under three

heads—the village, zemindary, and ryot systems. Under the first, which seems to have belonged to the earliest period of Hindu civilisation, the country was divided into villages or districts, the inhabitants of which formed an association, in which all trades and official duties were discharged by members, who received as a reward part of the produce of the soil. The potail, or general manager, collected the revenue, and paid it. The system chiefly prevails in the North-

west Provinces. The second system seems to have sprung from the Mohammedan conquest. The collection of the revenue in many places was intrusted by the conquerors to a class of tax-collectors known as zemindars. They gradually acquired a hereditary right to act in this capacity, and being intrusted also with the administration of justice, they were supposed, by the English rulers of India, to be landed proprietors, and were accordingly recognised as such. The third or ryotwary system is that under which rents are paid by the ryots, or peasants, under leases, direct to the government. The zemindary system was that adopted in Bengal by Lord Cornwallis in 1793. The ryotwary system was favoured in Madras by Sir Thomas Munro, when governor of the presidency. It was afterwards extended to Bombay. The fact seems so far to explain the poverty of the peasant in Bengal. All over India, the formation of railways and other public works

has wonderfully helped to benefit the working-classes, who have secured and retained for their own use the wages paid to them.

The north-eastern part of India, or the Punjab, belongs to the warm temperate zone, and in it the chief products are wheat, flax, and hemp. Wheat is the grain of the Upper Ganges. Where there is too little moisture for its cultivation, as in the southern basin of the Indus, millet and maize are grown. Rice is cultivated in the irrigated parts of the Punjab and in Bengal. Cotton is produced in all parts of India, and opium in Oude and Bahar. The commerce of India is chiefly with the United Kingdom. In 1872, the value of the imports was £42,651,560; of exports, £64,661,940. The chief exports were: cotton, £12,862,500; rice, £3,432,058; indigo, £1,905,132; tea, £1,398,106. The chief imports were: cotton goods, £13,078,831; iron, raw and manufactured, £956,921. In 1872, the revenue of India amounted to £50,110,215. Of this income, £20,520,337 was derived from land revenue, £9,253,859 from opium, and £5,966,595 from a tax on salt, and £2,369,109 from the excise on spirits and drugs. The chief item of expenditure was the army, £156,781,121. In 1881, the imports were £62,105,000; the exports, £76,000,000; revenue, £72,560,000; expenditure, £76,604,000; debt in India, £86,000,000; and in Great Britain, £71,400,000. The European army had 64,500 men; the native army, 126,000.

The government of India, in 1858, was transferred from the East India Company to the English crown, by an act passed in that year 'for the better government of India.' The executive authority of India is now exercised by a viceroy, appointed by the crown, and acting under the orders of the Secretary of State for India. A supreme council sits at Calcutta, and consists of six members, including the viceroy; an imperial legislative council, consisting of the supreme council and additional members; and separate councils for Bengal, Madras, and Bombay. The chief officers of the crown after the governor-general are governors in Madras and Bombay; lieutenant-governors in Bengal, the North-west Provinces, and the Punjab; and chief commissioners in Assam, the Central Provinces, and British Burmah.

A census of India was taken during the years 1868–1872, and another in 1881. By the latter the population under British administration was 198,755,993; in the native states, 55,150,456—total 253,906,449. The tables give the results of the last census.

Presidencies and Provinces.	Area in English sq. miles.	Population.
Governor-General of India—		
Ajmere	2,711	460,722
Coorg	1,583	178,302
Berar	17,711	2,672,673
Andaman Islands	880	14,628
Madras	139,900	30,868,504
Bombay	124,122	16,454,414
Bengal	156,564	66,691,456
North-west Provinces and Oude	106,111	44,107,869
Punjab	106,632	18,850,437
Central Provinces	84,445	9,838,791
Assam	46,341	4,881,426
British Burmah	87,220	3,736,771
Total under British Administration	874,220	198,755,993

Native States not belonging to British India, but more or less under English Control.	Area in English sq. miles.	Population.
Baroda	8,570	2,185,005
Central Indian Agency	75,079	9,261,907
Hyderabad	81,807	9,845,594
Mysore	24,723	4,186,188
Rajputana Agency	129,750	10,268,392
Bengal	36,634	2,845,405
North-west Provinces	5,125	741,750
Punjab	35,817	3,861,683
Central Provinces	28,834	1,709,720
Madras	9,192	3,303,563
Bombay	73,753	6,941,249
Total Native States	509,284	55,150,456

There were 87 millions of Hindus, 50 millions of Mohammedans, 3½ millions of Buddhists (mostly in British Burmah), 85,000 Parsees, and 12,000 Jews; and 89,798 British-born persons.

India is inhabited by races in all stages of human progress. Wild tribes, in the lowest state of savagery, occupy the hills and forests, and form a strange contrast with the civilised peoples of the plains. The latter belong to three races: (1) Mongols, resembling in all respects their neighbours, the Burmese and the Tibetans; (2) Dravidians, a dark race, totally differing from Mongols in appearance, and occupying the chief part of the Deccan; (3) Aryans, so called because believed to be the result of an amalgamation of the primitive inhabitants with Aryan invaders who at a remote period entered India from the north-west, just as the Saxons invaded England. The chief language of the first group is the Tibetan of Bhotan. The Dravidian languages are more important. Tamil is spoken by 10 millions of people south of Madras; Telinga by 8 millions north of the same point; Canarese in Mysore and Malayalam on the coast of Malabar. Among the Aryan languages are (1) Hindi, the vernacular of the North-western Provinces or Hindustan Proper; (2) Punjabi; (3) Gujerati; (4) Maharati; (5) Bengali—the names of which sufficiently explain the parts of India to which they belong. It is the Hindus (by religion) who speak the various Dravidian and Aryan languages we have just enumerated; and they in each province differ not only in language, but in character and habits, and even in dress. The Mohammedans, on the other hand, speak only one language, the Hindustani or Urdu, a modified Hindi intermixed with Persian, which sprang up at the court of Delhi, and which has become the spoken and literary language of the Mohammedans all over India.

In 1879, there were 1391 publications received in the Bengal Library, of which 983 were published in the town of Calcutta. In the Bombay presidency, 1097 native publications were issued; in Madras, 824; in the North-west Provinces, 541; in the Punjab, 926.

What is known or conjectured of the early history of Hindustan is to be gathered from the history of the two dominant religions (see MOHAMMEDANISM—HINDUISM—BUDDHISM; also HISTORY OF ANCIENT NATIONS). In the 11th and 12th centuries, Buddhism had almost entirely disappeared in Hindustan, or was confined only to the hilly districts south of the Himalaya, to Ceylon, and the countries of Indo-China and Malaya, in which it had taken root and flourished. It was

in the beginning of this period that another faith was introduced into India. In 1001, Mahmoud, the Mohammedan sultan of Ghuznee, in Eastern Iran, commenced his successful expeditions into India, and he continued them till 1029, making the destruction of pagan idolatry more the object of his visits than the acquisition of wealth or power. By his successors the Mohammedan dominion was established. Genghis Khan and Timur invaded India. In 1397, the latter sacked Delhi, and proclaimed himself emperor of India. He was followed by Baber, who, in 1526, entered Delhi, and had himself proclaimed successor of Timur and emperor of India. Baber established the dynasty of the Mogul emperors, or Great Moguls. One of these was Akbar, who flourished between the years 1556 and 1605. By his daring and judicious management, the central provinces were preserved in complete tranquillity, and Gujerat, Bengal, and part of the Deccan were added to his already extensive empire. His descendant, Aurungzebe, became Mogul emperor in 1658. He imprisoned his father, and, in the most unscrupulous manner, usurped the imperial power. He raised the Mogul empire to its highest point of splendour, and by sacrifice of the treasure amassed at his frugal court, for the relief of a great famine, so far atoned for the crimes of his youth. He died in 1707, and the decay of the Mogul empire followed. It was weakened by the growth of a power among the Mahrattas in the countries lying to the east of the Gulf of Cambay. They represented the Hindus, as opposed to the Mohammedans of Delhi, and formed several states. On the invasion of India by Nadir Shah, they succeeded in wresting a large territory from the Mogul emperors. The strife between them and the Mohammedans was terminated by the growth of a new power in India—that of the English. In 1498, the route to India had been discovered by the Portuguese, and in that year they landed in Malabar, and established themselves there. Their chief settlement was Goa. The Dutch next opened a direct trade with India, and they were followed by the English and the French.

The English desired to open a commercial intercourse with India as early as 1553; but their expeditions failed in reaching the country, from their want of geographical knowledge. They at length learned which was the true course to steer for India; whereupon, in 1600, a Company of merchants was formed in London to prosecute the traffic with the East, being empowered to do so by a charter from Queen Elizabeth, which was to last fifteen years. The first expedition of these adventurers cost £69,091, and consisted of five ships, the largest of which was 600, and the smallest 130 tons burden. The articles which they took were principally bullion, iron, tin, broadcloths, cutlery, and glass. This expedition proved remarkably successful, and led immediately to a repetition of annual voyages of the same nature. Unsuccessful attempts were made to secure favour with the Mogul emperor; but the affairs of the Company continued prosperous, and factories or warehouses for storing exports and imports were in many places planted on the coasts of India. From the real or pretended dread of being attacked by marauders, the keepers, merchants, and servants at these places at length began to strengthen the defences; and so, from being mere mercantile warehouses, the factories shortly partook of the decided character of armed garrisons. In 1640, the native authorities gave permission to build Fort St George at Madras; and in 1645, a factory was established on the banks of the Hooghly, a branch of the Ganges near its mouth, which formed the foundation of Calcutta. The island of Bombay was also procured as a settlement in 1664-65, after a struggle with its Portuguese possessors.

The French, who had acquired considerable territorial possessions in Southern Hindustan, came into collision with the British merchants. It would be needless to recount the particulars of the struggle for power; it will suffice to state that the French ultimately were deprived of their possessions. By the defeat of the French forces in 1761, the British were left at liberty to pursue their schemes on India. Calcutta had in the meanwhile rapidly advanced in wealth, and excited the envy of the Subahdar of Bengal, Suraja Dowlah. He attacked it in 1756, and capturing 146 prisoners, confined them in the memorable Black Hole, in which all but 23 were suffocated. Clive hastened from Madras to the rescue of Calcutta, and defeated Suraja Dowlah at the battle of Plassey, 1757. The Mogul emperors then appointed the Company dewannee, or perpetual collector of Bengal, Bahar, and Orissa, on payment of £260,000 per annum. In 1777, the French again made India the scene of a war with England. A Mohammedan adventurer, named Hyder Ali, also had established his power as sovereign in the southern part of the Deccan; and the Mahrattas, aided by French officers, attacked the English; but the confederacy was broken up in 1781, when Hyder Ali was defeated by Sir Eyre Coote. In 1790, Lord Cornwallis, with the Mahrattas and others, made war on Tippoo, the son of Hyder Ali. He, too, was defeated, and was compelled to cede half of his dominions to England. The principal war in which the East India Company was engaged after this successful contest, was that with the Pindarees, roving tribes of Mahrattas, who, without any territory, carried on predatory warfare against all whom they could rob with impunity.

The chief events in the more recent history of India may be referred to under the heads of the successive administrations. Lord Auckland was governor-general from 1835 to 1842, and under his rule the disastrous Afghan policy was adopted which led to the massacre of an English army in the Khyber Pass. Lord Ellenborough succeeded him. In his time, Afghanistan was invaded, and Cabul sacked; Sinde was also conquered by Sir Charles Napier, and annexed. Sir Henry Hardinge was governor from 1844 to 1848. His administration was remarkable for the Sikh war, the result of which was the conquest of the Punjab. Under the governorship of Lord Dalhousie (1848-55), the Punjab, Nagpur, and Oude were annexed. Lord Canning's administration was the period of the great mutiny of 1857-58. It is now believed to have been a Mohammedan conspiracy. The last of the Great Moguls, the king of Delhi, and heir of Timur, took part in the conspiracy, and was in consequence tried, and sentenced 'to be transported across the seas as a felon.' He died in Pegu in 1862. One

consequence of the Indian mutiny was a determination on the part of the English people that India should be ruled for the benefit of the Indian population. The government was transferred from the East India Company to the crown, Queen Victoria assuming the title of Empress of India. The new administration already referred to was then called into existence. Since then, great irrigation works, canals for traffic, railways, and telegraphs, have been constructed in all parts of India; every effort has been made to promote agriculture, and, by the foundation of schools and colleges, to spread education. We shall now glance hurriedly at the various divisions of the country, which may be conveniently arranged under the three heads of Western Hindustan, Eastern Hindustan, and the Deccan.

1. Western Hindustan.

Its principal divisions are:

1. Cashmere, a mountainous country of the Western Himalaya, ruled over by Ranbir Singh, who is bound by treaty to furnish troops to the British government if required. The chief portion is a valley 50 miles long, 10 or 12 miles wide, and 5300 feet above the sea. The soil is fertile and productive, and the country is one of the most beautiful in the world. The capital, Cashmere, has a population of 200,000.

2. The Punjab, consisting chiefly of a plain traversed by tributaries of the Indus, which divide it into great natural sections called Doabs. Where there is water for irrigation, the country is fertile. The population by census of 1881 is 18½ millions. The inhabitants are chiefly Sikhs, and speak Punjabi. West of the Indus, the Patans, or Afghans, are more numerous; two-thirds of them are Mohammedans, one-sixth profess the Sikh religion, the rest are Hindus. The Sikhs have no distinction of caste. Lahore (pop. 150,000) is the chief commercial town of North-western India. Mooltan (pop. 68,000) is one of the oldest Indian towns.

3. Rajpootana lies south of the Punjab. It is a fertile hill-country on the east, but on the west extends over the Thur, or Indian Desert. It is divided into 18 independent states, with 9 millions of inhabitants. They are all under the political superintendence of an agent of the governor-general. The inhabitants are Hindus, and speak dialects resembling the Hindi. In consequence of the rule of so many native princes, and their independent interests, no great public works are carried out, but in many places English schools have been founded. Bhurtpore (pop. 66,000) is the chief town.

4. Sinde (pop. above 2 millions), at the mouth of the Indus, has a hot and dry climate. The country is rich, and produces two crops a year near the river; but to the east, it becomes an absolute desert. The trade of the country is rapidly increasing. The capital is Hyderabad (pop. 48,000); the chief port, Kurrachee, is familiar to Englishmen as a chief packet-station.

5. Gujerat, a flat and fertile country (pop. 3 millions). The ruling race is the Mahrattas. It includes many petty states, the chief of which is that of the Guicowar. Baroda (pop. 101,000) has a great trade.

6. Malwah is a name given to the elevated country lying north of the Vindhyan Mountains. It is divided into a number of principalities, the chief of which are: Indore, or Holkar's dominion; Gwalior, or Scindia's dominion; Bhopal; Bundelcund, &c.

7. The North-west Provinces (of Bengal) are so called because they were included in the presidency of Bengal. They, however, form no part of Bengal in a geographical sense, and might be better described as Hindustan Proper. They form a great plain, divided by the Jumna and the Ganges, bounded on the north by the Terai, a narrow tract of forests and pestilential swamps, infested with wild beasts; on the south, by the elevated tract of Bundelcund. The plain is arid in the west near the desert, but better watered in the east. Costly canals have recently been constructed, which have marvellously increased the productiveness of the country. The people speak Hindi; but both that language and Hindustani, or Urdu, are taught in the schools. The common people live on chupatties, or unleavened wheaten cakes. Their dress is rather fuller than that of the Bengalees; and their houses, which resemble those of the latter, are covered with tiles instead of thatch. They are Hindus and Mussulmans. Among the chief towns of the country may be included Delhi, which, for administrative purposes, is now annexed to the Punjab. Delhi, however, belongs to the Upper Ganges. It had in the time of Aurungzebe a population of 2 millions. The number of its present inhabitants is only 173,000. It still contains splendid mosques, and the imperial palace is half a mile in circuit. In the width and cleanliness of its streets, Delhi appears like a European town. It anciently occupied 20 square miles, and that space is now covered with ruins. Near Agra (pop. 160,000) is the famous Taj Mahal. Benares (pop. 199,000) is the holy city of the Hindus. It is filled with numberless temples and palaces, and is visited by pilgrims from all parts of India. Oude, which previously formed a separate province, was joined to the North-west Provinces in 1877. It resembles them in soil and climate. Lucknow (pop. 261,000) is the chief town.

2. Eastern Hindustan.

1. In this division are included the lower provinces of Bengal. They form an alluvial plain, unsurpassed in the world for luxuriance of vegetation—from one end to the other is, indeed, one enormous garden. Rice is the chief object of cultivation, but all the other grains are grown. The opium poppy, indigo, cotton, the sugar-cane, the mulberry, tobacco, hemp, and flax form the other chief objects of cultivation. On the north, the plain is bounded by the great forest which runs along the base of the Himalaya, and which is infested with wild beasts. Its inhabitants are chiefly Bengalees, the great majority of whom are agriculturists. They are very poor, a great part of the wealth of the country passing into the hands of the *zemindars*, or aristocracy. The peasants are said to be 'as innocent, temperate, and moral as the people of any country in the world.' They are also said to be destitute of manly spirit and independence of character. Calcutta (pop. 800,000) is the capital of Bengal, and the seat of the supreme government. The

European portion is described as the City of Palaces. Behind it is ranged the native town, deep, black, and dingy, with various crooked streets, huts of earth baked in the sun, or of twisted bamboos, interspersed here and there with ruinous brick bazaars, pools of dirty water, cocoa-trees, and little gardens, with some fine large dirty houses, the residences of wealthy natives.

2. Assam is remarkable as the chief seat of the cultivation of tea, which it now sends in very large quantities to the Calcutta market.

3. Of Nepaul and Bhotan, native states, in which Buddhism still prevails, we shall not stop to speak.

3. The Deccan, or Southern Hindustan.

The chief divisions of this part of India are :

1. The Bombay presidency proper, which lies at the north-eastern corner of the table-land of the Deccan, and includes the Ghauts and the sea-coast from the Gulf of Cambay south to the town of Goa, and a long tract of the table-land. It produces cotton, rice, and millet. The labouring population are rapidly improving their condition, thanks chiefly to railway and European works. Mahratta and Canarese are the chief languages of the people, who profess Hinduism. The capital, Bombay (pop. 800,000), is spread over a considerable surface, the houses of the wealthier European inhabitants standing apart among gardens and orchards. In the native town, the houses are small, and the streets narrow and crowded. Bombay is the seat of a great trade with Europe by the Suez Canal, and with the Persian Gulf. Its population is of the most varied character. The Parsees, who are descended from Persian ancestors, who left their native country to escape Mohammedan persecution, are the most remarkable section of the population. They adhere to their old religion, and conduct, as merchants, a great share of the business of Western India. Poonah (pop. 130,000), which stands at an elevation of 2000 feet, is an important military post.

2. The Madras presidency, which occupies a great part of the eastern slope of the Deccan. The alluvial tracts watered and irrigated by the Godavery and Krishna, and other rivers, supply great crops of rice; maize and sugar are also cultivated. Along the coast and in sandy districts, the cocoa-nut and other palm trees are cultivated. The population exceeds 31 millions. The chief languages are Telugu and Tamil. The chief religion is Hinduism, and Brahmans are more numerous in the presidency than elsewhere in India. The Mohammedans are not numerous. Madras (pop. 406,000) is the seat of government. The shore is here low, and dangerous to approach by vessels, which have to load and discharge by means of boats, pulled through a heavy surf. On the beach stands Fort St George, a place of considerable strength. A noble range of public edifices, including a custom-house and court-house, also adorns what is called the north beach. Madras differs in appearance from Calcutta. It has properly no European town, the settlers residing in houses in the suburbs, in the midst of gardens, and transacting business in the district appropriated to the residence of the natives.

3. The Central Provinces, which have a population of 9 millions, more backward than any in India, and consisting of Mahrattas, Mohammedans, and Gonds. A great proportion of the people, including those last named, dwell in rude huts in the forests, and subsist by the chase. Nagpoor, the capital (pop. 98,000), consists chiefly of mud huts. It has only one good street.

4. Hyderabad, the name now given to the dominions of the Nizam of the Deccan. The state has a population of 10 millions. The climate is one of the most salubrious in India. The soil is arid, but, when irrigated, produces fine crops. Hyderabad, the capital of this native state, has a pop. of 354,000.

Ceylon.

The island of Ceylon, though closely connected with British India, and also a British possession, is administratively distinct, under its own governor. Ceylon is a rich and beautiful island, rising in the centre to a table-land, round which runs a low belt of coast plains. The population is above two and a half millions. The chief inhabitants are the Singhalese, who occupy the south and south-west coasts. They are Buddhists in the interior, Christians on the coast. In the north-east, there is a Tamil population, who are Hindus. Colombo (pop. 40,000) is the residence of the governor. Point de Galle (pop. 18,000) is the point at which the Indian and Australian steamers touch. Ceylon was successively Portuguese, Dutch, and English.

INDO-CHINA.

Indo-China forms a peninsula, bounded on three sides by the sea. It has not a well-marked frontier on the north. It consists of a table-land with an elevation of from 5000 to 6000 feet, and traversed by lofty mountain-chains, which, as they run south, spread out like fingers. The basins they form correspond, or nearly so, with the old political divisions—Burmah, Siam, Cambodia, and Cochin-China. The whole country lies within the tropical zone; but the northern table-land has a temperate climate. The whole peninsula is copiously watered, and very fertile. The population, including the semi-independent Laos or Shan states in the interior, is about 40 millions. The inhabitants (save in the long peninsula of Malacca, where they are Malays) are of Mongolian stock, speaking languages resembling the Chinese, but divided into five groups : (1) the Anamese, spoken in Tonquin and Cochin-China; (2) the Cambodian; (3) the Siamese; (4) the Burmese; (5) the Mon, a dialect spoken in the delta of the Irrawadi. In the east, the inhabitants in their personal appearance and habits resemble the Chinese most closely. In the west, they have been much influenced by the languages and civilisation of India.

The chief countries are Burmah, Siam, and Anam.

1. Burmah includes the basins of the Irrawadi and Saluen, and a narrow plain to the north and south of them running along the Gulf of Bengal. The lowland country forms an elevated tract, much of which lies at an elevation of 2000 feet. The maritime provinces are low and damp, with a rich soil. They are not, however, well cultivated. Rice is the chief product. In the towns, the manufacture of pottery, silver ornaments, and jewellery,

are the chief occupations of the people. The government of Burmah is hereditary and despotic. In 1823, the Burmese invaded British India; a war ensued. At its close, they were compelled to cede Aracan. Tenasserim was annexed in 1826, after a second war with Burmah. In 1852, Pegu, the delta of the Irrawadi, also became English. The whole of these territories were thrown into one province, described as British Burmah, and placed under the government of India. The kingdom of Ava, or Burmah Proper, is now an inland country. The old capital, Ava, is now deserted for Mandalay (pop. 70,000), on the right bank of the Irrawadi. Of late years the state of the kingdom has bordered upon anarchy. The population is about 4 millions.

The coast regions, Aracan, Pegu, Irrawadi, and Tenasserim, now forming British Burmah, are governed by a chief commissioner under the Indian government. All the towns are situated on navigable rivers, and no roads existed till they were constructed by the English. The land is divided into small estates of from 8 to 10 acres, held directly from the government. The houses of the peasantry are built of bamboos, and have floors raised on platforms, so as to be above reach of the annual floods. Since the English occupation, Europeans, Chinese, and Hindus have settled in large numbers in British Burmah, and carry on a large trade in rice, timber, and petroleum, and the other products of the country. The town of Aracan (pop. 15,000) carries on a large trade with Calcutta. Rangoon (pop. 134,000) is the most important town in Pegu. It has a large and rapidly increasing commerce. Moulmein (pop. 53,000), the chief town of Tenasserim, well drained and healthy, with fine wide streets, carries on a great trade in timber.

2. Siam (pop. 6 millions) almost coincides with the basin of the Meinam. In the interior and elevated tracts, the climate is healthy; but in the lower region, which is overspread with forests, fevers prevail. The soil is exceedingly fertile, and rice, sugar, and tobacco are extensively cultivated. Chinese and Anamese colonists form one-third of the whole population, and are largely engaged in ship-building, and the mechanical arts and commerce. The government is shared by two kings, one of whom is said to be supreme, and the other subordinate; the former having two-thirds, and the latter one-third, of the power. Bankok (pop. 500,000, one-third of whom are Chinese), the present capital, is built on both sides of a mouth of the Meinam; carries on a large and increasing trade by sea with Singapore and China, in pepper and tobacco and other products. The Siamese concluded a treaty with England in 1826, which led to friendly relations, ever since maintained. In 1881, the total exports from Bangkok amounted to £2,000,000, of imports, £1,200,000, about half of this trade being carried on in British and the other half in Siamese vessels. The chief export is rice; the chief imports, cloths, hardware, and opium.

