**FLAME FLOWER.** This is the popular name of *Tropaeolum speciosum*, one of the most beautiful of hardy climbing plants. It has pretty light green leaves and in late summer bears a profusion of scarlet flowers. It flourishes best in the cool, moist, northern counties and is often difficult to establish in southern districts. The roots should be planted in March or April in well dug soil to which leaf-mould has been added freely, and the position must be a shady one. It is often planted on the north side of an evergreen tree or hedge.

**FLAN.** This is a fruit pie or tart made by lining a flan ring or mould with flan pastry, and filling this, after baking, with tinned or stewed fruit and covering the fruit with a thickened syrup. Flans are usually eaten cold.

**Flan Pastry.** To make this, take 6 oz. flour, 3 oz. butter, ½ oz. castor sugar, ½ teaspoonful baking powder, 1 yolk of egg, and a little cold water. Sieve the flour, add baking powder, sugar and a good pinch of salt, rub in the butter, add the yolk of egg and a little water to bind stiffly. Rollout the pastry about ¼ inch thick. Well grease the flan ring, lay a greased piece of paper, a little larger than the ring, on a baking sheet, and place the ring on it. Line within the ring with the

pastry, pressing it on well, particularly at the bottom, where the ring touches the baking sheet, so that there is a firm, sharp line between the bottom and sides of the flan. Trim off the pastry that stands above the ring, with a knife. Prick the bottom with a fork to allow air to escape. Cover the bottom of the pastry with crusts of bread so that it will keep straight while baking. Bake in a fairly hot oven 30 to 45 minutes or until a nice golden brown. Remove the crusts when done, and fill the flan case as required.

Almost any kind of tinned, bottled or stewed fruit can be used for flans. Apples should not be allowed to stew to a mash, but are better cut in very thin slices and arranged in the flan case in circles, the slices overlapping each other slightly. Other large fruits, such as peaches, pears and plums, may be cut in slices, but they are often used whole. Tinned pineapple slices give a prettier effect than the chunks, and cherries or other small fruits of a contrasting colour can be arranged in the holes in the centres of the slices. Slices of orange, cut crosswise through the sections, with the pith and pips removed, make a delicious flan. In this case use the juice from other tinned or stewed fruit to make the syrup. Small fruits, such as cherries, strawberries, raspberries, gooseberries, red or black currants, are always used whole.

To fill the flan case, drain the juice from the tinned or stewed fruit, and arrange the fruit in the flan case. Put the juice in a saucepan and bring to the boil. For each gill of the juice allow a teaspoonful of cornflour, blend this with a little water and add to the juice when boiling. Stir until boiling again and simmer for about eight minutes or until it thickens a little. Then add a teaspoonful of castor sugar to the gill, boil up again and let it simmer until thickened and reduced a little. Allow this syrup to cool, then pour it over the fruit in the flan case to just cover it, and leave it to get cold and set before serving. The top can be decorated just before sending to the table with little mounds of whipped cream.

**FLANK:** Of Bacon and Beef. The side of an animal from the ribs to the thigh is termed the flank. It is used mainly in connexion with beef or bacon. Thick flank of beef, though coarser in fibre than some other parts of the animal, is well flavoured and generally tender. It has no bone and little fat, is reasonable in price, and is therefore one of the most economical parts to buy for puddings, pies, etc. Thin flank is rather fat, but is low-priced and suitable for stews. It is excellent pickled and eaten cold. *See* Bacon; Beef.

**FLANNEL:** Its Treatment. Fabrics not made from all wool cannot legally be sold as flannel unless qualified by some other word. Ceylon flannel, for example, is an accepted name for a wool and cotton mixture, and Canton flannel for an all-cotton cloth. Various district flannels have a celebrity of their own. Welsh flannel, apparently the original one, is of a slightly different character from Yorkshire, Lancashire, and Irish flannel.

The difference lies largely in the sort of raw wool

used in the several localities, as some are softer than others, and hence warmer and more soothing when worn next the skin. White flannels which are used for underwear are sulphur-bleached like blankets. Natural flannels are of a greyish or brownish mixture colouring, and this shade originated by the inter-mixture of wool from brown and black sheep with white fleeces. A similar colouring is now often the outcome of mixing wool dyed for the purpose. Grey flannels are made in several shades by blending white, blue, and black wool.

Flannels are also woven with stripes and checks in light and dark colours for men's shirts, but not all wool shirtings are strictly entitled to the name flannel.

White flannels are made for cricket and tennis trousers in a heavier material than for shirts and underwear, and West of England flannels are especially to be recommended.

The fancy flannels sold by tailors for summer suits in striped and other patterns with threads in several colours are of no constant character, although generally light, soft, and warm. They vary considerably in their capacity to keep their shape when made into garments. Good tailors allow carefully for the shrinking propensities of the flannels they sell.

More or less all flannels shrink upon washing, and the disposition to shrink is greatest in those made of the softest and finest wool. In dealing with baby flannels it is well to dry them by hand before the fire, counteracting the shrinkage by gently pulling out the fabric in each direction as drying proceeds. Harsh flannels shrink less because of the nature of the wool from which they are made. There are chemical processes, requiring very careful control, by which woollens can be rendered unshrinkable, but these are not invariably efficacious or beneficial to the finished effect.

The heavy West of England flannels made for trouserings, and for blue blazer coats, are treated slowly and laboriously in course of making, and this, while adding appreciably to the cost, adds also to the satisfaction in wear. Cheap flannels can be quickly produced which are exceedingly difficult to distinguish at first sight from the superior qualities, and dissatisfaction with them accounts in part for the superseding of flannel by other fabrics.

The easiest method of making a flannel seam is to join the two edges of flannel with a running stitch a little more than  $\frac{1}{8}$  in. from the top of the material. The right sides of the two pieces must face inwards. Neaten the edges with sharp scissors, open and press the seam flat and turn down the edges of the flannel on to their own pieces of material. Then commence from the left side, and catch the extreme edges down to the materials by a herring-bone stitch. Flannel seams used in the making of babies' clothes, flannel blazers, etc., are finished with a binding of narrow silk ribbon pressed to give a neat, flat appearance. *See* Blanket; Bleaching; Laundry.

**FLANNELETTE.** An all-cotton cheap imitation of flannel, flannelette is made in a variety of qualities, and can be had white, dyed in plain colours, and with either woven or printed designs. Some are twilled, others plain. Countless burning accidents have occurred from leaving flannelette-clad children near an open fire, and the inflammability of the material is its greatest drawback. Almost any fabric will burn if kept in sustained contact with flame, and the objection to cheap flannelette is not that it can be burnt, but that flame leaps along its hairy surface, quickly enveloping the wearer. To guard against this risk, the first essential is a fireguard, and care in keeping matches out of the way of young people. The second is to buy a good quality of flannelette with not too much fluff on the surface.

**FLASHING: Brick and Stone.** This name is given to an impervious material which is turned up into the joints of brickwork, or into a groove or raglet, about 1 in. deep, cut in stonework. It is intended to prevent injury to the brickwork by rain splashing from the roof, and in addition to form a watertight connexion between the tiling or roof covering the adjacent brickwork. The best material for this work is sheet lead of a thickness known as 5 lb.

*Fig. 1. Flashing. Stepped side flashing with secret gutter.*

*Fig. 2. Simple cover flashing.*

The flashings shown in Fig. 1 are fitted by cutting a strip of the lead to a suitable length, with one side cut into a series of steps equal in depth to the distance between the brick courses. The upper edges are then bent over and inserted into the joints between the brickwork, for which purpose the mortar

has to be raked out, the metal secured with wedges, and the joint pointed in cement. The other part of the flashing is turned under the tiles or roofing material, and in good work is worked over a board with a V-shaped fillet or tilt, upon which the tiles are set. There is thus extra covering which assists in resisting the entry of water.

The above relates to a common form of stepped side flashing. Occasionally a flashing known as a cover flashing is employed in a similar manner, but rests

upon the top of the tiles (Fig. 2). Various arrangements of horizontal cover flashings are given in Fig. 3. The householder will do well to see that flashings against exposed brickwork are in sound condition. *See Gutter; Roof.*

*Fig. 3. Examples of horizontal cover flashings.*

**FLASHLIGHT: In Photography.** For photography at night, both indoors and outdoors, flashlight in the form of magnesium powder, or the mixture sold as flashlight powder, offers great possibilities. Magnesium ribbon burns too slowly; the easiest and safest form is magnesium powder, burnt by being thrown through a flame.

*Flashlight. Fig. 1. Flashlight for magnesium powder made of churchwarden clay pipe with cotton wool soaked in methylated spirit round bowl.*

*Fig. 2. Home made tray for powders.*

The apparatus consists of a narrow cup in which methylated spirit is burnt, and an inner cup in which the magnesium powder is placed. The spirit is lighted, and when the photograph is to be taken the rubber bulb is pressed firmly, blowing the powder through the flame and giving a brilliant flash. An easily contrived home-made alternative is shown in Fig. 1, consisting of a long-stemmed clay pipe, round the bowl of which is fastened a piece of wick or cotton wool with wire. This is soaked with methylated spirit. The bowl is filled with magnesium powder, the cotton wool lighted, and air blown sharply through the mouthpiece, by means of a piece of rubber tubing with a bulb.

*Be sure that only magnesium powder is used; if any of the flashlight mixtures are put into this type of lamp a dangerous explosion is likely to follow.*

Flashlight mixtures are perfectly safe when used correctly, but the amateur should not make them himself. Flashlight powders give a much more powerful light than magnesium powder. They should be burnt in an open tray of some kind. The simplest form is a flat lid of a biscuit tin; the end of a broomstick is sawn off at an angle and the tin lid affixed to it by means of a nail, as shown in Fig. 2. This gives a forward slope to the apparatus, so that the light of the flash is thrown well, to the front of the operator. A strip of touch-paper with the flash powder heaped on it provides ignition.

Fig 3. "Easilight" for flash powders. Fig. 4. Johnson's flash-lamp. Fig. 5. Smoke-trapping apparatus for flashlight. (Fig. 3, courtesy of Ensign, Ltd.; Fig. 4, courtesy of Jonathan Fallowfield).

Two satisfactory forms of flashlight lamp are shown in Figs. 3 and 4. In the first the powder is on a tray, elevated on a cane or long stick: it is fired by bringing a lighted taper into contact with it. The second is in the form of a pistol, the flash powder being lighted by a percussion cap. For ordinary purposes in a room with light-coloured walls to reflect the light, a heaped teaspoonful of flashlight powder will give good results with a subject not more than 10 ft. from the camera, and a lens of not less than f8 aperture and a fast plate. For larger rooms with lenses of f11 aperture or less, and ordinary films, a heaped tablespoonful should be used.

*In all flashlight work indoors the utmost care must be taken to see that the flame does not come anywhere near curtains or other inflammable material.*

One great disadvantage is the smoke. The only way of getting rid of the trouble is to use an apparatus in which the smoke is trapped. Fig. 5 shows a form which can be made at home. The framework is wire or

bamboo, covered with tracing cloth or muslin which has been treated with fireproofing solution. The flashlight is fired by means of a touch-paper, and afterwards taken out into the open air to allow the smoke to escape; it is then ready for a second exposure.

Flashlight. A Sashalite bulb being fitted to an adapter which screws into the unit.

**FLASH BULBS.** Flash bulbs are the most convenient means of obtaining small flashes. Fired electrically from a small pocket battery, they are clean, easy to operate, and free from noise or smoke. They can be used in wind or rain and in positions which would be dangerous with any other type of flashlight. "Sashalite" bulbs, for instance, are sealed glass bulbs containing finely beaten aluminium foil and oxygen at low pressure. The advantage of such a rapid flash (about 1/75 sec.) is obvious, and the soft light contains a high percentage of red and blue rays, helpful in colour photography. Photo flash-bulbs are easily synchronized: synchronization of camera shutter and flashlight makes it possible to use the camera in the hand, facilitates very rapid exposures, and allows flashlight to be used in conjunction with other lighting. Synchronizing powder flashes (e.g., the Barrett synchronized flash-pan or the Driggs-Faber flash-pistol) is more difficult. In these two kinds the flash trips the shutter; in others, the shutter fires the flash. Others work electrically, using a small electro-magnet.

**FLASH POINT.** The lowest temperature at which the vapour given off by oil when it is heated slowly will flash up if ignited is termed the flash point. It should be noted that this is not necessarily the point at which the oil will burn, which is known as the fire point. Flash point of mineral lubricating oils varies from 300 to 600 deg. F. For ordinary lubricating oil it is about 350 deg. See Lubrication; Oil.

## FLATS: SOME HINTS ON FURNISHING Making an Attractive Home for the Town Dweller

See the entries Bachelor Flat; Basement; also those on the various rooms, e.g. Bathroom; Bedroom; Dining Room; Kitchen. Consult too Carpet; Colour; Cooker;

Cupboard; Decoration; Electricity; Fireplace, etc.

In the future anyone who has to live in the central districts of a big city seems destined to dwell in a flat, as this type of residence appears to be on the rapid increase owing to the high cost of land and the consequent necessity for more people to live under the same roof. Special furniture, heating and cookery equipments are being designed for flats, with a view to increasing comfort and convenience and at the same time taking into consideration the necessity of space saving.

**Advantages and Disadvantages.** From the family point of view flats have certain advantages and disadvantages. The rent of a flat usually includes rates and taxes, and sometimes lighting, an arrangement which simplifies the estimating of expenditure. The initial outlay of starting housekeeping in a flat is considerably lower, as less furniture is required. The fact that all the rooms are on one floor minimises the labour of housework, compared with houses with one or more floors.

Where the family are out a great deal and no regular maid is kept, the porter can receive parcels and take charge of the flat, thus giving a greater sense of security. Flats are particularly convenient for those who have a house or cottage in the country where they spend week-ends or holidays. A flat has also a distinct advantage over a house in that the latter cannot be left for long periods without getting damp, while the former, having occupied rooms either above or below, or both, remains comparatively dry.

The disadvantages of flats render them less suitable residences for families where there are young children. The entire lack of garden with its playing space within sight and call is a serious drawback. Many men also dislike this absence of a garden, and the cooped-up feeling of a small flat is objectionable to them. They like their own front door and their own back garden where they can grow flowers and plants, and, if space permits, fruit trees and vegetables. The absence of a garden also renders home laundry work, important where there are small children, exceedingly difficult, even with a specially fitted drying and airing cupboard. Without this modern arrangement, to dry a quantity of children's garments and household linen in the kitchen of most flats is too inconvenient, apart from the difficulty of keeping the laundered articles a good colour when drying them under such conditions.

It is also sometimes troublesome to check the consumption of coal, when this is stored on the ground floor, as is usual in many blocks of flats where the porter is responsible for bringing up the required amount daily. The scuttles must be put out by a definite time, or they are not filled. The disposal of house refuse presents some difficulty, especially in hot weather, unless absolute cleanliness is the rule. In flats where a kitchener is fixed, all combustible refuse, including dust, can be burnt. Broken china and glass and old tins are practically all that need go into the dustbin. Where a gas-cooker is used, all refuse has to go into the

dustbin, and this must be emptied daily.

House dwellers have more freedom with regard to music, dancing, etc., than those who live in flats, where practically all sounds are heard by neighbouring residents. Eleven o'clock is the usual hour after which unnecessary noise must be avoided. Even the careless shutting of doors and heavy walking may annoy a neighbour who is a light sleeper. Pet animals and singing birds are frequently barred in agreements, and even window boxes may be taboo. In short, occupiers of flats must be prepared to sacrifice a little of their individuality and study the communal interest.

**Modern Furnishing.** Kitchens in flats are usually small. It is important that the equipment should be of the labour and space saving kind. The smaller the room the more necessary it is to keep it spotlessly clean, free of anything likely to collect dust, and to have a place for everything, rather after the manner of a well-designed caravan. Ideas for such arrangement and equipment will be found in the article on Kitchen.

The decoration and furnishing of larger flats presents no particular problem. It is in the case of small rooms where every inch of space has to be utilised without being overcrowded that ingenuity and good selection are required. When buying furniture it should be chosen for its practical value as well as for its decorative appearance. If it takes up too much space it will not look decorative.

A writing-desk is best selected that can give the maximum amount of drawer accommodation, and therefore the merely beautiful writing table with cabriole legs but little storage capacity for papers will be eschewed in favour of a practical bureau or desk. The book table, the divan, the wardrobe compactum, the sectional bookcase, the fitted corner cupboard and dresser and the drop-end table are all suitable pieces for flats. In very small dining rooms and dining recesses metal furniture looks well because it is suitable. A step-shaped wall bookcase, the top of one "step" at a convenient level for a reading-lamp, and that of the lowest for an occasional table, is another useful piece of furniture. Rounded corners, sunken handles and flush edges are all excellent points in space-saving pieces.

**The Illustrations Described.** Fig. 1 shows an interesting example of a sitting room in a small flat. Comfort is ensured by the big easy chairs, with their pleasing upholstery, while the plainer surfaces of floor and painted walls give an effect of space increased by the facts that there is neither frieze nor cornice and that the ceiling is in one colour with the walls. The window and fireplace treatments are particularly good. The architrave designed for the former successfully obviates a curtain fabric pelmet, while the fireplace treatment has effectively disguised the usual ugly small mantelpiece found in many flats of this size. Just indicated on the left of the photograph is a convenient recess fitted with shelves for books and glass.

The other illustrations are of an ordinary London flat which has been treated in a style specially designed to do away with superfluity and yet achieve decorative value by means of good, line and colour. The dining room end of the living-room is furnished with chairs having frames of metal tubing, red canvas being used for the backs and seats. The table and small sideboard are topped with heavy opaque glass and framed in metal. The window treatment at the other end of the room is particularly attractive, aluminium strips being substituted for pelmets, while the outer curtains are brown and the glass curtains of pale yellow voile. The walls, distempered in light buff, are left bare of pictures. The writing table is a beautifully designed but simple piece of furniture in natural oak.

*Flat. Fig. 1. Sitting room in a small flat, where comfort is allied with an effect of spaciousness (Humphrey & Vera Joel).*

Cupboards play an important part in flat comfort, and many practical suggestions will be found in the article on them. Wherever there is available space in hall, passage or bathroom it should be utilised for a cupboard in which to store linen, plate, glass and china. If the hall and passage are dark and narrow, light-coloured walls are essential to create an illusion of space; if there is an angle turn in the passage a lighting fitting placed there will illumine both hall and passage.

*Flat. Fig. 2. Dining recess in the living-room of a London flat. The frames of chairs and table are of chromium-plated metal-tubing.*

**Legal Points.** The law governing flats is, in the main, similar to that for ordinary dwelling houses, as for legal purposes a flat is a separate house. Dealing first

with unfurnished flats, the tenant who is about to take a flat must determine what his tenancy will be—yearly,

quarterly, or monthly. He can take a lease of a flat for a number of years or for a shorter period.

*Flat. Fig. 3. The window treatment in the living-room of a London flat, the dining recess being shown in fig. 2.*

The chief thing is to have a proper agreement in which are set forth the term of tenancy rent, stipulations as to repairs, etc. Careful study of the agreement before signing will prevent trouble later. Particularly should the tenant note his position in regard to repairs, the amount of rent, and period of notice required to terminate the tenancy on either side. A schedule of fixture should be provided by the landlord. Occupiers of flats usually pay an inclusive rent, the landlord paying all rates and taxes. Gas and electric light are usually not included in rent.

In the case of flats where a number of tenants use a common stair and entrance, the precise obligation of each tenant in the matter of cleaning and lighting should be clearly defined. Where there are only two or three flats in a building the tenants usually come to an arrangement as to their respective share in cleaning and lighting.

Particular attention must be paid by tenants of flats in the matter of nuisances. Mats should not be shaken from a window so as to cause annoyance to the tenant in the flat below. Any noise, also, that disturbs the rest of the tenants, above or below, beyond what is reasonable, constitutes a nuisance, as also are late singing or playing on a musical instrument. If carried to excess and continued to a late hour a tenant or tenants can get a court injunction to have it stopped. A professional singer would be entitled to practise in a flat, but not at a late hour. The occupier of a flat must not leave objects on a landing so as to annoy the other tenants, e.g. bicycles, prams. All these matters are usually dealt with in the tenancy agreement.

In the matter of sub-letting care should be taken to see whether the agreement requires that the consent of the landlord should first be obtained. A tenant within the Rent Acts who sub-lets all the premises loses the benefit of the Act, i.e. he can be turned out.

Furnished flats are preferred by many persons, and these are governed by much the same conditions as regards tenancy as unfurnished. The rent is higher, and they do not come under the Rent Act. The chief precaution here is to see that the owner or superior tenant furnishes a complete inventory of all furniture

*(Continued in page 843)*

## FLATS: COMPACT LIVING BROUGHT TO PERFECTION

Most of these photos are of a beautifully designed flat in a small block that has the air of a charming country house set in a London garden. Top: two schemes for sitting rooms. Left: windows to give maximum daylight. Right: artificial "niche" lighting.

Left: a glazed chintz patterned with lilies-of-the-valley is used generously in the bedroom. Walls and woodwork are a creamy peach; the carpet is sage green, matched by painted furniture.

Right: a corner of the dining room, folding table against the wall.

Left: a well-equipped kitchen all in white, relieved with red-and-white curtains and red composition floor. Below: gay and sober contrasting motives for a bedroom, assisted by strip-

lighting and various electrical devices.

and fixtures. Household and table linen are not as a rule included therein.

In a case where a tenant having a lease of a flat sublets it to another party he is still himself liable to the landlord for the proper upkeep and conduct of the premises. If the sub-tenant proves undesirable he must be given notice to quit, and, failing that, a court summons must be taken out. Most landlords will stipulate for no sub-letting, or they will want to be satisfied as to the desirability of the sub-tenant.

A house may not be structurally converted into flats without the permission of the local authority, though a man can let his house to two or three tenants if he wishes, provided no change is made in the structure, and call these sets of rooms flats. For rating purposes he must acquaint his local collector of his action. This conversion into flats is highly technical, and legal advice should be obtained.