3. Anam (pop. estimated at 24 millions) includes Cochin-China, Tonquin, and Cambodia. A mountain-chain traverses it from north to south, bounded on the west by the basin of the Cambodia River; on the east, by the coast slope of the China Sea. On the north, the sea-board widens into the broad plain of Tonquin; on the south, forming the basin of the Cambodia into a broad delta. The products are rice, sugar, silk, pepper, and other spices. Tea of an inferior kind is also cultivated in the elevated tracts. The inhabitants closely resemble the Chinese, and are skilful ship-builders and mechanics. Roman Catholic missions had made, in spite of fearful persecutions, half a million of converts. A massacre of Christians broke out in 1857, which led to war; and Lower Cochin-China became permanently a French possession. Subsequently, Cambodia accepted the French protectorate. In 1883, France further occupied Tonquin; and ultimately the 'empire' of Anam has become practically a French dependency. Chief towns: in Anam or Cochin-China Proper, Hué (pop. 30,000); in French Cochin-China, Saigon (pop. 70,000); in Tonquin, Hanoi or Kesho (pop. 120,000).

The highlands of Indo-China form the Chinese province of Yun-nan, with a population of 5,600,000 inhabitants. It comprises a Mussulman population, known as the Panthays, who were recently in insurrection, but whose rebellion was erelong completely suppressed. Yun-nan is the great mining province of China, from which it is scarcely possible to reach it over the mountains and gorges by which it is traversed. Hence the vast importance of the new route up the Tonquin River, discovered recently by the French, by which steamers can reach the heart of the country. English attempts to open a route for trade to Yun-nan through Burmah have been unfortunate in their main purpose.

THE CHINESE COUNTRIES.

We have included under this name the whole of that part of Asia lying north of the Himalaya and the Gulf of Tonquin, and south and west of the Gobi. The area thus defined includes Tibet, China, Corea, and Japan. It is, as we have already seen, for the most part an elevated region. The loftiest table-land on the surface of the globe occupies its western angle, and stretches eastward towards China, where it passes into a country covered with parallel chains running south-west and north-east. North of this region, the Mongol table-land sinks into broad river-basins, and finally to the great plain of China, where the two chief Chinese rivers, the Yang-tze-kiang and the Hoang-ho, meet, and fall into the ocean. Corea is a promontory traversed by a range of lofty hills. The Japanese islands are rugged, but slope on the east to comparatively level tracts. The Chinese countries lie almost entirely within the warm temperate zone. South of the Nan-ling chain, however, China has a tropical climate, while north of Niphon the climate of Japan is that of the temperate zone. The inhabitants of the Chinese countries all belong to the Mongol race; but the Japanese and Coreans differ widely from each other, and from the Tibetans and the Chinese, in appearance as well as in language. All, however, have been influenced by a common civilisation, which connects them like the countries of the European continent.

CHINA.

The whole peninsula between the Gulfs of Tonquin and Pe-che-le, bounded by the Tibetan plateau and the Mongol Desert on the west and

north, and the sea on the east, has long been inhabited by one race, and united under one government, that of China. We have long been familiar with the coast region; but it is only within the last few years that the German traveller, Baron von Richthofen, has given us correct general notions of the geography of the interior. He has shewn that the chains represented in our maps are purely conventional. Southern China is a region of parallel mountain-chains running north-east and south-west, and the summits of which do not exceed, in general, an elevation of from 2000 to 3500 feet. No great plain is met with over this area, and the rivers which cross it pass from valley to valley between the parallel ridges by deep gorges. The streams thus run to and fro through the valleys to turn a barrier, and their courses are, in consequence, sluggish. On the north and west of the Chinese extension of the Kuen Lun, there is another system of mountains, running north-east and south-west, which separates China and the Mongolian plateau. This country sinks eastward into extended plateaux and broad valleys, covered with tertiary deposits, and finally into the great plain of China, into which flows the Yellow River. A great movement of upheaval is believed to be taking place on the northern coasts of the Chinese plain, which is damming up the mouths of the great streams, destroying their embankments and the canals fed from them, and thus causing inundations and a wide-spread misery, which has been the source of much of the present weakness of the government of Pekin. China south of the Kuen Lun, that is to say, the southern hill-country, is well cultivated in the valleys, and its hills are clad to the top with luxuriant vegetation. Everywhere the river-bottoms yield crops of the finest rice, and the hills, tea. Silk is also produced in large quantities. In the northern division of China, the surface is covered either with a rich and deep tertiary deposit, or with an alluvial soil, both of which are exceedingly fertile. There are bare ridges rising out of these, but they do not cover a great area. The northern river-basins and the great plain produce the finest crops of grain and vegetables. In addition to these products, the southern parts of the plain produce tobacco and cotton.

The government is despotic. The emperor is absolute in the empire; his governors, in the provinces. The emperor is assisted in governing by two councils, and his decisions are regularly published in the *Pekin Gazette*. A system of competitive examination exists in China, by which the most able men are supposed to be sifted from the general population, for employment as officers in the public service or mandarins.

A return published in 1844, and not very reliable, gives the revenue of China as £63,934,713. No statement of the expenditure is given in the public accounts, and it appears that the governors of provinces have constantly to make up deficiencies by extraordinary demands on the tax-payers. The trade of China is chiefly with the United Kingdom and India. The United States, as customers, stand next in importance. The exports in 1881 amounted to £20,000,000, and the imports to £25,660,000. The exports consist chiefly of tea, the value sent from the treaty ports to the United Kingdom in 1881 being £7,500,000.

The Chinese, generally, are strong and energetic. At home, they exhibit a bigotry, pride, and contempt of foreigners which were supposed to indicate stupidity. But this is not the impression they produce in America and the colonies, where the belief now seems to gain ground, that if they make themselves acquainted with the European arts and sciences, and, above all, with the modern art of warfare, the English and Russians will find them formidable rivals in any struggle for the possession of Asia. Baron von Richthofen has shewn that the population is divided by the Kuen Lun into two sections. In the south, the sea-boards, and the hills which separate them from the interior, have also produced an effect on language, and the dialects of Quang-tong and Fo-kien differ from that of the rest of China.

Neither the extent nor the population of China are known with anything like certainty. According to the most reliable estimates, the empire, with its dependencies (Mantchuria, Mongolia, Tibet, and Corea), has an area of about 4,000,000 English square miles, with a population of 375,000,000. The area of China Proper is stated at 1,538,000 square miles, with a population of 350,000,000. It is divided into eighteen provinces—Chih-le, Shan-tung, Shan-se, Honan, Keang-soo, Gan-hwuy, Keang-si, Foo-keen, Che-keang, Hoo-pih, Hunan, Shen-se, Kan-suh, Se-chuen, Kwang-tung or Canton, Kwang-si, Yun-nan, Kwei-choo.

The history of China goes back to a very remote period; but perhaps the first date that can be looked upon as historical was the erection of the Great Wall of China in 220 B.C. by the first emperor of the Tsin dynasty, as a barrier against the invasions of the Mongol Tatars. The same monarch is said to have conquered six nations, and appears to have extended his sway over the whole of China north of the Kuen Lun. About 201, the race of Tsin was followed by that of Han. In 406 A.D. two chief kingdoms appear in China, the capital of one being Honan, and of the other Nankin. They were united in 585; but after this period, civil wars and Tatar massacres weakened the country. Kublai Khan conquered the whole country in 1279, and in his time it was that Europeans first became acquainted with it from the writings of Marco Polo. In 1368, the Mongols were expelled, and the Ming native dynasty succeeded. The Mantchus invaded China towards the middle of the 17th century, and in 1651 were in possession of the whole country. Since this time they have retained supreme power, but they seem to be gradually losing control over the distant provinces of the empire. One of the most formidable revolutions the Chinese government has recently had to encounter was that of the Tae-ping rebels, who, under their leader, Hung-sew-tseuen, marched to Nankin in 1850–53, and who were only put down with the assistance of the English and French in 1864. The Mantchus were less fortunate in the western provinces of the empire, where Kashgaria threw off their yoke, and for a time was independent under a Mohammedan Emir. In early times, the Chinese do not appear to have been hostile to intercourse with foreigners. It was the attempt to proselytise made by the Spaniards and Portuguese, in the 16th century, that first excited their hostility to Europeans. For a long period, trade with England

was restricted to Canton; but dissensions between the English and Chinese officials led to the war of 1840-42, and a treaty of peace at its conclusion, by which five ports were thrown open to British trade. The war of 1857, and the capture of Pekin by the English and French in 1860, were followed by treaties under which the commerce of the country was to be fully opened up to Europeans, and Christians were to be protected in the open profession of their faith. It was subsequent to this treaty that European officers were permitted to drill the Chinese troops, and assist in putting down the Tae-ping rebellion. The Chinese government have not, however, given that assistance which was expected in opening up the commerce of the country.

We may enumerate a few of the chief towns of China. Tching-tou-fou (pop. 800,000), the capital of Se-chuen, the province just referred to, is a beautiful and opulent city, with wide streets and handsome shops. The houses are brightly painted, and very clean, reminding the visitor of the cities of Chinese pictures, more than the dingier coast towns. Canton (pop. 1,600,000) stands in a fine country south of the Nan-ling chain. At the mouth of the Canton River is the small English island of Hong-kong, 8 miles long, and from 2 to 6 broad. The chief town is Victoria, the best part of which is built after the European fashion. The population of the colony is 125,504, of whom 2034 are Europeans. Nankin, the capital of the Ming dynasty, had formerly a population, it is believed, of from 500,000 to 1,000,000. Since its destruction by the Tae-pings, more than half of the city is in ruins. Shanghae (pop. 300,000), at the mouth of the Yang-tze-kiang, is now the most important city of the Chinese empire. It is the headquarters of British trade in China. Pekin (pop. 1,600,000), the modern capital of China, is divided into two parts, a commercial city on the south, and a Tatar city on the north, in which are situated the imperial palace and the government offices.

COREA.

Corea lies to the north-east of China. It consists chiefly of a peninsula traversed by a range of mountains. It has a climate severe in the north, but in the extreme south belonging, like China, to the warm temperate zone. It is well cultivated, and in most respects resembles a Chinese province. The Coreans, however, have a language and literature of their own. They have been accustomed to pay tribute to both China and Japan, but have not had much intercourse with Europeans. Lately, our acquaintance with this curious people and country has been much extended; and commercial treaties, opening certain ports to foreign commerce, were concluded with the United States in 1882, and with Great Britain in 1884.

JAPAN.

The Japanese archipelago consists of the islands of Honshiu, Shikoku, Kiushiu, and Yezo, and a large number of smaller islands which surround these. Their surface is generally very rugged—some mountains attaining a great height. In Honshiu, Fusiyama (12,500 feet) is a dormant volcano, and Asama-Yama (8300) an active one. The plains are most extensive on the eastern coast. The greater part of the archipelago lies within the warm temperate zone, but there is a very great difference between the climates of the northern and southern islands. The surface is everywhere well cultivated. The chief products are rice, barley, wheat, and potatoes, tobacco, tea, cotton, silk, and all the fruits and vegetables of Southern Europe. The domestic animals are not much reared; buffaloes and oxen are only used for draught. In some manufactures, the Japanese have made great progress. Their paper, lackered and japanned wares, are unrivalled, and they excel in manufactures of silks and cottons, clocks, telescopes, and metallic goods generally. The area of Japan is about 150,000 square miles, the population 35 or 36 millions. Ethnologists are rather puzzled to say to what section of the inhabitants of Asia they belong. They differ from the Mantchus, Chinese, Malays, and Esquimaux, and yet, in some respects, they resemble all these races. The spoken language of Japan entirely differs from the Chinese, but the Chinese classics form the basis of their literature. Japan was till quite recently an oligarchy governed by the daimios or nobles, and the Tycoon or head of the executive. A civil war which terminated in 1868, restored power to the Mikado, the representative of the old sovereigns, and since then Japan may be considered a monarchy.

In 1542, the Portuguese settled in Japan; but there, as elsewhere, their attempts to proselytise led to strife, and they were expelled. In 1660, when the Dutch opened negotiations with the Japanese, they were allowed to send two ships annually for purposes of trade, but on condition that they should not interfere with the religion of the inhabitants. For two centuries and a half, the Dutch and Chinese had the monopoly of the Japanese trade. They were confined to a small island on the coast of Kiusiu, near Nagasaki. The government maintained its isolation until the islands were visited by the United States' expedition under Commodore Perry in 1854, which obtained entrance to the port of Simoda. The English followed the example set them in 1858, and since then the commerce of Japan has been opened to Europeans. A great revolution has been brought about: English books have been translated into Japanese; Japanese students have begun to frequent the European schools of medicine and law, our dockyards, and our engineering establishments; not one European art or science is now neglected by them; and they bid fair, in a generation, to rise to the level of European progress.

Yedo, now Tokio (pop. 823,000), the capital of Japan, covers a large space, 17 miles long, and 10 broad; this area, however, includes extensive gardens. Canals lined with trees traverse the principal streets.

AFRICA—OCEANIA.

THE continent of Africa is situated in the Eastern Hemisphere, to the south of Europe and the south-west of Asia, and lies between lat. 37° 20′ north and 34° 50′ south, and long. 17° 30′ west and 51° 30′ east. It is bounded by the Mediterranean on the north, by the Suez Canal and the Indian Ocean on the east, and by the Atlantic on the west. Five thousand miles in length, and 4700 in its greatest breadth, and comprising an area of 12,000,000 square miles, it is the second largest of the great divisions of the globe. Anciently, certain portions of Africa stood high in civilisation and advancement. Egypt, the cradle of civilisation, now contains the most renowned monuments of antiquity. Two centuries before our era, Carthage sent armies to the gates of Rome. North Africa, along with Egypt, was the granary of imperial Rome. Alexandria and Carthage were reckoned among the leading centres of learning and culture in early Christian ages; and in later times, the Moors, who succeeded in founding influential states in North Africa, extended their energy and enterprise far into the interior of the continent, and across to Europe. In more modern times, Africa had so relapsed into barbarism as to have interest for the outside world chiefly in connection with the gold and slave trades, the expeditions of the Morocco pirates, and as presenting a field for the adventures of travellers. But the rise of the united states of Liberia on the west; the possession and partial colonisation of Algeria by the French nation; the recent development of political and industrial life in Egypt; the opening of the Suez canal; the British expeditions to Abyssinia and the Gold Coast; the important and growing traffic between Central Africa and Zanzibar; the labours and explorations of Livingstone and other travellers; and the occupation and colonisation of the Cape of Good Hope, part of Kaffraria, and Port Natal, by Great Britain—have contributed somewhat to restore Africa to her place of interest and importance in the world.

PHYSICAL FEATURES, ETC.

Among the peculiar physical conditions of this great continent are—its remarkable compactness, the coast-line being marked by few indentations or projections; its insular position; and its lying for the greater part within the torrid zone. It has three main characteristics of physical conformation. These are: its mountain-system, which at a distance of from 50 to 300 miles from the shore, surrounds nearly the whole of the continent; the great raised plateau of which the interior of its triangular portion, south of Cape Guardafui and the Gulf of Guinea, consists; and the Sahara, or Great Desert.

The Atlas Mountains in the north, between the Mediterranean and the Sahara, and stretching from the Atlantic to Tripoli, are connected geologically with Southern Europe, and comprise several ranges, which ascend from the sea-board in successive terraces, and increase in height from Tripoli, where they are 2000 feet high, to Mount Miltsin (11,400 feet) and Jebel Tedla (13,000 feet) in Morocco. Between the spurs abutting to the north, lie the valleys which constitute the fertile region of the Tell. The low ground along the Atlantic, marked by a tropical luxuriance of vegetation, but with an unhealthy climate, is backed by the Kong Mountains, between the Gulf of Guinea and the Niger; the Cameroon Mountains, stretching eastward into the interior; and by several chains southward to Damara Land, the country in front rising in terraces. Similarly, in South Africa, the land rises in sandstone terraces intersected by granitic rocks, and having the Zwellendam range 20 miles inland, and 200 miles in length, whose crest is Table Mountain, 3816 feet in height; the Zwarte range, 30 miles farther back; and the range comprising Sneeuwveld (10,000 feet), Nieuwveld, &c. Along the east coast, at a certain distance from the sea, a continuous system of parallel ranges extends, increasing in height towards the equator, and bearing the names of the Drakenberg Mountains (10,000 feet), the Lupata Mountains in Mozambique (8000 feet), the Kenia and Kilimandjaro in Zanzibar (17,000 and 20,000 feet). The high table-land of Abyssinia and Upper Ethiopia forms the north-eastern crest of this system. Inside of this mountainous border the interior of the continent consists of an immense plateau, with a cup or basin shaped appearance, sloping on the whole from east to west. This table-land, by which the climate of Central Africa is to some extent modified, is of a diversified character, having undulations, mountains, valleys, plains, swamps, wastes, hollows, as well as immense lakes and rivers.

The Sahara, or Great Desert, stretches from Morocco on the west to the valley of the Nile on the east, and from the southern base of the Atlas range to Sudan. Its length, from the Atlantic to the western edge of the valley of the Nile, is about 3000 miles, and its average breadth from north to south 1000 miles. The surface of the Sahara is varied by depressions and broad plateaux from 1000 to 3000 feet above the surrounding ground. A remarkable feature of the Sahara is the Wed Mzi, which, rising in Djebel Amour, flows during almost its entire course of 400 miles underground. After an east, north-east, and finally south-east course, it falls into Chott Melr'hir. Over a great part of the Sahara, rain never falls, and everywhere it is rare; it is thus condemned to sterility. It consists partly of tracts of fine shifting sand, which frequent storms of wind raise into the air, so as often to overwhelm travellers. But the greater part of the surface consists of naked but firm soil, composed of indurated sand, sandstone, granite, and quartz rocks, often rising into ridges or hills. The desolation is interrupted at intervals by patches, sometimes of considerable extent, covered with bushes and coarse grass, and often of great beauty and fertility. These oases, or wadies, as they are called, are valleys lying below the general level of the Desert, having the water-bearing stratum, which is below the usual level of the Sahara, at or close to their surface. They are most numerous and fertile in the eastern portion of the Desert. The easiest route across the Desert to Sudan runs from Tripoli through the kingdom of Fezzan to Lake Tchad. The portion of the Desert lying east of the route above described is called the Libyan Desert; and it is chiefly in this region that the oases are susceptible of cultivation: the tracts of vegetation in the western portion are fit for little else than pasture, chiefly for goats and sheep. The chief production of the more fertile oases is dates; but other fruits and grain are also cultivated. Gum-arabic is another production. Some of the larger oases support thousands of inhabitants living in villages. Commerce is carried on across the Desert by various routes by means of caravans, consisting of from 500 to 2000 camels, with their attendants. The distance between the wells sometimes exceeds ten days' journey; and when a well is found dry, men and animals are in danger of perishing. The inhabitants consist of independent tribes of Moors, Berbers, and Arabs.

The *geology* of Africa is yet but imperfectly known. The sections recently traversed present a variety of schists, shales, limestone, syenite, sandstone, tufa, with protruding granite and trap rocks. 'The whole of the Sahara is but the upheaved bed of a tertiary, or even quaternary ocean; the deltas of the Nile, Niger, and other great rivers consist of recent alluvia; the formations of the Cape are chiefly mesozoic sandstones; the northern belt consists largely of soft tertiary limestone; the primary hills of Abyssinia and Nubia are known chiefly for their granites and porphyries; and most of the islands, whether in the Atlantic or Indian Ocean, are of recent volcanic origin.'

The *islands* connected with Africa are with one exception small, and generally far removed from the mainland. In the Indian Ocean are—Madagascar, separated from the continent by the channel of Mozambique, having an area of 230,000 square miles, or more than that of France, rich in mineral and vegetable produce, and with a population of upwards of 5,000,000; the important islands of Bourbon and Mauritius, the minor groups of Comoro, Amirante, and Seychelles, north of Madagascar; and Socotra, off Cape Guardafui. In the Atlantic are—Ichaboe and other islets along the south-west coast; St Helena, Ascension, Annobon, St Thomas, and Fernando Po, in the Gulf of Guinea; the Cape Verdes; the Canaries, which rise in Teneriffe to an altitude of 12,182 feet; Madeira, celebrated for its delighttul climate and wines—and lastly, the Azores.

The *rivers* of Africa are: on the west, the Niger, Joliba, or Quorra—for it goes by these and other names in different parts of its course—which rises in the Kong Mountains of Guinea, about 9° 25′ N. lat., 9° 45′ W. long. and flows first north, then north-east, and at last south into the Gulf of Guinea—its length is estimated at 2500 miles, and its navigability has been ascertained for a distance of 800 miles, but its banks are very pestilential; the Chadda, or Benué; the Senegal and Gambia, which enter the Atlantic near Cape Verde; the Congo, now identified with the Lualaba and Chambeze, in Central Africa; the Coanza; and the Orange River, forming the north boundary of Cape Colony. On the east, the Limpopo, falling into Delagoa Bay; and the Zambesi, rich in affluents, which falls into the Mozambique Channel. On the north-east, the Nile, which enters the Mediterranean by various branches, and is formed in Nubia by the junction of two streams—the Bahr-el-Azrek, or Blue River, rising in Abyssinia, and the Bahr-el-Abiad, or White River, which comes from the interior of equatorial Africa. The last tributary of the Nile is the Atbara, or Black River, from Abyssinia. Recent explorations have increased our knowledge of many of these rivers. Major Pinto, in his journey across Africa, 1878-9, found the Cubango rising to the west of Bihé on the west coast, and proved that it is not, as was long supposed, a tributary of the Zambesi, but that it loses itself in an enormous basin called the Makarikari in the Bamangwato country. The source of the Niger was determined by two clerks in the employment of a French merchant in Sierra Leone in July 1879. M. de Brazza, in 1875–8, traced the Ogowé close to its source, about 1° 45′ S.

Lakes.—The peculiar physical conformation of Africa, by which the water is thrown inwards on the central regions by the surrounding border mountain-ranges, makes it rich in lakes. In Northern Central Africa, between lat. 12° and 14° north, is Lake Tchad, which is of a triangular shape, and is about 180 miles long, and 100 broad. The other known principal African lakes are—N'gami, in the south, which drains the country between the Orange and Zambesi rivers; Nyassa, between lat. 14° 25′ and 10° 55′ south, being 210 miles long, and having an average breadth of 26 miles; Tanganyika, the southern end of which is in lat. 8° 42′ south, and which is 360 geographical miles long; Bangweolo, whose southern end is in lat. 12° south; Moero, 60 miles long, with exceptionally magnificent scenery; Kamolondo; Lincoln; the great Victoria N'yanza, whose southern point is in lat. 2° 44′ south, and which is 220 miles long, and 220 broad; the Albert N'yanza, about the equator, 300 miles long, and 90 broad; and the Dembea, or Tzana, in Abyssinia, through which the Blue Nile flows, about 65 miles long, and 30 broad, and situated 6000 feet above the sea-level. The aggregate area of the lakes of Central Africa has been estimated at not less than 100,000 square miles, and the lake scenery is often extremely beautiful and impressive.

CLIMATE—BOTANY AND ZOOLOGY.

The *climate* is wholly that of the torrid zone, with the exception of a belt on the north and the extreme southern projection.

The *vegetation* of Africa, without raising any question as to what may have been introduced from other continents, is decidedly less varied, and more unique, than that of Europe or Asia. Along the Mediterranean sea-board it greatly resembles that of Southern Europe. In Upper Egypt, Nubia, and Abyssinia, the characteristic plants are gum-yielding acacias, the cassia or senna-shrub, coffee, ginger, turmeric, cardamoms, the lotus or jujub, and the nelumbium or water-lily. Cape Colony is distinguished for its heaths, euphorbias, aloes, cactuses, thorn-apple, mimosa, and other prickly shrubs; and yields also luxuriantly such plants as have been introduced by the colonists. In the other known parts of the continent, the vegetation is strictly tropical, and often peculiar. Here flourish palms and dates, the banyan, gigantic adansonia, the dragon-tree, banana, papaw, tamarind, anona, sugar-cane, cotton-tree, cassava, tallow-tree, maize, manioc, yam, ground-nut, melon, pine-apple, and other forms native to warm regions; while in the islands are cultivated chiefly the vine, orange, melon, coffee, and sugar-cane.