**FLAT FOOT: Its Treatment.** This is a deformity in which the normal arch of the foot sinks and the sole tends to turn outwards, so that the person walks more on the inner border of the foot. Most frequently it is due to a gradual weakening and stretching of the ligaments and muscles which maintain the arch, from much standing. Acute cases are treated by putting the foot into plaster of Paris, thus ensuring rest for the overstretched structures.

From the outset in ordinary cases, the patient must be supplied with proper boots. These should be roomy enough, and the inner side of the boot should be raised  $\frac{1}{3}$  in. This is done by putting a leather wedge on the heel, the base of the wedge being on the inner side. The heel is also prolonged forwards on the inner side for  $\frac{3}{4}$  in. A similar wedge is put on the sole of the boot. The result is that the patient walks more on the outer side of the foot and the ligaments are saved from stretching. Even when his boots are off, the patient should be scrupulously careful that his weight is taken mainly on the outer side of the sole. The leg muscles should also be strengthened by tiptoe exercises, massage and electricity. A cold foot-bath at bedtime, followed by dipping the feet alternately in basins of hot and cold water, are helpful. *See Foot.*

**FLAT IRON.** In the ordinary household a flat iron is the most usual implement for ironing linen, etc., though in towns it has been largely replaced by the electric iron. Flat irons are sold by weight, and 4 lb. is a good medium size, though the professional laundress uses both heavier and lighter ones. *See Ironing; Laundry.*

**FLATTING.** In painting, a flat or lustreless surface is produced by the use of flattening paints. These are so prepared that they dry up with a dead surface like distemper, but with the lasting qualities of good oil paint, and when thoroughly dry and hard can be washed with soap and water. Such surfaces lend themselves to stencilled designs and similar ornamentation. Flat colours are obtainable from any oil

and colour shop. *See Paint.*

**FLATULENCE: Its Relief.** The accumulation of gas in the stomach or intestines is a very common and troublesome affection. In the stomach it may be due to dilation of that organ, the narrowing of the opening through which the digested food passes into the intestine, or to any other cause which allows fermentation to occur. People who eat in a hurry or do not chew their food properly, and those who allow bad teeth to remain unattended to, are frequent sufferers, and the affection is common in hysteria. Flatulence in the intestine is mostly due to fermentation of food caused by bacteria in cases of constipation.

For temporary relief any one of the following carminatives may be taken:  $\frac{1}{2}$  teaspoonful of tincture of ginger in a wineglassful of warm water; 2 or 3 drops of oil of cajuput on a piece of sugar;  $\frac{1}{2}$  to 1 teaspoonful of compound tincture of cardamoms in water; 10 to 20 grains of compound cinnamon powder.

For intestinal flatulence measures must be taken to prevent constipation (q.v.). In this form, which usually becomes troublesome two or three hours after a meal, intestinal antiseptics should be used. Useful drugs here are salol in five-grain cachets twice daily between meals. A pill which gives good results is made up thus, one being taken when the flatulence is troublesome and the dose being repeated next day if necessary:

Menthol	12 grains
Calomel	12 „
Powdered ginger	16 „
Glucose to make	8 pills

*See Diet; Indigestion.*

**FLAVOURING: In Cookery.** One of the most important processes in preparing a successful dish is the flavouring, which is generally added last. No hard-and-fast rule can be laid down as to quantities: the safest way is to use all flavourings sparingly, and for the cook to taste as she adds.

Where sweet dishes are concerned, the most common flavourings are vanilla, almond, and lemon. Vanilla can be procured either as an essence, of which one or two drops only are required, or in the form of a pod. The latter is boiled with the milk or other substance, and removed when the preparation is cooked. Almond essence is used in the same way as vanilla. These essences are added as the preparation is removed from the stove.

Almond flavouring is given to a custard or similar mixture by dropping a laurel leaf into the milk and bringing it to the boil. The leaf should then be taken out. Lemon rind boiled up in the milk to be used for a custard or milk pudding, etc., will give a delicate lemon flavouring; but care must be taken to pare the lemon rind very thinly, so that none of the white pith adheres, or a bitter flavour will result. A bay leaf gives a much-liked flavour to savoury dishes, minced meat, etc., and

is also used for pickled herrings.

For soups and other savoury dishes a favourite flavouring is a bouquet garni. This consists of sprigs of parsley, mint, thyme, blade of mace and a bay leaf, which are tied in muslin and put into the dish, being taken out before the dish is served. Other flavourings that are much used are nutmeg, ginger, cinnamon, allspice, mixed spice, and cloves. Celery seeds, parsley, chervil, and tarragon are used as flavourings for soups and sauces, and a few drops of essence of anchovies, tomato ketchup, and mushroom ketchup are also much favoured in savoury dishes. To give a delicate onion flavour to a salad, rub the inside of the bowl with piece of onion or garlic. *See* Almond; Clove; Essence; Onion; Spice, etc.

**FLAX.** There are some lovely garden flowers among the flaxes, suitable for the flower garden and rockery. They flourish best in well drained or rather light soil. The best two for the average garden are *Linum perenne* and *Linum narbonense*, which grow about 18 in. high and bear blue flowers in summer. *Linum flavum* and *Linum arboreum*, 10 to 12 in. high, with yellow flowers in summer, thrive best in the rock garden. *Linum grandiflorum rubrum* is a hardy annual with bright red flowers; from seeds sown out of doors in March-April, it blooms in July. The perennial kinds are easily propagated from seeds sown out of doors in April.

*Flax. The yellow flax (Linum flavum), a charming rock garden flower*

**FLEA.** The flea is a carrier of plague from rats to human beings. To get rid of fleas, dust the sheets with insect powder or sprinkle them with essence of peppermint. The underclothing should also be sprinkled with peppermint essence or a few drops of chloroform here and there. Dogs and cats should be washed every week or two and dusted with an insect powder. For the irritation of a flea-bite apply a dilute solution of carbolic acid or of ammonia. *See* Insecticide.

**Fleabane.** *See* Erigeron.

**FLEA BEETLE.** This insect, also known as the turnip flea, is a minute beetle, of which there are many allied specimens. They vary in length from  $\frac{1}{8}$  to  $\frac{1}{12}$  in.; the thigh joints of the hindermost legs are strongly

developed, which gives them power of leaping like fleas. The most familiar and most destructive of these has a longitudinal stripe of yellow on each wing-case. The mature beetles pass the winter in hiding under any rubbish left on the ground, and in spring when the seedlings of turnips appear they swarm on the young leaves, nibbling small holes in them until they become useless to the plant, which weakens or dies. The female beetles also deposit white eggs in batches on the lower surface of the leaves, which hatch about ten days later. The young grubs of the flea beetle bury themselves in the tissues of the leaves upon which they feed.

*Flea Beetle. Left, mature specimen of the turnip pest. Right, larval form.*

The pest should be dealt with first by clearing the seed ground of all debris which will shelter the beetles in winter. If, however, the seedlings are already attacked, they should be sprayed with a solution of soft-soap, quassia, and paraffin in water. To give the seedlings a chance of surviving the attack, the seeds should have been sown thinly, a course producing more sturdy plants. A scattering of nitrate of soda, 1 oz. per yard run of row, is helpful because it encourages the seedlings to grow quickly. Many of the beetles may be captured and destroyed by sweeping the seedlings with a butterfly net. Applications of lime and of soot are beneficial. *See* Insecticide.

**FLEECE.** Fleece is the coat of wool shorn from a sheep, but the word is also used to describe any soft, woolly material of a fleecy nature. The kind generally employed in dressmaking consists of a thin, machine-knitted woollen web, made specially with a view to being wire-brushed and having a fuzz of fibre teased to the surface. It is used for lining gloves, house slippers, and children's winter coats. The lining should fit the article exactly, and should be put in while the garment is in the making, not after it is finished. *See* Wool.

**FLEX:** In Electric Fittings.

This word is an abbreviation for a flexible insulated wire, generally used to connect movable electric fittings to a convenient point of supply of current. The

ordinary flex, as found in domestic use, is of three types. The common bell flex consists of two separate stranded wires, each composed of a number of very fine wires, and each separately insulated from the other; they are usually braided on the outside and then twisted together. Bell flex should not on any account be used for electric lighting appliances.

Lighting flex is similar, but comprises more fine strands, each of them larger in diameter than those in the bell flex, and the insulation is more robust. The heaviest form of flex wire is that known as workshop flex, and is again more substantial than ordinary lighting flex. It is usually braided on the outside over both of the wires, or may have an outer covering of a rubber compound. Such flex should be used for electric heaters, small motors, the vacuum cleaner, etc.

*Flex. Construction of flexible wire ends: above for push-in terminals; below, for terminal nuts.*

Flex should never be used if it is in a damaged condition, since, if the insulation is worn or cut, there is great likelihood of its breaking down and causing a short circuit. If the covering of the wire shows signs of wear or damage (e.g. where it enters a plug or lamp), new connexions should be made, the wire being cut back till a sound portion is reached. If the rubber insulation has perished a new length of flex should be substituted. The connexion of flex wires to electric light fittings should be done with great care. The insulating material must be removed to leave exposed the two separate bundles of stranded wires. These should be wiped with a piece of emery paper, and each bundle twisted together. The ends are turned over at right angles and doubled back upon themselves. The wires can then be inserted in their place in the fittings, and secured with a set screw in the usual way.

Where the flex is to be attached to a binding screw or terminal contact post, and secured by means of a nut, the wires are twisted round into the form of an eye. In either case it is essential to prevent any single strand of wire becoming separated from the rest, as this might cause a short circuit.

**FLOAT: In Plastering.** This tool is used by plasterers to lay on plaster and to bring it to a smooth or fine surface. It can be made from ordinary deal or other wood, but must be perfectly smooth in the face and very slightly rounded on the edges. The back should have a conveniently shaped handle set lengthways, as Figs. 1 and 2. See Plastering.

Fig 2

Fig 3

*Float. Diagrams showing dimensions and details of three types of plasterer's floats. Fig. 1. Hand float. Fig. 2. Derby float. Fig. 3. Angle float.*

**FLOCK.** The material known as flock is manufactured from the refuse of wool or cotton, or from old cloth or rags that have been broken up by a machine called the devil. Wool flock is used for cheaper upholstery and mattress stuffings, but its drawbacks are its liability to attacks of moth, and its tendency to harden into lumps.

Cotton flock, although neither so light, nor springy as wool flock, is said to be free from the danger of

moth, and is extensively used for upholstery in spite of its tendency to become seedy or lumpy after constant use. The least popular flock is that made from rags, but its employment need not now be feared, since under the Rag Flock Act (1911), the sale or manufacture of unclean flock is prohibited, and rag-flock must be sterilised and purified to a standard of cleanliness laid down by the various local authorities. *See* Bedding; Mattress; Upholstery.

**FLOCK PAPER.** This name is given to a variety of wallpaper covered with flock, or fine powder obtained from cloth and similar material. The use of flock paper for special decorative panels or miniature carpets in a doll's house, or to represent a lawn or grass on a model of a house, is effective. *See* Wallpaper.

## FLOORS AND FLOOR COVERINGS

### Methods of Construction and Repair

Various constructional and other articles in this work deal with the subject of floors and flooring, e.g. Architecture; Board; Bungalow; Cottage; House; Joint; Wood. *See* also Amateur Carpentry; Carpet; Damp Course; Linoleum; Rubber, etc.

The importance of a good sound floor to any dwelling cannot be over-estimated. Health and comfort alike demand a floor that is even and level, free from draughts and immune from damp.

The simplest floor is laid directly upon the earth, and many old country cottages still have floors of rammed earth, generally covered with bricks, stone slabs, or flooring tiles. Picturesque as they may be, such floors are always cold, prone to dampness, and generally very uneven. The best treatment is to remove the old tiles or bricks, excavate the earth for a depth of about 6 in., lay a good sound bed of concrete floated off level, and re-lay the bricks upon this foundation, after having treated the surface to a generous application of hot tar or asphalt. The bricks or tiles will be set in mortar and well grouted. Those badly worn can be laid upside down if the under side is in good condition. This saves buying new bricks.

Most dwelling-houses are floored with timber, consisting of flooring boards averaging 1 in. in thickness and 5 to 6 in. in width. These may have plain edges or be tongued and grooved, the latter being more rigid and draught-proof. Any wooden floor laid near the ground must be well insulated from dampness and thoroughly well ventilated. This is accomplished by first covering the whole site with a bed of concrete at least 4 in., and preferably 6 in., thick. The appearance of such a bed ready prepared is illustrated in Fig. 1.

Two courses are now open; one is to insulate dampness by treating the surface of the concrete with a thick coating of tar or mastic, and to lay the flooring direct upon it, having previously coated the under side of the floor-boards with some wood preservative. This method has disadvantages, including the absence of ventilation, and it results in a hard and unyielding surface. If the site is sloping, much making up is

necessary. A damp course is needed, and adds to the expense.

*Floor. Fig. 1. Concrete floor-covering before laying joists and floorboards.*

**Wood Floors.** Taking everything into consideration, a wood floor is best if laid on joists in the usual way. Particular attention is directed to the following points: the sleeper walls which support the plates upon which the floor-joists themselves are supported, the presence of air-bricks beneath the floorboards, and the double course of damp-course slates. Figs. 2, 3, and 7 show the relative arrangement of the parts.

*Fig. 2. Sleeper walls, showing damp course slates, upon which floor plate and joists are laid.*

*Fig. 3. Floor joists and sleeper walls for a ground floor.*

In such constructions, when the joists span the opening between the sleeper walls, they are known as bridging joists and the floor as a single floor; it is the simplest and the strongest construction. The joists are

usually spaced from 12 to 15 in. apart, their size depending upon the length to be spanned without support. Sizes of timber usually adopted are 4 in. by 2 in. for the ground-floor joists of small houses with rooms about 12 ft. wide, provided they are supported at intervals of 4 ft. or so by a sleeper plate and a honeycomb wall or supporting piers of brickwork, topped with damp-course slates, somewhat as in Fig. 3.

Fig. 4. Joists built into brickwork.

Fig. 5. Trimmers and trimming joist, showing tusk-tendon joint.

Fig. 6. Flooring and joist around a staircase well or opening.

The upper floors are constructed in a similar manner. A wall plate of timber is set into the brickwork, and upon this are set the flooring joists, which have to be of such strength that they can safely carry the load. Usual dimensions are 4 in. deep by 2 in. thick for an opening 5 ft. wide, but when the opening or span is, say, 10 ft. wide the joists should be 6 in. deep by 2½ in. wide. A 12 ft. opening requires a joist 7 in. by 3 in. or 9 in. by 2 in. In the latter case light diagonal struts are used in order to prevent the joists twisting sideways.

First-floor joists should be spaced 14 in. apart, centre to centre, and when the joists are more than 8 ft. long they should be stiffened by herringbone strutting, made from 1½ in. square deal nailed between the inner faces of the joists. The under sides of the floor joists are lathed and plastered or covered with beaver or other building board.

The upper surface of the joists is floored by laying the first plank against the wall and nailing it to the

joists: a second plank is then fitted up to the first and securely cramped with flooring cramps (*see Dog*), and nailed to the joists, continuing until the floor is covered.

If the nails are driven through the flooring into the joists, use the regular flooring brads, 2 in. or 2¼ in. long, and punch each one well down below the surface. This must be done when T. and G. (tongued and grooved) floorboards are used, but plain edge (P.E.) boards, especially when narrow, should be nailed through the edge, driving a nail at an angle of about 45°, as indicated in Fig. 9. This results in a smooth floor without any visible nail heads. The floor is finished by means of a plane.

Floor. Fig. 7. Diagram of principal parts of a ground floor.

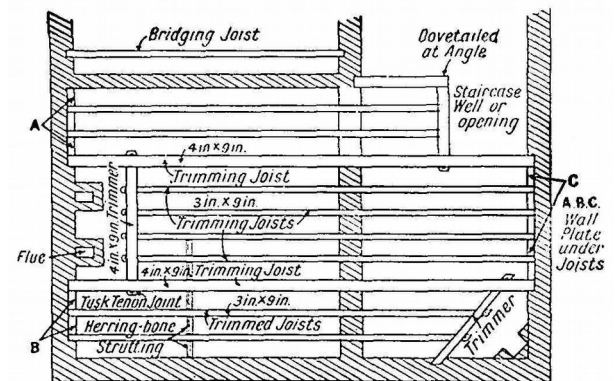

Fig. 8. Diagram of first floor, giving the names of the timber parts.

Fig. 9. Diagram illustrating the various methods of jointing ends of floor boards, and of nailing them to the joists.

**Trimmer Joists.** When the floor is not solid, but has an opening for a staircase, or has to be built around a fireplace or hearth, a somewhat different treatment of the joists becomes necessary. As the model by-laws prohibit the fixing of any woodwork nearer than 9 in. to any flue, it is necessary to provide a trimmer, or bridging piece, into which the ends of the joists are fitted and secured by a joint known as a tusk-tenon. Such trimmers are set securely upon wall plates, or firmly built into the brickwork, and should be at least  $\frac{1}{2}$  in. thicker, and of equal or greater depth, than the joists they support. Fig. 5 shows a trimming joist with trimmers tusk-tenoned.

The floorboards should not be terminated directly against a hearth or staircase opening, but should rest against a narrower board neatly mitred at the corners, and fitting around the opening. In some cases a trimmer is itself tusk-tenoned between two joists, which should be thicker than normal to carry the extra load imposed by the trimmer. A diagonal fireplace set in the corner of a room may have a trimmer tenoned into one joist and supported at the other end on the brickwork. Fig. 8 shows various customary arrangements of trimmers and joists and the names given.

Floorboards should be laid in long lengths, spanning the full width of the room, but whenever a joint has to be made it should invariably come over a joist, as shown in Fig. 9. The woods chiefly used for house floors are oak, teak, pitch pine and deal. It is usual to lay the boards in narrow widths, say, 4 in. to 5 in., instead of the 6, 7, or 8 in. boards of earlier days, and the finish is generally good enough to permit of polishing.

Wood block floors are employed in better-class houses, particularly for passages, etc. They are sometimes used in kitchens. They need a concrete foundation, and there must be some kind of bituminous sheeting interposed between foundation and blocks. Usually the under sides of the blocks are dipped in a bituminous mixture before being placed on the concrete. The wood blocks can be had in from  $1\frac{1}{2}$  to  $2\frac{1}{2}$  in. thickness. Parquet floors (q.v.) are laid with wooden blocks, usually  $\frac{1}{4}$  in. thick, some 9 in. long and 3 in. wide.

**Composition Flooring.** For kitchen, scullery, bathroom and other rooms of these kinds, it is possible to employ a jointless composition flooring by using a plastic material which sets in 24 to 48 hours. Various colours are available, and simple designs can be worked into the material. Stone and concrete floors are used in kitchens, larders, yards, and verandas. For ordinary paving purposes natural York stone is one of the best. There are also various artificial stones made with granite chippings and Portland cement, or clinker and cement. Outhouses and sculleries are generally laid with concrete or cement.

**Floor Repairs.** The repair of existing floors is a frequent problem. Cement floors do not present much difficulty. The bad places should be further broken away and deepened, all dust and dirt washed away, and

the deficiency made good with strong cement mortar. If the whole surface has worn badly it will be better to hack it all over with a chisel and hammer. Then brush the surface clean, wet it thoroughly and recoat to a thickness of at least  $\frac{1}{2}$  in. with strong cement mortar (gauged cement 1, and sharp sand 2). A hard surface, free from dust, is obtained by using cement and fine washed granite chips, adding some reliable water-proofing composition.

To repair wood flooring cut out the bad boards and replace by new, making all joints in the length of the timber over a joist or other firm support. To cut out a tongued and grooved board without damage to the remaining boards, saw through the tongues, using a keyhole or pad saw with as fine a blade as possible. The board can be sawn across by prizing it up at one end, slipping a piece of batten underneath, and cutting across the board with a tenon saw.

**Decorative Floorings.** The simplest method of decoration for a wood floor is by staining it. This may be done with one of the branded floor stains or an excellent stain can be homemade with vandyke crystals, which can be purchased cheaply from a chemist. These are melted in hot water; the amount of dilution depends on the colour required for the floor. Having thoroughly cleansed this with a strong soda washing and allowed it to dry, the stain is painted on with a good brush. The polish is not obtained until the floor has had several subsequent rubbings with a wax polish.

Bright colourings of considerable durability are obtained by the use of the floor paints sold for this purpose by most oil and colour merchants. Such paints are chiefly suitable for bedrooms. Tiles are a decorative flooring for certain types of halls, for bathrooms, kitchens and sculleries, but as they are expensive, substitutes are used, one of the most successful being tile designs in rubber flooring. Such floorings are durable, easily laid, comparatively low priced and hygienic. They also lessen noise, which is a boon in many homes. Obtainable in different qualities, these floorings are also designed in marbled and plain effects.

Besides parquet floorings, dealt with under that heading, linoleum in its various qualities, makes and designs provides useful floor covering and surrounds for carpets.

**Cleaning Floors.** A painted, waxed, or varnished floor should be wiped free of dust and dirt with a soft rag, and then treated to an application of crude oil and benzine, one part of oil being used to three parts of benzine. This is a good cleaning mixture which obviates the use of water, but only a small quantity should be used at a time. It should not be allowed to remain on long and should be wiped off with a woollen rag. If the floor has a waxed surface, any good wax paste can be

applied, and the polishing done with a rag, brush, or polishing mop.

Grease spilt on unfinished wood such as a kitchen or pantry floor is best treated with cold water. The latter should be poured on at once, so as to harden the grease and prevent it from spreading. The grease may then be scraped off with a knife, and the affected part scrubbed with warm water and washing soda. If the spot appears dark after this treatment, spread over it a paste made from fuller's earth and water, leaving it overnight.

All floors should be well swept in the morning, and if of the polished type, rubbed with a soft duster or mop. For scrubbing purposes, a bucket of hot water, a floor-cloth, a scrubbing-brush, a mat for kneeling, and some good household or soft soap are essential. Commence in that portion of the room farthest away from the door, and with the cloth wet the surrounding boards. Dip the scrubbing-brush into the water, rub some soap on the bristles, and scrub the wet patch vigorously, working the brush the same way as the grain of the wood. Then wring the cloth out of the water and wipe the floor as dry as possible.