The *Fauna*, as might be expected from the insulated nature of the continent, is in many instances peculiar, several of its forms being found in no other region. Among the more characteristic may be mentioned numerous apes and monkeys; the lion, panther, leopard, and other felinæ; the hyena, jackal, racoon, &c.; numerous species of antelopes and gazelles in the south; the buffalo, camel, dromedary, and giraffe; the horse, zebra, quagga; the elephant, rhinoceros, hippopotamus, and masked-boar; seals, dolphins, and other cetacea. Of *birds*—the ostrich, bustard, and guinea-fowl; the parrot family in great abundance; the flamingo, pelican, secretary-bird, and crane; the cuckoo, swallow, nightingale, and quail, which are only summer visitants in Europe. Of *reptiles*—crocodiles, alligators, monitors, &c.; serpents in great variety, many of which are poisonous; lizards and chameleons; and various species of turtle.

POPULATION.

The population of the whole continent is vaguely estimated at above 200 millions. The most characteristic races are those of the Negro group, occupying the central, western, and southern parts of the continent. The inhabitants of the north-east and north borders are believed to be allied to the Semitic peoples of Asia (see ANTHROPOLOGY). In the settlements belonging to European kingdoms, more or less of a foreign element has been introduced. The foreign powers having possessions in Africa are—*Britain*, occupying Cape Colony, which was taken from the Dutch in 1806; the Mauritius, with the minor islet-groups of Amirante and Seychelles, taken from the French in 1810; the islets of St Helena and Ascension; and the settlements of Sierra Leone and Cape Coast: *France*, possessing the island of Bourbon, the settlement of Senegambia, the somewhat expensive colony of Algeria, and since 1881, Tunis: *Portugal*, occupying some settlements on the Mozambique coast, the coast of South Guinea, the Cape Verde Islands, Madeira, and the Azores: *Spain*, to which belong the Canaries, and the forts or districts of Ceuta and Melilah, near

the Strait of Gibraltar: and *Turkey*, which holds a nominal superiority over Tripoli, Tunis, and Egypt.

Africa falls conveniently into five great divisions: Northern Africa, inclusive of the Great Desert; Western Africa; Southern Africa; Eastern Africa; and Central Africa.

NORTHERN AFRICA.

The countries of Northern Africa, known as the Barbary States—so named from the Berbers, the supposed original inhabitants of the district—are Morocco, Algeria, Tunis, and Tripoli, including Fezzan.

Morocco, a sultanate in the north-west, is bounded on the north and west by the Mediterranean Sea and Atlantic Ocean; on the east, by Algeria; and on the south, by a line running from Cape Nun to the Algerian frontier. It has an area of 230,000 square miles, and a population of eight millions, comprising Moors, Arabs, Berbers, Negroes, and Jews; the Moors being more than 4,250,000, and the Berbers over 3,750,000. The government is despotic. The religion is the Mohammedan. Civilisation is low. The manufactures are fine silks and leathers, in the production of which last, the Moors excel Europeans. The exports consist chiefly of wool, hides, grain, cattle and sheep, leather, &c. Two-thirds of the trade of Morocco are in the hands of British merchants. The navy, once powerful, is now inconsiderable.

Algeria.—Algeria (l'Algérie), a French colony, but belonging formerly to Turkey, lies between 2° 8′ W. long. and 8° 32′ E. long., and is bounded on the north by the Mediterranean, by Tunis on the east, by the Great Desert on the south, and by Morocco on the west. Its area is estimated at 160,000 square miles. The population at the last census was 2,921,246, of whom 217,990 were Europeans. The settled part of Algeria is divided into the three provinces of Algiers, Constantine, and Oran, which are subdivided into twelve departments. At the head of the colony is a governor-general, aided by a Colonial Council, whose members are appointed by the government of France. A French *corps d'armée* of 60,000 men is kept in Algeria. In 1870, the imports of the colony amounted to £6,907,628, and the exports to £4,978,250. Esparto for making paper, corn and flower seeds, are the principal exports. By far the largest part of the commerce is with France—on an average more than two-thirds. In 1877 the total imports were £8,112,132; exports, £6,880,251. In 1878, there were upwards of 400 miles of railway in Algeria.

Tunis, which lies on the Mediterranean, between Algeria and Tripoli, has an area of 75,000 square miles, and a population of about one million, of which the capital, Tunis, possesses 180,000, one-half being Jews; and Kairwan, the centre of the inland trade, 60,000. The state of Tunis, till 1881 practically independent, is now a regency under French protection. The recent Beys, as the rulers are styled, have succeeded in abolishing the slave-trade, and in establishing political equality. The territory of Tunis corresponds to that of ancient Carthage, and has a fine climate and fertile soil. Cattle, sheep, and horses are reared with success. Trade and manufactures flourish, particularly in Tunis and Susa.

Tripoli, a pachalik of the Turkish empire, situated on the Mediterranean, between Tunis, Fezzan, and the Libyan Desert, has an area of 200,000 square miles, and a population of 1½ million. The population of the capital, Tripoli, is 25,000. Vegetation in Tripoli is chiefly supported by copious dews. Tropical fruits are produced about the capital and Mesurata. The inhabitants rear sheep, cattle, horses, and mules. In addition to the products of the country, gold-dust, ivory, and natron, from the interior of the continent, are exported to Malta and the Levant. The natives are Berbers, Moors, and Arabs.

Fezzan, another Turkish pachalik, lying south of Tripoli, is an immense oasis, having a population of from 75,000 to 150,000. The arable ground is not more than one-tenth of the soil. Murzuk, the capital, is the starting-point from North Africa for Central Negroland. Fezzan enjoys periodic rain from the moist winds of the Mediterranean, which extend farther into the continent here than elsewhere.

WESTERN AFRICA.

The countries of Western Africa are: (1) *Senegambia*, which extends from the Great Desert to the Grain Coast. (2) *Upper Guinea*, stretching along the Gulf of Guinea, from the Grain Coast to the Bight of Biafra, and including, on the coast, *Sierra Leone*, *Liberia*, *Grain Coast*, *Ivory Coast*, *Gold Coast*, *Slave Coast*, *Calabar Coast*, and in the interior, several native kingdoms, of which *Ashantee*, *Dahomey*, and *Benin* are the chief. Sierra Leone is a British colony, founded in 1787, and since maintained, at a cost of nearly £8,000,000, with a view to the suppression of the slave-trade. Its population is about 50,000. Of the other British stations, which include *Elmina*, &c. recently ceded by the Dutch, *Cape Coast Castle*, on the Gold Coast, is the most important. Ashantee is a hilly country, but well watered and productive, having a population of 1,000,000 inhabitants, who have made some progress in agriculture and home-manufactures. Ashantee is rich in gold. It is under an absolute monarchy, and in 1873 signalised itself by a war with Great Britain, resulting in the destruction of Coomassie, and in the king's submitting to British terms, promotive of commerce and civilisation in that part of the world. Eastward from Ashantee is Dahomey, a kingdom also with an absolute monarchy, which is chiefly notorious for the human sacrifices enacted to escort into 'Deadland' a deceased monarch with a suitable ghostly retinue, or to furnish ghostly messengers to the king's departed relatives. The prevailing worship is fetichism. Dahomey is celebrated for its Amazons, or women-soldiers, who are called the king's wives, and who numbered 2500 when seen by Captain Burton. The most important state in Western Africa is *Liberia*, situated on the Grain Coast. Liberia was formerly a dependency of the United States of America, but was proclaimed a free and independent state in 1847. The total population is 720,000, all Negroes; of these, 19,000 are Americo-Liberians. The population of Monrovia, the capital, is estimated at 13,000. The revenue is 111,000 dollars. Thirty

coast-traders have been built by the Liberians, and they own other vessels, which are engaged in commercial intercourse with Great Britain and the United States. In 1881, the exports of Western Africa, including Liberia, were valued at £1,895,656.

(3.) *Lower Guinea* extends from the Bight of Biafra to Southern Africa, and includes the coast districts of Loango, Angola, and Benguela. This country remains in an undeveloped condition, and is still tainted by traffic in slaves. It belongs nominally to the Portuguese, who first discovered it, and made early settlements on its coast.

SOUTHERN AFRICA.

The *Cape Colony* was founded by the Dutch under Van Riebeek in 1652. The settlement had grown to considerable dimensions when the English took possession of it in 1796. Restored to the Dutch at the peace of Amiens, it was finally occupied by Great Britain in 1806. Inclusive of the Transvaal, now only under British suzerainty, the present boundaries of the Cape Colony in the wider sense are the Orange River and the Limpopo River, the encircled area of the Orange River Free State being, however, independent of Britain; on the south, the Indian Ocean; and on the west, the Atlantic. The area of Cape Colony proper is about 200,000 sq. miles; with dependencies, near 350,000. The dividing range of mountains, called by the various names of Stormbergen, Nieuwveld, &c. runs across the country in a south-westerly direction about 100 miles from the coast. On the east, between this principal range and the sea, lie two other ranges, less continuous and regular. Owing to the fact that the prevailing winds, which at different seasons are from the south-east and north-west, fail to deposit their stores on the opposite side of the Dividing Range, a transposition of seasons occurs in this latitude; harvest depending chiefly on the rainfall, the people are sowing and planting on the one side, while they are reaping on the other. The country is liable to long-continued droughts; it has, however, special natural adaptations for water-storage.

The population of the colony is extremely varied, including Portuguese, Dutch, English, French, Germans, Kaffirs, Hottentots, Malays, Mozambiquers, and Africanders or half-castes. Of the whole population—which, inclusive of British Kaffraria, amounts to 720,000—200,000 are Europeans, about 150,000 are Kaffirs, and over 80,000 Hottentots. Of the European population, the English are outnumbered by Dutch, Germans, and French. The colony is divided into two great provinces, the Eastern and Western, which contain sixteen divisions. Responsible government, as in the Australasian colonies, was introduced into the Cape of Good Hope in 1872. In 1871, the revenue of the colony was £836,174; in 1872, it had risen to £1,161,548. In 1871, the imports were valued at £2,585,298; and the exports, £2,531,609. In 1881, the revenue was £4,835,189; the imports, £9,227,171; the exports, £4,220,706. (It is to be remembered that between 1871 and 1881 the area of the colony had been much increased.) Wool forms the chief article of export. Other important exports are diamonds, copper ore, sheep-skins, ostrich feathers, wine, untanned hides. The agricultural farms are generally small, but the sheep-farms frequently contain from 3000 to 15,000 acres. A very large population was drawn to Griqualand West, on the discovery of diamonds there, a few years ago. Griqualand includes the territory along the Orange River, and around its junction with the Vaal. The area of the fields is 20,000 miles, of which, however, it has been calculated that the farms yielding diamonds form only a small part. Great prizes have been obtained and fortunes made on these fields, which are accessible from Port Elizabeth, Natal, East London, as well as Cape Town. One of the principal drawbacks, indeed, has been the lack of adequate means of transport; but the colonists are now face to face with the difficulties, and have made fair beginnings in opening up the country by means of railways. The colony is also deficient in good harbours, but the shipping at Cape Town is now secure, through a breakwater and docks. Cape Town, the capital of the colony, the most flourishing European settlement in Africa, is finely situated on Table Bay, has many good buildings, and contains a population of about 20,000. Its suburbs are extremely beautiful. Graham's Town, the seat of government for the Eastern province, has a population of 10,000.

Natal.—Situated between the 29th and 31st parallels of south latitude, Natal has a sea-board on the Indian Ocean of 150 miles, is bounded on the north-east by the Tugela or Buffalo River, and on the south-west by the Umzimculu, which separates it from Kaffraria; while the Quathlamba Mountains, a continuation of the Cape Range, divide it from the Free State and Basutuland. It contains an area of 25,000 square miles. The mountains which traverse the colony form it into a series of plateaux, suited for semi-tropical no less than European productions. The climate is very salubrious. Natal has but one important harbour, D'Urban or Port Natal. The chief rivers are the Tugela, Umcomanzi, Umgani, and Umzimculu. None of them is navigable, but the streams are permanent. The capital is Pietermaritzburg (pop. 2000), 50 miles inland, on a tributary of the Umgani River. Natal is a flourishing town with 1200 inhabitants.

Natal formerly belonged to Cape Colony, and was erected into an independent colony in 1856, when a constitution was granted to it, afterwards modified in 1870. It is governed by a lieutenant-governor, with an executive and legislative council. In 1871, the revenue amounted to £180,498. The population of the colony is about 315,000, and comprises original Dutch emigrant Boers, English and German settlers, and the remains of the broken Zulu tribes who originally possessed the country, the Europeans being about one-seventh of the whole population. The natives are generally docile, make good servants, and are largely employed in agricultural and pastoral pursuits. Some of them, indeed, headed by Langalibalele, rebelled in 1873, but were soon suppressed. Again in 1879 war broke out between England and Ketchwayo, king of the independent Zulu country, who inflicted several severe blows on the British army before he was finally defeated and taken prisoner. In 1871, the imports were of the value of £385,812, and the exports, £493,128. The chief export is wool; other exports are sugar,

ivory, hides, raw cotton. Coffee and maize are grown in considerable quantities.

The *Orange River Free State* consists of the territory lying between the two great branches of the Orange River, and separated from the coast by the mountain-chain of the Quathlamba, &c. It is occupied by Dutch Boers, who retired from Natal when declared a British colony, and formed a republic here, along with some coloured inhabitants. In 1880, the whites numbered 61,000 and the natives 72,500. The country itself is a vast plateau, rising from 3000 to 5000 feet above the sea-level.

The *Transvaal*, on which Dutch Boers founded a republic in 1848, became a British colony in 1877, but was restored to independence, though under British suzerainty, in 1881. It also consists of an immense plateau, sloping to the north, and having an area of 110,000 square miles. The European population is about 40,000. A considerable trade is carried on with Natal, and the Portuguese settlements are occasionally visited by trading parties. Copper, iron ore, and gold are met with in Transvaal.

EASTERN AFRICA.

EGYPT.

Egypt, properly so called, is a small country occupying the north-east corner of Africa, on both sides of the Nile, as far south as the first cataract, about 24° north lat.; but the territory now under the sway of the ruler of Egypt, embraces in addition, Nubia, Cordufan, Bariah, and undefined tracts of country in the basin of the White Nile. Previous to the acquisitions recently made by the expedition under Sir Samuel Baker, the area of Egypt, in this extended sense, was vaguely estimated at upwards of 600,000 square miles, with a population of 7,000,000.

The area of Egypt proper is only about 130,000 square miles. It consists of two great natural divisions — namely, a cultivated part, or the valley and Delta of the Nile, which are formed by deposits of that river, comprise only a tenth of the above area, and are of amazing fertility, due to the annual floods of the Nile, aided by irrigation; and barren table-lands and hilly tracts, which occupy the rest of the country, and lie on each side of the fertile part.

The valley of the Nile is, in Upper Egypt, six miles, and in Lower, twelve miles broad, on an average; at a few points, the hills approach the margin of the river, and the extreme breadth of the valley is 25 miles. The Nile, 90 miles from its mouth, divides into two widely diverging branches, called the Rosetta and Damietta branches. The space between is a triangular flat, 90 miles on each side, called the Delta, from its shape resembling the Greek letter Δ, or *Delta*. The Delta has an average height above the sea of 50 feet, and the highest parts are 100 feet. Anciently, the Nile ran in seven great divisions through the Delta into the sea; but the two extreme ones just mentioned are alone now navigable, the others having been silted up.

The grand phenomenon connected with the Nile is the annual overflow of the low lands of the valley and Delta along its banks. These inundations, and the fertility they produce, are due to periodical rains and melting of snow on the mountains of Abyssinia and in the basin of the White Nile. At Khartoum, the Nile begins to increase early in April; but in Lower Egypt, the inundation usually begins about the 25th of June, and attains its height in three months. It remains stationary about twelve days, and then subsides. The fertility of Egypt is entirely dependent on the rise of the Nile, for the country may be said to have no rain. At the end of November, the irrigated land has dried, and is sown, and is covered with green crops, which last till the end of February. In March is the harvest. The Delta and valley of the Nile consist of alluvium, or mud and sand brought down by the floods almost entirely from the Atbara, the last tributary received by the Nile. This alluvium contains few or no pebbles, and little detritus of any size. The Nile deposits every year a new layer; the average depth thus added to the soil is estimated by some at 4½ inches in a century, while others make it as much as six inches.

The climate of Egypt is very dry and warm. The chief drawbacks are the occasional hot winds of spring and summer, and the moistness of the Mediterranean sea-board. Among the chief productions of Egypt may be mentioned the date-palm; the papyrus, anciently used as material for paper, now, however, rare; and the lotus or water-lily of the Nile. The sugar-cane, cotton, indigo, and tobacco are cultivated, and gourds and melons abound. Wheat, barley, maize, and durra are raised. The country is deficient in trees.

Egypt, formerly a pashalik of the Turkish empire, came, in 1873, to be governed by a semi-independent sovereign, with the title of Khedive, but paying an annual tribute to the sultan. Since the rebellion under Arabi Pasha in 1882, Egypt has, however, been occupied by British troops, and administered under British influence. In 1873, the sultan granted the khedive the right of concluding treaties. From remote times, Egypt proper has been divided into three great districts—Lower Egypt, Middle Egypt, and Upper Egypt, which are subdivided into eleven administrative provinces. The whole population was stated in 1870 at about 5,000,000. The town population comprises 150,000 Copts, descendants of the ancient Egyptians; 8000 Jews; 3000 Armenians; and 25,000 domiciled Europeans. The total town population is 500,160, of which Cairo, the capital, contains 256,700; Alexandria, the chief port, 164,400; and Suez, 4160. The rural population is in a condition of serfdom. In Cairo and Alexandria, there are many slaves. The total commerce of Egypt averages in value £35,000,000, the greater proportion of which consists of goods in transit between India and Great Britain, being 70 per cent. of the whole. The opening of the Suez Canal, which was constructed by a French company, at a cost of £16,000,000 sterling, and was opened for navigation on November 17, 1869, has had an important influence on Egyptian commerce. In 1870, 491 ships, with a total tonnage of 436,618, passed through the canal; in 1871, the number of ships had increased to 3198 (of which 2565 were British), and the tonnage to 7,122,156. The receipts of the Suez Canal Company, in 1882, amounted to £2,500,000. Egypt possesses considerable railway and telegraph systems, which are almost wholly state

property. The revenue in 1881 was £9,229,965. The principal source of revenue is a land-tax. The Egyptian finances were managed from 1879 till 1882 under the joint control of England and France, each represented by a Controller-General. The military movement of 1882 led to the intervention of England, a short campaign, and the attempted reorganisation of Egypt under the Khedive as a constitutional sovereign. Close on this followed the rebellion of the Soudanese provinces belonging to Egypt, under the Mahdi or soldier-prophet, the English expedition to the Soudan, the siege of Khartoum, and the death of Gordon Pasha.

Nubia, lately Egyptian, lies to the south of Egypt. It contains many old Egyptian monuments from Philæ to the island of Argo. Nubia consists of two parts: the southern, which is within the limits of the tropical rains; and the northern, which is beyond those limits, and, like Egypt, is extremely dry; being, in fact, desert, excepting within a quarter of a mile on either side of the banks of the Nile, which flows through it.

ABYSSINIA.

Abyssinia, lying to the south-east of Nubia, and along the Red Sea, is for the greater part mountainous, having high table-lands and deep ravines. The Samen or Samien Mountains rise to a height of 15,000 feet. Between the highlands and the Red Sea is Adal, a flat country. The chief rivers are the Bahr-el-Azrek, or Blue Nile; the Takazze, a tributary of the Nile; and the Hawash in the south, which flows eastward into Lake Assal in Adal. Tzana, or Dembea, is the largest lake, round which the country is extremely fertile. The climate and productions vary with the varying characters of the country. Abyssinia is divided into three main districts: Tigré, which is the northern promontory of the table-land; Amhara, which is the middle province, and in which Gondar, usually reckoned the capital, is situated; and Shoa, which is the southern extension of the highlands. Abyssinia has acquired an interest from the late self-styled Emperor Theodore, who, having subdued the other chiefs or kings, began a frightful course of tyranny and cruelty. At last he imprisoned the British consul and other Europeans, and compelled the British government to send an expedition of 10,000 troops, which (1868) took his fortress of Magdala, where he was found among the slain. On the withdrawal of the British forces, the native chiefs began to struggle, as usual, for the supremacy. From the 4th century, the Abyssinians have professed Christianity, which among them is mixed with Judaism and paganism. Their bishop, or Abuna, is consecrated by the Coptic patriarch of Alexandria. The state of civilisation is low.

Somaliland, the triangular tract lying south-east of Abyssinia, is bounded on the north by the Gulf of Aden, on the east by the Indian Ocean, and on the south and west by the Indian Ocean and the river Jub, and has an area of 330,000 square miles. The principal rivers are the Jub, the Haines, and the Nogal. Between the Jub and the Haines, the country is grain-producing; between the Haines and Nogal, it is well adapted for pasture-land. The Somali are a people of Arabian descent, and addicted to pastoral pursuits. Somaliland excels all other countries in odoriferous gums, which are conveyed to Aden. The chief trading-place in Somaliland, which was explored, in 1854, by Burton and Speke, is Berbera, on the coast opposite to Aden.

ZANZIBAR.

The sultanate of Zanzibar consists of the island of that name, and a coast-tract on the mainland, extending more than 1000 miles from Somaliland to Mozambique, with an undefined breadth towards the interior. The island, which is about 25 miles from the continent, has an area of very nearly 620 square miles, with a population of 200,000, of which the town of Zanzibar, the capital of the sultanate, contains 100,000. They consist of Arabs, Banyans or Hindu traders, and negroes. Zanzibar is the commercial emporium for the central regions of the continent. A large part of the traffic has hitherto been in slaves; but the sultan, at the instance of Great Britain, has undertaken to suppress it. Zanzibar, which from 1784 was under the government of the Imaum of Muscat, became a separate dominion in 1854.

MOZAMBIQUE.

Mozambique extends from Cape Delgado to Delagoa Bay, and is divided by the Zambesi river into Mozambique Proper and Sofala. The area is 283,500 square miles, and the population 300,000. The country belongs nominally to the Portuguese, who have a governor-general there, but their actual possessions are confined to a few stations, of which Mozambique, Quilimane, Sena, and Teté are the principal. Mozambique, the capital, is situated on a small coral island, a little distance from the shore, and has a population of 8522, of whom 7000 are slaves. The country is rich, but it has an unhealthy climate.

CENTRAL AFRICA.

Central Africa includes the whole of the interior of the continent south of the Great Desert. The efforts of English and French travellers in the 17th and 18th centuries, were directed to explore the country of the Niger, in Northern Central Africa, called Sudan or Nigritia, and to reach the famous city of Timbuktu, reported as being situated on its banks. For a time, the English supposed the Gambia, and the French the Senegal, to be the outlet of the Niger. At length, in 1795, Mungo Park, having landed on the African coast, set out from the village of Pisania, on the Gambia, and after various adventures came in sight of the Niger, near Sego. In 1805, at the instance of the government, he undertook another journey with the purpose of 'proceeding up the Gambia, crossing the country to the Niger, and travelling down that river to its termination.' Mungo Park succeeded in tracing the course of the Niger eastward beyond Timbuktu, and southward as far as Boussa. Richard Lander, in 1830–31, solved the mystery attaching to the river, which was found by several outlets, and with a large delta, to enter the Gulf of Guinea. This delta is about the size of Ireland. In the years

1850–55, Dr Barth, crossing the Great Desert from Tripoli, explored the country of Nigritia as far south as Adamawa, and from the east of Lake Tchad westward to Timbuktu. From Kakawa, the capital of Bornu, a kingdom which lies west of Lake Tchad, he travelled southward to Yola, the capital of Adamawa, which is three miles in length, and has 12,000 inhabitants. Here he came upon the river Chadda, or Benué, flowing in a broad and majestic course from east to west, which joins the Niger by Kororofa. Dr Barth expressed his conviction that 'along this natural high-road, European influence and commerce will penetrate into the very heart of the continent.' He also visited Masena, capital of the country of Bagirmi, which lies upwards of a hundred miles to the south-east of Lake Tchad, and which contains a population of about a million and a half, nominally Mohammedans. He next proceeded through the Houssa states, in the direction of the Niger. Of this region the dominant inhabitants are the Fulbe, or Fellatah, an intelligent and energetic people, strongly Mohammedan. Their principal city, Kano, contains a population of from 30,000 to 40,000. Cloth is manufactured and dyed in this chief commercial emporium of Central Negroland. The capital is Sokoto. Dr Barth spent eight months at Timbuktu, and reports that city as being provincial, but important as the seat of Mohammedan learning and worship, and as being upon that point of the Niger which is nearest to Morocco. The settled population of Timbuktu is about 13,000, and the floating population from 5000 to 10,000. It has a circumference of between two and three miles. The houses, as is usual in Central Africa, are of clay. Gold, salt, and kola-nut are the chief articles of commerce. The population of Negroland is about 10,000,000.