**Floor Polish.** Beeswax (q.v.) usually forms the main ingredient of floor polishes, but a cheap and effective substitute is to be found in tallow candle ends. To make a polish of these, melt down  $\frac{1}{2}$  dozen or more ends, according to size, and mix the tallow with 1 pint each of paraffin oil and turpentine.

**Florence Cream.** This is a name given to a salad dressing of the mayonnaise type. *See* Mayonnaise.

**FLOSS SILK.** Used in needlework, floss silk consists of silk fibres so lightly twisted together that the thread spreads out and gives a glossy appearance. The stitches must be short, for the silk frays easily. A 2-ply or 3-ply floss is the best, and embroidery floss should be asked for by name, as there are many varieties of twist. Boiling colours are to be preferred. *See* Embroidery; Silk.

**FLOUNDER.** One of the commonest of the flat fish found in English waters is the flounder. Its flesh is nutritious, and is easily digested. It should be well washed and rubbed over with salt an hour before it is to be cooked. Dry the fish well and dip it into beaten egg and then into breadcrumbs before frying it in hot fat. Serve it garnished with some fried parsley.

To boil a flounder put it in a fish-kettle with just sufficient water to cover. Add salt and a little vinegar to taste, then bring it to the boil and simmer gently for about ten minutes. It should be served with anchovy or parsley sauce. Flounders can also be grilled. *See* Grilling.

**FLOUR.** Fine soft powder prepared from grain, e.g. cornflour, rice flour, maize flour, wheat flour, etc. If flour is mentioned without any indication as to source, wheat flour is implied.

Flour is described as soft or hard. Soft flour is made

from wheat that has a low percentage of gluten, and that of an inelastic kind. A hard or strong flour has a high proportion of gluten, and that of a tough kind, which becomes elastic under certain influences when made into dough.

For short bread, piecrusts, biscuits, or scones, only the soft flour should be used, because, in these goods the shortening agent is butter or fat, and the aerating agent baking powder, and neither fat nor baking powder has the property of softening gluten and making it elastic. If hard flour is used it should be sifted first. If bread, or something fermented by yeast, is to be made, then only hard or strong flour may be used. The yeast possesses the property of making tough gluten very elastic, and as the yeast produces gas from the sugar of the flour, so the elastic gluten retains it, and bread of large volume is thus made possible.

The colour of flour is in some respects dependent on the wheat used, on the method of milling, or on the grade. White wheats make white flour, and red wheats produce a yellowish tinge. If the flour has been made in a stone-grinding mill—a method very nearly extinct now—it will be darker than if made in a roller mill and, as a rule, will not keep so long sound.

For some years there has been a growing practice of bleaching flour, generally with nitrous oxide gases, but also with chlorine. This takes away the yellowish colour, but the quantity used is so minute, and there is so little left in the flour, that no deleterious effects can be discovered in the baked articles. Certain other substances, called persalts, are also used to effect a slight bleaching action, while calcium and other phosphates are sometimes added to make soft flour somewhat stronger.

**Flour Hutch.** Regarded now as an antique piece of furniture, this was originally used to hold flour and bread. The hutch is a form of cupboard standing on four legs and strengthened by stretchers. The lid is on the top, and inside are usually two divisions, one for bread and the other for flour. Most of the existing pieces are of oak. With a little ingenuity a hutch can be converted into a modern piece of furniture; for instance, a dresser. In this case a back is necessary, the hutch itself serving for the cupboard.

**Flour Sifter.** This term usually implies either a flour dredger, used for small quantities, or a wire sieve for larger amounts. The object is to aerate and thus lighten the flour, and to remove lumps or any foreign matter. An ordinary sifter requires shaking before the flour will pass through, but mechanical ones are obtainable inside which, by turning a handle, wire rings are made to revolve, thus forcing out the flour. *See* Baking; Bread.

**FLOWER BASKET.** Hanging flower baskets as shown in Fig. 1 are intended to hold a potted plant, and are very useful in the garden, conservatory, or hall. They are easy to make, and provide a means of putting

any waste strips of wood to a useful purpose. If deal is used, it would be best to finish with paint, leaf green being suitable. Any hardwoods could be left plain, or stained and polished with linseed oil.

Fig. 1

*Flower Basket.*  
Figs. 1-6. Hanging basket for a pot plant and method of making it from waste strips of wood.

Fig. 2

Fig. 3

Fig. 5

Fig. 4

Fig. 6

Fig. 2 shows an elevation, and Fig. 3 a plan of a basket of useful size, in the making of which 20 strips similar to Fig. 4 and four strips similar to Fig. 5 will be required. The strips are intended to be  $\frac{3}{4}$  in. square, but sizes may be altered as required. The baskets are wired together, holes being bored through the long strips for the purpose. Two wires are used, one at each side, and each runs through the bottom strip and up through the corners, as shown by the dotted lines in fig. 2.

Galvanized or copper wire is most suitable, each piece being some 6 ft. long. In building up, thread the wire through two strips, and across these thread two other strips, as shown in Fig. 6. The bottom is formed by nailing the short strips over the bottom strips, and the basket is completed by threading the

remaining strips over the wires. Care must be taken to have the ends of the wire which project above of equal length; they are twisted over a stout ring, which is used for hanging (Fig. 1). See Basket Plants.

**FLOWER BED.** Flower beds, preferably of simple design, are made on the lawn and in other parts of the garden and filled with massed flowering plants for the purpose of ensuring a brilliant show of spring and summer bloom. They are planted in October with bulbs and spring flowering plants and late in May or early in June with others which will bloom throughout summer and autumn. See Bedding Out.

**FLOWER GARDEN.** The chief features of a modern flower garden are the herbaceous border, formal flower beds, rock garden, shrubbery planted chiefly with flowering shrubs, lawn, and water lily pool, with perhaps an adjacent bog garden. The little formal garden, its beds and borders intersected by paved paths, is fashionable and is generally represented even in plots of restricted size.

The principal needs of most hardy flowering plants are a sunny position and deeply dug and manured soil, and if those are provided there is every likelihood of a successful issue. The herbaceous border of hardy perennial plants is perhaps the most important feature of all, for, if planted with a representative selection, it will remain gay throughout the summer and autumn months.

Any kind of land can be made suitable for a flower garden by correct cultivation. Clayey ground is improved by autumn and winter digging and by adding such materials as lime, finely sifted coal ashes, old potting soil, sand, grit from garden paths, leaf-mould, decayed garden rubbish and wood ashes from the bonfire. Light land is improved by digging in leaf-mould, decayed garden rubbish, pieces of turf, hop manure, and stable or farmyard manure. It is better to apply the manure in spring and to fork it in lightly than to dig it in during the autumn or winter.

Planting may be done in autumn or spring or in mild weather in winter. Some of the chief hardy herbaceous perennials are lupin, delphinium, phlox, Michaelmas daisy, erigeron or summer starwort, geum, peony, pyrethrum, bellflower, columbine, sea holly or eryngium, globe thistle or echinops, evening primrose, purple sage, mauve catmint, shasta daisy, coneflower or rudbeckia, and perennial sunflower. The spaces between the perennial or permanent plants are filled with gladiolus, lily, montbretia, and dahlia, and with hardy annuals, of which seeds are sown in spring. Sweet william and Canterbury bell may also be planted in autumn to bloom the following summer.

Formal flower beds on the lawn or elsewhere should be of simple design; those of elaborate shape cause a good deal of labour and they are not so pleasing as circular, rectangular or oval beds. It is usual to fill them with spring bulbs, wallflowers, polyanthus,

forget-me-not and other early flowers by planting in October. In late May or early June these are taken up and are replaced by summer flowering plants, e.g. zonal geranium, marguerite, lobelia, tuberous begonia, snapdragon, dahlia, etc.

The rock garden must be in a sunny place, and the site must be well drained; if these conditions are provided, and if leaf-mould, sand, grit and stone chips are added freely to the mound of soil, most of the rock garden plants will flourish.

There are so many beautiful flowering shrubs which are hardy in Great Britain that there is no longer any excuse for a shrubbery planted with uninteresting evergreens. By making a suitable selection one or another of them will be in bloom throughout the spring and summer months. Some of the chief kinds are early spring heath (*Erica carnea*), *Forsythia spectabilis* or golden bell, broom, *Pyrus floribunda* (flowering crab), Japanese cherries, rhododendron, azalea, laburnum, mock orange, lilac, guelder rose, bush honeysuckle or weigela, hydrangea, ceanothus and witch hazel or hamamelis.

#### How to Make a Water Lily Pool

A water lily pool can be made a delightful feature even of a small garden. It must be in a sunny place, for water lilies will not bloom well in the shade. Some of the small water lilies will flourish in water 18 inches or so deep, so an elaborate excavation is not necessary. By lining the sides and bottom with stones and covering these with cement, it is not difficult to make a watertight pool. The water-lily plants should be put in mounds of soil at the bottom of the pool in early May; the use of a few large stones will keep the plants at the bottom of the water. The moist soil at the margin of the pool provides an ideal home for bog plants such as monkey musk, *Iris sibirica*, Japanese primrose, and many more.

A delightful formal garden can be made by filling the beds with some of the old-fashioned flowers such as columbine, poppies, peony, mauve catmint, lavender, rosemary, pansies, snapdragons, and so on, and paving the paths with stone or brick. A sundial or bird bath might well mark the centre of the garden. If flower beds are made on the lawn they should be few in number and near the edge.

Arches covered with climbing and rambling roses and clematis add to the beauty of the flower garden, and a trellis so placed as to provide a background to a garden seat or ornament could be covered with climbing plants. *See* Arch; Border; Carnation; Clematis; Climbing Plants; Daffodil; Dahlia; Digging; Garden; Herbaceous Border; Hydrangea; Lily; Pansy; Rose, etc.

**FLOWERING CURRANT.** This is the popular name of ribes, a genus which includes the gooseberry and red, white, and black currants and some useful hardy flowering shrubs. *Ribes sanguineum*, the common flowering currant, will thrive in shady places; it bears reddish flowers in spring. *See* Ribes.

**FLOWERING RUSH.** The common name of

*Butomus umbellatus*, a British wild plant suitable for planting by the waterside in gardens. It grows 2 to 3 feet high, with rose-coloured flowers in summer. *See* Rush.

**FLOWERING TREES.** These are well suited to planting in small gardens, and might be used with advantage to screen unsightly surroundings. They provide shelter without casting too much shade. Autumn is the best time to plant, though the trees may be put in the ground in spring and in mild weather in winter. Some of the most ornamental are the flowering crabs (*Pyrus spectabilis*, *floribunda*, *Eleyi*, and others), thorn, laburnum, *Magnolia conspicua*, the purple-leaved plum (*Prunus pissardi*), Japanese cherries, and lilac.

**FLOWER POT.** Flower pots of burnt clay are too familiar to need description, but as nurserymen usually refer to them by name or number, their sizes in inches, taken from the diameter at the top of pots, are given to prevent confusion. Thimbles, 2 in.; thumbs, 2½ in.; small sixties, 3 in.; large sixties 3½ in.; fifty-fours, 4 in.; forty-eights, 5 in.; forties, sometimes called small thirty-twos, 5½ in., large thirty-twos, 6 in.; twenty-fours, 8 in.; sixteens, 9 in.; twelves, 10 in. The sizes may possibly vary slightly according to different makes. *See* Potting.

## FLOWERS AND THEIR ARRANGEMENT

### How to Make the Most of Floral Decoration

The reader is referred to the entries on the various flowers mentioned in the article, e.g. Carnation; Rose; Tulip; as well as to Bouquet; Bulb; Colour; Table; Vase, etc.

Unless a pantry and sink are available when arranging flowers, it is best to place a tray with vases and bowls on a table, the bunches of flowers on a newspaper, with another one spread at hand for rubbish; a big jug of water, scissors and a knife complete the preparations. To obviate the use of newspapers and afford complete protection to a sitting-room table, the American cloth tidy illustrated is a useful accessory to flower arrangement, and one which is quickly made. It requires a yard of brightly coloured American cloth, a cotton galon to tone, a pair of scissors attached to the latter, and a motif of floral cretonne applied to a corner of the tidy by means of buttonhole stitch. (*See* Appliqué.)

If not arranging the flowers in a flat bowl the lower leaves should be removed, as they choke up a vase. All woody stemmed flowers, such as lilac, roses, chrysanthemums, will last better if the stalks are peeled at the ends so that they are free to absorb water.

Should flowers not seem very fresh they may be revived by being placed in quite warm water. The water should be changed at least every second day, and

Suggestions for the arrangement of bowls on dinner or luncheon table.

**FLOWERS IN THE HOME: SUGGESTIONS FOR THE ARRANGEMENT OF MANY BEAUTIFUL VARIETIES.** See text. (By courtesy of Webb & Corbett)

when flowers suddenly become limp the stalks should be cut again. If cut flowers have to be bought, it is worth remembering that they last much longer when they are just coming into their natural growing season than when they are forced or when the species are practically over for the year. Flowers also last longer in well aired rooms than in stuffy ones.

*Flower Tidy made from a yard of brightly coloured American cloth, a motif of floral cretonne being applied to a corner, as shown below. The scissors are attached to the cotton galon edging.*

**Japanese Ideas.** Japanese influence has affected the arrangement of flowers. It is no longer thought sufficient just to stick a bunch into a vase, but rather to make each arrangement a piece of decoration, taking into consideration the relative characters of the flowers, their supports and containers, the colour of the walls, etc., and the shape required to make a pleasing effect. Thus an arrangement of peonies in a bowl, as shown in page 854 Fig. 1, would be suitable for a table or a bookcase below the eye level and where the view from above would take in the rather bushy nature and the flat setting. The pink peonies are held in position by a glass flower block and are placed in a grey blue bowl, the effect being further enhanced by an ebony stand. Bowl arrangements look particularly well on such stands, and plainer ones are available in lacquered wood of various colours. They are not only decorative but protect the table from water marks. Glass squares, ovals or rounds also serve the latter purpose and are suitable for tall vases.

Varieties of holders and blocks are sold which enable flowers to be placed so as to form a good design, the line of the water in the vase or bowl being taken as the soil, and the stems supported to suggest natural growth.

Most bulb flowers can be treated in this way, and look their best in flat bowls, rising from a bed of moss. Under the moss can be concealed a support, made of strips of lead, each about 2 ft. long, 1 in. wide, and 1/12 in. thick, which can be obtained at any iron-mongers. These strips are bent round the bottom of the stems, the lead being twisted backward and forward between the flowers to keep the balance.

While daffodils and tulips are happy in shallow water, flowers with short woody or fibrous stems are better when placed in bowls if supported by deep glass blocks. The beautiful arrangement of pink and yellow roses in a black Wedgwood bowl, Fig. 2, has been achieved with the aid of such a block, and so has that of the sweet peas in Fig. 7. Again, both these flower arrangements are for a position at a table level, and the pottery bowls are well chosen to set them off. Sweet williams also require to be massed in a wide vase or bowl, and certain other flowers, such as primroses, wallflowers, and pinks, whose great charm is in scent and colour rather than in form. Tulips are an example of flowers which require a background of wall to look their best, owing to their beauty of line.

Carnations are essentially flowers which look best with a detached treatment of bloom. In a cut-glass vase, as seen in Fig. 4, they are perfectly suited. The asparagus fern softens the slightly hard effect of the stalks supported by a wire holder. Geraniums require a formal treatment and look well in a square glass with maidenhair fern. Violets also are a joy in a low crystal vase.

The decorative note is stressed in Fig. 5, an arrangement of Fire King snapdragons in a pale green jug, set on an oak window-sill and harmonising with the printed linen of the curtains. Such long-stalked summer flowers require depth of water and are better placed in a tall jug or vase. Stocks are beautiful in a pewter tankard, as seen in Fig. 6, the pink, mauve and plum-coloured tones of the flowers and their delicate greenery contrasting exquisitely with the grey metal.

**For Heavier Flowers.** Where it is desired to get a beautiful effect with heavy flowers or sprays of flowering shrubs, an easy method of support is the following: Choose a big, wide vase of some metal or strong pottery. Measure the top opening across and cut two strips of thin wood to fit. Lay these about 1/2 in. apart and nail some cross way pieces about 1 in. from the end; this forms a slot. After soaking in water to make the wood swell a little, place this rough framework about 1 in. from the top of the vase, wedging it in. Because of the wedging, this method is not suitable for glass or china vases. The flowers will rest in the slot, apparently growing from the centre of the vase. Such a support could be used to assist an arrangement of mock orange blossom by the possessor of a Somerset cider jug or other large suitable receptacle, such as a big copper vase, to form the delightful empty grate screen shown in Fig. 8. Through the summer bold arrangements of foliage and tall

flowers such as foxgloves, gladioli, dahlias, and Michaelmas daisies can be used in this way to decorate a country sitting-room.

High graceful flower arrangements form entirely satisfactory corner furnishings, and particularly decorative in a dark corner are tall white flowers in a white vase. White lilac, chrysanthemums and madonna or Harrisii lilies are all suitable for this purpose. The last named are shown in Fig. 9, brightening a dull hall. Another charming scheme for a hall window-sill is seen in Fig. 3. Here opium poppies make a brilliant show of colour in a hammered brass vase. Nothing could give a more inviting welcome to an oak furnished interior unless it was a square tall vase of amber glass containing bronze chrysanthemums. It is a point worth noting that these flowers must be placed in deep water as, unlike certain others, they do not last well in bowls.

Mixed flowers can be used to create beautiful effects for the table or to be set against a wall. Colour and shape must be well considered. Such mixtures as pink tulips, mauve irises and various kinds of the narcissus family can be well arranged together. Short stalked cottage garden flowers are delightful mixed with apparent carelessness in a green pottery bowl. Another scheme for the country room would be marigolds, cornflowers, big white daisies and field grasses in a pewter jug. Mauve lilac and pink peonies will make a handsome corner decoration. Later in the year dahlias in a pinky mauve shade will look beautiful with mauve scabious, and if arranged in a big jar spikes of pink gladiolus may be added with excellent effect.

**Winter Decoration.** In the winter months tall spreading arrangements of foliage and berries, such as spindle, the various barberries, cotoneasters and rowans will brighten rooms when flowers are scarce. Another floral decoration which pleases the thrifty housewife is achieved with honesty. Beautiful effects can be obtained by using the flat silvery seed pods of this old-fashioned plant in their natural state combined with those dyed in shades of pink and mauve against a background of dark evergreens. Baskets of dried everlasting flowers are liked by some people and can be made attractive combined with statice in mauve and yellow and the introduction of sprays of conifer foliage.

The seed heads of candytuft also remain fresh for a long time in water and look charming in a silver or pewter mug against a dark background. Physalis, with its orange scarlet Japanese lanterns, will look beautiful with pine foliage and branches of larch, the stems and cones of the latter dusted with silver frost powder after the fashion of Swiss Christmas bouquets.

**Packing.** When it is desired to forward flowers by post it is best to cut them in the cool of the day and put in water some time before packing in a cardboard box. Layers of thin wadding between each layer of flowers help to keep them fresh, and it is a mistake not to pack as closely as possible without crushing the blooms.

Flowers for funerals should be sent to the house early on the day fixed. The old custom of using only white flowers has been modified and there is nothing to

forbid the use of coloured ones for this purpose. Roses, carnations, tulips, in fact flowers of all colours, made up into wreaths, crosses, etc., may be sent. If in the announcement of the death it is also mentioned that no flowers are desired, such wishes naturally will be respected.

**Pressing.** Some people like to press botanical specimens while they are away on a holiday or at other times, while children sometimes do this as a hobby. Such specimens are best carried in a metal case when they are picked and should be pressed shortly afterwards in a botanical press. Sheets of white blotting paper, cotton wool, photographic paste and a small paint brush are needed. For mounting the dried flowers either an album is required or the specimens may be mounted on loose sheets of thick drawing paper and stored in a cabinet obtained quite cheaply for this purpose.

**FLOWER SHOW.** In Great Britain July and August are the chief months for flower shows. The following suggestions are offered to those gardeners who may desire to enter the lists at the local horticultural society's show, but who do not know the way in which exhibits may be prepared and staged to the best advantage. Those interested should secure the society's schedule as soon as issued, study its various classes, and select those in which it is desired to compete. They should study the rules and send the entry form carefully filled in to the secretary well in advance of the advertised date for closing.

The next matter of importance is concentration upon the cultivation and management of those plants from which exhibits will be drawn. If cut bloom is the object in view, these generally will be taken from the hardy plant border. Plants selected should have fairly frequent doses of weak liquid manure, alternately with watering. Cut out all weakly flower spikes and use them for indoor decoration, and stimulate strong growths in order to reach perfection.

Flowers for a show are best gathered during very early morning, and after they have been placed in clean, soft water should be sheltered in a cool, dark space until ready for packing. If the show is a long distance away they should be sent in an exhibitor's box, which will allow them to travel in good order. If the show is near at hand simply place damp moss round the stems and pack them in boxes lined with clean tissue paper.

**Roses and Sweet Peas.** Roses that are grown for exhibition purposes require attention not only for stimulating cultivation, but also for intelligent disbudding. The best blooms will need shading from bright sunshine when they are opening, bearing in mind that on the morning of the show it will be the opening bud that will be the right one to cut, as its expansion will have developed just about the time when judging is taking place. Tie a band of soft wool

round the bud before cutting and do not remove it until the blooms are staged. Always cut with long stems, and see that flowers are sprayed with clean water from a very fine sprayer.

When arranging sweet peas see that the spikes are so placed that each is clearly visible, and be careful to put only the exact number in each vase, as called for in the show schedule. Each variety must be correctly named, and apart from form and colour, perfect freshness is absolutely essential.

Pot specimens of such plants as fuchsias, zonal pelargoniums, tuberous begonias, etc., will require stopping or disbudding well before the show, and a safe rule is to remove all flower stems appearing above the leaves at least a month in advance.

Most exhibitions have classes for table decoration. Points towards success are lightness and grace combined with simplicity of colour and daintiness. Overcrowding is a fatal mistake, and it is too often forgotten that ample space should be left for diners.