Of *Southern Central Africa* but little was known previous to the laborious explorations of Dr Livingstone; although the continent had been crossed by two Portuguese, and on two occasions the route from Teté to Cazembé had been made. Having commenced as a medical missionary among the Betjuans, or Bechuanas, north of the Orange River in 1840, Livingstone crossed the Kalihari Desert in 1849, and came upon Lake N'gami, which drains the country between the Orange and Zambesi rivers. In 1850, he visited the chief of the Makololo, a Betjuan tribe, in the valley of the Upper Zambesi, whose capital is Linyanti. To counteract the slave-trade carried on by the Mambari, a tribe intermediate between the Makololo and the Portuguese settlements on the west coast, Livingstone returned to Linyanti in 1853, with the object of finding a direct route to the west coast. He first explored the Zambesi valley north to lat. 14° S. where the rivers Leeba and Liambye unite. This country is very fertile. The Makololo rear cattle and grow maize, beans, vegetables, and durra. In cultivating, they employ the hoe, a native manufacture of iron. Afterwards, proceeding from Linyanti, Livingstone came to the country governed by the Muata Yanoo, a flat region, with some wooded tracts, and striking westward, arrived at Loanda, the capital of the colony of Benguela, on the 31st May 1854. Returning to the interior, he next resolved to try whether a better commercial route could not be found eastward, along the Lower Zambesi. Hindered from descending the river in boats, by the great Victoria Falls, he struck north-east to the confluence of the Kafne, thence by the Zambesi to Teté, and finally to Quilimane. In 1859, Livingstone and Kirk penetrated to Lake Shirwa, and traced the Shiré to Lake Nyassa. In 1857–58, Lake Tanganyika was discovered by Burton and Speke, who crossed from Zanzibar, exploring on their way the plateau country of the Unyamuezi. Speke thereafter discovered the great Victoria N'yanza. In 1860, Speke and Grant found the northern outlet of this lake; but being obliged to part with it at its westward bend, the travellers held northward, and reached the White Nile, above Gondokoro, where they met Sir Samuel Baker, to whom they reported that they had heard of another lake lying to the west of this route. In 1864, Sir Samuel Baker explored this lake, which he called the Albert N'yanza, a great inland sea, 300 miles long, and 90 broad. In 1866, Dr Livingstone set out with the object of discovering the true source of the Nile. Starting from the east coast, he made his way into the interior, passing Lake Nyassa, and reaching the elevated region south of Lake Tanganyika. He there discovered the Chambeze, which he subsequently found to rise about 11° S. and flow westward into Lake Bangweolo, and beyond is known as Luapula and Lualaba. It has since been proved to be the head-waters of the Congo, but was regarded by its discoverer as belonging to the Nile basin. At Ujiji, Livingstone, whose long absence in the interior had caused great anxiety, was found by Stanley in November 1871. His next attempt to explore these regions more fully ended with his life at Ilala, near Lake Bangweolo, 4th May 1873, and thence his body was brought to be buried in Westminster Abbey. Lieutenant Cameron, after exploring Tanganyika, followed the Lualaba to Nyangwe, whence, striking across the continent, he reached Benguela on the Atlantic seaboard in October 1875, after a march of about 3000 miles, H. M. Stanley, in his expedition of 1874–77, conclusively proved what Cameron had rendered almost certain—that the Lualaba or Luapula is identical with the Congo. Starting from the east coast at the head of 300 men, he circumnavigated the Victoria Nyanza, examined part of Tanganyika, and, striking the Lualaba at Nyangwe, forced his way in spite of enormous difficulties along the course of the river, and arrived at the mouth of the Congo in August 1877. Since, Stanley has headed the Belgian expedition for establishing four civilising stations on this river. Major Serpa Pinto, in 1877–79, accomplished the journey across Africa from Benguela to Natal, exploring the upper waters of the Zambesi.

A remarkable incident in the recent history of Africa is the formation of the Free State of the Congo, mainly the outcome of the enterprise of Leopold II., king of the Belgians, and the traveller Stanley. A conference of the great powers at Berlin sanctioned the constitution of such a state under a European or American governor and officers. The state comprises the greater part of the basin of the Congo River from the great lakes to the Atlantic, with a coast line of nearly 40 miles on the Atlantic shore. Léopoldville is the chief station in this vast area.

OCEANIA.

This term is employed by geographers to denote the numerous islands scattered over the great ocean which extends from the south-eastern shores of Asia to the western coast of America. Oceania is separated from Asia by the Strait of Malacca, the Chinese Sea, and the Channel of Formosa ; and from America by a broad belt of ocean, comparatively free of islands. It may be said to extend from latitude 50° south to 30° north, and from longitude 96° east onward to 115° west, in the opposite hemisphere. It naturally divides itself into three great sections—Malaysia, Australasia, and Polynesia—whose aggregate area has been vaguely estimated at 4,132,000 square miles, and population at from 30,000,000 to 40,000,000.

MALAYSIA.

This division takes its name from the Malays, who are the principal inhabitants, and includes the archipelago immediately adjoining the south-eastern coasts of Asia, perhaps more generally known as the East India Islands. It lies between latitude 12° 40′ south and 20° north, and longitude 95° and 134° east.

As to *government*, the civilised powers having possessions in Malaysia are the Dutch, Spaniards, and Portuguese. The Dutch possess the whole of Java ; the greater part of Sumatra, where they are continually extending their dominions ; the Moluccas, or Spice Isles ; and generally exercise a predominating influence over all the southern portion of the archipelago. Java, inclusive of Madura, has an area of 51,000 square miles, and a population of near 20,000,000. The 'culture-system' of forced native labour prevails in Java, which is the granary of Malaysia. The imports are about £5,000,000 a year, and the exports about £8,000,000. Rice, sugar, salt, coffee, indigo, and tobacco are the staple exports. The Dutch supremacy in Sumatra has been lately challenged by the sultan of Acheen. Hostilities were begun in 1873, and though important advantages have been gained by the Dutch, the contest is hardly over yet. The greater part of Borneo, which, after Australia and Papua, is the largest island on the globe, is also ruled by the Dutch. The Dutch are also dominant in the great island of Celebes, somewhat smaller than Sumatra. The Spaniards possess the greater part of the Philippine group ; and the Portuguese retain only a portion of the island of Timor. Great Britain has possession of the island of Labuan, which has an extensive bed of excellent coal, besides other natural advantages.

AUSTRALASIA.

Australasia, which is used by some geographers in much the same sense as that here given to Oceania, is applied in its stricter sense to the central and largest section of Oceania, consisting of the great island of Australia or New Holland, and the belt of islands that lie north-east, east, and south-east of it. The chief islands forming this belt are — Papua or New Guinea, New Britain, New Ireland, Solomon's Islands, New Hebrides, New Caledonia, Norfolk Island, New Zealand, Chatham Islands, Auckland Islands, and Van Diemen's Land or Tasmania.

The island of Papua, separated by Torres Strait from the north of Australia, extends about 1300 miles in length, with an estimated area of 300,000 square miles. It is little known. Of the other islands forming the northern section of the belt, New Caledonia, taken possession of by France in 1854, is the largest, being 400 miles long, though not more than 30 miles broad. The population is estimated at about 60,000.

The great island, or rather continent, of Australia, together with New Zealand, and Tasmania, Chatham Island, &c. being British possessions, require more particular notice.

AUSTRALIA—COLONIES.

Australia extends from 10° 45′ to 38° 45′ S. lat. an extreme breadth of about 2000 miles ; and from 112° 20′ to 153° 30′ E. long. the greatest length being 2600 miles. The area is estimated at 2,970,000 square miles, or about three-fourths of that of Europe. It is probable that Australia had been long known to the Chinese ; but the first certain discovery of its existence by Europeans is due to a Spanish expedition sent from Peru in 1605, one of the commanders of which gave his name to Torres Strait. The south-east coasts were discovered by Captain Cook in 1770, who gave the country the name of New South Wales.

With the exception of two tracts—one on the south coast, between Southern and Western Australia, and the other on the north-west coast—the island is girdled by a range of mountains varying from 2000 to 6500 feet in height, sometimes approaching close to the shore, and at other times leaving from 30 to 100 miles of plain between them and the sea. The mountain range is most continuous and elevated on the east and south-east. Within the colony of New South Wales, it is called the Dividing Range ; and the southern section has the distinctive name of the Australian Alps.

The inner slopes of the bordering mountains consist of thinly wooded terraces or grassy downs, traversed by rivers rising in the heights ; and these downs form the great sheep-pastures of the colonies. They sink down towards the interior, which in some parts is well grassed and watered, and fitted for pastoral purposes.

Many of the rivers or water-courses of Australia have a peculiar character ; they spread out into marshes, lagoons, and muddy ponds, covering large tracts in the rainy seasons, and at other times forming merely a string of deep ponds or water-holes, or becoming altogether dry. The stagnant surface-water retained in the water-holes is, in the level country, the only resource of men and animals in the dry season.

The *climate* of Australia, excepting on the marshy shores of the north-west, is singularly salubrious, though liable to sudden and great changes of temperature. There is, on the whole, a deficiency of moisture, and, in the interior, the aridity and heat are sometimes excessive.

The colonies of Australasia constitute one of the most important possessions of Great Britain. For the past thirty years, they have been outlets for no small amount of British capital and enterprise. Of immense area, having extensive regions with a temperate climate, affording illimitable scope both for agricultural and pastoral pursuits; rich in minerals, particularly in gold; they have attracted a very large share of the attention of emigrants. The initial difficulties of early settlement have been already overcome throughout nearly the whole of Australasia. Connected with the great centres of civilisation by electric telegraph, Australasia has several main lines of ship communication with Great Britain—one through the Suez Canal by way of India; another by San Francisco, in special favour in New Zealand; a third by the Cape of Good Hope, returning in general by Cape Horn. Vessels also ply between the Australasian colonies and the Mauritius, Cape of Good Hope, India, China, South America, and the surrounding islands. Within the colonies, not only are there the advantages of law and order, but also of education and religion, which have kept pace with the rapid material advancement. The responsible system of government obtains throughout all these colonies, with the single exception of Western Australia.

British Colonies in Australasia.	Area in sq. miles.	Population in 1881.	Revenue in 1881.	Imports in 1881.	Exports in 1881.	Public Debt in 1881.
New South Wales	309,175	781,265	£7,377,786	£17,409,326	£16,049,503	£16,924,019
Victoria	87,884	882,232	5,186,011	16,718,521	16,252,103	22,426,502
South Australia	903,690	286,324	2,171,988	5,224,063	4,407,757	11,196,800
Queensland	668,224	226,968	2,023,668	3,601,906	3,289,253	13,245,150
Western Australia	1,057,250	32,359	254,313	404,831	502,769	510,000
Tasmania	26,215	118,923	505,872	1,438,524	1,555,576	2,003,000
New Zealand	104,403	534,032	3,737,493	7,457,045	6,060,866	29,659,111

New South Wales.

New South Wales, discovered by Captain Cook in 1770, was colonised by convicts in 1788, when a convict establishment was formed by the British government at Sydney Cove, near Botany Bay. Originally, New South Wales comprised the territories which are now included in Victoria, South Australia, and Queensland. The present colony of New South Wales is situated within the parallels of 28° and 37° south lat. and 141° and 154° east long.; its greatest length is 900 miles; its greatest breadth, 850 miles; and it contains an area of 323,437 square miles. It is bounded by the Pacific Ocean on the east, by Victoria on the south, by South Australia on the west, and by Queensland on the north.

The Dividing Range, which opposite to Sydney is called the Blue Mountains, and farther north, the Liverpool Mountains, in the southern part of the colony, attains a height, in Mount Kosciusko of the Australian Alps, of 7308 feet. The numerous streams that rise on the west side of the watershed within the colony, all converge and empty their waters into the sea through one channel within the colony of South Australia. The southern and main branch of this great river-system is the Murray, which forms the boundary between New South Wales and Victoria; on entering South Australia, it turns southward, and enters Lake Victoria, which communicates with the sea by shallow channels, impassable even to boats. The Murray is navigable for steamers for a great part of the year. The other great trunks of the system are the Murrumbidgee, also navigable; the Lachlan, at times reduced to a string of ponds; and the Darling. The Macquarie, which passes through the Bathurst district, is a large tributary of the Darling, but reaches it only in the rainy seasons. The rivers on the eastern side descend with great rapidity, and in oblique tortuous courses, their channels often forming deep ravines. Many of them are navigable in their lower course for considerable vessels. The principal are the Richmond, Clarence, Macleay, Manning, Hunter, Hawkesbury, and Shoalhaven. The Hunter River, about 60 miles north of Sydney, opens up one of the most fertile and delightful districts in the country.

Climate.—The seasons are the opposite of those of Britain. The average temperature of summer is 72°; of winter, 55°. There are occasional frosts at Sydney, and snow in the interior. The hot winds that sometimes come from the deserts raise the thermometer to 120°, and scorch vegetation. The annual fall of rain is about 50 inches. Rain sometimes descends in continuous torrents, and causes the rivers to rise to an extraordinary height. Sometimes the rains almost fail for two or three years in succession.

In 1788, the whole population of New South Wales was 1030; in 1828, 36,598—14,156 of these being male, and 1513 female convicts. (In 1840, transportation to New South Wales ceased.) In 1871, the total population, exclusive of aborigines, was 503,981; of which number Sydney, including the suburbs, contained 134,755. In 1871, the imports amounted to £9,609,508, and the exports to £11,245,032. The principal export is wool, of which the quantity exported in 1871 was 65,503,306 lbs. valued at £4,740,632. In 1872, there were 3495 runs in New South Wales; 5,615,054 sheep; 2,271,923 horned cattle; 233,220 horses; and 146,091 pigs. Land then under cultivation, 297,575 acres; under wheat, 154,030 acres; 4152 acres under vines; and under grass for hay, 31,903 acres. The other principal crops were, barley, oats, maize, potatoes, sugar-cane (acreage, 4393), and tobacco. Free selection in land prevails here, as in Victoria (under which it will be explained). New South Wales is the chief coal-producing colony of Australasia. In 1871, the three mines which were worked produced 898,784 tons of coal, value £316,340. The colony has three main gold-fields, known as the Northern Fields, the Southern Fields, and the Western Fields. Three-fourths of the whole supply comes from the Western Fields, of which Bathurst is the capital. The total gold-yield in 1871 was 296,928 oz.—value, £1,143,781. The copper mines in 1871 produced 667 tons of copper, value £44,123. Oil and tin mines are also profitably worked. In 1871, the revenue was £2,218,699—of which £1,720,722 was derived from taxation, and £497,977 from the lease and sale of crown-lands. The debt of the colony, contracted chiefly for railways and public works, amounted to £10,614,330. There are in New South Wales four railway lines—the Southern, Northern, Western, and the Richmond Line, which in 1871 conveyed 1,067,686 passengers, the receipts for the year being £307,142. In the same year, there was an electric telegraph system, which comprised 5579 miles of wire, with 89 stations. The zigzag railway across the Blue Mountains impresses travellers as remarkable. There are in New South Wales three main roads.

Sydney, the capital, is situated (35° 52′ south lat. 151° 10′ east long.) on the shores of the magnificent harbour of Port Jackson, which is one of the finest in the world, and the scenery of which is exquisite. The city is well paved, lighted with gas, and supplied with water by a tunnelled aqueduct, and has many fine buildings. The harbour is possessed of excellent defences. The mean summer temperature is 74°; winter, 55°; mean, 67°. The other principal towns are Newcastle, Maitland, Paramatta, Bathurst, and Goulburn; the first four having a population of from 5000 to 7500. Newcastle stands in importance next to Sydney, and is celebrated as the centre of the coal-mines. Paramatta, on the river Paramatta, 14 miles from Sydney, is famed for its orange-groves. Bathurst, 200 miles north-west from Sydney, is in the centre of the richest pastures, and is the capital of the best gold-diggings in New South Wales. Maitland is the chief town in the Hunter River District, the richest agricultural portion of the colony, subject, however, to frequent inundations from the river. The Riverine District, on the Murray, is a vast pastoral country belonging to New South Wales, but owing to the facility for transit afforded by the Victorian railways, close to it, its traffic is more with Melbourne than Sydney.

Since 1855, the government has been vested in a governor, a legislative council, and legislative assembly, both elective. With the exception of a few points involving imperial rights, the chief Australian colonies have now the entire management of their own affairs. Sydney has a good university, inaugurated in 1852. There are several high schools, maintained by the fees of the scholars, and a number of primary schools throughout the country supported by government.

The kangaroo, the opossum, the iguana, and a kind of bear are the most notable beasts of the country, and of Australia as a whole. Snakes are common. The emu, the cockatoo, the parakeet, the magpie, and the laughing jackass are the principal birds.

Victoria.

Victoria, the smallest of the Australian colonies in point of extent, but the most important in wealth, population, and progress, is situated on the south-east of the island, and is separated from New South Wales by the river Murray on the north and north-east; on the west, from South

Australia by the meridian of 141° east long.; while on the south and south-east it is bounded by Bass's Strait. Its greatest length from east to west is 500 miles, and its greatest breadth from north to south is 300 miles, the area being 88,198 square miles.

The eastern and central portions are variegated by mountain-ranges and hills, interspersed with plains; the north and north-west districts, lying between the Murray and the parallel of 37° south lat. are mostly flat and monotonous deserts of sandy or meagre clay-soil, covered with hard rigid plants and shrubs, interspersed with salt-bushes, on which, however, sheep thrive. What is called the 'Mallee Scrub,' consisting of dwarf eucalypti, covers extensive tracts in various parts of the colony. The eastern portion is occupied by the Australian Alps, or Snowy Mountains, a continuation of the 'Dividing Range' of New South Wales. The highest peak is 7000 feet. It ends in Wilson's Promontory, the southernmost point of the colony, and is continued in a chain of islands to Tasmania. The loftiest range west of Port Phillip is the Grampians, about longitude 142° 20′, reaching, in the summit of Mount William, 4500 feet. Eastward from the Grampians are the Pyrenees (longitude 143°), a granitic range; and north-north-west from Melbourne lie the Mount Macedon and Mount Alexander ranges, containing the chief gold-diggings. A great part of the colony is of volcanic origin, and many of the mountains are evident craters. The soil resulting from the decomposition of the lava covers large tracts of great fertility.

Victoria is much better watered than the adjacent colonies. The rivers flow either north into the Murray, or south into the ocean, the watershed or axis of the colony being about 100 miles from the coast. The chief tributaries of the Murray, beginning at the east, are the Mitta Mitta, the Ovens (both auriferous), Broken Creek, Goulburn (navigable at times for 300 miles), the Campaspe, and the Loddon (rising near Mount Alexander). These rivers are greatly reduced in the dry season. Three considerable rivers—the Avoca, the Avon, and the Wimmera—rise in the Pyrenees and Grampians, and flowing northward, terminate in lakes, without outlet, in the Mallee Scrub. The southern rivers are—the Snowy River, in the east (longitude 148° 30′), and several that fall into Lakes King and Wellington, the Yarra Yarra (on which stands Melbourne), the Barwon, the Hopkins, and the Glenelg. A remarkable feature of the colony is the great number of salt-lakes.

The splendid natural harbour of Port Phillip was discovered in 1802 by Lieutenant Murray, and named after the first governor of New South Wales. The permanent settlement was begun in 1835 by two associations of colonists from Van Diemen's Land, headed by Batman and Fawkner, the latter of whom encamped on the present site of Melbourne. In 1851, the district became a separate colony, under a lieutenant-governor; and in 1855 a new constitution was granted, establishing responsible self-government.

The white population of Victoria in 1836 was 177; in 1841, 11,738; in 1851, 236,798; in 1861, 540,322; while in 1871 it amounted to 731,528 persons, of whom 17,935 were Chinese, and 1330 aborigines. Of the Chinese in the colony, only 36 were females. The town population is one-half of that of all Victoria, Melbourne, with her suburbs, containing 206,000; Ballarat, 47,201; Sandhurst, 21,987; and Geelong, 15,026. From 1835 to 1871, 1,019,553 immigrants arrived in the colony; and during the same period, 563,277 left it; leaving a balance of 456,276.

The chief pursuits are those of the squatter, the miner, and the farmer. Till within a few years ago, the squatters, run-holders, or sheep-farmers, were the principal class in Victoria. Renting large tracts of land from the crown, and grazing immense flocks and herds, they succeeded in establishing themselves in the first position in respect of wealth and influence, and when the lands came to be disposed of, they were able to buy up enormous portions. The best runs are in the western districts. Much of the wool-growing land of Victoria now belongs to the squatters by right of purchase. As the squatters threatened to endanger the growth of the colony by their continued absorption of land, the legislature, after many attempts, succeeded in devising, some few years ago, an effective counteracting measure, which is known as the system of 'free selection.' According to this, large sections of land are successively thrown open to the public by the Department of Lands, of which any one who is willing to become a *bonâ-fide* settler, and is able to cultivate and improve so much a year, and to pay a small rental, which, standing to him as purchase-money, makes the land his own in ten years, may select from 40 to 640 acres. This system has succeeded in settling a large number of people on the soil. It is administered by a body of land agents, whose business it is to collect the rents, and see that the stipulated improvements are annually made. When the settler is unable to pay the rent, and shews generally that he is unfit to grapple with the difficulties of his situation, as not unfrequently occurs in the case of small selectors, the land reverts to the state, and is resold. On the whole, notwithstanding incidental disadvantages, the plan has succeeded well for all the purposes for which it was introduced.

For a good many years, gold-mining has been an extensive pursuit in the colony of Victoria. Before gold was discovered in Australia in 1851, Sir R. I. Murchison in Great Britain, and the Rev. W. B. Clarke in the colony, had declared their belief that it must exist, owing to the resemblance of the geological formation to that of California, and of the gold regions of the Ural in Russia. The gold is found by washing the surface detritus of the water-runs, and 'digging' holes into the strata overlying the so-called pipe-clay. Another source is the quartz-rocks, which commonly run in reefs, and are crushed by machinery, to extract the gold. A large amount of capital is invested by companies in quartz-reefing speculations; and shares change hands as railway or mining scrip in Great Britain. Large pieces of ore called 'nuggets,' have been occasionally found from 20 to 45 pounds-weight. As a settled industry, gold-digging is found to require steady labour, skill, organisation, and capital to render it remunerative. On the whole, the yield amounts to about a fair day's wage. In 1871, there were at work in Victoria 58,279 miners, of whom 15,669 were Chinese. The mining operations were carried on over 985 square miles of auriferous ground, the

chief centres being Ballarat, Sandhurst, and Castlemaine.

A few somewhat extensive vineyards, and numerous smaller ones, now exist in nearly all the most important districts of the colony. Every man who has a piece of ground may, if he chooses, rest under his own vine. Gardens are easily kept in Victoria, where, in addition to the peach, the apricot, the apple, the pear, the cherry, the almond, and other European fruit-trees, pines, cypresses, an immense variety of splendid shrubbery, and flowers of every description, flourish under ordinary care. A Victorian garden in the season of fruit-blossom presents an exquisite appearance.

Melbourne, the capital, on Hobson's Bay, is in some respects one of the finest cities in the British empire. It is situated on an undulating piece of country, admirably adapted to be the site of a large city. The reservoir of Melbourne is the Yan Yean, situated in the Plenty Ranges, 20 miles to the north, and containing an unlimited supply of water. Among the physical drawbacks of the city are the dust which attends the hot winds in summer, and the considerable streams which flow along the streets during heavy falls of rain in winter.

Ballarat is the second city in Victoria, and a great gold-digging centre. Geelong is a beautiful town, built on the westerly arm of Port Phillip. As a watering-place, it has great attractions, though, in point of fact, Queenscliffe is preferred. Like Melbourne and Ballarat, Geelong has the advantage of excellent public institutions. Education, religion, and the charities are extremely well attended to throughout the colony. The system of education is national.

For purposes of administration, Victoria is divided into 37 counties. In 1871, Victoria had 150,618 inhabited houses. In 1871, the imports were of the value of £12,341,995, and the exports, £14,557,820. The staple exports are gold, which, exclusive of coins, amounted in 1871 to 1,647,389 oz.—of value, £6,590,962; gold coins, £347,513. Preserved provisions exported amounted to 14,876,100 lbs.—value, £355,373; wool, 76,334,480 lbs.—value, £4,702,164; tallow, £401,124; hides and untanned leather, £124,976; copper, £130,366. Paper and cloth are now manufactured in the colony. The colonists strongly desire to promote native manufactures. The revenue in 1871 was £3,717,155.

The Victorian railway system consists of three main lines; its telegraph system is complete.

The legislature of Victoria consists of two chambers: a Legislative Council, consisting of 30 members, and composed of gentlemen who possess the property qualification of £250 a year; elected by persons having an income from property of £5 per annum, in municipal districts; and £100 a year beyond those districts; and a Legislative Assembly of 78 members, elected by manhood suffrage and by secret ballot. A fifth of the council retire every two years, and a complete change is made every ten years. The Legislative Assembly is elected for three years. The crown is represented by a governor-general, who has a salary of £10,000 a year. The ministry consists of nine members.

Australia is the land of bright sunshine. On the whole, the eye wearies of the perpetual blaze and the continuous blue. The finest seasons are the spring and autumn. The winter in Victoria is humid. From November to February, which is the Victorian summer, the heat is very great. Fires are frequent. The hot winds, which are from the north, blow as off a furnace. But they are rather favourable to health than otherwise. The mean temperature at Melbourne is about 59°; the mean of the warmest month, January, being 68°; of the coldest, 49°; fall of rain, 32·33 inches.

South Australia.

South Australia includes the entire centre of the Australian continent comprised between the Southern and the Indian Oceans, and between the 129th and the 141st degrees of E. long. Its area is 760,000 square miles. The population of the colony in 1871 was 189,018, of whom there were in the settled districts 3369 aborigines. The city of Adelaide, the capital, situated on the river Torrens, 7½ miles distant from Port Adelaide, having in the background the Mount Lofty Range, contains 27,208 inhabitants, and the suburbs 34,474; in all, 61,682. Adelaide is well built, and has some fine buildings. South Australia, which has a beautiful climate, is the principal wheat-growing province in Australia. In 1870–71, the harvest of South Australia yielded 6,961,164 bushels of wheat, which produced £1,827,305. The bread-stuff exported amounted to 104,000 tons, in value £1,253,342. In 1871–72, there were 692,508 acres under wheat. In 1872–73, the whole land under cultivation was 1,164,846 acres. Red rust and locusts, however, interfere with the success of farming to an uncomfortable extent. The country is also liable to serious droughts. In 1871, there were 5823 acres under vines, which yielded 896,000 gallons of wine. In 1871, the imports amounted to £2,158,022, and the exports to £3,582,397; the staple articles of the latter being corn, wool, and copper. The wool exported was in value £1,170,885, and the copper £648,569. The chief copper mines are the Moonta and Wallaroo on York's Peninsula, Gulf St Vincent, worked by from 2000 to 3000 miners; and the Burra-Burra, employing about 1000 miners. 80,000 tons of copper ore were sent to England during the first six years' working of the Burra-Burra. The bulk of the ore is now made into fine copper before shipment. In 1871, there were 133 miles of railway in the colony—7½ miles from Adelaide to Port Adelaide, and 125½ miles of north line to the copper mines. The telegraph system of South Australia is good, including, as it now does, an overland line between Adelaide and Port Darwin, opened in 1872, extending over the whole continent, a distance of 2000 miles, and connecting Australia with all the main centres of civilisation in the world.

In 1871, the revenue of the colony was £778,094; the chief sources being the sale of crown lands and customs duties.

Queensland.

Queensland comprises the whole north-eastern portion of Australia, including the adjacent islands in the Pacific Ocean and in the Gulf of Carpentaria. In 1856, its population was 17,082; in 1871, it had risen to 120,104, exclusive of

aborigines. Brisbane, the capital, situated on Brisbane River, in the district of Moreton Bay, has a population of 12,000. Next to Brisbane in population are the towns of Rockhampton and Ipswich, the former containing 5226, and the latter 5021, inhabitants in 1868.

Queensland is in general well watered. At a distance of from 50 to 100 miles from the eastern sea-coast, runs north and south a great mountain-range, which throws out numerous spurs (composed principally of quartz) towards the sea, and whose summits rise from 2000 to 6000 feet above the ocean-level. The chief rivers are the Logan, the Brisbane, the May, the Caliope, the Fitzroy, the Pioneer, and the Burdekin. The Brisbane is navigable for 75 miles by good-sized vessels. The Fitzroy, which is navigable for 60 miles, drains an area of 50,000,000 acres. Beyond the Dividing Range there are immense plains, composed of rich black soil, and watered by numerous streams. Queensland is, in several respects, among the most promising colonies of Australasia. It is a great sheep country, although not to the extent anticipated some years ago, when sheep were driven overland from some of the other colonies to its pastures. It is liable to serious periodical droughts, which wither the grass. It is admirably suited for cotton and sugar-cane. A system of free selection in land prevails here, as in New South Wales and Victoria. The imports of the colony in 1871 amounted to £2,434,480, and the exports to £1,539,968. The staple exports are wool, valued in 1871 at £517,515; tallow, of the value, in 1870, of £60,483; raw cotton, in 1871, amounting to 18,512 cwt. of the value of £73,292. In 1870, there were 5000 acres under sugar-cane in Queensland, 39 sugar-mills, and 10 distilleries. Labour from the South Sea Islands is employed in connection with the growth and manufacture of sugar. In 1867, gold was discovered. The principal gold-field is at Gympie's Creek. The total gold-produce of the colony in 1870 was in value £489,539. In that year there were 12 gold-fields and 15,000 miners. The form of government is the same as that of Victoria.

The climate of Queensland resembles that of Madeira.

Western Australia.

Western Australia includes all that portion of New Holland situated to the westward of the 129th degree of E. long.; its greatest length being 1280 miles from north to south, and its breadth from east to west about 800 miles. The area is about 1,000,000 square miles. Western Australia was first settled in 1829. In 1849, at the request of the colonists, convicts were sent to it, and the colony has the fruits of their labour in roads, bridges, &c. In 1860, the sending of convicts was discontinued. In all, there were sent to Western Australia 10,000 convicts. The whole population of the colony is 25,353. In 1871, the imports amounted to £198,010, and the exports to £199,280. The chief exports are wool, copper, lead-ore, pearl-shell, and timber. In 1871, there were 671,000 sheep, yielding an export in wool of £111,061. In 1871, sandal-wood was exported to the value of £26,926; and pearl-shell, of £12,895. Perth, the capital, is situated on a lake of brackish water formed by the Swan River, and has 6000 inhabitants. The revenue of Western Australia in 1871 was £97,605. It has no public debt.

TASMANIA.

Tasmania, formerly Van Diemen's Land, is an island lying off the southern extremity of the mainland of Australia, from which it is separated by Bass's Strait. The length of the island is 240 miles, and its breadth 200. It was first discovered in the year 1642 by Abel Jansen Tasman, a celebrated Dutch navigator, and was by him called Van Diemen's Land, in honour of Anthony Van Diemen, at that time governor-general of the Dutch possessions in the East Indies. In 1803, it was formally taken possession of on the part of Great Britain, as a receptacle for convicts, and to this purpose, Van Diemen's Land was exclusively devoted until 1819, when it was thrown open to free settlers. Convicts ceased to be sent to Tasmania in 1853.

Tasmania presents a constant alternation of hill and dale, with occasional flats or plains. These plains are in general exceedingly fertile, and being often but thinly interspersed with trees, present a most delightful appearance. The land already alienated amounts to 3,413,810 acres, leaving 13,468,971 acres of unalienated land. The climate is exceedingly pleasant and salubrious, and is especially adapted to the constitutions of the natives of Great Britain. The mean temperature of Hobart Town is 54° 92′.

In 1870, the population of Tasmania amounted to 99,328 persons. Hobart Town, the capital, contains 20,000 inhabitants. The emigrants were in excess of the immigrants in the years 1868–71. In 1871, the imports amounted to £778,087, and the exports to £740,638. The staple export is wool, of value, in 1871, £298,160. The minerals include copper, iron, lead, zinc, gold, coal, &c. The revenue in 1872 was £234,608; and the public debt, £1,455,900. A railway 43 miles in length, opened in 1871, connects Launceston with Doleraine. In April 1869, telegraphic communication with the mainland of Australia was established by a submarine cable. There is a telegraphic system with 14 stations on the island. A constitution was given to Tasmania in 1854, similar to that of the Australian colonies.

The aborigines, who numbered 3000 at the date of the first colonisation of the island, have all died out.

Determined efforts have been made by the colonists to introduce salmon and British trout into the Tasmanian rivers; the trout have succeeded, but no salmon have yet been caught. The sperm-whale abounds in Bass's Strait. Tasmania grows British fruits admirably, and produces excellent timber.

NEW ZEALAND.

New Zealand, first visited by Tasman in 1642, and surveyed by Captain Cook in 1769, is situated about 1200 miles eastward from Tasmania, between the parallels of 34° and 48° S. lat. and the meridians of 166° and 179° E. long. being about the antipodes of Great Britain, from which it is 16,000 miles distant. It consists of three main islands, lying in a line nearly north

and south, called North Island, Middle Island, and South or Stewart Island, and the area of the whole is estimated at 102,000 square miles. A great portion of the surface is occupied by mountains, among which there are many extinct, and a few active volcanoes. Many of the summits are always snow-clad. Ruapahu, an extinct volcano, is 9000 feet high, and the active volcano of Tongariro is 8500 feet. Numerous hot springs and earthquakes testify the existence of subterranean fires. In the North Island, the mountains are mostly clothed with forests of luxuriant growth, interspersed with fern-clad ranges, and occasionally treeless grassy plains; while extensive swamps, overgrown with flax and reeds, occupy much of the low-lying ground. In the Middle Island, a range of mountains runs along the west coast, of which the highest peak, Mount Cook, is 14,000 feet in height; the eastern coastline, at a varying breadth, is well adapted for agriculture; while the interior affords excellent pasture. The climate is humid, and the mountains feed numerous streams and rivers, none of which, however, are of any considerable length, or of great importance for inland navigation. No country, perhaps, is more abundantly furnished with excellent harbours.

New Zealand, formerly divided into eight distinct provinces, has now one central government, the names of the provinces being retained for the 'provincial districts,' as they are called. The most notable is Otago. Founded in 1848 by Captain Cargill, as a settlement in connection with the Free Church of Scotland, it has grown to dimensions which the original colonists could hardly have anticipated within so brief a period. Considerable progress had been already made in agricultural and pastoral pursuits, when in 1861 gold was discovered. The discovery was made near Tuapeka in Otago, and subsequently in Auckland, and at Hokitiki on the west coast. Mining operations are conducted on a large scale in the various localities in which gold occurs. Coal is found here, as in the other parts of the country, in large quantities. Dunedin, the capital of the province, with a population of about 27,000, is picturesquely situated at the head of a bay, about 9 miles from Port Chalmers, the chief port of Otago, with which it has railway communication. The scenery in the vicinity is very fine. Oamaru, in the north of the province, possessing a good harbour, with cultivated farms in the immediate neighbourhood, and sheep-runs to the north and west, is one of the most promising places in New Zealand. From Oamaru to the river Clutha, the country, including Otepopo, Hampden, Palmerston, Goodwood, and the plains of Taieri and Tokomairiro, is more or less farmed to great advantage. Otago has a fine lake-district in the interior, the principal lakes being Wakatip, Teanau, Manissori, and Wannika. On Lake Wakatip is situated Queenstown, a township with about 2000 inhabitants. The province is well watered. Otago, as a whole, along with the rest of the Middle Island, is hilly, and almost destitute of trees, which at first sight makes its aspect rather disappointing to the British emigrant. The population of Otago is 60,578; its revenue exceeds £520,000; it has more than a million acres under cultivation; the number of sheep is upwards of 4 millions; of horses, 20,000; and of horned cattle, 110,000. Its chief products are gold and wool. The provision for the educational and religious wants of the people is nowhere better than in Otago, which has a university, a first-rate high school, and an admirable system of public schools.

The province of Auckland, in the North Island, has a population of European descent of 62,335. The staple products of the province are preserved meat and wool. Of the 2,702,582 acres held by Europeans, only 2455 acres were under wheat in 1872. In the same year there were 181,521 acres under artificial grasses. The Maoris own 11,275,036 acres in the province, 2,587,350 of these having been fixed by the recognition of the crown. Gold was discovered in the province as early as 1852, but not in payable quantities; in 1867, a rush took place to the Thames River. The city of Grahamstown is the capital of the gold-fields of Auckland. The export of gold in 1871 was valued at £1,888,708, and, in the same year, kauri gum was exported to the value of £167,958. The province of Auckland is famed for its lakes and hot wells. The principal lakes are—Taupo, Iti, Kakiki, Tarawera, Kaiteriria, and Mohana, with its white and pink terraces. The Waikato, the chief river in the North Island, rises in Lake Taupo, and flows into the sea on the west coast. The town of Auckland, with a population of 20,000, has a capacious and fine harbour, and was for some time the seat of the general government.

Canterbury, inclusive of Westland, has a population of 62,158. Westland is the gold territory on the west, of which Hokitiki is the capital. As a wheat-producing province, Canterbury excels the rest of New Zealand. In 1870, it exported to the other provinces corn and flour to the value of £127,000. Christchurch has a population of 12,000. The port of Christchurch is Lyttelton. Timaru is the other principal port of the province.

The other provinces of New Zealand are Wellington (pop. 24,000); Nelson (pop. 22,501); Hawke Bay (pop. 6059); Marlborough (pop. 5235); Taranaki (pop. 4480). The whole population of New Zealand, in 1851, excluding aborigines, was 26,707; in 1878, it was 414,412.

In 1879, the Maoris, as the indigenous inhabitants call themselves, numbered 42,819—a decrease of over 4000 within four years. During the ten years, 1858-68, they had decreased at the rate of 30 per cent. They are all nominally Christian, and many of them can read and write. On the whole, they have shewn themselves more susceptible of the influences of European civilisation than any other aboriginal race. They are of Polynesian extraction. They are of average height, with black hair, broad nose, and large mouth. Of excellent physique, with good minds, skilful in the use of arms, and availing themselves of their natural fortresses, they were able, when, owing to misunderstandings about the land, wars arose, for a long time to withstand the British forces. Witnessing the occupation of their country by a race of foreigners, and imagining themselves defrauded of their ground, they flew to arms, and many Europeans fell victims to their vengeance. To some considerable extent, they were themselves the victims of competing interests and different policies. While the British troops remained in the colony, intermittent outbreaks continued; since their withdrawal, the colonists have found themselves

in a position to deal successfully with refractory Maoris, partly because they are in earnest, and partly because they are better acquainted with bush life and practices than the home soldiers. The Maoris are turning their attention to trade, agriculture, and pastoral pursuits.

In 1871, there were 10,083 immigrants into New Zealand, and 5297 emigrants from it: by far the larger part of the excess remaining in the colony, belonged to Otago. In 1852, the imports of New Zealand amounted in value to £359,444, and the exports to £145,972; while in 1871, the imports were of the value of £4,078,193, and the exports of £5,282,084. In 1878, the wool exported from New Zealand amounted to 59,270,256 lbs., of the value of £3,292,807. Ship-building and the timber trade rank next to wool. The minerals are gold, copper, iron, and coal. From the time when gold was first discovered, to 1879, the gold exports amounted to 9,107,196 oz.—in value, £35,594,938. Of this, Otago contributed 3,856,065 oz.; West-coast, 2,357,435 oz.; and Nelson, 1,620,841 oz. In 1879-80, the revenue amounted to £3,452,000. The chief sources of revenue are customs-duties, the sale of crown lands, depasturing, and gold-mining licenses. The public debt in 1879 amounted to 21½ millions.

In 1852, New Zealand received a constitution, which is in some respects peculiar in a British colony, as being modelled to some extent on that of the United States of America. Besides the general parliament, each of the provinces has its own elected superintendent and provincial council, administrative of provincial affairs in as far as they are purely provincial. The general parliament consists of a Legislative Council, composed of 46 members, nominated by the crown for life; and a House of Representatives, of 78 members, elected by the people for five years. The Maoris have equal political rights with the colonists, and four Maoris sit in the House of Representatives for Maori constituencies. The crown is represented by a governor-general. In 1863-64, the control of native affairs, and the responsibility connected with them, was transferred to the colonial government. In 1865, the seat of government was transferred from Auckland to Wellington, as being more central. The town of Wellington has a population of 8000.

The climate of New Zealand varies considerably. It is on the whole fine and bracing. Auckland in the north is warm, and Otago in the south is somewhat wet and windy; Nelson has the best climate in New Zealand. But Canterbury and the northern parts of Otago are very enjoyable. The morning is the most delightful part of a New Zealand day, and is often clear, bright, and exhilarating.

New Zealand abounds in ferns, some of which reach the size of trees; the root of one species was formerly much used as food by the natives. The forest trees grow to a very great size, many of them being larger than those of America or any country in the world.

The *Phormium tenax*, or New Zealand flax, is another important vegetable production. The fibres of the leaf of this plant have been proved capable of all the applications made of European flax.

The country is remarkably deficient in native animal life. Wild pigs, the offspring of some pigs left by Captain Cook, a so-called native dog of inferior description, and the rat, were the only quadrupeds which the colonists found on the islands. Remains of the moa, a gigantic bird, from eleven to thirteen feet high, are found in many places. The moa is now extinct.

Irregular settlements by Europeans began in New Zealand early in the 19th century; but it was not till 1840, when the native chiefs entered into a treaty ceding the sovereignty of the islands to Great Britain, that it became a regular colony.

Other islands claimed by Great Britain are:

The *Auckland Islands*, which lie 180 miles south from New Zealand, in south latitude 51°. The largest is about 30 miles long, with an area of 100,000 acres. The climate is mild and salubrious.

The *Chatham Islands*, which are situated 300 miles east from New Zealand, in south latitude 44°, east longitude 178°. Chatham Island, the largest of the group, has an area of more than 300,000 acres. The climate and soil are excellent. The inhabitants, numbering 133, are now mostly Christian. The islands are under the protection of the government of New Zealand.

And *Norfolk Island*, for some time a convict establishment, which has an area of 14 square miles, and is situated in south latitude 29°, east longitude 168°, about 900 miles east-north-east from Sydney.

POLYNESIA.

Polynesia—from two Greek words, signifying *many isles*—is the name given to the numerous groups scattered over the central parts of the Pacific Ocean, within 30 degrees on both sides of the equator. The chief clusters north of the equator are the *Sandwich* group in the east, and the *Ladrones* and *Carolines* in the west; and south of it, the *Marquesas* in the east, the *Society* Islands in the middle, and the *Friendly*, including the *Fiji* and *Navigator's*, in the west. The Fiji Islands, which were ceded to Great Britain in 1874, have acquired importance from a rising trade in cotton, which is grown there under the auspices of Australasian speculators. Honolulu, on the island of Oahu, the seat of the government of the Sandwich Islands, which is modelled on that of Great Britain, and consists of a native king and two houses of parliament, is the port of call for the line of steamers from San Francisco to New Zealand and Australia. It has a population of about 10,000. The whole population of the Sandwich group is 150,000. Within the last fifty years, a large proportion of the inhabitants of the Sandwich, Society, and Friendly Islands have embraced Christianity; and missionaries from the United States of America, Great Britain, and the Australasian colonies, have taught them reading, writing, and a number of useful arts. The population of Polynesia is about a million and a half.

The only foreign powers having possessions in Polynesia are the Spaniards, who have occupied the Ladrones since the end of the seventeenth century; and the French, who, since 1843, have established a protectorate over the Marquesas, and to some extent also over the Society Islands.

NORTH AMERICA.

THIS is the largest, and in every respect the most important division of the western hemisphere. It is bounded on the east by the Atlantic; on the south, by the Gulf of Mexico and the Pacific, save where joined to South America by the narrow Isthmus of Panama; on the west, by the Pacific; and on the north, by the Arctic Ocean. Including Greenland (which, however, is probably insular, and not continental), the area of the known continent may be stated at 8,000,000 square miles—the great mass of which lies within the northern temperate zone.

SUPERFICIAL FEATURES.

The general physical characteristics of the continent are remarkable for the magnitude of the scale upon which they are presented; the plains, lakes, and rivers being superior to those of all other countries. The following summary of these, compiled from a variety of reliable authorities on the subject, will give the reader a good idea of the geography of North America: 1. The narrow region which separates the Gulf of Mexico and the Caribbean Sea from the Pacific, traversed throughout its whole length by mountain-ranges, which leave a narrow tract of low land lying along the sea-coasts, while in certain portions of the interior they form elevated table-lands. Here the mountains—which may be considered as the commencement of the great Rocky chain—attain a culminating point in Guatemala of 14,900, and in the Mexican volcano of Popocatepetl of 17,880 feet; while the table-land of Mexico

is from 5000 to 9000 feet in general altitude. 2. The maritime region between the Pacific Ocean on the west and the ridge of mountains which extends from Cape St Lucas in California northward to Alaska. This ridge has a general elevation of 8000 or 10,000 feet, but rises near the Columbia River in several peaks—Mount Jefferson, Mount Hood, Mount St Helen's—to upwards of 15,000 feet, and in Mount St Elias, to upwards of 17,000 feet. 3. The elevated region which forms a sort of table-land between the maritime chain before mentioned on the west and the Rocky Mountains on the east. In its southern portion, it presents the arid salt plains of the Californian desert; between 40° and 45° north, it presents a fertile region, with a mild and humid atmosphere; but beyond the last-mentioned parallel it is barren and inhospitable. 4. The great central valley of the Missouri and Mississippi, extending from the Rocky Mountains on the west to the Alleghanies on the east, and from the Gulf of Mexico northward to the 45th or 50th degree north lat. Between these parallels, runs in a waving line the water-shed which divides the basins of the St Lawrence and the Mississippi from those of the streams that flow to Hudson Bay and the Arctic Ocean. On the east side, this region is rich and well wooded; in the middle, it is bare prairie-ground, but not unfertile; towards the west, it is dry, sandy, and almost a desert. The Rocky Mountains, the greatest and most continuous of the North American chains, rise from 8000 to 10,000, occasionally to 12,000, and between lat. 52° and 53° north in Mount Hooker to 15,700 feet, and in Mount Brown to 15,990 feet; while the Alleghanies reach their culminating point in Mount Washington, 6428 feet, and have an average elevation of 2500 feet. 5. The eastern declivities of the Alleghany Mountains and the maritime region, extending to the shores of the Atlantic. This is a region of natural forests, and of mixed but rather poor soil. 6. The great northern plain beyond the 50th parallel, a large part of which is a bleak and desolate waste, overspread with innumerable lakes, and having a very rigorous climate. Yet much of it is excellent wheat-bearing land, and more is suitable for pasture.

The islands, peninsulas, promontories, and other features which give diversity to the sea-coast, appear to be most numerous in the north—the region of least importance, and with which we are the least acquainted. Passing, therefore, the *islands* in that quarter, the principal on the east are—Newfoundland, a large island lying at the mouth of the Gulf of St Lawrence; Anticosti; Prince Edward Island; and Cape Breton, all in the same gulf; and the West India Islands, to the south-east of the continent. On the west or Pacific sea-board, the most important are—Vancouver's Island; Queen Charlotte's Island, Prince of Wales Island. The most striking *peninsulas* on the east or Atlantic side are—Nova Scotia, Florida, and Yucatan on the east and south; California and Alaska on the west. The more prominent *capes* are—Farewell, the southernmost point of Greenland; Capes Chudleigh and Charles in Labrador; Race in Newfoundland; Sable in Nova Scotia; Cod, Hatteras, and Sable in the United States; Catoche in Yucatan: on the west or Pacific side—St Lucas in California; Mendocino and Prince of Wales Cape in the United States: on the north side, jutting into the Arctic Ocean, are—Icy Cape, Point Barrow, and Cape Bathurst. The principal *isthmuses* are—Chignecto, connecting Nova Scotia with the continent; Tehuantepec in the south of Mexico, and most important of all, the Isthmus of Darien or Panama. Its breadth is less than 30 miles. Various routes for a ship-canal across it have been discussed; and the cutting of that promoted by M. Lesseps was begun in 1883. A railway was opened in 1855, from Aspinwall in Navy Bay, near Chagres, to Panama on the Pacific. The length is 50 miles, and the summit-level only 250 feet.

HYDROGRAPHY.