Make sure that exhibits are strictly according to schedule, otherwise disqualification may follow. If a class calls for six blooms do not include seven. Cut all blooms before the sun gets on them, and they will retain their freshness until the crucial moment of judging.

Do not stretch time too fine on the morning of the show, and remember that whether your exhibit is finished or not nobody will be allowed in the tent while the judging takes place. Clear up all rubbish from the neighbourhood of your stand, and, after putting everything in proper order, leave the tent and await results. If in doubt or difficulty go to the secretary, but do not worry this busy official unnecessarily. *See* Carnation; Chrysanthemum; Rose. etc.

**FLOWERS OF SULPHUR.** This is another name for sublimed sulphur, which occurs as a gritty yellow powder. It is used internally as a laxative, and is especially useful in chronic constipation, piles, and chronic rheumatism. The dose is 20 to 60 grains, and it may be taken with marmalade or in milk or treacle. Externally, in an ointment, it is used in scabies or itch, and in other skin complaints. In chronic rheumatism benefit may be derived from sprinkling the affected part with flowers of sulphur in fine powder and wrapping flannel bandages round. *See* Laxative; Sulphur.

**FLUE:** In Chimney and Range. Flues are internal passage ways or channels to discharge the smoke and fumes from a fire, foul or hot air from a room, or to supply fresh air. In a cooking range the flues are the internal channels by which the hot gases are conducted past the oven or boiler, as desired.

A brickwork construction with one or more vertical flues is generally known as a chimney stack. A typical stack is shown in the accompanying diagram. In domestic architecture a flue is usually carried out in brickwork, and is part of the fabric of the building. Flues for gas fires may be formed in the wall itself. In a dwelling-house a flue deals with the smoke, conducts the heated and foul air from the room, and acts as

a ventilator. Consequently it should never be closed up, unless other means of ventilation are provided. Most flues have been designed for open fireplaces, intended for the use of ordinary coal, and in these cases the grate should be deeply recessed. The back should slope towards the front, so that the smoke has to curl over before ascending the flue proper. The cross sectional area of the flue should be as small as possible and the sides as smooth as practicable, in order to present the minimum of resistance to the ascending air.

*Flue. Showing how flues are gathered into a single chimney stack.*

To retard down draughts and to stop the passage of rain in wet weather, all flues should have at least one bend with an easy slope. The height of the flue opening above the roof should be at least 3 ft. above the ridge or adjacent roofs, and in restricted areas the height can with advantage be much greater.

Ventilating flues are constructed in brickwork in much the same way as a smoke flue, but the opening is often long and narrow, as such an arrangement can be built into the cavity between two walls. Such flues terminate on the exterior in a special elbow or bent box having an opening and flap valve. Indoors the flue openings may terminate in the form of a cast-iron grating with a movable cover, permitting the flue to be opened or closed at will.

Portable coppers, central heating boilers, and fittings of a like character are usually provided with a flue pipe made of cast iron. All such flues must be kept well away from any woodwork, and, where they pass through a wall, should have a proper cast-iron wall box or plate built in. This type of flue can economically be combined with a simple brick chimney stack, several of the iron flue pipes being conducted into the brick stack.

**The Kitchen Range.** A regular kitchen range, when built into brickwork, has a rather elaborate arrangement of flues. The provision of two or more flues is for the purpose of changing the direction of flow of the flames and hot air, dampers or controlling valves being provided to check or stop the passage of air through one flue, and to vary the cross-sectional area of a flue. Constricting the area of the flue will, up

to a certain point, increase the speed at which the hot air ascends; hence the faster the heated air ascends the more fierce will be the fire, as more air is consumed. Further closing of the damper so far restricts the flue opening that it can no longer pass sufficient air, and the fire is damped down or checked and burns more slowly. By these controlling devices the heat from the fire can be concentrated on the oven when the oven flue is open and the other closed, or concentrated on the hot-water boiler, etc.

The flues need to be cleaned weekly. To do this, open the damper and top flues, insert the flue brush in each, in turn, and twist it well in every direction. Next open the rounds on the top of the hot-plate and, with the scraper and brush, gather the soot and scrape it into the dustpan. The lower flues should be cleaned in the same way. *See Anthracite Stove; Bricklaying; Chimney; Grate; Range; Stove; Ventilation, etc.*

**Flue Brush.** A brush with a long, annealed wire handle is best for cleaning a flue. Four strands of stout wire are tightly twisted to grip small knots of the material which makes the brush, the remaining length of twisted wire forming the handle. For everyday use a brush is made of black China bristle, and the stiffer the quality the better. A wire brush used occasionally will remove hard carbon or soot deposits and slight corrosions. Long chimney flues can be swept out with a circular brush screwed to the top of a rod of hickory or other suitable wood; joints are made by screwed sockets, and any number of extra rods can be attached as the brush is forced up the chimney. *See Brush.*

**FLUFF.** The short fibre which shakes out of beddings and is swept out of carpets is collected with the dust, and is best burnt, unless, of use for the garden. It has a value as manure and may be mixed with garden soil. The fibre assists a light soil to hold moisture and contains plant food. Woollen fluff is bought by hop farmers, being specially useful in growing hops.

Fluff from the woollen cloth mills and shoddy factories is used for stuffing cheap mattresses and furniture. A kind which makes the best stuffing for pin-cushions is blanket cardings.

**FLUMMERY.** This makes a delicious and wholesome cold sweet. Wipe 3 lemons, chip off their rinds very thinly and lay them in a basin with  $\frac{1}{2}$  pint of boiling water and  $\frac{1}{2}$  lb. of white sugar for  $\frac{1}{2}$  an hour. Then dissolve  $\frac{1}{4}$  oz. good weight of gelatine in 2 or 3 tablespoons of hot water. Strain this to the water, and add the juice of the lemons and the yolks of 4 eggs. Put this mixture into a jug, which stand in a pan of boiling water. Stir gently over the fire till the mixture thickens like a custard. On no account overheat it. Strain it, and when cool add a glass of sherry. Serve in custard glasses.

**FLUSH BOX.** This is a metal or wooden box or cistern used to supply a sudden rush of water to a

closet. A common form comprises a galvanized iron cistern with a siphon arrangement; as the water rises in the tank the air is expelled from the siphon box, and the contents of the tank are discharged with considerable flushing force.

The device may be used in connexion with a rain-water tank; it will then collect the rain-water as it trickles from the rain-water pipe, and store it until a sufficient quantity has been accumulated to dispel the air from the siphon box, when the contents are forcibly discharged, thus cleansing the drains. In fixing such flush tanks there must be free ventilation to the siphon outlet, and the pipe line must be free from a trap; if such a fitting exists it must be removed, or be provided with a ventilating pipe. *See Sanitation; Water Closet.*

**FLUSHING.** This affection is apt to be troublesome to many women at the change of life. It may be produced at other times by indigestion, eating hastily, drinking alcohol, tight lacing, and the use of tight neckwear. The remedy is to avoid the occasion of the trouble. Bromides and ichthyol are useful.

**FLUSH PANELLING.** In furniture this is a method of joining up stiles, panels, etc., of wooden doors so that all are on the same plane, no part projecting in front of any other. The tops of tall pieces of furniture are often treated in this way to prevent the formation of a hollow well that tends to harbour dust behind the cornice. *See Door; Panelling.*

**FLUTE: How to Play.** The transverse, concert, or, as it was formerly called, the German, flute is an instrument made either of ebonite, cocus, or metal. Of these materials, the best is ebonite, which resists better than cocus the deleterious effects of the moist breath. The silver flute requires a less strong embouchure than the others, which recommends it to amateurs, but on the other hand its tone is not so good.

*Flute. Boehm concert flute, cylindrical. 26 in. Type in use from about 1834.*

The instrument has a chromatic compass of about three octaves divisible into three registers:

The quality of the lowest register is rather reedy. The middle register, produced by increasing the air pressure, is fuller and more mellow, while the highest, produced by still greater air pressure, and by cross  
(Continued in page 860)

# FEBRUARY

## What to do in the Garden

### Flowers

Syringe azaleas, heaths, and other hard-wooded plants

Keep calceolarias, fuchsias, and other summer bedding plants at a temperature of about 50° F.

Take off tops of fuchsias and start them in gentle heat to increase supplies

Pot up another lot of lilies

Sow half-hardy annuals in boxes

Plant the herbaceous border with hardy perennial plants. Plant leaf-losing trees and shrubs. Prune winter jasmine. Transplant autumn-sown annuals

Give gravel paths a first and strong dose of weed-killer

Finish planting hardy roses

Patch and edge turf on playing lawns

Plant hedges of leaf-losing shrubs

Knock off snow, if any, from branches of evergreens with a broom or rake

Towards end of month, lower slightly the temperature in which summer bedding stuff is growing

Sow annuals in boxes for transplanting later

### Fruit

Finish pruning fruit trees of every description

Give top dressing of farmyard manure, where available, to hardy fruit borders

Cut back stocks for grafting

Use the knife only lightly upon black currant bushes

Wash indoor vines, and paint them with a mixture of sulphur, soot, lime, and soap-suds

Plant a new strawberry bed

Spray fruit trees with lime sulphur

### Vegetables

Sow early peas on a warm border

Sow any kinds of early salad crops in frames that can be spared

Look over stored vegetables, and take out any that show signs of decay

Set seed potatoes in a light, frost-proof place

Plant Jerusalem artichokes in an unwanted corner

Sow broad beans for early crop

Bend the leaves of flowering broccoli inwards, to protect them from frost

Give the cabbage patch a dressing of lime

Sow short horn carrots for an early crop on a warm border

Sow onions for spring thinnings

Plant seakale and rhubarb; also shallots and onion sets

## Food in Season

### Fish

Barbel; bream; brill; carp; cod; dory; eels; flounders; gurnet; haddock; hake; halibut; herring; ling; mackerel; mullet (red); perch; pike; plaice; salmon; skate; smelts; soles; sprats; tench; turbot; whitebait; whiting

### Shellfish

Crab; crayfish; lobster; mussels; oysters; prawns; scallops; shrimps

### Meat

Beef; house lamb;

mutton; pork; veal; venison

### Poultry and Game

Capons; capercaillie; chicken; duck; fowl; geese; hares; larks; landrails; partridges; pheasants; pigeons; pintail; plover; ptarmigan; pullets; prairie-hen; quails; rabbit; snipe; teal; turkey; wild fowl; widgeon; woodcock

### Vegetables

Artichoke; beetroot; broccoli; Brussels sprouts; cabbage; cardoons; carrots;

celeriac; celery; chervil; chicory; cress; cucumber; endive; horseradish; leeks; lettuce; mushrooms; onions; parsnips; potatoes; radishes; salsify; savoy; Scotch kale; seakale; spinach; tomatoes; turnips; turnip tops

### Fruit

Almonds; apples; bananas; Brazil nuts; chestnuts; cob nuts; cranberries; grapes; lemons; limes; medlars; oranges; foreign peaches; pears; pine-apple; rhubarb; walnuts

## Notes for the Month

FEBRUARY 8 .. Half-quarter Day  
FEBRUARY 14 .. S. Valentine's Day

fingering, is pure and brilliant, except in the extreme notes. On the whole, however, the scale is fairly even.

After using, the instrument must be thoroughly wiped inside and out, especially near the joints where moisture is apt to collect, and, if not removed, to cause inevitable mischief. An oily rag passed through it now and again will help to keep it in good order, especially in hot weather, and all springs and moving parts should be periodically cleaned and made to work freely, oiling if necessary, but with a very sparing hand. Should the holes become dirty, cleanse them with a soft rag or brush, but never use anything which may in time enlarge the holes, or faulty intonation will be the result. The flute in its case should be kept in a dry but not too warm a place.

**FLUTING.** As applied to work done on wood, stone and on silver and similar metals, fluting is the regular semi-cylindrical ornament with which many pieces are decorated. Examples are often found on the pillars of candle-sticks and the bases of teapots, and in stone, plaster or wooden pilasters and pillars. In small woodwork, fluting can be obtained by the use of a reeding plane, or hand beader, an implement in the form of a spokeshave; when applied to plaster work or cement construction it may be either moulded or run in with a templet or horse.

**FLUX:** In Metal Work. Fluxes are used in uniting metals during welding, brazing, and soldering, to prevent oxidation, to clean the surfaces, and ensure a sound joint. A flux in common use is zinc chloride, otherwise known as killed spirits, when it has been prepared for use by dissolving in hydrochloric acid as much zinc in the form of odd little pieces or cuttings as the acid can attack. Rosin and sal-ammoniac are other useful fluxes.

Fluxes for brass and copper include ammonium chloride, rosin, zinc chloride. Tallow or rosin are good fluxes for lead. Zinc is soldered with hydrochloric acid as the flux, and the same acid may be used as a flux on galvanized steel. Chloride of ammonia is a good flux for soldering steel and wrought iron. The soldering of aluminium presents some little difficulty, as the fluxes mentioned are ineffective. Various proprietary solders are sold for the purpose. In addition to the fluxes enumerated there are several preparations on the market, including one, in the form of a paste, that combines the properties of a flux and a solder.

The flux commonly used for silver soldering is borax, prepared by rubbing a lump on a clean piece of slate, slightly moistened with water; the creamy paste so produced is then applied to the parts to be jointed, and is an efficient flux for small work. Borax may be applied in powder form, and in some cases mixed with small pieces of solder. The same flux is in extensive use for all classes of brass brazing where spelter, or brazing wire, is employed. *See* Brazing; Soldering; Welding.

**FLY:** The House Pest. The fact that flies are active agents in spreading infectious diseases is now generally recognized. In a count made of the microbes on the

bodies and legs of a number of house-flies the average was found to be over a million. The diseases of which flies are the most active carriers include typhoid fever, dysentery, tuberculosis, cholera, and the epidemic diarrhoea from which large numbers of children die in summer and early autumn.

*Fly. Left, adult house fly. Below, eggs. Both considerably enlarged.*

Flies lay enormous numbers of eggs, and in hot weather female flies developed from the eggs may themselves be laying eggs within so short a period as three weeks. The eggs are laid in manure, human excreta,

garbage, etc.

*War on the house-fly should be carried out relentlessly by every prudent householder.*

*Foot of house-fly.*

The most necessary measures are to remove manure and garbage heaps to a distance from the house, to keep dust-bins constantly covered and to burn all vegetable and other food waste. The dust-bin should be thoroughly washed from time to time, and then dried before using it again. In hot weather it should be disinfected once a week with some dry disinfectant. Manure or garbage heaps should be sprinkled with chloride of lime.

In the larder all food must be kept in a ventilated safe or covered with gauze. Food which must be exposed on the table or elsewhere should be protected by wire or muslin covers. Care must be taken to keep the baby's milk free from contamination.

If a dead fly is found in the milk, the milk should not be given to the baby. Fly-papers should be placed about the larder, kitchen, and dining room, and other parts of the house if necessary. One device for keeping flies away is a fly screen of the type illustrated. This is an adjustable screen of fine wire mesh, fixed on a wooden frame, and its purpose is to prevent flies from entering through an open window. In this way a free current of air can enter the room, but flies cannot get through the wire.

**Fly Papers and Repellents.** A fly paper can be made by coating pieces of paper with a mixture of powdered resin and colza oil, in the proportion of three parts of the resin to one of colza. It will suffice if the resin is melted over a slow fire, and the colza stirred into it to form a sticky substance, which is then applied while hot to the paper.

*Fly. Effective screen made from fine wire mesh fitted into a frame and inserted below the raised sash of a window.*

*Fly killers of different kinds. Above, wire mesh killer. Below, A, made of wire; B, of wood; C, of leather. (Courtesy of A. W. Gamage, Ltd.)*

A somewhat different system is to repel the flies by the use of blotting paper soaked in equal quantities of oil of pennyroyal and eucalyptus oil, the pieces being placed on the window sill or any place where the flies are likely to enter. Another method is to soak a sponge or some crumpled blotting paper in hot water, and pour a little oil of lavender upon it.

An effective method of catching flies is to cover the top of a jam jar with a twisted piece of paper in the form of a cone, with the smaller end downwards. The flies will easily find their way in, but cannot escape, as they seem unable to get through the small end of the cone from the inside of the jar.

Another simple form of fly trap can be made by smearing the inside of a plate, a saucer, or a small ornament with a mixture containing pepper, and inverting it over two sticks or pieces of wood, leaving just room enough for the flies to crawl in underneath. An effective mixture for this purpose is composed of  $\frac{1}{2}$  teaspoonful of ground black pepper with a little brown sugar and either cream or margarine, a little water, being used to dissolve the sugar and make a paste. Quassia chips are also employed, and a recipe for them is to boil  $\frac{1}{4}$  oz. of quassia chips for 10 min. in about a pint of water and add 4 oz. of treacle or syrup. The trap should be cleaned and reset every morning, the result fully justifying the trouble taken.

*Fly. Attracted by bait, flies enter the inner cone of the trap from beneath the overhanging metal band at base, afterwards emerging through a hole at the top of the cone into the fine wire mesh globe. (Courtesy of A. W. Gamage, Ltd.)*

Beer is frequently used in fly-traps. A recipe of this kind contains a tablespoonful of beer, 2 drams of formaldehyde, and a tablespoonful of sugar, the mixture being put into saucers with some small pieces of bread dipped in for the flies to settle on. Formalin is generally effective for the same purpose, a teaspoonful being added to a little milk in a saucer.

A useful instrument for killing flies comprises a straight handle, on which is fitted a flap made either of wire or leather. It is used by striking at the insects with the flap, which is more or less hinged. Several types are shown in the illustrations. The construction can be carried out in wire or wood. A short piece of leather

strap shaped somewhat in the form of a handle at one end, and as a brush-like shape at the other, can be of great service. *See* Blow-fly.

**FLY POWDER.** This term is generally applied to a powder for sprinkling upon sheep to prevent flies striking the skin. It is also applied to powdered borax or powdered hellebore, which are employed for destroying the larvae of the house-fly by sprinkling upon manure heaps. Hellebore is poisonous, but borax is harmless to human beings and domestic animals.

**FLY-TRAP: The Plant.** This plant, *Dionaea muscipula*, has fleshy, circular leaves, at the edges of which are hairs. By the sides of the centre rib are bristles or springs. When these springs are touched by the weight of a fly alighting upon them, the two sections of the leaves close up, the exit is sealed by the hairs at the edges of the leaves interlocking. These carnivorous plants are grown in a heated greenhouse. They flourish best in a wet, peaty soil. *See* Venus Fly Trap.

**F/NUMBER: Of Lenses.** The f/numbers engraved on the lens mount of a camera refer to the size of the aperture of the lens, the lowest figure being the full aperture when the diaphragm is fully open. They govern the speed at which the lens works, and consequently the length of the exposure. A fast and expensive lens will work at f/4.5, f/3, f/2, or even lower, while the lenses on the cheaper snapshot roll film cameras generally work at f/8 or f/11. The f/number of a lens represents the number of times that its diameter is contained in its focal length; thus, if the focal length of a lens is 6 in. and its diameter is  $\frac{3}{4}$  in., the latter divided into the former gives 8, which is the f/number.

*F/Number. Lens front of a hand camera with usual series of f/numbers marked at bottom.*

The more the diaphragm or stop of a lens is closed and therefore the higher the f/number, the greater the sharpness of detail in the picture, both in

foreground and distance. This is called increasing the depth of focus, as explained under the heading Focus. The speed of the lens is directly indicated by its f/number at full aperture, one working at f/4.5 requiring only a fraction more than a quarter of the length of exposure required by a lens working at f/8; that is, the second lens, which is one often found on film cameras, requires an exposure 4 times longer than the first lens to give a good negative.

The usual series of f/numbers or stops is in the sequence 5.6, 8, 11.3, 16, 22.6, 32, each of which

requires an exposure twice that of the stop immediately preceding it. For instance, if the exposure time for f/8 is known and it is necessary to stop down to f/11, the time of exposure is doubled; if f/16 is used it is multiplied 4 times. These are the numbers usually marked on lenses, but there is also another system, called the Uniform System, or U.S. stops. Some foreign-made lenses have numbers marked on them which are not the ordinary series, such as 6.3, 9, 12.6.

In general, the rule for the calculation of exposure for any unusual f/numbers is that the time of exposure for the lowest number having been found, exposures for the other numbers in a particular series are proportional to their squares. To do this, take the square of each of the numbers on the lens mount, and then, taking the lowest as the unit, make a table showing the proportions of each of the other squared numbers to it. *See* Focus; Lens; Stop.

**FOAM FLOWER.** The botanical name of this hardy plant is *Tiarella cordifolia*. It is hardy, 10 to 12 inches high, and bears white flowers in April. It is easily grown in soil with which sand and leaf-mould have been mixed and is suitable for the rock garden or shady border. It is propagated by seeds sown in a frame in spring.

**FOCAL PLANE SHUTTER.** A form of shutter used in cameras, particularly reflex and press cameras, for objects moving at high speed. It consists essentially of a blind wound on spring rollers and having transverse slits of different widths. It passes up and down immediately in front of the plate, i.e. it is at the point or plane at which the lens throws an image sharply in focus, hence the name.

The blind is arranged to work at various speeds by increasing or decreasing the tension on the spring in the roller. By varying the tension and the width of the slit used, a great variety of times of exposure may be obtained, exposures as short as 1/1250th of a second being possible.

A certain amount of practice is required for the successful use of a camera with a focal plane shutter, when snapshotting fast-moving objects, as, for instance, a cricket ball leaving a bowler's hand, or a football entering the goal. When looking at the screen of a reflex camera the tendency is always to make the exposure a fraction of a second too late, inasmuch as there is an appreciable time between the release of the mirror and the actual exposure. It is therefore necessary to anticipate very slightly the action to be snapped, and if the camera is properly focussed beforehand, it is best to watch the subject directly. A quick eye and a sure hand are essential; fast plates are best. *See* Camera.

**FOCUS: In the Camera.** Points to be considered with a camera lens are its focus, or focal length, and its depth of focus. The focus of a lens is that point at

which, when the camera front is racked out, a clear image, sharp in detail, of the object being photographed is thrown on to the ground glass focussing screen or the plate. In the case of a simple lens, or a simple double lens (not an anastigmat), this point is roughly measured in the following way. The lens is racked out until clouds, or some far-distant object, are seen sharply on the focussing screen. The distance then found between the ground glass screen and the front surface of the lens, in the case of a single lens, and midway between the two lenses in the case of a doublet, gives roughly the focus, or focal length of the lens.

For various purposes very different focal lengths are required. In the cheap folding camera a very short focus lens is generally used, which has a wide angle, and covers a large field of view, giving a picture with relatively small detail. The other extreme is seen in the telephoto lens, which has a very long focus with a particularly narrow angle. It covers a small field of view, but gives objects on the plate in relatively large scale. For ordinary purposes the amateur is best served by a medium long focus lens. Photographs taken with a long focus lens have a more natural appearance than those taken with a short one. For a camera of  $\frac{1}{4}$ -plate size a lens of about 6 to 7 in. focus will give satisfactory results; a 5 in. or shorter lens will give the wide angle effect referred to.

The length of focus of an anastigmatic lens cannot be measured in the fashion described above for simple lenses, because difficult optical questions arise.

The depth of focus varies with the class of work which the lens is designed to carry out, and according to its aperture as indicated by its *f*/number. By depth of focus is meant the distance at which all objects in the field of view are seen sharply in focus on a ground glass screen. Thus with a short focus, small aperture lens working at *f*/11, practically everything from a point about 4 ft. away from the camera to infinity, or the farthest distance, will be rendered on the film with pinpoint sharpness. Such a lens is said to have maximum depth of focus.

This is by no means an advantage, as in landscape photographs it destroys all sense of distance, and in portraits gives unpleasing results, making the background, for instance, as prominent as the sitter. With a long focus wide aperture lens, working at about *f*/4.5, the sharpness of focus quickly falls off, and more distant detail is greatly softened. When the maximum depth of focus is required with such a wide aperture lens, it is obtained by the simple process of stopping it down to *f*/11 or more.

In cheaper cameras lenses are sometimes described as being of fixed focus. This simply means that the distance between the lens and the film cannot be varied, and when the camera is opened it will be always in focus.

**Errors in Focussing.** Many photographs are spoiled by being out of focus through inaccurate judging of distance, particularly in the case of more or less hasty snapshots. The only remedy is practice. This is easily obtained if a camera with a focussing screen can be

acquired, or a temporary screen of ground glass fitted to the back of a film camera in place of the film holder, care being taken to see that the ground glass is at the same distance from the lens as the surface of the film. It is necessary to see not only that the principal object is in sharp focus, but that the range of sharpness is properly distributed. A photograph will be quite spoilt if, while the principal object is sharply in focus, the foreground is fuzzy.

If it is found that photographs are obtained which are out of focus in spite of careful estimation, it is well to look to the focussing scale as a possible source of the failure. Photograph an object at an accurately measured distance with two or three others at short distances in front and behind it; a print will show the amount of error in the scale, this process being repeated for one or two other distances, and the scale corrected as necessary. Errors in focussing are often due to careless adjustment of the moving pointer; the pointer should be viewed from immediately above and not from the side.

**Range-finding.** The modern miniature camera of the more expensive type usually includes a range-finder which is coupled to the lens so that the precision in focussing which the small negatives require is made simple. Range-finders are also fitted to some of the more expensive roll-film cameras. The reflex camera affords a ready means of focussing the object direct on to a ground glass screen and in its modern form is available in many sizes from the 35mm. miniature type to the 120 roll-film. Focussing may be further assisted by the provision of a special magnifying lens above the screen. *See* Camera Enlarging; *F*/Number; Lens; Photography.

**FOIE GRAS.** This is the French term for the fat liver of the goose. Made up into *pate de foie gras*, it is regarded as a great delicacy. *See* *Paté de Foie Gras*.

**FOIL:** In Architecture. This term is used in ornamental tracery to denote one of several almost circular lobes tangent to the inner side of an arc, and meeting each other at points called cusps. *See* Trefoil.

**FOLDING TABLE.** The structural necessities of a folding table are that it shall be perfectly rigid when open, and fold away into the smallest possible compass when not required for use; if possible it should also have no loose parts to get lost, but this is not always practical. In Fig. 1, the only loose part is the centre bar running through and between the diagonal rails. To put the table away, the top is taken off and the loose bar withdrawn; this leaves the framework free to fold up, the top folding either inward or outward, and the lower part automatically folding in the opposite direction, forming a quite flat arrangement. The two ends are made first. These consist each of two  $1\frac{1}{2}$  in. legs with 1 in. cross rails screwed to them, as in Fig. 3;

at the top is screwed another rail, which equals in width the thickness of the leg and the cross rail together. The diagonal rails are rounded at the ends so as to clear the side rails when being folded. They are secured to the legs by nuts and bolts, with a washer between. It will be noticed that the rails are fixed to the inside of the legs except at one of the corners, in this case at the bottom right corner (Fig. 2); this is necessary to allow them to clear themselves.

**Folding Table.** Fig. 1. Table standing rigid; when not in use the top is removed, the central loose rail withdrawn, and the framework folded upon itself. Figs. 2-4. Details of construction.

When the whole frame has been assembled, the hole for the centre bar is bored; this may be a narrow brass rod with a knob screwed on at each end. The top is of 1 in. stuff glued up to width and strengthened with battens slot-screwed to the under side; three will be

sufficient for a 4 ft. 6 in. table. To keep it rigid and in position four small buttons are screwed to the cross battens, as in Fig. 4, these being simply turned to release the top. Allow the top to project to the extent shown.

**Folding Occasional Table.** A small table very useful for occasional use and folding into a still smaller space is depicted in Fig. 5. The top hinges over, the legs folding across each other from the centre (Fig. 6). The legs are cut off 2 ft. 4 in., 1 in. being allowed for the top, turned according to the pattern, and then mortised to take the rails. It should be noticed that the gates fit one inside the other, so that the rails of the one will be closer together to the extent of the width of the two rails. Fig 7 shows the table open, and the position of the rails of the movable gate are shown in section in the centre leg. Having glued them together, the gates may be fixed at the centres with dowels.

**Folding Table.** Fig. 5. Circular gate-leg table. Fig. 6. Top hinged over and legs folding across each other.

Fig. 7. Side view, showing by dotted lines in centre leg the position of rails of movable gate.

Fig. 8. Table top, showing two stops to limit extent to which table opens.

A 1 in. top piece is now screwed to the one gate, as in Fig. 8, being slightly wider than the two gates when folded, and occupying in length just the space between the projection of the legs at the top. To this piece the main top is hinged with three hinges. The whole job should now be opened till the gates are at a right angle and two stops fixed to the top as in Fig. 8, this being the extent to which the table should open. The contours of the turnings are most suitable for oak, but apart from this the table can be made in any wood. *See Gate-leg Table; Table.*

**FOMENTATION:** **How to Apply.** A fomentation consists of a piece of flannel or other absorbent material wrung out of boiling water. It is a very convenient method of applying moist heat, produces the same effects as a hot poultice, and is more easy to renew as it becomes cool. Fomentations relieve tension, pain, and spasm. They form valuable measures in intestinal colic and the intense pain attending the passage of a stone from the kidney to the bladder, or of a gall-stone. A hot fomentation may give much relief from the pain due to a sprain. Applied to a bruise, it not only gives relief, but diminishes the subsequent discoloration.

Place a thick roller towel over a deep basin and pass a stick through each end. In the centre of the towel lay a piece of coarse flannel or a piece of blanket, folded into two or more thicknesses. Pour the boiling water over the flannel, and let it soak for a few seconds. Then twist the sticks in opposite directions, so as to wring all the water out of the flannel. The fomentation must be wrung as dry as possible and shaken out lightly. Apply it quickly to the painful part and cover it with a piece of jaconet or thin mackintosh. This should overlap the flannel by 1 in. or more all round, otherwise the fomentation will cool too quickly. Over all place a sheet of thick cotton wool. Bandage to prevent displacement. When the object is the relief of pain it should be changed every 20 min. The skin should be dried before applying the fresh fomentation.

A turpentine fomentation used to produce counter-irritation, as in lumbago, is made by adding 1 or 2 teaspoonfuls of oil of turpentine to a pint of boiling water, and applying as before; or the turpentine may be sprinkled on the fomentation just before it is applied. In cellulitis, whitlow, or any other acute suppurative condition, a fomentation prepared by adding one teaspoonful of glycerin of boracic acid to a pint of boiling water often gives great relief. *See Bandage; Poultice.*

**FONDANT.** Largely used in the making of confectionery, the fondant forms the basis of many different kinds of sweets. To make it, melt 4 lb. of granulated or loaf sugar in about  $\frac{3}{4}$  pint of cold water placed in a saucepan over a low fire. Stir the syrup gently until the sugar is completely dissolved; then pour in 2 tablespoonfuls of liquid glucose. Cover the pan, and boil its contents rapidly for a few minutes, removing any scum. Let the syrup boil to 240° F., continue skimming without stirring, and brush the

sides of the pan occasionally with cold water. This will prevent the fondant from becoming granulated.

When 240° has been reached, pour the whole on to a marble slab, which has been rinsed with cold water, sprinkle a little water on top of the fondant, and allow the latter to cool slightly before working it with a wooden spoon. When it has cooled sufficiently, it may be kneaded with the hands until it is white and smooth, and then flavoured and coloured to taste. Store it in an airtight box.

Fondant required for coating purposes should be boiled to a temperature 5° higher.

It should be kneaded and stored in the same way, and when required for use placed in a saucepan, together with a little sugar syrup, colouring and flavouring, and melted over a low fire. The fondant should be beaten all the time with a wooden spoon, and must not be overheated. Occasionally it should be removed from the fire and beaten vigorously. Enough sugar syrup is added to make the fondant of a thick, cream-like consistency. When lukewarm, the centres for sweets or small cakes which are to be coated are dipped into it and left to dry.

The sugar syrup is prepared by dissolving  $1\frac{1}{2}$  lb. of granulated sugar in 1 pint of water, then bringing it to the boil and boiling it for 5 min. in a covered pan. The lid is removed and boiling continued for 25 min. This syrup may be bottled when not required for immediate use. Fondants may be crystallized by leaving them to stand in cold crystallizing syrup for about 9 hours, and then drying them upon trays.

**Fondant Icing.** A quick fondant icing can be made by mixing in a pan  $\frac{1}{2}$  a gill of cold water, the juice of  $\frac{1}{2}$  a lemon and 1 lb. of icing sugar. Warm until a creamy liquid is formed and pour over the cake as required. *See Cake; Chocolate; Sweets.*

## FOOD: ITS VALUE AND PRESERVATION

### A General Survey of this Vital Domestic Subject

This article may well serve as an introduction to those on the various items of food and drink that are found in this work, e.g. Bacon; Beef; Bread; Butter; Cake; Cheese; Fish; Fruit; Jam; Mutton; Pork, etc. *See also Breakfast; Diet; Digestion; Dinner.*

The principles regulating the proper rationing of food are discussed under the heading Diet. The claims of the palate must give way to soundness in dieting, and difficulty, on the score of expense, in providing a proper diet can be overcome quite well by a judicious choice of food-stuffs, as many of the cheap foods are intrinsically as valuable as the more expensive. Skilful cookery can do much to give attractiveness to food-stuffs which are not in themselves very inviting, and this is perhaps the most important factor in solving the dietetic problems of households with very limited resources.

Meat may be (1) home-fed and killed; (2) fed abroad

but killed at home; (3) refrigerated, or chilled; or (4) frozen; the last is generally mutton. The second class is that of prime animals but has probably lost fat during the voyage. The third class can be recognized by its pink fat and by the outside of the meat lacking the lustre of fresh meat. The fourth class, if unthawed, will be stiff, and, if thawed, the outside will have a faded or perhaps even a parboiled appearance, while fluid will drip or ooze from the meat, which has not the mottled appearance of fresh meat; the fat has a dull, white colour.

It should be understood, however, that chilled and frozen meat are quite as nutritious as fresh meat, and that the inferior cuts of any meat are from this point of view quite as good as the better. As regards digestibility, mutton is more digestible than beef, and beef than veal. Pork, because of its large content of fat, is difficult to digest. Tripe and sweetbreads are easily digested.

Rabbits are in season from September to February; a young animal is distinguished by its smooth, sharp claws and soft ears. The meat is easily digested. Game derives its flavour by being hung for from five to ten days, until, in fact, decomposition has begun; this, however, has no ill consequences because the meat is dry.

In choosing a fowl an old one will be recognized by its stiff, horny feet, long spurs and dark-coloured thighs. The skin of a fowl should not be discoloured and the flesh should be firm. The meat of duck or grouse contains a considerable amount of fat and is correspondingly harder to digest. The breast of a chicken is the most easily digested kind of meat.

Only fresh fish should be accepted. A fresh fish is stiff, the eyes are prominent and bright and the gills are bright red. Salmon and eel contain a considerable proportion of fat, and so require good digestive powers. Owing to their cheapness, herring are one of the most valuable foods. Oysters, if raw, are very easily digested. Crab and lobster are difficult to digest.

The qualities of bread are discussed under its own heading. Macaroni and vermicelli are preparations of wheat flour and are rich in gluten. Barley has a composition like that of wheat, but it does not form gluten. It is a good food, though barley cakes are less palatable than, and not as easily digested as, bread. To make pearl barley, the grains are deprived of the husk, rounded and polished. Barley meal consists of the whole grain ground; in Scotch, mulled or pot barley, the grains are husked and roughly ground; patent barley is merely flour formed from pearl barley. Rye makes a dark, somewhat heavy and acid loaf, not so easily digested as wheat bread.

Oatmeal contains relatively large amounts of protein and fat and, apart from greater difficulty of digestion, is a better food than white bread. It might with advantage form a part of every dietary. Maize resembles oats in composition but is rather harsh in flavour. From it cornflour and hominy are prepared. Rice is deficient in protein, fat and salts, and therefore is mainly a starchy food. Polishing the

rice deprives it of vitamin.

#### Constituents of some common articles of food

Arrowroot, tapioca and sago consist of starch simply. There are various kinds of arrowroot on the market, Bermudan arrowroot being the best. Tapioca is got from cassava root, sago from the sago palm. When these are used as milk puddings, protein and fat are supplied by the milk. The pulses, namely peas, beans and lentils, are rich in protein, but peas and beans are rather difficult of digestion and much of the protein is not assimilated.

Potatoes contain a large proportion of starch with a little protein. Experimentally, vigorous health has been maintained on a diet of potatoes and vegetable margarine with a flavouring of onion. But the water in which the

potatoes were boiled was also taken, the potatoes being very thinly peeled before cooking. The water contains valuable salts and vitamins taken out of the potatoes. The loss of these salts can be prevented, or lessened, by boiling potatoes in their skins.

For convenience vegetables and fruits are grouped in five classes according to their content of carbohydrate, which is their principal constituent as regards caloric value. Their vitamins, salts and acids are of great importance, in many cases of most importance. The carbohydrate content of each group is shown in the table of foods given below. The vegetable and fruit groups are as follows: A. Cabbage, lettuce, cauliflower, sprouts, spinach, tomatoes, watercress and radishes. B. French beans, onions, carrots, turnips and beets. C. Strawberries, gooseberries, oranges, peaches, pineapples and melons. D. Pears, apples, currants, raspberries, cherries, apricots, peas, parsnips and artichokes. E. Bananas, plums, prunes and potatoes.

By reference to the table on previous page and to the particulars given under the heading Diet as to the relative proportions of proteins, carbohydrates and fats in a diet, and the number of calories needed by various people, it should be possible to construct correct dietaries. These can be varied very largely to suit the family purse.

**Storage and Preservation.** In the storage of food cleanliness and coolness are essential. On no account should milk, fish, meat or similar food-stuffs be kept on the floor of the larder, and they should always be covered or screened to protect them from dust and from the visits of flies. A gauze screen is not sufficient protection against the blue-bottle, as the female deposits her eggs on the gauze and they drop down on to the meat; a piece of muslin should be placed over the meat or on the top of the gauze cover. Weighted gauze covers should be put over jugs or other receptacles containing milk, jam, etc. It is advisable that root and green vegetables should be stored separately. Coolness may be secured by free ventilation of the larder through a gauze-screened window; by having a moistened canvas cover over a food container; by placing ice on fish, meat, etc., or by placing food in an ice-chest.

Much of the food used nowadays is canned or bottled, and a considerable amount of bottling is done in the home. To make such food keep it is subjected to heat in the tin, in the lid of which an opening is left to allow the escape of vapour. This opening is then soldered up, and the contraction which occurs when the tin and its contents cool usually causes the ends of the tin to bulge inwards.

*If the end of a tin bulges outwards it should be rejected, as the bulging is due to gases formed by putrefaction. Such a tin is said to be blown.*

Unscrupulous traders may perforate the tin, allowing the escape of the gases, then reheat and reseal. The presence of two soldered openings should therefore be viewed with suspicion. Bottled fruit and vegetables are

treated similarly. Jam is usually covered after it is cold, and the surface may be sprinkled with some chemical preservative; indeed, something of this kind may be found in any kind of preserved food.

*When a tin has been opened the food should be used at once; it is dangerous to allow it to stand in the tin or even, having once heated the food emptied from the tin, to allow it to stand.*

The use of chemical preservatives for food can hardly be dispensed with, as so much food is imported, and both this and home-produced food require to be stored, sometimes for considerable periods. Some chemicals used for preserving are harmful if taken in the amounts which might well be ingested in the course of ordinary diets containing a fair proportion of preserved food. Boracic acid is an example.

The Public Health (Preservatives, etc., in Food) Regulations, 1925, prescribe the articles which may contain chemical preservatives and the appropriate preservative and amount of it for each. The only preservatives allowed are sulphur dioxide and benzoic acid.

**Poisoning by Food.** Food poisoning may be due to metallic poisons, copper, tin, or lead, from containers or cooking utensils, but is relatively infrequent. Strict care, however, is necessary to keep such utensils clean and not to allow foods containing acids, fatty or otherwise, to remain long in a copper utensil. Defects in the lining of a tin may cause chemical contamination of food.

Most cases of food poisoning are due to the activities of what are called the salmonella group of bacilli, for example, bacillus aertrycke and bacillus enteritidis. The symptoms may be caused by the poisons produced by the bacilli, poisons which remain active even if the food is raised above the boiling point of water; or by the living bacilli themselves.

There is vomiting, diarrhoea, abdominal pain, cramps in the limbs and some fever. Vomiting and diarrhoea are usually sufficiently severe to clear the bowel, but it will be useful to aid cleansing of the stomach by giving large draughts of tepid water and, if the bowels are not acting freely, a dose of salts or of castor oil. The patient must be kept lying down and be kept warm; stimulants also may be needed. Pain and cramps should be treated by hot applications.

Another kind of bacterial food poisoning is known as botulism (q.v.).

Formerly much importance was attributed to ptomaines, alkaloidal products of putrefactive organisms, but it is now clear that such poisons are destroyed in the stomach and are extremely unlikely to give rise to symptoms.

It must be borne in mind that food capable of causing poisoning is rarely offensive or in fact noticeably altered in any way.

**FOOL.** This is a popular variety of English sweet. The name is taken from the French word *fouler*, meaning to crush or bruise, and is given to stewed or crushed fruit mixed with cream or custard, and sugar. *See* Gooseberry; Rhubarb; Strawberry.

**FOOLSCAP.** This word is used for paper of a size frequently used for writing, though too large for correspondence, and for drawing. A sheet of it measures 17 in. by 13½ in. A sheet of double foolscap measures 27 in. by 17 in. *See* Drawing.

**FOOL'S PARSLEY.** Also known as the lesser hemlock, the botanical name of this plant is *Aethusa cynapium*. The leaves have been eaten in mistake for parsley, though, as they give off a nauseous odour when rubbed together, such a mistake should not occur. It is said that the roots have been eaten in mistake for young turnips. The drug has narcotic properties, and possibly poisoning may occur from eating it. The treatment is to empty the stomach by an emetic such as a tablespoonful of mustard in half a glass of water. Give a dose of castor oil, and then draughts of strong, hot tea, and keep the patient warm. *See* Poisoning.

**FOOT.** The bones of the foot compose three groups: the tarsus, comprising seven bones, which form the heel and instep; the meta-tarsal bones, five in number, on the fore part of the foot; and the phalanges, of which there are two in the great toe and three in each of the others. The inner border of the great toe is in line with the inner border of the heel, and the axis of the foot is a line from the centre of the heel through the mid point of the end of the great toe.

A number of deformities of the foot are caused by wearing badly-shaped boots, the usual fault being too pointed toes; but sometimes, and perhaps in addition to the first, the boots are too short. The toes tend to be crowded together, the great toe being displaced outwards (*hallux valgus*), and perhaps one or more of the other toes actually overriding the others. *Hallux valgus* is likely to be accompanied by a bunion on the inner side of the joint connecting the great toe with the foot, and this joint may be inflamed and enlarged.

A short boot or one with a too high heel may give rise to hammer toes, a condition in which the toe is bent upward at its junction with the foot and bent sharply towards the sole at the joint in front of this. One or all of the smaller toes may be affected. Corns form readily on these toes, and form on the toes apart from deformities when the boots are too tight. Soft corns between the toes are due to the latter being crowded together and to the spaces between not being kept clean and dry. It is obvious that the first thing in the treatment of all these conditions is to have properly fitted boots.

There are two arches in the foot, one from before backward and the other from side to side. The maintenance of the former is largely due to the long plantar ligament, the action of which resembles that of a bow-string. When the arch sinks down in flat foot

(*q.v.*), this ligament and other structures which assist its action are stretched.

The foot is liable to several varieties of deformity besides flat foot, for example, claw foot and club foot and drop foot. Trench foot is a condition resembling frostbite, occurring in those who have to remain for long periods with wet and cold feet, without the opportunity to remove their boots frequently.

**Ingrowing Toe Nails.** The toe nails need a good deal of attention in order to keep them in good condition. Both in the case of children and of adults they should be cut regularly.

Some persons suffer from an ingrowing toe nail, a very painful condition. It is often caused by a badly fitting boot or one with a very narrow toe. The best preventive is to wear square-cut boots, raised or blocked at the toes. Cut the nails straight across, never cutting the outer edges, as this only encourages the sides to grow deeper into the skin.