The chief gulfs are—Hudson Bay, between Labrador and the Hudson Bay Territory, a large inland sea, 800 miles long by 600 broad, frozen for the greater part of the year, and girdled by sterile desert shores; its southern extremity, known as James Bay, 250 miles long by 150 broad; while from its western side, a narrow arm, called Chesterfield Inlet, stretches westward for 250 miles; Hudson Strait, 500 miles in length, and only about 80 miles at its narrowest part, connecting Hudson Bay with the Atlantic; Davis Strait and Baffin Bay, between Greenland and the continent of America, with its northern prolongation known as Smith's Sound, through which Arctic navigators vainly try to pierce into the Polar Sea. The highest latitude yet reached is 83° 20′ 26″. From the north-west end of Baffin Bay runs westward a long channel, known in different parts by the names of Lancaster Sound and Melville Sound, and forming the famous 'North-west Passage,' though as yet nobody has really managed to push a ship through; Belleisle Strait, separating Newfoundland from the mainland; the Gulf of St Lawrence; the Bay of Fundy, between Nova Scotia and the mainland, 180 miles long, and about 35 in breadth, of dangerous navigation, in consequence of fogs and the velocity of the tide, which sometimes rises as high as 70 feet; Chesapeake Bay, a valuable inlet in the United States, 200 miles in length, with a breadth varying from 4 to 40; the large landlocked Gulf of Mexico, with a basin of 800,000 square miles, noted for its low alluvial shores, the high temperature of its waters, and its currents (Gulf Stream), which pass with great velocity through the narrow Strait of Florida; the Caribbean Sea, bounded on the east and north by the West India Islands, through which it communicates with the Atlantic by numerous passages. On the west or Pacific coast, the Gulf of California, penetrating north for 700 miles, with a breadth varying from 40 to 170 miles, celebrated for its pearls; and the Strait of St Juan de Fuca, at the south of Vancouver's Island, through the middle of which (according to the decision of the German emperor, 1872) now runs the boundary between the United States and British North America.

The fresh-water lakes of North America are the largest, and in many respects the most valuable, in the world. The whole region between 42° and 67° north is so completely covered with them, that geographers have styled it, by way of eminence, the Region of Lakes. We can only mention a few of the more important: 1. Superior, 355 miles long by 160 broad, covering an area of

about 32,000 square miles; its surface is 600 feet above that of the ocean, its mean depth upwards of 1000 feet. It has, like all the others, no tidal ebb or flow, is studded by few islands, and, from the unsheltered nature of its shores, affords no great facility for shipping. It discharges its surplus waters by the river St Mary, which, after a course of 40 miles, and a descent of 32 feet, falls into—2. Lake Huron, having a length of 280 miles, and a breadth of 250; area 20,000 square miles, and medium depth 1000 feet. It has several large islands, among which are the Manitoulin chain, which almost separates that portion known as Lake Iroquois or Georgian Bay from the main body of the lake. 3. Michigan, on nearly the same level with Huron, with which it is connected by the Mackinaw Strait, little more than four miles across. This sheet is 320 miles long, and about 70 broad; area 18,000 square miles, and depth 1000 feet. The shores, which are bold, and at certain seasons dangerous, are guarded by 23 lighthouses. Along with the lower lakes and the St Lawrence, it forms a natural outlet for one of the richest grain-growing regions in the world. 4. Lake Erie, receiving the surplus waters of Huron by the navigable rivers St Clair and Detroit—the former, after a course of 30 miles, expanding into a shallow lake, which again contracts into the latter, also about 30 miles long. Erie is 240 miles long, and from 30 to 60 broad; area 9600 square miles; its level 560 feet above the sea, and mean depth 120 feet. The shores of this sheet are low, with a marshy or sandy beach. 5. Ontario, receiving the surplus waters of Erie by the Niagara, has a descent of 330 feet, 165 of which are by the celebrated Falls of that name. This lake is 190 miles long, and 55 at its broadest; area 7200 square miles, depth 500 feet. Its shores are in general flat. The navigation has been facilitated by a system of lighthouses on both sides of the lake. Ontario discharges its waters by the Lake of the Thousand Islands, which afterwards becomes the St Lawrence. The other principal lakes are—Athabasca, Winnipeg, Great Slave Lake, and Great Bear Lake in the Hudson Bay Territory; the Great Salt Lake in Utah, and Nicaragua in Central America.

With respect to rivers, no country is more bountifully supplied than North America, almost every part of its interior being accessible by their means. The Mississippi—reckoning from the source of the Missouri, its true head—has a course of 4500 miles, for 3950 of which it is navigable for boats. It has been calculated that the basin of this river has an area of 1,220,000 square miles, and that the whole amount of boat-navigation afforded by the river-system, of which it is the main trunk, is nearly 40,000 miles. It has 1500 navigable branches, of which the principal are the Red River, Arkansas, Platte, and Yellowstone on the west; and the Tennessee, Ohio, Wabash, and Illinois on the east. The St Lawrence, estimating its course from the head-waters of the rivers flowing into Lake Superior, drains a territory of 560,000 square miles, and affords a partially interrupted boat-navigation of 4000 miles. The other large rivers are the Mackenzie, nearly 1800 miles in length, and flowing through a succession of lakes into the Arctic Ocean; the Columbia or Oregon, the largest river west of the Rocky Mountains, but with a current so rapid and obstructed that it is of little value for inland navigation; the Bravo del Norte or Rio Grande, the boundary between Mexico and the United States, and next to the Mississippi the largest river flowing into the Gulf of Mexico, being fully 1800 miles in length; and the Colorado, which rises in the Rocky Mountains, and after a broken and rapid course of 1200 miles, falls into the Pacific at the head of the Gulf of California. These, as well as many others of the minor rivers, exhibit in their course some of the magnificent and picturesque water-falls, of which Niagara (165 feet) and Montmorency in Canada (250 feet), the Katerskill (175), and Great Falls (150) in the United States, may be taken as examples.

GEOLOGY.

The geology of the New World presents some remarkable contrasts to that of the districts in the Old World which have supplied the types of geological classification. None of these is more striking than the enormous extent of country which one formation occupies, and that without interruption. American strata often stretch from the Atlantic west beyond the Mississippi. They have, on the whole, been subject to few disturbing agencies. It is not many years since attention was first directed to American geology; but during the short time that has intervened, its progress has been very remarkable. The oldest strata are a range of crystalline rocks, which occupy an area that extends from the northern shores of Lake Superior and the banks of the St Lawrence north-west to the Arctic Ocean, and lies between the line of minor lakes and Hudson Bay. The average width of this area is about 200 miles, and its length from Lake Superior to its termination on the shores of the Arctic Sea is more than 1500 miles. The rocks are chiefly gneiss with granite and trap. They also form the western slopes of the Rocky Mountains. On either side of this tract there exists a Silurian district. That on the eastern side, reaching to Hudson Bay, has a low and uniformly swampy aspect. The other covers a large extent of the continent. It bounds the southern limits of the azoic rocks along the line of the great lakes, extending in a broad band of some 200 miles, parallel to the more ancient formation, till it nears the Arctic Sea. These Silurians have been divided into Lower and Upper, each of which contains three periods. The Lower Silurian periods are the Potsdam, the Trenton, and the Hudson, comprising beds of slate, sandstone, limestone, clays, and shales, with numerous fossil remains. The Upper Silurian periods are the Medina-Clinton, the Niagara-Onondaga, and the lower Helderberg, comprising sandstone, shale, and limestone, also rich in fossil remains. The Silurian beds on their southern and western borders dip under the Devonian rocks, which are developed to a large extent north of lat. 72° N. Vast beds of conglomerate overlie the Devonian rocks, and form the basis of the carboniferous strata. This formation covers large districts in New Jersey and Pennsylvania, and in the Ohio and Mississippi valleys, with an enormous thickness of limestone, shale, and other beds. Volcanic activity has long ceased in the Appalachian range, but one can still trace its former presence in the highly metamorphosed Silurian

and carboniferous rocks of New York and Pennsylvania, which were long supposed to be primary granite, &c. The igneous agency, which at first raised the western range, is still active at intervals throughout its course. The cretaceous beds in Texas and Nebraska shew that the Mexican Gulf once covered those states. The Tertiary formation is developed as a band of about 60 miles, forming the southern extremity of North America, and stretching from North Carolina to the peninsula of Yucatan, leaving the coast-line only at the delta of the Mississippi. The only post-tertiary bed is the boulder-clay, which largely occurs in the region north of 40° N. lat., and which is so called from the immense boulders which it contains, some of them being as much as one or two thousand tons in weight.

CLIMATE—BOTANY—ZOOLOGY.

A continent of such vast extent necessarily presents a great variety of climate. It may be remarked generally, that the west coast is warmer than the east: at New Archangel, for instance, in what used to be Russian America, the mean temperature is 12° Fahrenheit above freezing; at Nain, in Labrador, in the same latitude, it is 7° below freezing. The east coast, again, is colder than the west coast of Europe; the difference between Nain and Gottenburg in Sweden being about 21°. This difference, however, diminishes towards the south; New York is only 7° colder than Naples, and Florida has the same temperature as Cairo.

The higher temperature of the west of Europe, as compared with the opposite coast of North America, is owing, partly at least, to the Gulf Stream (see PHYSICAL GEOGRAPHY), which carries the warm water of the tropical seas into the latitude of Britain and Norway, while a cold current from the polar seas flows south along the east coast of America.

On the discovery of America, Europeans regarded with astonishment its vegetable and animal productions, so different from all that they had ever seen before. The difference is least remarkable in the northern regions. There the vegetation greatly resembles that of Lapland in Europe—dwarf willows, larches, birches, and pines; mosses and lichens; and a scanty herbage, interspersed by a few wild-flowers and berries during summer. In the Canadas, and generally in the basin of the St Lawrence, the true forests of American pine and fir prevail, though the trees are inferior in size to those of the United States. Interspersed with these, and becoming more frequent as we proceed southward, are the white cedar, sugar-maple, basswood, hickory, several species of oak, and wild cherry. Here also flourish the Canadian lily, the ginseng, Venus's fly-trap; the cultivated grains and fruits of temperate Europe; with tobacco, hemp, and flax. In the United States—which present three very different zones of climate—are found a greater variety of species than in almost any other region of the same dimensions. The first zone, north of lat. 44°, exhibits birch, elm, red and white pines, sugar and other maples, a variety of oaks, and the vegetation common to Canada. Between this zone and 35°, oaks, ash, hickory, plane, white cedar, sassafras, witch-hazel, cornel, yellow birch, and red maple become more frequent, as do also fine flowering-climbers and aquatics. South of this middle zone, and up to 27°, most of the foregoing are found, with deciduous cypress, Carolina poplar, magnolias, swamp-hickory, lobelias, and a greater variety of climbers and aquatics. South of 27°, the vegetation merges into the tropical, or that to be described under the West Indies and South America. As already stated, all the common garden-fruits of Europe are reared in the north; pomegranates, melons, figs, grapes, olives, almonds, oranges, &c. in the southern zone. Maize is grown all south of Maine; tobacco, as far north as lat. 40°; cotton, to 37°; the sugar-cane, to 32°; rice, in the Carolinas, Louisiana, and Georgia; wheat, all over the Union; oats and rye, principally in the north; hemp, flax, and hops, chiefly in the western and middle districts.

The Fauna of North America is in many respects peculiar. Of *mammalia*, we may mention the tailed monkeys of Mexico, the puma, lynx, glutton, wolf, American fox; polar, black, and grisly bears, badger, otter, racoon, opossum, beaver, skunk, ermine; prairie-dog; bison, wapiti, prong-horned antelope; moose, red, Virginian, and other deer. Among *birds*—the white-headed and other eagles, various vultures, wild turkey, Canada goose, passenger-pigeon, bell-bird, mocking-bird, humming-birds, &c. Of *reptiles*—the alligator, tortoise, rattlesnake, black-snake, siren, &c. Of *fish*, a vast and useful variety—as cod, sprat, mackerel, salmon; crab, oyster, and other shell-fish. Of useful *insects*, the continent possesses the bee and cochineal insect, and is infested with the mosquito. All the domestic animals of Europe have been introduced with success.

POPULATION—COUNTRIES.

The people who inhabited the continent at the time of its discovery in 1492, belonged exclusively to the American variety of our species, but subdivisible into numerous families and tribes, differing not so much in physical aspect as in manners and customs. Without descending to minutiæ, the aborigines might be classed into the Aztecs, a civilised race who inhabited Mexico, and had made considerable progress in the domestic arts; the other Indian tribes, who led a savage life, obtaining their subsistence chiefly by hunting and fishing; and the Esquimaux, who peopled, as they do now, the shores of the northern seas. Soon after the discovery, several European settlements were formed at various points along the eastern shores of the continent, from the Isthmus of Panama to the Gulf of St Lawrence; and these settlements have been gradually extending, either by purchase from the natives or by conquest, till now nearly the whole of the country may be said to be under European supremacy, before which the Red Man is gradually but surely passing away. The Spaniards colonised Mexico; the French settlements extended along the St Lawrence and Mississippi; and the English chiefly along the eastern shores; where also settled Scotch, Dutch, Germans, and Irish. Out of all these have been formed the now dominant Anglo-American family, which uses the English tongue, but which is beginning to develop mental and temperamental characteristics that are quite distinguishable from English. In addition to the

white races of European origin, we must note the large African population, originally imported as slaves, and the various half-breeds resulting from the intermixture of the white and the negro, or the white and the Indian, *e. g.* the *Mulatto* of the States, and the *Mestizo* of Mexico.

Politically, the original settlements have undergone many mutations: most of them have declared themselves independent, and adopted republican governments; some have changed masters; and only a few remain in unaltered connection with the mother-country. The following table exhibits the existing political divisions of the continent of North America, with their areas and population, according to the most recent available authorities:

Governments.	Area in square Miles.	Population.	Capitals.
Danish America (Greenland)	380,000	9,825	Lichtenfels.
French Possessions	81	4,915	St Pierre.
British North America:			
1. The Dominion of Canada, comprising the provinces of			
Quebec	193,355	1,359,027	Quebec.
Ontario	107,780	1,923,228	Toronto.
Nova Scotia	21,731	440,572	Halifax.
New Brunswick	27,322	321,233	Fredericton.
Manitoba	14,340	65,954	Winnipeg.
Prince Edward Island	2,173	108,891	Charlotte Town.
British Columbia	213,000	49,459	Victoria.
North-west Territory	2,880,000	56,446	Regina.
2. Newfoundland	40,200	161,374	St John.
United States of America	3,603,884	50,442,066	Washington.
Mexico	761,640	9,577,279	Mexico.
San Salvador	7,334	554,785	San Salvador.
Nicaragua	47,090	300,000	Managua.
Honduras	58,168	350,000	Comayagua.
Guatemala	40,776	1,252,497	Guatemala.
Costa Rica	21,493	185,000	San Jose.
	8,420,367	67,176,507	

Such are the existing divisions or governments, the physical, political, social, and industrial features of which (omitting Danish America, as not of sufficient importance to merit special notice) we shall now endeavour to describe, as fully as our narrow limits will allow.

BRITISH NORTH AMERICA

comprehends the colonies of Canada, New Brunswick, Nova Scotia, Cape Breton, Prince Edward Island, Newfoundland, the Red River Settlement, or Manitoba, with the rest of the territories once belonging to the Hudson Bay Company, and British Columbia, including Vancouver's Island. The whole of these, with the exception of Newfoundland, are now politically confederated, and form the 'Dominion of Canada.' Formerly, they were separate and independent colonies. Now, they are 'provinces' of a great state, embracing half a continent, and send representatives to an imperial parliament, which assembles at Ottawa in Upper Canada, though their local legislatures are still preserved for provincial purposes.

DOMINION OF CANADA.

The act by which provision was made for their confederation passed the British parliament in 1867. It orders that the constitution of the Dominion shall be 'similar in principle to that of the United Kingdom,' that the executive authority shall be vested in the sovereign of Great Britain and Ireland, and carried on in her name by a governor-general and privy-council; and that the legislative power shall be exercised by a parliament of two houses, called the 'Senate' and the 'House of Commons.' The members of the Senate are nominated for life by summons of the governor-general, under the Great Seal of Canada, and are 78 in number—24 from the province of Ontario, 22 from Quebec, 12 from Nova Scotia, 12 from New Brunswick, 2 from Manitoba, 3 from British Columbia, and 3 from Prince Edward Island. A property qualification of 4000 dollars is required to make a person eligible for the office of senator. The 'House of Commons' is elected by the people for five years, at the rate of 1 representative for every 17,000 of the population. According to the census returns of 1881, it consisted of 213 members—93 for Ontario, 65 for Quebec, 21 for Nova Scotia, 16 for New Brunswick, 5 for Manitoba, 6 for British Columbia, and 7 for Prince Edward Island. The constituencies vary in the different provinces. An urban voter in Ontario and Quebec must be the owner or tenant of real property of the assessed value of 300 dollars, or of the yearly value of 30 dollars; a rural voter, of property assessed at 200 dollars, or of the yearly value of 20 dollars. In New Brunswick, a man cannot vote unless he has real property worth 100 dollars, or an annual income of 400 dollars; in Nova Scotia, the limitation is a little higher. Voting is open in every province except in New Brunswick.

Church and Education.—There is no state church in the Dominion, or anywhere in British North America. Certain portions of territory in Canada Proper were originally set apart as *clergy reserves*, for the support of the Protestant religion, and the proceeds were given chiefly to the Church of England, with a small pittance to the clergy connected with the Church of Scotland. But these 'reserves' have now been secularised. The Church of England, in the Dominion, is governed by 9 bishops; the Roman Catholic Church, by 4 archbishops and 14 bishops; and the Presbyterian Church of Canada, by annual

synods, presided over by moderators. In 1881, there were 1,792,000 Roman Catholics in the Dominion, the mass of the inhabitants of Quebec Province being French Catholics. The Presbyterians numbered 676,000; the Methodists, 743,000; Baptists, 225,000; and the Episcopal Church, 575,000. Lutherans, Congregationalists, Mennonites (21,000), and others are represented.

Education is carefully fostered in the Dominion. The province of Ontario has some 5000 educational establishments, including nearly 20 called colleges. Quebec has 3 universities, one being Catholic, and above 20 classical and industrial colleges. Manitoba has already a university at Winnipeg. Over 500 newspapers and periodicals are published in Canada, mostly in Ontario.

Revenue.—The total ordinary revenue of the year ending June 1880, was $23,307,407; but with loans, &c., amounted to $53,177,629. The ordinary expenditure was $24,850,634; but with payments on account of funding the debt, &c., it was $50,879,271. In 1882–83 the revenue was calculated at $30,600,000, and the expenditure at $27,600,000. The debt of the Dominion, incurred chiefly on account of public works, amounted in 1880 to $156,900,000.

Commerce.—The trade of the Dominion is chiefly with Great Britain and the United States. Of a total exportation of $94,000,000 in 1880–81, 54 millions went to Great Britain, 33 millions to the United States; while of a total importation of $92,000,000, 43 millions came from Great Britain, but 36 millions from the United States. The staple articles of export are wood and bread-stuffs; also fish, furs, cotton, &c., and minerals. The chief imports from the United Kingdom are iron, wrought and unwrought, woollen manufactures, and cotton goods. The protective system lately in vogue is held to promote Canadian manufactures. In 1882 there were 11 cotton-mills at work, and 9 building.

Shipping.—The merchant shipping of Canada is remarkably extensive. In 1880 there were 7377 vessels on the books of the Dominion, measuring 1,311,218 tons. Canada is, accordingly, the fifth in rank of the shipowning states of the world, following, for extent of shipping, Britain, the United States, Norway, and Italy; but taking precedence of Germany, France, and all other maritime powers.

Fisheries.—The total produce of the Canadian fisheries in 1880 was valued at £2,400,000. In that year, fish to the value of £1,400,140 were exported. This includes the fisheries of British Columbia, but of course excludes those of Newfoundland. In 1879 there were seven establishments in Canada for artificial fish-culture, from which, in the preceding year, 13,500,000 young fish (salmon, speckled trout, and white fish) were sent forth into the waters of the Dominion.

Mines.—In 1870–1880, Canadian mines produced (including coal, gold, gypsum, manganese, mineral oil, copper, iron, lead, silver, salt, slate, and stone) a value of over £700,000 a year.

Canals and Railways.—In the matter of communication, Canada is unrivalled. The St Lawrence, with its lakes and extensive canals, forms admirable waterways. In 1881 there were 7600 miles of railway in operation. There were, besides, about 3000 miles in construction, including part of the Dominion railway from the Atlantic to the Pacific, as a rival to the great Pacific line of the United States. Details are given under the particular provinces.

Canada.

Canada, as a geographical designation, has had in history a variety of meanings. Originally, it denoted an extensive range of country, reaching, under the French, as far as even the Mississippi, away beyond the boundary lakes. It was subsequently limited to a region occupying chiefly the basin of the St Lawrence, which, in 1791, was divided into two provinces—Upper or Western, and Lower or Eastern Canada. In 1840, these were re-united under one Legislative Council and House of Assembly; but in 1867 they again, under the respective names of Ontario and Quebec, became separate members of that great confederation before mentioned—the Dominion of Canada. The country composed of these two provinces extends westward from the Gulf of St Lawrence to the frontier of the district of Keewatin (lying north and east of Manitoba), in long. 90° 30′ W.; and northward from the Great Lakes and the St Lawrence to the ridge of land which forms the water-shed between that river and Hudson Bay. The northern boundary is very irregular in outline, and has not been definitely surveyed; and the westernmost portion of the province of Ontario (formerly Canada West) is a strip of land lying north of Lakes Huron and Superior, and varying in width from 30 to near 200 miles. A considerable portion of Quebec province (Canada East) lies on the south or south-east side of the St Lawrence. The principal river of Canada is the St Lawrence. Its principal tributary on the north or left side is the Ottawa, which forms the boundary between the provinces of Ontario and Quebec. Those from the south are insignificant in point of size.

Quebec, or Lower Canada, was originally a French colony; five-sixths of the population are of French descent; old French usages prevail, and the French language is generally spoken. Ontario, or Upper Canada, is occupied mainly by settlers of British descent, a very large proportion of whom are from Scotland, both Lowlands and Highlands. The two provinces have presented a striking contrast in their rates of progress. To take, for instance, the growth of towns: in Quebec, Sherbrooke, the capital of the eastern townships, situated on the river St Francis, with about 6000 inhabitants, forms almost the only addition to Quebec, Montreal, and Three Rivers—the three French foundations; while in the province of Ontario, the towns of Toronto, London, Kingston, and Hamilton, have an aggregate population of more than 100,000. A great part of both provinces, more especially the shores of Lake Superior, is valuable only for mineral resources, such as iron, zinc, lead, copper, silver, gold, cobalt, manganese, gypsum, marl, granite, sandstone, limestone, slate, and marbles of nearly every imaginable colour. Considerable portions also, though heavily timbered, chiefly with pine, are yet but little adapted to settlement and cultivation. Towards the Gulf of St Lawrence, again, a large section of territory derives importance mainly from the fisheries, being, with partial exceptions in Gaspe, comparatively worthless for every other object. Thus the area for the profitable production of ordinary

cereals cannot materially exceed 40,000 square miles, containing, however, within this space a singularly small proportion of irreclaimable surface. This cultivable block increases regularly in width and fertility, from its commencement on the Lower St Lawrence to the shores of Lake Huron. Below Quebec—to say nothing of the precarious nature of the crops—there may always be seen, on one or on both sides, the primeval forest. Between that city, again, and the basin of the Ottawa, a gradual improvement shews itself even on the north side; and towards the south, there stretches away to the frontier of the United States a broad belt of generally undulating character, probably the best field in the country for the blending of pasturage and agriculture. From the basin of the Ottawa inclusive, the parallel of the south end of Lake Nipissing may be said to cut off, towards the south-west, the entire residue of the practicable soil, in the shape of a roughly defined triangle, which, as a whole, is at least equal in the growth of grain in general, and of wheat in particular, to any region of the same extent in the whole continent.

In the matter of communications, Canada is unrivalled. The St Lawrence, with its lakes, puts it in connection at once with the most commercial sections of the United States, and with the open ocean. The navigation of this great water-system has been much assisted by art. Below Montreal, Lake St Peter has been deepened so as to admit vessels of over 1800 tons burden; and above that city, a series of cuts, skirting the rapids, admit sea-going vessels into Lake Ontario. Beyond this, the Welland Canal, a magnificent achievement, connects Lake Ontario with Lake Erie, affording passage for vessels of large size, and thus escaping the insuperable obstacle of the Falls of Niagara. The 'Allan' line of steamers plies weekly between Liverpool and Montreal in summer, and between Liverpool and Portland in winter. In addition to the navigation of the main artery, there are numerous canals and navigable streams and lakes throughout the province. Of the former, the principal is the Rideau Canal, connecting the river Ottawa with Lake Ontario.