To cure an ingrowing toe nail, insert a small pledget of cotton wool sprinkled with boracic acid under the ingrowing part. The pledget should be renewed every morning and the toe anointed with boric ointment every night.

**Care of the Feet.** If the feet get very quickly tired, and the ankles are weak, one of the best remedies is to bathe the feet night and morning in warm water to which has been added a tablespoonful of brown vinegar or a handful of Tidman's sea salt. The feet must then be dried and well rubbed with methylated spirit or toilet vinegar.

In cases of excessive perspiration the feet should be bathed three times a day at least, and directly after exercise, in warm water to which a little disinfectant lotion has been added. After drying, a change of stockings must be made, and fine woollen stockings should be worn. It is advisable to put on clean stockings every day until the trouble disappears. A little boric powder may be dusted into the feet of the stockings before putting them on.

To prevent blisters the feet should be bathed in warm water to which either a little powdered alum, permanganate of potash or toilet vinegar has been added. An excellent powder for the purpose is made by mixing together 1 oz. each of alum, rock salt and borax. A tablespoonful of this mixture can be added to the bathing water. The feet should be thoroughly dried and rubbed with methylated spirit or toilet vinegar, particular attention being given to the heels and the sides of the foot. A little fuller's earth dusted into the inside of the foot of the stocking is useful. If, in spite of all precautions, a blister makes its appearance, it must be carefully dressed to prevent it from sticking to the stocking or being irritated by further friction. A useful preventive is to rub the feet over with witch hazel, and dust them with talcum powder.

For rheumatic and gouty feet relief may often be

obtained by means of a footbath of water as hot as can be borne, with a tablespoonful or more of bicarbonate of soda added. The feet should be soaked in it for a period varying from  $\frac{1}{4}$  to  $\frac{1}{2}$  hour, hot water being added to maintain or increase the heat.

**Treatment of Cold Feet.** Amongst infants and children indigestion and colic may result from cold feet, while in the case of adults sleeplessness is very often brought about in the same way. The underlying cause, which should be treated, may be anaemia, chronic digestive trouble, neurasthenia, etc. As a palliative thick woollen stockings and roomy boots (not low shoes) should be worn in winter. A pair of fibre or loofah soles in the boots is an excellent preventive of cold feet. No one should go to bed with cold feet. Warming them at the fire is not free from the risk of aggravating the condition. Exercise is a better method, and has more lasting effects. Another plan is to dip the feet for one or two seconds in cold water and then rub them briskly with a warm towel.

**FOOT.** This measure of length, one of the commonest in use, consists of 12 inches. Three feet make a yard, and there are 5,280 feet in a mile. A square foot consists of 144 square inches, and 9 square feet make a square yard. A cubic foot consists of 1,728 square inches, and 27 cubic feet make one cubic yard. The usual abbreviation for both singular and plural is ft., which is used throughout this work. *See* Long Measure; Square Measure.

**FOOT AND MOUTH DISEASE.** This is the popular name for Aphthous fever of animals. It occurs in epidemics which may be widespread. Large and small blisters appear on the lining of the mouth and on the feet. Cattle, sheep and pigs are chiefly affected, but it may extend to other domestic animals. From them it may be conveyed to human beings by milk, butter, cheese, through wounds, and by other means. It is generally a mild disease in human beings, usually lasting 6 or 7 days, but fatal cases do occur. Milk should be boiled when the malady prevails.

**FOOTBALL.** There are two kinds of football, a round one used in the Association game and an oval one used in the Rugby game. In both the inflated inner ball is protected by a leather covering. When the outer covering gets torn or worn through in a particular spot it can be easily repaired by sewing on a fresh piece of leather. Damage to the bladder involves a little more trouble. A usual method of repairing a puncture is to cut out a circular piece of sheet rubber large enough to cover the damaged part completely and leave a margin over. This piece is applied to the bladder with a solution of india-rubber and naphtha.

A tire repair outfit generally includes patches and solution which are suitable for repairing a football, but the solution may be purchased separately and old pieces of bicycle tire can be used to cover up the puncture. For an effective repair it is essential that

pressure should be maintained until the solution has dried thoroughly, and the football should not be used for at least a day afterwards.

A practical method is to lay the bladder on a hard, flat surface, press the patch in its place, then put a book or other flat object over the patch, and cover the whole with an iron weight from a kitchen weighing machine, or any other available weight.

**Football Boots.** Since the first essential of the football boot is strength, care should be taken when purchasing to examine the stitching and to see whether there are any flaws. The best boots have several rows of stitching at each seam, and those showing any signs of broken threads, or stitches so near the edge of the leather that they fail to catch it up, should always be rejected.

Next to strength it is most important that the boots should be waterproof. To ensure this the soles of the best boots are made of first quality chrome-tanned leather. There are many qualities, and it should be remembered that the mere fact of tanning with chrome salts will not turn a poor quality hide into first-class chrome leather.

There are good makes of chrome that are not stamped, and the grain should be examined for imperfections. In good leather this will be firm and even over the whole surface, and should feel firm and hard to the touch. The grain side should be entirely free from surface cracks, however minute, as these indicate that the leather has probably been tanned from what are termed drysalted hides. A boot made from leather of this sort will quickly become cracked and perished. Chrome-tanned leather is considered to be absolutely waterproof, and is recognizable in general by its dark green colour. A football boot made of sound vegetable-tanned leather will be found almost equally serviceable, provided it is kept well greased to render it waterproof.

A good pair of boots should last several seasons, provided that they receive proper treatment. The leather studs on the sole should be renewed as soon as they show signs of wear, and the services of the shoe repairer or harness maker immediately requisitioned to make good any burst stitches. After play the boots should be thoroughly dried away from the fire, all mud removed, and cod or other fish oil well worked into the leather. Failing fish oil, Russian tallow or mutton fat may be used with good effect. This will keep the boots supple and waterproof, and prolong their life much beyond the average. They should be well cleansed and greased before they are laid aside between seasons.

**FOOT BATH.** When a foot bath is taken to check a cold, or for any reason to draw blood from other parts, it should be as hot as can be borne. An ounce of mustard or a cupful of salt added to the hot water increases the beneficial effects. The legs should be covered with a blanket during the process, the feet should be quickly dried with a warm towel, and then

covered with a piece of warmed flannel or a pair of thick woollen stockings.

A warm foot bath promotes sleep and removes the feeling of tiredness after a day's walking. When a full bath is not taken every day, a cold foot bath in the morning is very refreshing and keeps the feet warm in winter. Alum, or enough permanganate of potash just to tinge the water, will help to diminish the tendency to sore feet when much walking has to be undertaken. *See Bath.*

**FOOTMAN:** The Manservant. The indoor duties of a footman are in some respects those of a parlourmaid, and include laying and waiting at table, answering bells, looking after the fires and lighting, cleaning the silver, and opening the door to visitors. During the earlier part of the day he will be expected to clean windows and knives, fill coal-scuttles, and clean boots. He will also be expected to valet when required and to carry messages or letters. In large establishments several footmen divide these duties and are under the butler.

A footman wears a livery provided by the employer. The old male servant's licence costing 15s. a year has been abolished, but a footman must be insured under the National Health Insurance scheme. His employer is also liable for him under the Workmen's Compensation Acts. *See Insurance Servant.*

#### **FOOTMAN: The Piece of Furniture.**

The name of footman is given to an antique metal stand used for keeping plates and dishes hot in front of the fire in the dining room, and usually made of polished brass or steel. They are still used as a decorative and practical accessory on the old-fashioned hearth.

*Footman. Eighteenth century English example in wrought iron with cut steel front.*

*(By permission of the Director, Victoria & Albert Museum, S. Kensington)*

#### **FOOT RULE.**

Foot rules are made of boxwood, with folding joints, or of steel, either in a single piece or jointed. They may be from 1 to 3 ft. in length; the average is 1 ft. subdivided into fractions of an inch,  $\frac{1}{2}$ ,  $\frac{1}{4}$ ,  $\frac{1}{8}$ , or even as small as  $\frac{1}{64}$ . More accurate measurements should be taken with such instruments of precision as a caliper gauge or a micrometer. Boxwood rules should be kept in a dry place, and the metal joints occasionally oiled to prolong their life. Steel rules require oiling from time to time to prevent rusting, or they can be nickel-plated. A folding rule with a firm joint can be used as a bevel square in cases of emergency.

**FOOTSTOOL.** This stool is made in many shapes

and sizes. It may be low and circular, octagonal or square, and covered in bead work or needlework, or in such materials as tapestry, leather, imitation leather, velvet, and carpet. It may be an oblong stool with feet and a wooden frame upon which cane or rushwork is stretched. It may extend the width of the hearth and be known as a fender stool. The modern footstool may also be amplified into a high stool to serve the double purpose of a support for the feet or a low seat. *See Pouffe; Tapestry.*

**FORBIDDEN FRUIT.** This is the popular name given to *Citrus decumara*. It is a good greenhouse pot-plant for decorative purposes, flourishing in a mixture of loam and silver sand. If given an annual dressing of animal manure it does not need repotting for years. The plants may be stood out of doors during the summer months.

**FORCEMEAT.** Forcemeat is a savoury mixture, the foundation of which is breadcrumbs mixed with eggs and seasoning. It is used to stuff boned joints, veal, fowls and other birds, hares, fresh haddocks, and other baked fish. Forcemeat balls are sometimes used in addition as a garnish.

The following is a simple recipe for a forcemeat that can be used with veal. Add 4 oz. of very finely-chopped suet to 6 oz. of breadcrumbs, and the grated rind and juice of half a lemon. Season it with salt and pepper, and add a dessertspoonful of mixed herbs. Bind the forcemeat with a beaten egg, and, if more moisture is necessary, add a little milk.

**Forcemeat Balls.** To make forcemeat balls form the mixture into balls, using a little flour if too moist, dip in beaten egg and fry golden brown. Or they can be baked in the dish with the meat with which they will be served.

Brain cakes or balls are made from calves' or sheep's brains, and are used for garnishing a calf's or sheep's head. *See Brains; Breast; Chestnut; Hare; Liver; Oyster; Pigeon; Sausage; Veal.*

**FORCING:** In Cookery. Forcing is the process by which ornamentation of sweet or savoury dishes by cream, butter, or sugar mixtures is carried out. Forcing pipes are of many varieties, and they determine the pattern or design of the decoration. A syringe or bag to which funnels of different shapes are attached is used. Forcing sets can be bought for a few shillings and, although the process is not easy to a novice, practice soon brings mastery of the forcing syringe. The icing, which should be of a firm, creamy consistency, should be placed inside the syringe, about half filling it. The handle, with the pump pulled out as far as possible, is screwed on and then gently pressed downward, the icing being forced out through the funnel. *See Decoration; Icing.*

*Forcing Bag made of paper, as shown in the diagrams below. The cream is expelled through point of tube by pressure.*

*Forcing. Figs. 1-3. Method of folding a square of greaseproof paper to form an*

*effective bag for making cream decorations. Below, how to cut the tip of the bag, A, for plain piping, B, for leaves, and C, for making stars.*

**FORCING:** In Gardening. The art of bringing crops to maturity in advance of their natural season by means of artificial heat is known as forcing. In large gardens the process is usually carried out in forcing-houses, scientifically heated; but it is quite practicable under less elaborate conditions, and out-of-season crops may be obtained by means of a small, warm greenhouse, a hotbed in the open, or even in the cellar of a dwelling-house.

*Forcing. Examples of methods of forcing in gardening. Explanatory details of the above diagrams will be found in the text.*

Fig. 1 shows how mushrooms can be forced beneath greenhouse staging in soil kept in position by boards, and secluded from light by sacks or draping tacked to the edge of the staging. Sea kale, rhubarb, chicory, etc., may be forced in this manner. Other methods are shown in Figs. 2 and 6, the former being merely a

flower-pot inverted over another containing the plants, with a cork plugging the top drainage hole (a), while the latter displays a box holding roots, with another turned upside down and placed on top. These three methods are equally useful in the greenhouse, or sheltered in a cool, dry cellar or shed.

Methods of forcing in the open air are shown in Figs. 3 and 5, the former being a sectional drawing of a good type of forcing-pit, by means of which many crops may be raised with success. It consists of a hotbed sunk 2 ft. deep, resting on a layer of brickbats, and boarded round the sides. A frame, some 9 in. narrower than the pit, is placed on top, with about 9 in. of soil inside. Such a pit must always be situated in well-drained land, where the manure will not get water-logged during wet periods, and during frost it should be banked round with leaves or litter, as at a.

Fig. 5 shows how rhubarb, seakale, etc., may be forced by means of a box placed over the plant, this in turn being covered with leaves or stable litter. A hole is cut in the bottom of the box, so that growth progress may be observed at times, the hole being covered with a removable slab, as shown. Old baths, flower-pots, and other cast-off receptacles, may be used.

Fig. 4 shows how early potatoes may be secured in pots placed in a light, warm greenhouse. A tuber is planted with a single sprout in a pot, with about the quantity of soil shown in the sketch, the pot being filled up with rich soil as soon as the plant has grown to a height of about 6 in. *See Asparagus; Frame; Frost; Greenhouse; Hotbed; Manure.*

**FORFEITS.** In many children's games failure to accomplish a task set, such as guessing something, or breaking a rule, e.g. answering out of turn, or failing to escape from a pursuer, is punished by the offender forfeiting something, e.g. a trinket or handkerchief. At the end of the games these forfeits are called and redeemed, and the process often affords considerable amusement.

One player is chosen to act as judge. He may kneel or sit, but it is essential that he does not see the forfeits. These are held, one by one, over his head, and a jargon which takes various forms is gone through. The judge may be asked: "What is this I hold over your head?" or words to that effect. He in return asks whether its owner is a lady, or a gentleman. He is told and is then asked what the lady or gentleman who owns the forfeit must do to redeem it. Ignorant of the identity of his victim, he then pronounces sentence, and the victim must endeavour to do what he or she is ordered.

The humour of the game lies in these sentences, for they consist of silly and apparently impossible tasks, or actions likely to make the performer look foolish. Such are, bite 2 in. off the end of the poker, which is done by biting with the poker 2 in. away; leave the room with two legs and return with six, which is done by returning carrying a chair; pile two or three chairs upon each other, take off your shoes and jump over them, them referring to the shoes. The player may be

told to pay a compliment to every person in the room; to crawl under the table and bark like a dog; to answer "No" to questions put to him by each member of the company in turn; to repeat a verse, stating the number of the word after saying each one; or to hold one foot in his hand and hop round the room. A popular forfeit is for a person to be asked to spell the word Constantinople a syllable at a time. As soon as he gets to the letter i, all the other players shout 'No,' which is the following syllable. The speller, however, naturally thinks that he has made a mistake, and begins again, only to meet with the same disconcerting shout when he reaches it the second time. Another forfeit invariably affording amusement is to require the person to laugh in one corner of the room, to sing in another, to cry in another, and to whistle in the fourth. See Children's Party.

### FORGES AND FORGING PROCESSES Equipment and Instructions for the Amateur Metal Worker

This contribution may be usefully supplemented by reference to such entries as Bent Iron Work; Brazing; Soldering; Welding; Wrought Iron Work. See further the articles on Boring; Hardening; Metal Work, etc.

A knowledge of elementary smith's work is of value to the amateur worker. Much can be done with a few simple tools and a homemade forge. The materials mostly used are wrought iron and mild steel. The latter may have a blue-coloured surface, when it is known as Bessemer. A cold-drawn mild steel is preferable for many purposes, as it has a clean bright surface and is better for cold working, since it avoids the necessity for much cleaning and filing.

Practically speaking, the methods here de-scribed for the hot working of the metal can be applied to cold bending, except that the metal cannot be bent to such a sharp angle when cold without risk of cracking at the bend. Wrought iron should seldom be bent cold, except when the bends are in the nature of a long curve, and free from any suggestion of a right-angle bend. The essentials are a forge, an anvil, some hammers, and a few simple forge tools, such as tongs, which the amateur can make, one or two chisels for cutting metal, and some sets and swages, as well as a strong leg vice.

**Making a Forge.** The simple forge shown in Fig. 3 can be made as follows, and deals with metal up to 1 in. or so thick. The pan (Fig. 1) is made of a piece of stout sheet iron about No. 18 gauge and cut to the shape shown (Fig. 2) with a cold chisel, the sides bent up at right angles and the corners riveted together. The stand is made from four pieces of angle iron about 1½ in. by 3/16 in. thick, riveted to the corners of the pan at the top, and braced together at the back and two sides with diagonal struts of flat iron strip about 1 in. wide and ¼ in. thick, riveted at the top and bottom to the angle pieces.

The bellows should be of the double action type. The

outlet pipe is connected by an iron pipe to the back part of the pan, using standard iron gas fittings for this purpose, and taking care to make an airtight connexion by the use of red lead paint smeared on all joints before screwing them together. The tuyère can be purchased if desired, but an efficient substitute can be made from a short length of iron pipe screwed to the air pipe in the manner shown in the diagram (Fig. 4), and fitted with a reducing bush at the outlet end, or nozzle. The nozzle should be about 6 to 8 in. from the back of the pan, and nearly at the bottom.

*Forge. Figs. 1 and 2. Pan for a home-made forge. Fig. 3. Pan and framework complete.*

*Fig. 7. Above, round or hollow-jawed tongs; below, open-mouth tongs.*

*Fig. 8. Above, top and bottom fullers; below, top and bottom, rounding tools.*

The fire can be lighted with paper and pieces of wood in the usual way, and the bellows worked gently to draw up the fire as soon as it has taken hold. The fuel should be coke or fine slack coal, the former for preference, as there is less smoke. It must fill the pan and be heaped up in the form of a mound, and as the bellows are worked the air will escape through the fire and form a crater of intense heat. It is then known as a clean fire, and is in the required condition for working.

The iron is placed inside and covered with more fuel to exclude the cold air. The surrounding coal may be damped slightly from time to time. The clinker and slag is raked out from the fire, and new coal added as required. The metal should always be covered with the fuel, as this saves much waste and ensures a good heat. The metal is withdrawn occasionally to ascertain the progress of the heat, and as soon as the iron is a good bright red heat, generally known as a cherry red, it is in a fit state to work.

**Anvil and Tools.** The anvil should not be less than 1 cwt. in weight, and heavier for preference. It should stand on a solid box as a base, and the top of the anvil should be about 26 in. above the floor. The parts of an anvil are lettered as follows in Fig. 5: A is the body, generally made of wrought iron; B is the horn, and C the base of the horn; D is the face, made of hard steel welded to the body; E is the hardie hole, and F the pritchel hole. The hardie hole is used to hold the shanks of the tools, and the pritchel hole to permit the passage of stock metal while making bolt heads and the like. The two side edges of the face are often rounded off for a short distance from the horn in order to facilitate the bending of rod metal.

The best hammer for all round use is a ball peine one weighing 1½ lb. to 2½ lb. The face should be rounded off slightly so as not to mark the hot metal, and to assist in preventing the face of the hammer breaking away at the corners. The front edge of the face is known as the toe of the hammer, and the back or face nearest to the worker as the heel. A 3½ lb. cross peine hammer, or a hand sledge of about the same weight, will answer practically all requirements. A sledge hammer is only needed when a helper or striker is available, and one who is capable of handling the tool in the proper manner, otherwise the amateur had better be content with the hand hammer.

A pair of flat-jawed or open-mouthed tongs, and a pair of hollow-jawed tongs can be made or purchased. Their form is shown in Fig. 7. To hold the work properly the tongs should be fitted to the thickness of the job by heating the jaws to a red heat and hammering them together while a piece of the metal to be held is gripped between the jaws, as in Fig. 6. The tongs should not be left in the fire.

Other tools that may be purchased as occasion demands are a flatter, one or two fullers, and one or two rounding tools or swages. The appearance of these can be judged from the illustrations (Fig. 8). The flatter (not shown) resembles the top fuller, but has a large square head. Flatters, fullers and swages require an assistant to hold the tools. The shank of the bottom tool

rests in the hardie hole of the anvil, as shown in Fig. 11 on the next page. The vice must be a good strong one of the regular blacksmith's or leg type, as shown in Fig. 9, and in addition it must be firmly fixed to a strong bench.

*Fig. 9. Blacksmith's type of leg vice.*

**Simple Manipulation.** As a first attempt an angle bracket can be made, measuring 6 in. long, 4 in. wide, and from stock 1 in. wide and ¼ in. thick. Take a piece of metal of this size and at a distance of 4 in. from the end make two heavy centre punch marks, one at each side of the bar. Place the metal into the fire with these marks in the centre of the fire, and blow it to a cherry-red heat. Do not use more air than is needed to get a hot fire, as an excess of air causes scale or hard deposit on the surface of the metal. When the metal is red-hot remove it from the fire and place it on the anvil with the centre punch marks on the edge of the face, the bulk of the bar resting on the face of the anvil and the 4 in. part projecting. Hammer it over by hitting the extreme end until the metal is nearly close up to the body of the anvil, then hammer the corner to make it square and true.

It will probably be found that the bar has been knocked over so that the two legs of the angle are not in line, and this has to be corrected by placing the metal on the face of the anvil and beating it flat. Do not work on the metal after it has cooled to a black heat; it must be reheated and the work may then proceed. To flatten the angle faces, they are laid flat on the face of the anvil, and the flatter held by an assistant, while the worker strikes the top of the flatter with the heavy hand hammer.

The same result is obtained by careful use of the hand hammer. The metal can then be cut off to length, either with a chisel and hammer or by the use of the hacksaw. While the work is being heated the greatest care must be taken not to burn the metal, this being apparent by the appearance of bright star-like sparks, or it will be useless.

All manner of flat bends are made in the same way. As an example of curved work, assume that it is desired to make an S hook from metal about ¾ in. diameter. The first step is to cut the bar to length and true up the ends by means of a file. Heat about half of the metal and, holding it in a pair of tongs, lay it on the

horn of the anvil and hammer on the far side of the horn in such a way as to bend the bar downward. Draw the bar back and forward and continue the hammering until the bar is bent nearly into a circle. Heat the other end and hammer it over as before, using the end of the horn as a guide to the shaping. Then lay the hook on the face of the anvil and flatten it with a blow here and there as requisite to cause it to lie flat. If necessary, reheat the metal and lay it flat on the face, and with a few well-directed taps complete the shaping.