Over and above all these facilities in the way of navigation, Canada is not deficient in roads of every description. The government has laid out, in the newer and remoter townships, two great systems of highways; seven lines for the Upper province, and five for the Lower; subsidising, as it were, the same by free grants of 100 acres to each holder of land on both sides of every route, under condition of residence and cultivation. The Grand Trunk Railway of Canada is the longest line in the world owned by any one company, and under one management. It has an unbroken line of communication from Portland to Lake Huron and Detroit. In 1881, progress began to be made with the gigantic undertaking of a railway for the Lakes through Manitoba, the North-west Territory, and British Columbia, thus connecting the Atlantic provinces with the Pacific. The company received large grants of land along the line, and undertook to finish the railway within ten years, the British government guaranteeing a loan. The Canadian Pacific Railway was completed in 1886, much within the specified time. The Megantic International and the Intercolonial give Montreal railway communication with St John and Halifax, the chief cities respectively of New Brunswick and Nova Scotia.

The *climate* of Canada presents very opposite extremes of heat and cold, and the transition from the one to the other is much more sudden than in Great Britain. Notwithstanding this, however, it is healthy. The spring in Canada generally commences about the end of April, and the fields are well covered with vegetation by the beginning of May. The thermometer rises in summer to from 80° to 90°, and even above 100°; but the average heat of the summer is generally about 75°. Spring, summer, and autumn extend from the end of April to October. 'As indications of the climate of Canada increasing in warmth as you ascend the river, it may be stated that the Isle of Orleans, immediately below Quebec, is famous for its plums, and the island of Montreal for its apples; and from the neighbourhood of Toronto to the head of Lake Erie, grapes and peaches ripen without any aid whatever. Melons, again, of large size come to maturity, through the settled parts of the province, in the open air; and pumpkins and squashes attain enormous size, some of them near Toronto having weighed 300 lbs.' Winter commences in November, when thick fogs and snow-storms are frequent. By the middle of December, the ground is generally covered with snow, and the frost, especially in Lower Canada, becomes sometimes very intense, the thermometer sometimes falling to 25° below the freezing-point.

In Upper Canada, again, about Toronto, the sleighing season, which, at Quebec, lasts for five months, is seldom longer than as many weeks. The sky of a Canadian winter is generally almost cloudless, the air bracing, and, from the absence of wind, in spite of the low temperature, the cold is not felt to be disagreeable. From Quebec to Montreal and upwards, the St Lawrence and other rivers, and also the lakes, cease to be navigable; but the firm icy surface serves as a road for the sleighs and carioles; and although the entire face of nature is now changed, yet the snows and frosts of Canada are hailed as ushering in a season which brings with it no small amount of social enjoyment.

The *chief towns* in Canada are Quebec and Montreal in the province of Quebec; and Toronto, Hamilton, Ottawa, London, and Kingston in the province of Ontario. Ottawa, the new capital of the Dominion of Canada, is picturesquely situated on the south bank of the river of the same name, about 90 miles from its junction with the St Lawrence. At the west end of the city, the river rushes over the magnificent cataract known as the Chaudière Falls; and at the north-east end there are other two cataracts, over which the Rideau tumbles into the Ottawa. The immense water-power of the city is made use of in numerous saw-mills, which send forth vast quantities of sawn timber. The finest buildings in the city, and among the finest on the American continent, are the Houses of Parliament for the Dominion. The population in 1871 amounted to 21,500, and has of late increased rapidly.

The city of Quebec stands on the extremity of a precipitous cape, on the north bank of the St Lawrence, opposite the island of Orleans. It is the great military stronghold of British North America, completely commanding the navigation of the

river, and deemed by authorities impregnable. The city is divided into an upper and lower town. The upper town is more open, regular, and better built. It is situated within the gates and walls, and is approached by a steep, serpentine street and carriage-way. On the eastern end and point stand the Grand Battery, and portions of the fort, barracks, and town; towards the north, the Esplanade; and on the west, the Citadel, which crowns the heights. The institutions are, in many instances, of French character, and the language of the inhabitants is French and English. As a port, Quebec is the first in Canada, and the third in the Dominion, coming after Halifax in Nova Scotia, and St John in New Brunswick. Its great business is ship-building and the lumber-trade. Millions of feet of timber are annually exported. Quebec is the summer port of departure of the Allan line of steamers for Liverpool and Glasgow; also of a weekly line of steamers for the gulf ports and maritime provinces. By railway, it is now connected with Western Canada and the United States. Population (1871) 60,000.

Montreal is the largest city and the commercial emporium of the Dominion of Canada. It occupies one of the most commanding positions in America, and stands on a large fertile and beautiful island of the same name, 30 miles long by 10 broad, formed by the confluence of the Ottawa and the St Lawrence. It may be said to be at the head of the sea or outward navigation, and at the end of the great chain of lake, river, and canal navigation which extends westward to Chicago and Fond du Lac, a distance of about 1400 miles. As a port, Montreal is accessible to ships over 3000 tons burden. It is also the chief seat of manufacturing operations in the Dominion. From Point St Charles, at the head of Montreal Harbour, to St Lambert, on the southern shore, a distance of about 2 miles, the St Lawrence is spanned by the Victoria Bridge, the most costly and magnificent tubular bridge ever constructed. It gives the Grand Trunk Railway an unbroken line of communication from Portland to Lake Huron and Detroit, and Montreal unrivalled facilities and advantages for commerce, whether foreign or domestic. Population (1871) 107,000.

A few words may suffice for the towns in the province of Ontario, or Upper Canada. Ottawa has been already described. Toronto, 'the Queen City of the West,' and the capital of the province, is situated on the north-west shore of Lake Ontario, and faces a spacious bay. It has many industrial establishments, including foundries, mills, tanneries, breweries, distilleries, and a great variety of other factories, all in a thriving condition. The population in 1871 amounted to 56,000.—Hamilton, called the 'Ambitious City,' is beautifully situated on Burlington Bay, at the western extremity of Lake Ontario, on a plateau of slightly elevated ground. It is in the very centre of the finest grain-producing region in the Dominion. The population in 1871 was 26,700.—London, the westernmost city in the Dominion, can boast a more rapid growth than any city in British North America. It is surrounded by a rich agricultural district, which furnishes it with a large trade in wheat and other produce. The population in 1871 was 15,700.—Kingston lies pleasantly at the head of the Thousand Islands, on the north-east shore of Lake Ontario, where the waters of the Canadian lakes issue to form the St Lawrence. It is one of the oldest settled localities in Upper Canada. The population of these towns in 1881 was as follows: Ottawa, 27,500; Quebec, 62,500; Montreal, 140,750; Toronto, 86,500; Hamilton, 36,000; London, 20,000; Kingston, 14,100.

Nova Scotia.

The province of Nova Scotia consists of the peninsula of that name and the island of Cape Breton. The peninsular part, which is connected with the mainland of New Brunswick by a narrow isthmus, is about 280 miles in length, and from 50 to 100 in breadth, and faces the Atlantic with a north-east and south-west incline. The coast-line is 1000 miles long, and the shores, which are much indented, abound in excellent bays and harbours; among others, Chedabucto Bay, Halifax Harbour, St Margaret's, Mahon, and St Mary's Bays, Chignecto and Annapolis Basins, and Pictou Harbour. Along the Atlantic sea-board, and extending inland from it for about 20 miles, is a range of highlands, while the Cobequid Mountains (1100 feet high) traverse the interior from the Bay of Fundy to the Gut of Canso. There are numerous lakes, the greater number occurring near the southern and south-western coasts, and covering about one-tenth of the entire superficies. There is no part of the land 30 miles distant from navigable water, and in all parts there are numerous small streams. The soil along the Atlantic coast is naturally rather poor; but in the valley north and south of the Cobequid Mountains, it is extremely fertile, and agriculture is carried on with great success.

The province abounds in mineral riches, including gold, coal, and iron. Copper and lead are also found. Gold was first discovered in the colony in March 1861, on Tangier River, about 40 miles east of Halifax. Since then, it has been found in more than 100 different localities. The coal raised at the various Nova Scotian collieries in 1872 amounted to 880,950 tons, being more than 200,000 tons over the produce of 1871. The cause of this great increase was the enormous advance in the price of iron and coal in Great Britain. The yield of coal in 1875 was 781,000 tons; of iron ore, 4500 tons; of gold, 11,000 oz. In the three years 1879—1881 the total value of exports ranged from $7,365,000 to $8,250,000; and the imports from $7,000,000 to $8,000,000.

The climate of Nova Scotia, like that of the adjoining districts, is salubrious and pleasant, though exposed to sudden changes of temperature and frequent fogs. From its insular position, the extremes of summer heat and winter cold are not so great as farther inland on the North American continent.

The fruits produced in the country are numerous. Besides a great variety of wild fruits, gooseberries, strawberries, cherries, and raspberries, there are pears of various kinds, all the varieties of English plums, apples of a very superior quality, and some finer fruits. The other vegetable products are cucumbers, potatoes, artichokes, cauliflowers, cabbages, beans, and peas. The grains cultivated are summer and winter wheat, rye, Indian corn, buckwheat, barley, and oats. The natural forests are elm, cherry, white, black, yellow,

and gray birch, red oak, beech, white and yellow pine, white, red, and black spruce, maples, &c. The rivers abound with the finest fish, among which are salmon and trout; and the shores yield large supplies of white and shell fish.

Halifax, the capital of Nova Scotia, is pleasantly situated on the slope of a rising ground, facing a fine spacious bay or natural harbour in front, on the eastern side of the peninsula. The harbour is easy of access for ships of every class, capacious enough to afford anchorage for all the navies of Europe, and finely sheltered from the violence of winds. Population in 1871, 29,852; in 1881, 36,100. Other important towns in the province are—Pictou, on the north coast, the headquarters of the coal export; Liverpool, on the Atlantic seaboard, and Yarmouth, at the south end of the peninsula, both engaged in the lumber-trade, ship-building, and fisheries, and each having a population of over 3000; Windsor, in the interior, built in the midst of great beds of gypsum or plaster of Paris, which is extensively quarried; and Sydney and Arichat, in the island of Cape Breton.

The most important branches of industry in Nova Scotia are the timber-trade, mining, cod-fishery, ship-building, and agriculture.

New Brunswick.

The province of New Brunswick, lying on the mainland of North America, contiguous to the United States and Lower Canada, consists of an extensive tract, comprising 27,000 square miles, the greater part of which is still covered with dense forests. The land, however, is generally fertile, and excellently adapted for the settlement of emigrants. One-third of the surface of New Brunswick is covered by a bed of coal; gold and silver occur; and copper, iron ore, gypsum, and plumbago abound; yet the total value of the mineral produce exported only amounts to $200,000 a year. The climate is salubrious; the natural products are numerous and valuable; wild animals are plentiful; the rivers and lakes abound in fish; the coasts, in cod, haddocks, salmon, and other fish. As yet, New Brunswick, though capable of supporting a population of 3,000,000, has only (1881) 321,233 inhabitants. The principal settlements are along the river St John and its lakes. At the mouth of this fine river (500 miles in length) stands St John, the commercial capital of the province, and, in 1871, the fifth largest city in the Dominion. It occupies a commanding position, and, when approached from the Bay of Fundy, presents an imposing appearance. The position of its harbour, and its entire freedom from obstruction by ice, give it great advantages over all other ports in the Dominion. Ship-building and the lumber-trade are still the principal sources of its prosperity. Since 1872, it has been connected by railway with all parts of the Dominion and the United States. Population, 26,150. Ninety miles above St John, on the same river, lies Fredericton, a small but beautiful city, the seat of the provincial legislature and university. Other places that must one day become important are: Dalhousie and Bathurst, on the Bay of Chaleur; Chatham, at the mouth of the Miramichi; Shediac, opposite to Prince Edward Island. Though little more than villages at present (with the exception of Chatham, which has a population of 3000), and almost wholly dependent on the lumber-trade and the fisheries, they are destined to increase rapidly when the agricultural and mineral resources of the country begin to be developed. Progress can be discerned. In 1871, two lines of railway were in operation, and 450 miles of telegraph. Along the coasts and the banks of the rivers, there are excellent public roads.

Manitoba.

The province of Manitoba, formed out of the Red River Settlement, was admitted into the Dominion of Canada in 1870, and commenced legislation in 1871. Its area was enormously increased in 1882 (from 13,400 square miles to about 123,200), and it now extends from 49° to 53° N. lat., and from 91° to 102° W. long. The population, which in 1870 was about 12,000, had in 1880 increased to 37,207, three times that number; and the capital (Winnipeg, formerly Fort Garry) had itself about 12,000 inhabitants. In 1869–70, the Red River region was the scene of a rebellion, headed by Louis Riel. Before its suppression in 1870, a provisional government had been established. Riel led another rising of the half-breeds and Indians of the North-west in 1885; after their defeat by General Middleton, their leader was hanged. This last rebellion cost more than £1,000,000. The soil is naturally good, and the pasture offers splendid facilities for rearing sheep, cattle, and horses. It is declared to be the best wheat-bearing soil in the world, and its fertility is something remarkable. Root crops grow admirably. The development of the province of late years is unprecedented. The imports doubled in the three years 1879—1881. The Canadian Pacific Railway, which was completed in the spring of 1886, passes through Manitoba, and has favoured its swift progress. The branch railways also aid in developing the country; a line from Winnipeg to Hudson Bay was begun in 1886.

Prince Edward Island.

This rich and productive island is situated in the south of the Gulf of St Lawrence, and is separated from New Brunswick and Nova Scotia by the strait of Northumberland. It measures 130 miles in length, and is 34 at its greatest breadth. The general appearance of this island from the sea is level, but on landing, the scenery is varied with gentle undulations. The coasts are guarded by a bold line of red sandstone cliffs, varying in height from 20 to 100 feet. It abounds with streams and lakes, and in many places it is indented with bays, several of which, as Cardigan Bay on the east, the entrance to Georgetown, and Hillsborough Bay on the south, to Charlottetown, are deep and spacious, affording safe anchorage for large vessels. Almost the whole area consists of good land, and all the fertile land, except a very small portion, is already under cultivation. The soil is exceedingly fertile, and large crops of wheat, oats, barley, beans, peas, maize, and potatoes are produced. The climate is in some respects similar to that of the neighbouring countries, but the atmosphere is noted for being free of fogs.

Prince Edward Island is poor in minerals, but its waters are rich in fish—cod, herring, mackerel, and hake. The total value of the imports for a year may amount to between £400,000 and £500,000; of the exports, to £300,000. A railway traverses the whole length of the island. The capital, Charlottetown, on the east side of the island, has about 12,000 inhabitants. The whole population of the province in 1881 was 108,891. Prince Edward Island became a province of the Dominion of Canada only in 1873.

British Columbia.

This province comprises part of the North American mainland, together with Vancouver's Island. The former is situated in lat. 49° 55′ north, and long. 115°—132° west; and measures about 420 miles in length, by 300 miles in breadth, its total area being estimated at 213,000 square miles. On the north, it is bounded by the Simpson River; on the east, by the Rocky Mountains; on the south, by the United States; and on the west, by the Pacific and Queen Charlotte Sound. The adjacent island of Vancouver has an area of about 18,000 square miles. Each of these divisions formed an independent colony till 1866, when both were united. In 1871, British Columbia entered the Dominion of Canada. The interior of the mainland—*i.e.* the region between the Rocky Mountains and the Cascade Range, facing the Pacific—is, on the whole, rugged and lofty; and though streams are numerous, they do not serve the purposes of irrigation, being often confined within deep ravines. The principal river is the Fraser, which rises in the north-east of the province, and maintains a southerly course, till at Fort Hope it is bent sharply to the right by a mountain barrier, and flows west into the Gulf of Georgia. The seaboard is singularly broken—long and narrow inlets of the Pacific running far into the land, forming splendid harbours, and communicating by navigable waters with the interior. Vancouver's Island is also in the main a mountainous region, reaching in Mount Arrowsmith an elevation of nearly 6000 feet, but possessing here and there, especially in the east and south-east parts, open stretches of fine grass-land.

The best harbours on the mainland are Burrard Inlet, on the Gulf of Georgia, a few miles from New Westminster, and the chief port for the lumber-trade; Howe Sound, north of Burrard Inlet; Bute Inlet, still farther north; and Millbank Sound, which will become valuable as the gold mines on the Peace River attract a population. In Vancouver's Island may be mentioned Victoria Harbour, which is narrow, intricate, and shoaly; Esquimault, the best harbour on the Pacific north of San Francisco; Nanaimo, in the neighbourhood of the coal-mines; and Barclay Sound, which is safe, but difficult of entrance. There are considerable tracts of arable land in the province; but the pastures, which are almost endless, are likely to prove more valuable. The forest-lands are also of immense extent, and yield most valuable timber. The Douglas pine is almost universal on the sea-coast, and up to the Cascade Range; the cedar, white-pine, and maple are found everywhere; the Scotch fir, the willow, and cotton-wood on the bottom lands. But the lumber-trade is only beginning. Whales and seals abound off the northern coasts; sturgeon are plentiful in the rivers and estuaries; the salmon of the Fraser River are famous over the American continent; so are the oulachans, small sprat-like fish, so full of oil, that, it is said, they will burn like a candle. Cod, herring, halibut, haddock, anchovies, &c. are caught in great quantities. Of wild animals, the most valuable are the black and silver fox, the sea-otter, red fox, fur seal, marten, and beaver. Buffalo are found on the plains, bears and goats on the mountains, elk on the sea-coast, and deer on the islands. The mineral resources of British Columbia are great. Coal is found extensively in Vancouver's Island; while the mainland seems to possess inexhaustible veins of gold. It is found everywhere, from the frontier of the United States up to the Simpson River, but is only beginning to be worked. In 1881, the value of the total yield of the mines was about £300,000. Silver and copper are also found in large quantities. The climate varies. In Vancouver's Island, and on the coasts of the mainland, it is moderate—the temperature ranging from 20° in winter to 80° in summer; but in the high interior it is more severe, though everywhere healthy. The total value of the exports (mainly skins and furs) from British Columbia to the United Kingdom amounts to about £80,000 a year, and of the imports from the same country to somewhat more. British Columbia sends 6 representatives to the imperial parliament at Ottawa.

The North-west Territory.

This territory, organised as part of the Dominion of Canada in 1875, occupies most of the region formerly known as the Hudson Bay Territory. Originally limited to the districts drained by the rivers falling into Hudson Bay, the Hudson Bay Territory was, after the union of the Hudson Bay and North-west Companies in 1821, held to comprehend the whole of British America, with the exception of the settled provinces. But the organisation of British Columbia in 1858, and again of Manitoba in 1870, greatly restricted its area. The remainder may be regarded as constituting the North-west Territory, which extends from the boundary of Ontario to the Rocky Mountains and Alaska, and from the frontier line of the United States on the south to the shores of the Arctic Ocean in the north. In the north, vegetation is scanty and stunted; as we travel southward, the pine-forests begin to appear, till in the southern regions on both sides they become dense, with open spaces of lake, morass, and prairie-ground. The whole territory may be regarded as a vast hunting-ground, occupied by buffaloes, musk-oxen, deer, bears, wolves, foxes, beavers, lemmings, ermines, and other fur-bearing animals—the skins of which constitute the principal value of the territory. The population consists chiefly of various Indian tribes who roam over the interior; and of Esquimaux, inhabiting the northern and eastern coasts.

The Hudson Bay Company, which was chartered in 1670, was invested, not only with the monopoly of the trade, but also with the absolute proprietorship and government of a vast but undefined territory. In honour of the king's cousin, who was a leading member of the corporation, the region was called Rupert's Land,

by which it is still historically known. In 1821, the Hudson Bay Company coalesced with a new and powerful corporation, the North-west Company of Montreal, established to secure the rights of Canadian explorers over the Indian territories; after which date the authority of the amalgamated companies extended from Labrador to the Pacific, exclusive of the colonial settlements. In 1869, the British government acquired possession of the domains of the Company; and in 1870, the region entered the Dominion of Canada. In 1882, the best part of the North-west Territory was divided into the provinces of Assiniboia, Saskatchewan, Alberta, and Athabasca.

NEWFOUNDLAND.

This colony—the only part of British North America which has not yet (1886) entered the Dominion of Canada—consists of the large island of Newfoundland, the island of Anticosti, and the coast of Labrador on the mainland. The island of Newfoundland, the area of which is estimated at 40,000 square miles, is separated from Labrador by the Strait of Belleisle, twelve miles wide. Its greatest length is about 370 miles, its greatest breadth 290 miles. It is extremely irregular in shape; the coasts are bold and lofty, and are deeply indented with spacious bays and estuaries. The surface is hilly and rugged, with numerous tracts of moss, intersected by rivers and lakes, or 'ponds,' as they are here called. As seen from the sea, it presents a wild and sterile appearance. It is but thinly wooded, except near the rivers. The settlements are confined to the coasts, and are chiefly on the peninsula of Avalon, at the south-east of the island. Here, wheat, oats, barley, potatoes, turnips, have been produced of the best quality. The island is rich in useful minerals, and lead, silver, and copper mines are being worked, but the results are still small. The atmosphere is humid, and subject to dense fogs, but is, notwithstanding, more salubrious than any part of the continent. Fishing is the great object of industry; and the exports consist almost solely of dried and pickled cod, seal, cod, and whale oil, seal-skins, herrings, sprats, and salmon. The fisheries are of two kinds—the 'shore' fishery, and the 'bank' fishery. The former comprises the bays and coasts of Newfoundland; the latter, a great tract, known as the Banks of Newfoundland, from 500 to 600 miles in length, and about 200 miles in breadth. These banks form a vast submarine plateau, from 20 to 100 fathoms under the surface of the ocean. In 1881, the value of the exports to Great Britain, chiefly fish and train-oil, amounted to £595,500; and of the imports from the same country, to £451,230.

The administration of the colony is vested in a governor, with executive and legislative councils, and a House of Assembly. The capital, St John's, is situated on the peninsula of Avalon, with a population of 30,000, and a well-protected harbour. The whole population of the island, according to the census of 1884, amounted to 196,411. The French have a small establishment on the islands of St Pierre and Miquelon, as a shelter for their fishermen; and they are allowed to catch and dry fish on the north-east and west coasts of the main island.

UNITED STATES.

These States occupy the middle division of the continent, and are bounded on the north by British America; east, by the Atlantic; south, by the Gulf and Republic of Mexico; and west, by the Pacific. They extend from lat. 24° 20′ to 49° north, and from long. 66° 56′ to 124° 30′ west; the greatest length being 2768 miles, and greatest breadth about 1600. The area is about 3,607,600 square miles, and the population in 1880 was 50,442,066. The length of coast-line is stated at about 22,600 miles.

The *United States* were originally British colonies, but in 1776 declared themselves independent. At that time, the territory extended only from the Atlantic to the Mississippi; all the country to the west of that river belonged to or was claimed by France; Florida, to Spain; and Texas, to the Mexican Confederation. In 1803, the French territory was added by purchase; in 1819, Florida was ceded in compensation for spoliations on American commerce; in 1845, Texas—which had revolted from Mexico in 1835, and erected itself into an independent republic—became part of the Union by annexation; in 1846, a large accession of territory was gained by the Oregon treaty with Great Britain; and in 1848, California and other tracts were ceded by Mexico. In 1861, a civil war broke out between the free and the slave-holding States. It lasted for four years, ending in the complete defeat of the latter, and in the formal abolition of the institution of slavery. The only states in the confederation at its first formation were the following thirteen, the others having been formed since: New Hampshire, Massachusetts, Rhode Island, Connecticut, New York, New Jersey, Pennsylvania, Delaware, Maryland, Virginia, North Carolina, South Carolina, and Georgia.

When a new tract of country is first settled, it is administered as a *territory*, under the direction of the federal government, until it is organised and admitted as an independent state. The size of the states and territories may be realised from the fact that one of them, Texas, is considerably larger in area than the Austro-Hungarian Empire; while four others are each larger than the United Kingdom.

Population.