*Forge. Fig. 10. Drawing down a piece of metal. Fig. 11. Using the swage tools. Fig. 12. Increasing the diameter of a bar. Fig. 13. Forming the eye around a bolt hole. Fig. 14. Twisting a hot bar with tongs. Fig. 15. Making an angle bend in the vice.*

Both the foregoing are examples of simple bending which could be accomplished cold. The use of a forge is more apparent when the sectional area or shape of the bar is to be altered, as, for instance, when converting a round to a square. An example of this is found in a simple bolt which can be made by taking a piece of square stuff equal to the size of the head, and drawing down the bar to a round shape. This is done by hammering it over the base of the horn with the hand hammer, as shown in Fig. 10, thus increasing its length without widening it very much. The bar is drawn out square, hammered on the sides and made octagonal, then rounded and finally finished with the rounding tools or swages in the manner shown in Fig. 11.

#### Increasing the Diameter of a Bar

The process of increasing the diameter of a bar is known as upsetting, and is accomplished by holding the heated bar upright on the anvil and striking it on the end, thus reducing its length. If the heat is located at the end of the bar, and that end dropped vertically on the anvil, and then struck a blow, it will bulge out at the bottom. By localizing the heat, that is, by heating

as nearly as possible at the desired spot, and cooling the adjacent parts with water, the bar will bulge at the hot part and nowhere else when it is struck on the end as shown in Fig. 12. Local swellings, as for example the eye around a bolt hole, are formed by driving a punch through the hot metal and then inserting a mandrel, or tapered piece of steel, and hammering the edges of the metal while the bar is in the hole, at the same time keeping the bar driven up into the hole (Fig. 13).

Some very effective work is accomplished by twisting a bar of hot metal. This is done by gripping the bar in the vice and twisting the other end with a strong spanner or with two pairs of strong tongs, as in Fig. 14, of a size to suit the bar being twisted. Instead of doing all the bending on the anvil, the amateur will find that good results are given by grasping the work in the vice and then knocking over the part to be bent; but this must be done quickly (Fig. 15).

**FORGET-ME-NOT.** The popular name of myosotis, of which several kinds are grown in gardens. Some of them are suitable for the rockery, while others are used for filling spring flower beds in association with bulbs. The common early spring forget-me-not is *Myosotis dissitiflora*; it is a mistake to grow the ordinary kind, for there are modern varieties with rich blue flowers which provide a finer display. Royal Blue is one of the best. Seeds are sown out of doors on a prepared seed bed in May, and the seedlings, once transplanted, are finally planted in autumn where they are to bloom in spring. The easiest way to raise a fresh stock of forget-me-nots is to lift a few old plants when the blooms have faded and replant them on a reserve border where the seeds will fall and produce numerous self-sown seedlings. *Myosotis palustris*, the water forget-me-not, is a beautiful flowering plant very effective for the bog garden and water side.

*Forget-me-not. Flowers and foliage of a variety of Myosotis.*

One of the best rock garden forget-me-nots is *alpestris*; it flourishes in well-drained gritty soil and is raised from seeds sown in a pot of light sandy soil placed in a frame in spring. The so-called New Zealand forget-me-not is *Myositidium nobile*, a vigorous plant 15 in. or more high, with large evergreen leaves and blue forget-me-not like flowers in summer. It is a difficult plant in many gardens and is usually happy only in the mild western maritime counties.

**FORK:** For the Table. Some forks are entirely made of silver or plated metal, but fruit and fish forks may have handles of ivory, mother of pearl, bone, or

their substitutes. Silver forks will last a very long time, but electro-plated ones tend to become tarnished as time goes on.

Pickle forks are obtainable with telescopic handles, which enable them to be extended to reach to the bottom of a tall jar and obviate soiling the fingers. In choosing carving forks attention should be paid to the safety claw. In the best makes of stainless steel, the claw ensures perfect control over the joint or poultry which is being carved.

An implement exists for cleaning between the prongs of a fork. It consists of a number of small spiral brushes mounted in a wooden surface, the brushes being so placed that they just fit in between the prongs.

The table fork seldom calls for more in the way of repair than a re-shaping of bent prongs, which are easily straightened out with a small hammer and a hardwood block. At the same time, the points may be re-sharpened, or re-shaped, with the aid of a small file. In both operations care should be exercised to avoid damage to the plate, should the fork be electro-plated, by hammering cautiously and lightly, and by only using the file in order to take off any roughness on the prong.

Carving forks, and others, such as those used for table condiments, are often made with ivory, horn, or bone handles, and these become loose and require refixing. Many of the modern forks are made with a serrated tang which is claimed to be immovable, whereas the earlier forks were nearly always secured by rivets passed through the handle and the tang of the fork. If the tang has been riveted and the rivet be broken, it merely requires a new rivet, and to load the hole in the handle with liquid cement immediately prior to inserting the tang in its place. If the tang is broken off at the rivet hole, as is often the case, the amateur will do well simply to refix the fork on to the handle by filling the hole in the handle, then pushing the fork into place, allowing it to set hard, and then drilling a small hole through the handle and the tang and securing it with a rivet.

The cement used may be composed of resin and white sand, or 6 parts of resin,  $1\frac{1}{2}$  parts of beeswax, and  $1\frac{1}{2}$  parts of plaster of Paris, dissolving this by first heating the beeswax and resin, and then stirring in the plaster until a thin, soft paste is formed. The tang should be warmed prior to inserting it into the cement-filled hole in the handle.

**Broken Guards.** Carving forks frequently suffer from a broken guard. Their repair depends upon the design. Generally a flat spring sunk into a recess formed in the fork keeps the guard in place. Should this break, punch out the old pin, while holding the fork over a suitable hole in an anvil or on a block of wood or lead. Then clean out the slot and remove the old piece of spring; obtain a new one to pattern, insert it, replace the guard, and grasp it in a vice or strong pair of pliers, using a piece of leather to prevent the fork from being scratched.

Then with the assistance of a piece of steel wire of appropriate thickness, previously prepared and pointed at one end, feel for the holes, drive the pin through, test

the guard to see that it works properly, finally cut the wire off close to the fork at each side and slightly rivet up. Take care not to rivet the guard too tightly, or it will be prevented from working. *See Carvers; Cutlery; Knife; Pickle Fork; Silver; Toasting Fork.*

**FORK: For the Garden.** A garden fork is usually a three-pronged implement, the fork part being of iron and the shaft or handle of wood. It is used for turning up the soil, digging up potatoes, and for other work where it is more suitable than the spade. A good fork should have the handle well fastened to the prongs. It should not be left exposed to damp, as the wood may rot. *See Digging; Spade.*

**FORM.** This simple design of seat has its domestic uses. Fig. 1 represents a type suitable to be made in deal. The necessary dimensions are indicated in Figs. 2 and 3. The end uprights are cut from  $1\frac{1}{4}$  in. stuff to the size given, allowing  $1\frac{1}{4}$  in. for the thickness of the top. At the top edges, corner notches are cut away to take the side rails (Fig. 2), which are screwed in, and a mortise cut lower down in the centre for the lower rail.

*Form. Fig. 1. Simple design for a deal form. Fig. 2. End upright, showing notches for side rails. Fig. 3. Part of side elevation. Fig. 4. Lower rail, showing wedges.*

A small shoulder is cut on both edges of this rail, so that allowance must be made for this in the mortise; also for the wedges (Fig. 4). Having made the joints, the shapings may be cut on the ends and the three rails prepared. It will be noticed that the top rails project beyond the ends, this giving greater strength to the screws, which would otherwise be apt to break away at the ends.

When putting the job together glue the lower rail in first and wedge it, and screw the other rails on afterwards. The top may be secured by screwing from

underneath, or may be nailed on if desired, in which case the nails should be punched in. For a hall the form might be stained dark oak and polished. If intended for a nursery it can be enamelled white or any pale shade, the uprights and corners being decorated with suitable stencils.

**FORMALIN.** A watery solution of formaldehyde, formalin is a powerful antiseptic. It is much used as a disinfectant, as it has the advantage of not affecting coloured materials. *See* Disinfectant; Fumigation.

**FORSYTHIA** (Golden bell shrub). This is one of the finest of all early flowering hardy shrubs. In March and April the leafless branches become wreathed in yellow bell-shaped blooms. The best for the average garden is *Forsythia spectabilis* 6-8 ft. high. *Forsythia suspensa*, which is of slender, rather drooping growth, may be planted in the open but it is better on a wall; it thrives fairly well on a shady wall but better on a sunny one. The pruning of forsythia is carried out as soon as the flowers are over; old branches may then be cut out and others shortened. The object is to force the shrub to make fresh shoots which will bloom well the following spring. *Forsythia* flourishes in ordinary soil and is easily propagated by bending down the tips of branches and pegging them in the soil. When firmly rooted the ends of the branches should be transplanted.

*Forsythia. Spray of the brilliantly coloured flower-ing shrub known as the golden bell tree.*

**FOULARD.** Foulards are often, but not invariably, woven with a fine twill, and are firm without being stiff or heavy. The name is given rather to the design than to the fabric itself, which may be woven of silk or mercerized cotton.

The commonest type is blue with a white bird's-eye spot. Black and brown are other favourite colourings with a white spot, which is obtained by discharging the colour, so showing the white of the original silk beneath. Oriental and conventional floral designs are also frequently used.

Cotton foulards have not the good appearance of silk, soil more quickly, and when creased do not lose their folds readily. *See* Silk.

**Foundations.** *See* Brick; Concrete.

**FOUR-STROKE** or Otto Cycle. This is the term given for the cycle of operations in the most common type of internal combustion engine. The full cycle occupies two revolutions of the engine crankshaft; a complete operation is performed by a half-revolution of the crank, it being understood that a half-revolution completes the full distance travelled by the piston. The sequence of the cycle is (1) induction: the gases are

drawn in by the descending piston; (2) compression: the gases are compressed by the rising piston; (3) explosion: the gases are fired, and force the piston down (power stroke); (4) exhaust: burnt gases are expelled by the rising piston. *See* Internal Combustion Engine; Motor Car; Two-Stroke.

**FOWL: Choosing and Trussing.** In selecting a fowl for roasting, choose one that is young and plump. Male birds are superior to hen birds for roasting; they should have big feet and knee-joints, and the claws and beak should be easily broken, while the breastbone should be supple. If the neck and feet are very thin and a purple tinge is visible through the skin of the thigh, the bird is old. Old birds may be used for boiling or in the preparation of many made dishes, and the carcasses are excellent for improving the strength and flavour of stock for gravies and soups. An old fowl which would be tough if roasted in the ordinary way can be rendered eatable if boiled gently for an hour and then roasted for half an hour in a moderate oven.

When the bird is prepared at home, commence plucking from under the wings, then gradually work all the feathers off the bird, clearing the breast first. Care must be taken not to break the skin by dragging off the feathers roughly. Pick out the stumps remaining in the wings and legs, and singe off the hairs with a lighted piece of white paper. Lay the fowl on its back on a table and sever the neck where it joins the body. Remove it with the head, but leave sufficient skin in front to turn neatly underneath and cover the opening. Draw out the crop and loosen the entrails, cut across the vent and insert the fingers in the bird to find the gizzard. Pull this out, together with the remainder of the inside, and wash the neck, heart, liver, and gizzard, cutting open the last-named and removing the bag of stones inside it. It is important that the gall-bag should be taken away unbroken, otherwise anything it touches will be bitter.

**How to Truss.** Before trussing the fowl, scald and scrape the feet and scaly part of the legs. Cut off the feet and throw them into the stockpot, then wipe the bird inside and out with a cloth dipped in hot water. The bird may now be stuffed at both ends with veal forcemeat, if desired. To truss the bird for roasting, twist back the wings so that they form triangles at the back; then thread a trussing needle with string and make a knot at the end. Pierce the nearest pinion, taking the needle out at the back and catching in the skin of the neck, which should be folded neatly over. Draw the needle through the pinion on the other side, then return, piercing the wing lower down and catching in the top of the thigh on each side. The needle should come out through the lower portion of the pinion. Unthread the needle, tie the two ends of the string securely, and the wings should be in shape.

To truss the legs, pass a threaded needle through the end of the thigh-bone at the back and arrange the legs

neatly, folding the skin of the lower portion of the breast under them. Draw the needle back, catching in the legs, passing through the flesh and come out through the wings; then tie the string securely. If fowls are trussed without skewers they are more easily dished up, and all that is necessary to untruss them is to cut the string and pull the knotted end. To truss for boiling, loosen the skin of the legs by working it free with the fingers. Cut the bones of the feet right up to the flesh, and push the legs up into the body until they have disappeared under the thigh. The trussing may now be completed as for roast fowl, except that the stumps of the legs must be so arranged as to be invisible. All the methods of cooking chickens can be applied to fowls. *See* Boning; Carving; Casserole; Chicken; Curry; Duck; Egg; Forcemeat; Giblet; Goose; Poultry; Stuffing; Turkey.

**Fowl Manure.** This is of great value in the garden, but it is potent and must be used with care. The best plan is to keep it under cover and to mix it with twice its bulk of soil before use. The mixture may be applied to fruit bushes, vegetables and flowering plants in spring at the rate of 3 oz. per square yard or yard run of row.

**FOX: The Fur.** This fur ranges in value from that of the Japanese, Kitt, Turkish, and Patagonian foxes to the more expensive white, blue, and silver. The cheaper kinds are almost invariably dyed, and may be obtained in a variety of colours. The fur sold as black fox is almost always a red or white skin dyed, as the genuine black fox is rare and extremely expensive. Silver fox is also rare, and for firmness and softness it has no equal. Blue fox fur is brownish grey in colour, or, in the best specimens, a deep slate.

Arctic or white fox is considered the best kind for dyeing purposes, as its skin is less likely than others to change colour after the process. As a white fur, however, it needs frequent cleaning, and should not be worn in a smoky atmosphere. Hot bran, rubbed into the fur and brushed or beaten out again, is the best cleaning medium.

Cross fox is of the same species as red fox, but its coat is marked with yellow streaks and a dark line runs down the centre of the back. Grey fox is used largely for making rugs and footbags, Fox furs generally, because of their softness and tendency to mat, are not recommended for durability. *See* Fur.

**FOX AND GEESE.** This is an excellent game for a children's party, either indoors or out. One person, usually an adult or one of the older children, is the mother goose, while a second is the fox. The remainder form a long chain behind the mother, with arms round each other's waists. It is then the business of the fox to catch the geese.

The mother attempts to stop him doing so by holding out her arms as widely as possible and turning him back whenever he tries to get past her. As he may only take the last member of the chain, and may not force his way past the mother, it requires considerable agility

for him to circumvent her. As the chain grows shorter the difficulty increases. The game continues until all the geese have been captured by the fox.

**FOXGLOVE.** The common foxglove is *Digitalis purpurea*, a well known plant suitable for the shady border, and for open spaces in the woodland garden. It sows itself freely and there is usually no difficulty in maintaining a supply. Often the seedlings are so numerous as to be a nuisance. The old reddish-purple varieties are far inferior to the modern ones, and these ought to be grown. The Shirley strain of foxglove provides tall plants with fine flowers in many showy colours. The yellow foxglove also is beautiful. *See* *Digitalis*.

**FOX TERRIER.** This dog has quick intelligence and most of the virtues that recommend a dog for companionship in the home or on a ramble. It is true, he is properly a sporting dog, bred definitely with the object of entering a fox's earth and driving out the recluse for whom both hounds and hunters are waiting; but he adapts himself quite easily to a domestic rôle, contenting himself with an occasional rat-hunt or the discomfiture of tramps.

*Fox Terrier. Left, specimen of the smooth-haired breed ; right, wire-haired fox terrier.*

For his legitimate business he should be rather small, though the show standard permits him to scale anything up to 20 lb. He should have a rather narrow, flat head, with the muzzle tapering to the always black nose. The ears should be small, V-shaped, moderately thick and drooping, and the eyes small, dark and intelligent; the legs straight, the feet round and compact, the hind legs strong and muscular, with long and powerful thighs. White should be the predominating colour, and the markings should be in either brindle, red, or liver colour.

There are two breeds of fox terrier: the smooth and the wire-haired. The former has a short, smooth and dense coat, of which the individual hairs are scarcely apparent. The wire-haired terrier has a similar coat, but it is overlaid by longer and harder hairs which break up the smoothness of the surface and give an entirely different appearance and feeling. *See* Dog.

**FOX TROT.** The slow fox trot, most difficult of modern dances, is of great assistance in acquiring good

style and balance. Long gliding steps are employed, some taking two beats, counted "Slow" (S.), others one beat, counted "Quick" (Q.), and these, together with the correct use of contrary body movement (C.B.M.) make this dance one of graceful curves, not merely a series of straight steps.

*Fox Trot. Figs. 1 and 2. Steps of the natural turn for both partners. Figs. 3 and 4. Those of the reverse turn.*

The fundamental steps are the walk and the three-step. For the walk forward, take a long gliding step (S.) straight from the hips, on heel first but going immediately on to flat foot and keeping the weight of the body over the front foot. Repeat with the opposite leg. For the walk backward swing leg well back from hip, going on to the ball of foot first and keeping weight over front foot. As step continues the weight should be carried between the feet and the toes of front foot leave the floor so that the pressure is on the front heel. Repeat with opposite leg. For the three-step take three natural length steps to four beats of music, counted Q.Q.S. When moving forward, go on to heel first, rising on to ball of foot. Take second step on ball of foot, and lower as the third step forward is taken on to heel first. When moving backward, take first step on ball of foot, rising up as the second step is taken on to ball of foot and lowering the heel of this foot as the third step is taken back on to ball.

Standardized figures are the feather step, natural turn (Figs. 1 and 2) and reverse turn (Figs. 3 and 4).

The gentleman's feather step (S.Q.Q.S.) consists of a long step forward with right foot (R.F.), and a three-step taken as follows. Forward with left foot (L.F.), preparing to pass outside partner, forward R.F., outside partner, forward L.F., in front of partner. C.B.M. is used on the first and fourth steps. A rise is taken at the end of the first step, retained for the second and third, and dropped as the fourth step is taken. The lady's feather step commences with a long step back with L.F. followed by a three-step, back with R.F., back with L.F. (her partner steps outside), back with R.F. C.B.M. and rise and drop are the same as for gentleman.

The gentleman's step in the natural turn (Fig. 1) counted S.Q.Q.S.S.S., is as follows: Forward with R.F., turning on it to R. to side with L.F. (commencement of three-step), still turning, back with R.F., back with L.F.,

turning on it to R.; pull R.F. back to L.F., turning from L. heel on to R. heel, forward with L.F. The lady (see Fig. 2) steps back with L.F., turning on it to R., closes R.F. back to L.F., turning from L. heel on to R. heel, steps forward with L.F., forward with R.F., turning on it to R., to side with L.F., and brushes R.F. through (close to L.F.) and steps back with it. Both dancers use C.B.M. on first, fourth and sixth steps. The figure makes just over three-quarters of a turn.

The reverse turn (Figs. 3 and 4) is counted S., Q.Q.S., Q.Q.S. The gentleman steps forward with L.F., turning on it to L., then takes two three-steps, the first consisting of a step to side with R.F., still turning L., back with L.F., back with R.F., turning on it to L. The second three-step is taken to side with L.F., forward with R.F. outside partner, forward L.F. in front of partner. The lady steps back with R.F., turning on it to L., closes L.F. back to R.F., turning from R. heel on to L. heel, steps forward with R.F., and again forward with L.F., turning on it to L.; steps to side with R.F., back with L.F., and back with R.F. Both dancers rise and drop as in the ordinary three-step on the second, third and fourth steps, rise again at end of fourth and remain up for the fifth and sixth, dropping as the seventh step is taken. C.B.M. is employed on the first, fourth and seventh steps. The complete step makes just over three-quarters of a turn.

The diagrams show R.F. shaded; L.F. in outline; position of foot after turning on it, in dotted outline. To follow them face direction of toes, turning diagrams at same time. See Dancing; Quick Step; Waltz.

**FRACTURE.** The usual cause of fracture is external violence. It may be direct, as when a cartwheel runs over a limb, or indirect, as where the jolt caused by a fall on the shoulder or elbow breaks the collar bone.

There will be swelling over a fracture, and a shortening may occur. In the course of a few days the broken ends are connected and surrounded by a mass of soft tissue known as callus, which is later converted into bone. Strong bony union usually takes place, but, instead of bone, gristle or cartilage or simply fibrous tissue may be formed, allowing of more or less bending of the bone, and in this way constituting an un-united fracture.

First aid consists in checking dangerous bleeding by pressure on the main artery, and in the application of an antiseptic or clean dressing to the wound in the case of a compound fracture. In all fractures the ends of the broken bone must be kept at rest to prevent further damage, and if the doctor can be on the spot early, or the accident occurs indoors, this may be accomplished by using pillows, cushions, bricks, etc., to support and restrain the limbs. If the patient requires to be moved at once, splints should be applied, and any material may be used for the purpose if it is sufficiently rigid, e.g. sticks, umbrellas, folded newspapers, etc. When there is difficulty in obtaining splints, an upper limb

may be fixed against the trunk, or the lower limbs can be tied together until splints are available. The splints should be padded with clothing or other soft material and should be applied on the inner and outer sides of the limb.

In removing persons suffering from fractures of the thigh or leg the stretcher should be a rigid one. A door taken off its hinges would be very suitable if a stretcher has to be improvised. If a person suffering from broken thigh has to be carried uphill he should be carried feet first, and the reverse on going downhill, so that the weight of the trunk may not press down on the injured limb.

The first thing done in the treatment of a fracture by a doctor is to set or reduce it, that is, to bring the broken ends as nearly opposite to each other as is possible. Then splints of some sort are applied to keep the bones in their correct position. After a few days the limb is massaged each day, and the doctor makes passive movements at the joints to prevent stiffness. After some weeks the patient will make movements for himself. Before putting the full weight of the body on a broken lower limb he should use for some time a crutch, and later a stout stick.