No other country has been peopled by so many European races. New England was settled by English Puritans; New York, by the Dutch; Pennsylvania, by Swedes, and by English and German Friends or Quakers; Maryland, by English Roman Catholics; Delaware and New Jersey, by Dutch, Swedes, and English; Virginia, by English Cavaliers; the Carolinas, in part by French Huguenots; Louisiana and Michigan, by the French; Florida, Texas, and California, by Spaniards; Utah, by Mormon immigrants from all quarters. But of late years the stream of immigration from Germany, Ireland, England, Sweden, Scotland, Switzerland, Denmark, and Norway, has been so great, that representatives of the different nationalities are found scattered over the whole territory of the Union—especially in the new western states. In 1882, the total

immigration amounted to 788,992; but fluctuates much from year to year. In 1877 it was only 138,000—the smallest number in any year of the period 1870—1880. From 1820 to 1880 the immigrants from Great Britain and Ireland numbered over 4,700,000. It is said that the Irish and Germans, with their descendants, constitute one-third of the entire population; about 10,000,000 being set down as of Irish descent; 6,000,000 as of German stock. At the census of 1880, of the whites foreign born, 2,772,169 were natives of the United Kingdom; 1,966,742 were Germans; 717,084 were British Americans. The coloured population amounted to 6,580,793; and there were 105,465 Chinese. In 1880, there were 180,000 tribal Indians not included in the census.

Government—Army—Navy.

Each of the English colonies established in America had had a certain form of government assigned it for maintaining the necessary order. This consisted generally of a House of Assembly, chosen by the people, with governor, judges, and other officers, appointed by the king, but paid out of taxes levied by the representatives. On acquiring independence after their war with the mother-country, the different colonies, now called *States*, made such alterations, each in its own constitution, as they believed to be suited to their circumstances; and a general government, framed and appointed by the consent of the whole, was formed to take charge of such national affairs as the States could not manage separately. The States have each a Senate and House of Representatives; the members of the former are fewer in

number than those of the latter, and a part of them only is chosen at each election, so that they remain in office for several years: the House of Representatives is generally elected anew every year. The resolutions agreed to by these two bodies for the government of the state, are afterwards submitted to a president or governor, whose sanction constitutes them part of the law.

The imperial government or Federal Congress of the United States is, like that of the states individually, a representative democracy, in which the people intrust the administration of affairs to executive and legislative officers of their own choice. At the head of the executive is a President, who, with a Vice-president, is elected every four years. The Federal Congress or legislative body consists of two Houses—the Senate and House of Representatives. The Senate is composed of two members from each state, chosen by its legislature for six years. The members are required to be at least thirty years of age, to have lived nine years in the United States, and to be at the time of election residents in the state by which they are returned. The House of Representatives is composed of members elected every second year by the vote of all male citizens over the age of twenty-one of the various states of the Union. They must be not less than twenty-five years of age, citizens of the United States for seven years, and residents in the particular state for which they are chosen. The number of representatives increases with the increase of the population. In 1880 there were 293 in all. The House of Representatives performs the duties allotted by the British constitution to the Commons' House of Parliament, and has the right, like them, of originating all bills for raising revenue; while the Senate, on the other hand, exercises functions analogous to those of our House of Lords. Bills which have passed the two Houses have not the sanction of law till they are signed by the President, or, on his refusal, are voted a second time by two-thirds of each of the Houses. Congress is prohibited, by the American constitution, from making any law concerning establishment or free exercise of religion, the liberty of the press, and freedom of speech, or the privilege of public meetings to express their opinions on the measures of government.

The judicial power is vested in one supreme court, and in such district courts as Congress may from time to time establish. The supreme court consists of a chief-justice and seven associate justices appointed by the President for life, who hold a court in the city of Washington annually; besides which, each judge attends in certain districts to hold circuit courts with the local justices.

The supreme court has jurisdiction in all cases arising under the constitution, laws, and treaties of the United States; in causes affecting ambassadors and consuls, of admiralty and jurisdiction; in controversies to which the United States is a party, or between a state and the citizens of another state, citizens of different states, and citizens and foreign states.

According to the original constitution of the United States, all men are equal, but this doctrine was not thoroughly carried out till the close of the civil war in 1865. On December 18 of that year, Congress solemnly declared slavery to be abolished: 'neither slavery nor involuntary servitude, except as a punishment for crime whereof the party shall have been duly convicted, shall exist within the United States, or any place subject to their jurisdiction.' The vast change in the political and social organisation of the Republic made by this new fundamental law (the 13th amendment of the constitution), was completed by the 14th and 15th amendments, passed in 1868 and 1870, which gave to the former slaves all the rights and privileges of citizenship.

In 1882, the revenue was $403,525,250, and the expenditure, $186,905,232. The public debt was $1,918,312,994, or about £383,662,600—nearly the whole of this was incurred in the course of the civil war. Between 1870 and 1882 no less than $482,500,000 of the public debt had been paid off. The chief sources of the public revenue are the customs and taxes; the principal items of expenditure are the interest on the public debt, the civil list, the army and navy, and pensions. Before the struggle of 1861–65, the *army* of the United States consisted of about 14,000 regular troops. But during these years, the federal government was forced to call into the field no fewer than 2,670,874 men, or nearly one-fourth of the entire male population of the Union States; while the Confederate Secessionists had at least 400,000 men under arms. Since then, the army has been again reduced to its normal size, and in 1881 (exclusive of the militia) numbered only 26,660 men. The term of service is five years. Each state is further supposed to have a numerous militia force; but the system is imperfectly organised. The *naval forces*, in 1881, consisted of 24 iron-clads, 65 other steamers, and 23 sailing-vessels.

Religion and Education.

Religion is free from any interference of either federal or state governments, and all denominations have equal privileges. There are a great number of different denominations of Christians in America; the principal are the same as in this country, consisting of Catholics, Protestant Episcopalians, Methodists, Presbyterians, Quakers, and the various classes of Independents. In some of the states, certain denominations are more prevalent than others. New England, for instance, was settled, as has been stated, by the Puritans in Cromwell's time, and its religious condition bears the impress of that origin. Roman Catholics are still numerous in Maryland; Quakers or Friends in Pennsylvania; while Episcopacy is strong in Virginia, the Carolinas, and Georgia. The first Presbyterians settled in Delaware and New Jersey—in the latter of which is Princeton College, their great theological seminary.

In a country where almost every adult has a voice in the management of the commonwealth, it is of vital importance that none grow up ignorant and undisciplined. Accordingly, in the United States, public schools and education generally receive a large share of public attention. It has been uniformly a part of the land-system of the federal government to provide for public schools. The articles of confederation (1787), the acts admitting the new states into the Union, all provided for the appropriation of lands in each township for the use of public schools. Where

the portion of the public school-fund of the state allotted to a district is not sufficient, the inhabitants assess themselves to meet the deficiency; more than half the expense of the primary schools is thus raised. These common schools are managed by local committees, and are entirely unsectarian.

According to the census of 1870, the total number of schools of all classes in the United States was 141,629; of pupils, 7,209,938; of teachers, 221,044; of whom 127,713, or considerably more than one-half, were females. The number of public schools was 125,059, or six-sevenths of the whole; and their total income from all sources, endowment, public funds, taxation, and tuition, was $64,030,673, or rather more than $500 for each school. In these figures are not embraced the Military Academy at West Point in New York; or the Naval Academy at Annapolis in Maryland. In 1880, there were 272,686 teachers, and, 9,424,000 pupils.

The proportion of illiterate persons in the United States is by no means so small as might be supposed from the elaborate educational machinery of the country. In 1880, the number of persons above 10 years of age who could not read was 4,923,451; of course, the majority of these were the recently emancipated slaves of the southern states, or the Irish immigrants in New York and Pennsylvania, but even Massachusetts had 75,650 illiterates.

In 1880, the total number of newspapers of all kinds published in the United States was 11,403, of which 980 were dailies, 8718 weeklies, and 1167 monthlies. There were besides 10,560 periodicals.

Minerals.

The United States are rich in mineral productions. Coal is very widely diffused. Its area is estimated at 250,000 square miles, and has been divided into four tracts: 1. The great central Appalachian coal-field, extending from Tuscaloosa in Alabama, to Pennsylvania on both sides of the Alleghanies, and covering about 40,000 workable square miles. 2. The coal-field occupying the greater part of Illinois and Indiana. 3. The coal-field of Missouri and Iowa. 4. The coal-field of Michigan, comprising almost the whole state. At Pittsburg in Pennsylvania, there is a hill principally composed of coal, and in this district it is found at many places within a few feet of the surface. In 1880, the total yield was 71,067,500 tons, of which two-thirds was obtained from Pennsylvania. Iron is found everywhere, from the richest ores in mountain masses to bog-ore. According to the census of 1880, it was worked in twenty-four states, the total production of pig-iron amounting to 4,295,414 tons, of which Pennsylvania furnished one-third. The states next in order were Ohio, New York, New Jersey, Michigan, Illinois. As, in 1874, the produce was only 2,690,000 tons, it will be seen that during the decade 1870–80, the development of the iron industry has been very rapid. Michigan, on the shores of Lake Superior, possesses perhaps the richest copper mines in the world. Masses of almost pure metal (as much as 90 per cent.) are found weighing thousands of pounds. Four-fifths of the whole produce come from this state; but it is worked in eight others, of which the most productive are Vermont, Tennessee, North Carolina, and Maryland. At the census of 1870, 181,263,502 gallons of petroleum were obtained from the four states of Pennsylvania, West Virginia, Ohio, and Kentucky, of which the first yielded 171,250,000 gallons. Lead exists in rich deposits in Missouri, Arkansas, Illinois, and Iowa; zinc, in considerable quantities in Wisconsin, New Jersey, and Pennsylvania. Tin has been found in Maine and California. Silver and gold are scattered over a pretty large area. The former is abundant in New Mexico, Arizona, Nevada, California, and Utah. Gold is found in small quantities in the eastern states; in larger deposits in Virginia, North and South Carolina, and Georgia; and in great quantities in California, Oregon, Nevada, Colorado, Washington, Arizona, New Mexico, Idaho, and Montana. The total yield of both, in 1881, was estimated at $77,700,000, of which Colorado produced the greatest amount, $20,500,000, and California the next greatest, $19,000,000.

Agriculture and Crops.

In point of productive industry, the United States is yet more an agricultural than a manufacturing country, though of late years an immense impetus has been given to the latter department. Oats, rye, and barley are raised in all the northern states, and also in the hilly districts of the south. Maize is common to every part of the Union; it is indigenous, and adapted to a greater variety of soil and climate than wheat, and yields a much larger produce. Wheat is also cultivated through the whole Union, but especially in the middle and western states.

The cultivation of tobacco begins in Maryland, in latitude 39°; it is raised to a greater extent in that state and in Virginia and Kentucky than in any others of the Union; but it thrives also in all the western states. Cotton does not succeed well further north than the latitude of 37°, though some of the districts raise it for domestic use; it forms the staple of all the districts south of the river Roanoke. The best kinds grow in South Carolina and Georgia, in dry situations, upon the sea-coast. The cultivation of rice occupies nearly the same region as that of cotton. The climate which is favourable to sugar does not extend beyond the latitude of 32°; it is raised in the States chiefly for domestic use, and is not an article of export to any extent. The crop is rather precarious, from the frosts which sometimes occur even in the most southerly districts. The vine grows spontaneously in most of the southern and western states, and is cultivated as a fruit about Philadelphia. The mulberry-tree, hops, and hemp, all succeed well in the middle and western states.

The timber-trees of the States are of numerous kinds, and many of them of the best quality. The country east of the Mississippi, except the prairies of Illinois and Indiana, was at its settlement heavily wooded; and there are still vast forests of valuable timber—beech, birch, maple, oak, pine, hemlock, spruce, walnut, hickory, ash, elm, &c.; and in the south, live-oak, water-oak, magnolia, palmetto, tulip-tree, cypress, cotton-wood, cane, &c. Forests also occur in the Rocky Mountains; and California, Oregon, and Washington Territory have the largest timber in the world.

In 1885, the acreage of maize was 73,000,000 acres, and of wheat, 34,000,000. The cereal crops of 1884 were unprecedentedly large. The production of wheat in 1884 was 512,000,000 bushels, in 1885 it was only 257,000,000; of maize, there were 1,795,000 bushels in 1884. The advance in production between 1870 and 1880 was unprecedented, amounting to about 100 per cent. The production of cotton advanced from 1540 million lbs. in 1870 to 2773 millions in 1880. More than two-thirds of the world's cotton crop is grown in the States. Till 1859, the United States used occasionally to import wheat from Europe; now they produce one-fourth of the world's crop, and have a vast yearly surplus for exporting. The shipments of cattle and meat from the United States exceeded, in 1880, the value of $25,000,000.

Manufactures.

The manufactures which are followed with most advantage in America, and without fear of English rivalry, are those which produce articles too bulky or too heavy, in proportion to their value, to bear the expense of a long carriage, or of which the materials are found in the country, and can be wrought up there at less expense than by carrying them to cheaper tradesmen at a distance. Some of these branches may be mentioned—such as the making of soap, candles, and hats; tanning and working in leather, particularly bulky articles; building of carriages; making of all kinds of agricultural implements; carpentry, sawing, and turning of most descriptions; constructing and putting up of mill-work and machinery; distilling; the employments of goldsmiths, tinsmiths, and printers.

The cotton manufacture was introduced in 1790; and at the census of 1870, there were in the United States 956 cotton manufacturing establishments. The States having the largest numbers were Massachusetts, Rhode Island, Pennsylvania, and Connecticut. The mills employed 448 steam-engines, of 47,117 horse-power; and 1250 water-wheels, of 102,409 horse-power. There were 157,310 looms, 3,694,477 frame-spindles, and 3,437,938 mule-spindles. The hands employed numbered 47,790 males above 16 years of age, 69,637 females above 15, and 22,942 under those ages. The woollen factories amounted to 2891, Pennsylvania possessing the largest number; New York came next; and then Ohio, Massachusetts, Indiana, Missouri, Delaware, Kentucky, Illinois, Connecticut, and Maine, in the order specified. These factories used 1050 steam-engines, of 35,900 horse-power; and 1092 water-wheels, of 59,333 horse-power. The hands employed numbered 42,728 males over 16 years of age, 27,681 females above 15, and 9643 children. In 1880, there were 253,840 manufacturing establishments, 2,738,930 hands employed. The cotton mills had 230,223 looms, and employed 181,628 persons. In addition to the cotton and woollen industries, agricultural implements, machinery, india-rubber goods, oil-cloth, paper, carriages of all sorts, musical instruments, soap, candles, and various sorts of spirits, are extensively manufactured.

In the southern states, there is little manufacturing: the inhabitants there depend on the northern states, or on foreign countries, for their supplies, and their exports are cotton, sugar, and other raw materials.

Commerce.

The wealthiest class in the United States are generally the merchants of the large towns. Of late years, more particularly since the outbreak of the civil war, and still more particularly since its close, swindling on a gigantic scale has been rampant in New York and elsewhere; but it would be a foul slander to insinuate that Mr Jay Gould or his confrères in rascality are a fair sample of American 'business men,' or anything more than an ugly excrescence on the surface of commercial life. Among the merchant-princes of the New World are to be found men as honourable as any in England or the world. The subjoined table gives the total value in dollars of the imports and exports for various years:

Years ending June 30.	Imports.	Exports.
1868	357,436,440	476,902,839
1869	417,506,379	439,134,529
1870	462,377,587	529,519,302
1875	553,906,153	643,094,767
1880	760,989,056	851,482,804
1882	767,111,964	776,720,003

The principal items of export were wheat, flour, cotton, tobacco, pickled pork, hams, butter, cheese, and fresh meat. More than half goes to Great Britain and Ireland.

The mercantile shipping of the United States has greatly declined since 1861. The carrying-trade is passing into the hands of other countries, and mainly into those of Great Britain. Only 241,500,000 tons of American imports and exports were carried, in 1882, in American bottoms, and 1,241,350,000 in foreign vessels.

Years ending June 30.	U.S. Tonnage.	Foreign Tonnage.	Excess of U.S. Tonnage over Foreign.	Excess of Foreign Tonnage over U.S.
1830	967,227	131,900	835,327	....

1873	3,612,631	8,083,087	....	4,470,456

The growth of the railway system in the United States dates from 1827, when the first line was opened for traffic at Quincy, Massachusetts. Three years later, there were only 23 miles in operation; in 1840, there were 2818; in 1850, 9021; in 1860, 30,635; in 1870, 53,399; and in 1882, 104,324. Railways extend from the Atlantic to the Pacific, intersecting the republic in every direction. The total amount of capital expended on the various lines at the close of 1881 was £1,115,600,000. The number of telegraph offices, on the 1st of January 1881, was 11,320; the length of lines, 120,000 miles; and the length of wires, 395,000 miles.

MEXICO.

Mexico, occupying that portion of the North American continent which lies between 16° and 32° north latitude, and 95° and 115° west longitude, was conquered by the Spaniards, under Cortes, in

1521, and continued a colony of Spain till 1821, when it became an independent republic. From 1821 to 1837, the states were severally independent, but united into one federal republic like the United States; in 1837 they resigned their separate independence, and became a consolidated or central republic. Mexico originally comprehended Texas, which revolted in 1835, and is now part of the United States; and California, which declared its independence in 1836, and in 1848 also joined the United States. In 1862, Napoleon III. declared war against Mexico, and a French army invaded the country. An Austrian archduke, Maximilian, was forced on the people, with the title of emperor; but at the close of the civil war in America (1865), the United States ordered the French to withdraw. This was done, and Maximilian was afterwards taken prisoner, and shot at Queretaro, July 19, 1867. The so-called empire immediately disappeared, and Benito Juarez, the successful leader of the national party, again became president of the republic. On his death, in 1872, he was succeeded by Lerdo de Tejada, who was overthrown in 1876 by Porfirio Diaz. The history of Mexico since its separation from Spain has been a series of anarchic insurrections, varied with unscrupulous dictatorships. The government of Juarez was distinctly one of the best. That ruler was an able, intelligent, liberal-minded man, penetrated with modern ideas. But the Mexicans are very ignorant, unpatriotic, and corrupt, and it is impossible to be seriously sanguine about their future. The area of the country is stated at 745,000 square miles, with a population, according to the government estimates for 1884, of 10,460,700—of whom about one-third are Indian aborigines, from 500,000 to 1,000,000 whites, and the remainder mixed races. By the constitution of 1824, persons of all colours are admitted to the equal enjoyment of civil and political rights. The Mexican Congress consists of a president, vice-president, and of two legislative bodies—the Senate and the House of Representatives. Capital, Mexico, with a population of 200,000.

Geographically, about one-half of Mexico lies within the tropics, while the rest belongs to the temperate zone; but a large proportion of the tropical region enjoys a mild temperate climate in consequence of its elevation—being from 5000 to 9000 feet above the sea. This table-land is formed by the three great chains of mountains or cordilleras which run parallel to each other in a northerly direction; the most eastern chain is called the Sierra Potosi; the central, the Sierra Madre; and the western, the Sierra Sonora. The highest peaks are Orizaba (17,370 feet), Popocatepetl or 'Smoking Mountain' (17,880 feet), and Istaccihuatl or 'White Woman' (15,700 feet). The coast is humid, and unhealthy for strangers; but the table-land is remarkable for its salubrity, and it is here that the population is concentrated. Maize is the chief object of culture; besides which, the banana, manioc, cereal grains, rice, and the potato, form the common food of the people. All the fruits of Central and Southern Europe are here produced abundantly, oranges, lemons, grapes, olives, &c. The narrow insalubrious plain along the coast called the *tierras calientes*, or hot country, is remarkable for its luxuriant vegetation. The chief productions of this region are the sugar-cane, cotton, cocoa, indigo, and tobacco. The southern part of the country forming the isthmus is celebrated for the variety and importance of its woods and drugs, including mahogany, rosewood, ebony, logwood, caoutchouc, vanilla, jalap, sarsaparilla, and the trees upon which the cochineal insect feeds. Vast herds of horses, mules, and horned cattle also cover the plains of the southern district.

'The mines of Mexico, however, constitute the chief source of its wealth, particularly those of silver. Gold is also to be found, though in lesser quantities; and copper, tin, iron, lead, and mercury occur in various districts. Manufactures are generally in a rude state; agriculture indifferently attended to; and trade and commerce incessantly injured and obstructed by the internal dissensions of the country.' The total value of the imports of Mexico, consisting chiefly of cotton and linen goods, wrought-iron and machinery, amounts to about £5,500,000; of her exports, chiefly silver, copper ores, cochineal, indigo, hides, mahogany and other woods, to £5,000,000. More than two-thirds of the trade of Mexico is carried on with the United States. The railway system is being introduced into the country. The 'National Mexican' line, from the capital to Vera Cruz, 300 miles long, was completed in 1869, and others are being made. At the end of 1881, there were 11,000 miles of telegraph laid down and in operation. The public debt in the same year amounted to £86,000,000. The chief ports for foreign trade are Vera Cruz, Tampico, Matamoras, and Campeachy, in the Gulf of Mexico; and San Blas, Mazatlan, and Acapulco, on the Pacific sea-board.

CENTRAL AMERICA.

The Central States include that narrow tract of the continent which lies between Mexico on the north and the Isthmus of Panama on the south—being about 1000 miles in length, and from 80 to 250 in breadth. The states were at first united in a confederation; but now constitute five separate and independent republics—namely, San Salvador, Nicaragua, Honduras, Guatemala, and Costa Rica, with the protected kingdom of Mosquitia. (The British settlement of Honduras will be noticed in the following number, in connection with the West India Islands.) The country is extremely diversified, well watered, fertile, rich in minerals, favourably situated for commerce, has numerous ports on both sea-boards, and is altogether calculated to support a large and thriving population. The great curse of these countries is the want of a settled and firm government. Their commercial intercourse is chiefly with Great Britain and the United States. The exports chiefly consist of specie, indigo, coffee, cochineal, brazil-wood, and other articles of tropical produce. The imports are cotton and woollen fabrics, hardware, and other dry goods from Britain; silks, wines, and trinkets, from France and Spain. The total value of the exports from Central America to Great Britain amount to about £1,500,000; and the imports, to £1,000,000. The chief ports for foreign trade are Izabal and San Jose in Guatemala, La Libertad in San Salvador, San Juan in Nicaragua, Port Cortez in Honduras, and Punta Arenas in Costa Rica. This last-mentioned state has got a railway, which was opened for traffic in 1873.

SOUTH AMERICA—WEST INDIA ISLANDS.

THIS great division of the western hemisphere is a triangular peninsula, joined to North America by the Isthmus of Panama. With its apex projected far into the Southern Ocean, its western shores are washed by the Pacific, its eastern by the Atlantic, and its base by the Atlantic and the Caribbean Sea. It extends from 12° 10′ N. lat. to 52° 30′ S. lat. or, including the archipelago of Tierra del Fuego, to 56°—Cape Horn in this parallel being generally reckoned the extreme point of South America. Taken at its widest part—from Cape St Roque in Brazil to Cape Blanco in Peru—it extends from longitude 35° to 82° west. Its area is estimated at 6,429,853 square miles, of which about two-thirds lie within the tropics.

SUPERFICIAL FEATURES—GEOLOGY.

The surface of the continent falls into the following natural divisions: 1. The low, narrow belt of country skirting the Pacific, of which the

extremities are fertile, and the middle sandy and arid. 2. The basin of the Orinoco, consisting of extensive plains called *llanos*, covered with high herbage. 3. The basin of the Amazon, a vast plain of more than 2,000,000 square miles, with a rich soil and humid climate, and covered with dense forests. 4. The valley of the Plata, occupied by plains called *pampas*, in some parts barren, but in general covered with weeds, thistles, and tall grasses, on which feed prodigious herds of wild horses and cattle. 5. The high country of Brazil, eastward of the Parana and Uruguay, presenting alternate ridges and valleys, covered with wood towards the Atlantic, but opening into grassy steppes in the interior. 6. Patagonia, consisting of a succession of terraced plains called pampas, often sterile, but containing large tracts covered with coarse grass, shrubs, and thistles, the home of large numbers of guanacos, ostriches, pumas, armadillos, &c.

Two systems of mountains—the Cordilleras or Andes Proper, and the Brazilian Andes—traverse the continent. The former extend from the Strait of Magellan to the Caribbean Sea, embracing lofty table-lands and mountain-lakes, and intersected by steep valleys, ravines, and water-falls. At Popayan, the main chain divides into three ridges, one of which shoots off into the Isthmus of Panama; a second separates the valleys of the Cauca and Magdalena; and a third divides the valley of the Magdalena from the plains of the Meta. The chain attains its greatest elevation in Chili, where Aconcagua, the highest summit of the Andes, and the highest known volcano in the world, rises to 22,296, and the mountain-passes are seldom under 12,000 feet. In the Bolivian Andes, Illimani and Sorata are respectively 21,181 and 21,286 feet high. The Peruvian and equatorial portions of the chain are less elevated. Altogether, the Andes present a most magnificent spectacle—their lofty summits permanently snow-capped, and vast volumes of smoke and fire being occasionally poured forth from the numerous volcanoes which stud the entire range. The Brazilian Andes occupy a greater breadth of country, but seldom exceed an elevation of 6000 feet.