The term extension for fractures means the mechanical stretching of a limb or part of a limb, and is required most often in fractures of the shafts of the bones. One way of doing this is to fix long strips of adhesive plaster to the sides of a limb, say, the leg. The ends of the strips are attached to a horizontal piece of wood, or stirrup, a few inches below the sole of the foot. A stout cord is attached to the centre of the stirrup by drilling a hole through the latter, and is then led over a pulley and made taut by having a weight attached to its lower end. *See* Ankle; Arm; Bandage; Colles' Fracture; Dislocation. First Aid; Shoulder; Splint.

**FRAME:** For the Garden. Every gardener realizes that a frame removes many of the restrictions which hamper his operations all the year round. It is indispensable for the raising and growing of flowers and vegetables in spring and summer, whilst during autumn and winter it is a means of rearing and preserving plants that would otherwise succumb to the first hard frost. Various types of frames are here illustrated.

It is an advantage to set the frame on a hotbed of manure or of manure and leaves; the hotbed, which can be made up in March, should project 12 inches beyond the frame.

A suitable compost, which should be 1 ft. deep in most cases, is composed of three parts loam and one part leaf-soil. Protection is necessary during severe weather, and this may consist of sacking, mats, bracken fern, etc.

Ventilation lights should always be raised on the opposite side from which the wind blows, using wedged or stepped blocks for the purpose, similar to those shown. Watering should be done early in the day, so that foliage may be dry before night. Plants are more easily cut down by frost while their leaves are damp. Amongst plants and seedlings for raising, growing,

forcing, or bringing-on, in frames possessing a mild hotbed, are the following:

Brussels sprouts, cauliflowers, celery, lettuce, mushrooms, parsley, strawberries, rhubarb, onions, tomatoes, cucumbers, early potatoes, leeks, melons, marrows, begonias, violets, pansies, half-hardy annuals, etc.

*Frames for the Garden.* Fig. 1. Brick frame: a, cement foundations; b, toplight; c, compost; d, hotbed. Fig. 2. Same extended for outside heat; a, outside walls; b, hotbeds; c, compost. Fig. 3. Movable wooden frame: a, hotbed; b, compost; c, toplight. Fig. 4. Turf-walled frame: a, turves; b, soil level; c, support for toplight; d, toplight. Fig. 5. Another turf structure with wooden rests for toplights. Fig. 6.

Section of sunk frame for hardening-off seedlings: a, fine ashes; b, cinders; c, bricks to support toplight; d, toplight; e, ground level. Figs 7 and 8. Ventilating wedges.

*Frame.* Fig. 9. Portable garden frame with sliding lights. Figs. 10 and 11. Details of guides and slides, showing water grooves.

Fig. 12. Side elevation. Fig. 13. Front elevation.

A handy type of emergency frame is shown in Fig. 4. This will be found useful, as a protection for hardening-off tender seedlings, for the growing of early salad vegetables, and for sheltering plants that will not withstand the rigour of winter.

In gardens of ample accommodation a plain brick example may be devised according to Fig. 1, and if necessary by extension as in Fig. 2, in order to obtain increased heat from hotbeds placed outside. Such a frame should be erected in a position with a south aspect. A good average size is 6 ft. wide, 2½ ft. deep at the back, and 18 in. high at the front. If a wooden frame is preferred, the dimensions may be the same.

Where the garden is small a movable frame, similar to that shown in Fig. 3, is recommended. A structure of this kind, during early spring, autumn, or winter, may easily be removed to a position facing south. In summer it can be situated in a spot screened from hot sunshine. The fourth type figured is one built of turves, with a glazed wooden top-light. Another style of turf frame is displayed in Fig. 5, a type often used for the growing of early potatoes.

**A Portable Frame.** Fig. 9 shows a useful frame of convenient size which the amateur can easily construct for himself. The glazed tops are made to slide. Suggested dimensions are indicated in Figs. 12 and 13. The lower portion can be made in 1 in. matchboarding, nailed together, and with corner blocks screwed inside. At each end, and projecting just the thickness of the top, i.e. 2 in., a guide is screwed from the inside, as in Figs. 11 and 13. A centre slide and guide is made as in Fig. 10, and fixed to the back and front, the slide being cut into these to bring them to the same level. The water grooves formed in the slides should be carefully noted.

The front rail of the top glazing frame is thinner than

the other rails, and the glass runs right over it; this is necessary in order to allow the water automatically to run off at the front. The frame is rebated on the inner edge and mortised together, the joints being dowelled to fix them; they should be put together with white lead paint, as glue is unsuitable. The cross-bars may be cut in the solid and rebated, or they can instead be of two pieces screwed together; in each case they are mortised into the main frame. A water groove is cut at the under side about ½ in. from the front to prevent the water from creeping back into the frame. If several small panes of glass be used, the upper square should overlap the lower one about ¾ in., and a tack be put at the bottom of each glass to prevent it from slipping; putty is used to secure it in the rebate. All the woodwork should receive at least two coats of paint.

The great value of a portable frame is that it can be placed in the sunniest position during the winter months and in shade for the summer. A most useful type is that which is built against the wall of a heated greenhouse, openings being left in the brickwork to allow the warmth to reach the frame.

In the latest type of garden frame, steel instead of wood is used in its construction. The advantages of this type are that the framework is more durable than in the old wooden type, more light is admitted as the steel sashes are thinner, and the trouble of warping is eliminated. Another type of frame favoured by modern gardeners is the span-roofed. In this the "lights" are hinged to a central ridge, and when open they are held secure by means of steel hoops or rods. Such frames are easy to manipulate as regards ventilating, watering and shading, and can be obtained with either wooden or steel framework.

A garden frame is invaluable for raising plants from seeds and cuttings. In early spring many kinds of half-hardy annuals, herbaceous perennials, and vegetables can be sown in boxes in an unheated frame, the seedlings being planted out in the open garden when danger of frost is past. In early summer the frame may be used for rooting cuttings of rock garden and herbaceous plants, to be followed in late summer by cuttings of summer bedding plants and many kinds of shrubs. Plants that are frost-tender may be grown in the frame during winter, their safety being ensured by covering the frame with straw mats during severe weather. It is wise always to set a garden frame on a foundation of brick or concrete; it will then last for many years. *See Forcing; Garden; Hotbed Kitchen Garden.*

**FRAME AERIAL.** The form of wireless receiving aerial which is built into a portable or transportable receiver. It usually comprises a number of turns of wire wound round the framework of the set, though in some instances it is made as a separate unit and fixed flat up against the inside of the back of the cabinet.

It is not an efficient type of aerial, but, owing to the

sensitivity of modern circuits, good performances are possible with small self-contained sets employing the principle.

A frame aerial is highly directional. It receives at its best when its plane is in line with the transmitting station. That is why the majority of self-contained sets have turntables in their bases so that they can easily be swung round. There are advantages attached to this effect. For example, the effective selectivity of the receiver is increased and interference, particularly that from other stations, can often be greatly reduced by judicious adjustment of the position of the set. Also these directional qualities of a frame aerial can be used for controlling volume in addition to the automatic or manual volume control incorporated in the set. *See Aerial.*

**FRAME SAW.** A frame saw is a large flexible saw blade carried in a wooden frame which has a certain amount of "give," so that the saw blade can be tightened by turning a bottle screw. The teeth of a frame saw are coarse, as the tool is intended for rough work, such as firewood. *See Bow Saw; Saw.*

**FRANCOA.** These graceful plants, popularly known as bridal wreath, are not quite hardy, and are generally grown in pots for greenhouse, conservatory, and window decoration, or they are planted out in conservatories. In mild districts they may be grown out of doors all the year round; in other places they should be kept in a frame during winter. They are propagated by seeds sown under glass in spring or by cuttings. *Francoa ramosa*, with white flowers, is the favourite kind; it is a perennial, 2-2½ feet high.

**FRANGIPANE.** This perfume was intended to combine all the chief odours; it has the reputation of being the most lasting perfume made. The recipe is as follows, the ingredients being mixed and allowed to stand for a month, then filtered through absorbent paper:

Bergamot oil	100 drops
Vanilla essence	100 "
Tolu tincture	60 "
Musk essence	50 "
Rose extract	½ oz.
Cassia extract	½ oz.
Jasmine extract	4 "
Alcohol	½ pint

**FRANGIPANE CREAM FILLING.** This is the recognized term for a filling for pastries, tarts, etc., although often other flavourings, such as vanilla, almond, and so forth, are substituted. It is made in the following way: Melt 3 oz. of butter in a stewpan, add 1 pint of milk, and when nearly at boiling-point beat in ½ lb. of dry sieved flour. Beat this well together until smooth. Stir and cook it over a gentle heat for a few minutes, or until it leaves the sides of the pan without sticking. Cool it for a few minutes, then beat in separately 2 whole eggs and 2 extra yolks. When well

blended add 4 oz. of castor sugar, and some flavouring essence. When cold it may be used as desired for filling tartlets, cakes, etc.

**FRAUD.** Fraud is sometimes a criminal offence. For instance, obtaining goods or money by fraud is a crime. It is also a civil wrong, giving rise to an action for damages. Fraud consists in making a statement of fact knowing it to be untrue, or with wilful or reckless disregard as to whether it is true or not. If such a statement is made with intent that it shall be acted upon, and the person acting upon it suffers loss, it is an actionable fraud. If the person making a false statement honestly believes it true, he is not guilty of fraud.

There is one exception, namely a false statement made in a company prospectus. In such a case, when the statement is proved to be false, every director, promoter, or other person responsible for the prospectus is liable in damages unless he proves that he had an honest and reasonable belief in the truth of the statement.

Any contract induced by fraud may be avoided by the innocent party. He can resist any claim made against him on the contract or can have the transaction set aside, and claim the return of anything paid or transferred under it. But he must be careful to take steps to set it aside as soon as he knows of the fraud. If he does not, or if it is impossible to put the parties back into the original position, the transaction will not be set aside, but the innocent party will be left to his remedy in damages.

As a general rule mere silence or failure to disclose some fact relating to the contract will not amount to fraud. One party is not bound to reveal to the other all the facts known to him about the subject matter of the contract. Sometimes, however, a false impression may be created if certain facts are stated but others are withheld. Where it was truthfully stated that a company had paid dividends for a certain number of years but the fact that these dividends had not been paid out of profits but out of reserves was not revealed, it was held that a false impression was conveyed.

In the case of certain contracts—called contracts *uberrimae fidei* ("of the utmost good faith")—it is not sufficient that each of the contracting parties should merely refrain from making any untrue statements. They must disclose voluntarily everything they know that is material to the contract. The best example of such contracts is insurance. A man who is insuring his life must tell the insurance company every fact that is material—e.g. that he had a serious illness as a child.

**FRECKLES: Their Treatment.** For freckles the following remedy is for outward application only, to be applied at night.

Ammoniated mercury	1 part
Bismuth subnitrate	1 "
Olive oil	6 parts
Glycerin	8 "

Soft paraffin 8 „

A lotion which is intended to be applied to the exposed parts of the face, neck, hands, and arms before going out into the strong sunlight, and which speedily dries, leaving little trace of grease, is made up as follows:

Zinc oxide	2 drams
Powdered calamine	2 „
Olive oil	3 oz.
Solution of ammonia	1 „
Rosewater to make	6 „

The following bleaching lotion applied daily with a camel-hair brush has the effect of lightening the colour of the freckles. It should be kept tightly corked.

Fresh peroxide of hydrogen (10 vols.)	1 oz.
Eau-de-Cologne	1 „
Glycerin and rosewater	1 „

See Beauty Culture; Face; Skin.

**FREEHOLD.** In old English law this is one of the ways in which land is held, others being copyhold and leasehold. Freehold land is the nearest approach to absolute ownership that is recognized by the law. Such land cannot be held by a definite term of years as leasehold can, but must be for an indefinite term or in perpetuity. The owner of it is subject, therefore, to no dues except the ordinary rates and taxes. If he builds a house upon it he is the absolute owner of house and land.

In 1925 an Act was passed which provided for the abolition of copyhold and other antique tenures in England at the end of three years, and therefore for the establishment only of freehold and leasehold landholding. See House; Land; Leasehold.

**FREESIA.** These greenhouse winter and spring-flowering bulbs are much admired for their delicate flowers and sweet scent. As they may be grown in small pots, they are suitable for small greenhouses and also for windows. Many people purchase fresh bulbs every year, but this is unnecessary if ripening and drying the bulbs is properly carried out. The bulbs should be potted in July or early August, putting about six in a 5 in. pot. One pot of freesias is enough for a room. The best soil is a compost of  $\frac{2}{3}$  loam and  $\frac{1}{6}$  each of sand

and well-decayed cow manure. Cover the bulbs with  $\frac{1}{2}$  in. of this mixture. Place them in a cold frame and growth will be evident in a few weeks.

*Freesia. Flowers and leaves of one of the new coloured varieties.*

Keep the plants close to the light and water very lightly, increasing the quantity as growth

develops. Hard forcing is not desirable. After flowering,

water freely until the leaves turn yellow, decreasing the supply as the leaves die down. They are easily increased by offsets in August.

In recent years many charming new varieties in a wide range of colour have been raised. There are now mauve, heliotrope, crimson, rose and orange coloured freesias. Some of these later varieties are less fragrant than the old white and yellow ones.

**FREESTONE:** For Building. Any building stone that can be dressed easily or freely is called freestone; it is generally taken to be the most easily worked stone in a given district. The surface finish can be varied according to the tools employed, and the beds or joints are left rough to prevent slipping, and to provide grip for the mortar.

The principal varieties of freestone in common use are termed the quarry-faced, which is the natural face of the stone as it comes from the quarry; hammer-faced, with the lumps knocked off with a hammer; and chiselled, where the surface is rough and the marks of the tool irregular. When the surface is smoothed and finished it is known as tooled. Rusticated freestone is worked over with chisels in imitation of old and decayed stone, and is capable of producing a very pleasing surface if treated on broad lines and on large areas. See Stone.

**FREE WHEEL.** This is a device on a cycle by which a rider is enabled to keep the pedals stationary, thus allowing the machine to coast while at the same time a restful position is maintained on the saddle. Differing types are the ratchet, the roller, and the coaster hub, the latter being a combination of free wheel and back pedalling brake.

In the first mentioned type of free wheel, ratchet teeth are cut on the inner circumference of the chain ring, and a number of pawls are mounted flush on the outer circumference of the inner member, which latter is screwed on to the hub of the wheel. These pawls engage the faces of the ratchet teeth, thereby transmitting the drive from the chain ring of the wheel.

In the roller or wedge type of free wheel, the inner circumference of the chain ring is ground quite smooth. The rollers, usually five, are on the outer circumference of the inner member in recesses cut with an inclined face. When free wheeling the friction between the inner face of the chain ring and the rollers tends to push the latter towards the bottom of the inclined recesses, but when pedalling it tends to push the rollers up, and thus wedges the chain ring and the inner member as solid, thereby driving the wheel.

This result is attained because the distance between the inclined face and the inner face of the chain ring at its narrowest part is slightly less than the diameter of the rollers. It is usual to fit light springs behind the rollers to keep them in contact with both faces. As a general rule the chain ring runs on a double ring of balls, the races for which are formed on the inner faces of the cover plates and the faces of the chain ring.

The chief essential with all types is to ensure freedom of movement of the parts, and to this end the free wheel should be lubricated at intervals, say every 250 miles or so. It is advisable to wash out the free wheel occasionally with paraffin. To do this properly, lay the machine on its side and apply the paraffin while at the same time rotating the wheel, and keeping the pedals stationary. Leave the machine to drain, then oil the free wheel. *See Bicycle; Coaster Hub.*

**FREEZER: For Ice Cream.** There are many good makes of freezers. One type of small freezer requires about 5 lb. of ice to freeze a gallon of ice cream. In many ways the most satisfactory method is to use the freezing tray of the household refrigerator.

*Freezer. Right, Rapid vacuum freezer. The ice cream compartment opens from the top and the salt and ice container from the bottom. Above, another type of freezer, handy for use at a picnic.*

Vacuum freezers are also obtainable in which ice cream is made by two operations. The ice and freezing salt, in the proportion of three cups of crushed ice to one of salt, are inserted in the outer container after the freezer has been inverted. When this container is half full, pack the ice and salt well down, finish filling and then pour in a cup of cold water, clamp down the lid and reverse the container.

Ice cream is prepared according to instructions given with the freezer and poured into the smaller inner container and covered with a lid. The freezer is again inverted so that the ice and salt compartment is uppermost. Such vacuum freezers are obtainable in various sizes. *See Ices; Refrigerator.*

**FRENCH BEAN: How to Cook.** French beans should be used when very young, for they become tough and stringy when old. Wash the beans and top and tail them, then cut them lengthwise into thin strips resembling grass blades. Small ones need not be cut. Leave them in cold salted water till ready to cook. Put the beans in a saucepan of boiling salted water and boil very quickly with the lid off for at least 20 min. Drain, and shake them over the fire to dry them, add a small lump of butter and a little pepper and salt, and serve them very hot.

French beans can also be stewed. Put  $1\frac{1}{2}$  to 2 lb. into a greased casserole, leaving them whole if they are sufficiently tender, or slicing and stringing them if there are any signs of toughness. Cover them with 1 pint of white seasoned stock, then put the lid on the casserole

and cook until tender. Drain the beans, taking them and the stock out of the casserole. In the casserole melt a lump of butter about the size of a hen's egg, afterwards mixing in a tablespoonful of flour. Then pour on the stock, stir the whole until it boils, and put in the beans. Heat thoroughly and serve in casserole. The cultivation of the beans is described in the article Bean (q.v.). *See Bean Cutter; Diet.*

### FRENCH BULLDOG.

A French bulldog differs so much from the British that one is unable to see the relationship between the two. The bat or upright ears, for instance, are the antithesis of those that are seen on the British national dog; the under-jaw does not project in the same manner, there is less wrinkle about the head, and in addition the chest is not so wide.

Whatever may have been the case originally, the French breed is now distinct in build and temperament. He is quick and active, instead of being slow and lethargic, and he makes an excellent house pet, his average weight being from 20 lb. to 24 lb., though some are a trifle heavier.

The favourite colour is brindle. The coat is short and smooth, the tail short and carried downward in bulldog fashion. *See Bulldog; Dog.*

**FRENCH CHALK.** This powder has a smooth soapy feel, and is used for sprinkling inside boots or gloves to make them slip on freely. In flat cake form it is used by tailors and dressmakers for making marks on dark cloth or other fabric.

The powder is also employed for absorbing grease from silk or other material, for which purpose it is sprinkled upon the grease spot and then ironed with a warm flat iron. It is used as an ingredient in dusting powders and for clearing turbid liquids. For the last-named purpose powdered French chalk is shaken up with the liquid, and the powder, in settling down, leaves it bright and clear. French chalk, alone or mixed with paraffin wax, is sprinkled over a floor to make it smooth for dancing.

**FRENCH COOKERY.** Genuine French cookery does not consist entirely of highly sauced and decorated dishes. It embraces the knowledge of combining flavours so that one does not unduly predominate. Garlic, for instance, should merely accentuate other flavours, and its actual presence should not be detected.

No waste is permitted and no portion from the boiling or stewing of the meat is thrown away. The liquor portion appears as a good brown soup, well flavoured with vegetable and thickened with sago, macaroni or some other similar substance, while the meat is thoroughly impregnated with the taste of vegetable, a little bacon, and a suspicion of spice and red pepper.

In French cookery the sauce always receives due consideration, containing in the stock from which it is made the essence of meat or fish which it is intended to accompany, and flavoured with herbs such as tarragon and chervil.

Dressed vegetables are a distinct feature of French cookery, and make a course by themselves. Cold vegetables are formed into salads, and with a mayonnaise sauce or salad dressing make relishes for cold meat. Salads of all kinds are popular with the French, but great stress is laid on the dressing. Almost any kind of salad herb is used in salads, with portions of meat or fish chopped up, and covered with mayonnaise sauce. *See Casserole; Salad; Sauce.*

**FRENCH CRICKET.** This is a game well adapted to small gardens. It is played by any number, without sides, and there is no scoring. Each batsman plays until he is out, and is then succeeded by the next.

The wicket is represented by the batsman's feet and legs up to the knee. He stands with his feet together, the bat held vertically in front of him, and the first ball is bowled from a spot some few paces off. The batsman must not allow the ball to hit his feet, neither must he move them, or he is out. Any member of the field who stops the ball then bowls it from the spot at which he stopped it, but the batsman must not alter his position except in so much as he can without moving his feet. If the ball is caught by any player he is out.

**FRENCH CURVE.** The French curve is used in drawing and design work, and consists of a thin piece of pear wood, celluloid, vulcanite, or similar material, cut to a series of scientifically designed curved forms. Its use is of the utmost assistance to those who are unable to depend upon a free-hand drawing. The method of use, illustrated above, consists of laying the curve flat on the paper and marking around the edge with a pencil. French curves are sold separately or can be obtained in sets, and are made in a wide range of shapes. Almost any curve can be drawn by combining the various elements from different-shaped curves, but when doing this it is necessary to note if one curve flows freely into the other. As a guide, it is preferable to draw around a greater distance than that actually required for the operation, and then by trying the other curves it is possible to judge which of them is most suitable. The juncture of two curves should be indicated with a pencil-mark, so that when inking in the drawing the distance which should be drawn by the use of one curve will be apparent and the commencement of the other will be clearly defined. By these means the component curves may be prevented from having any suggestion of a sudden change of form or an ungraceful bulge. *See*

Drawing.

*French Curve. Device used by the draughtsman to enable him to dispense with free-hand drawing.*

**FRENCH FOLD.** Raw edges may be finished by what is known as a French fold. This is a wide fold or bind enclosing the edge, turned over to the wrong side and slipstitched down. The strip for the fold may either be cut on the cross or on the straight, according to the shape of the edge to be bound. A French fold may be used to renovate worn or frayed hems, cuffs, etc., or to finish the sleeves and hem of a child's frock.

*French Fold. Method of finishing or renovating edges of material.*

A French fold may be 3 or 4 in. wide or a very narrow fold may be used, but if a narrow one is required a small rolled fold of material called a rouleau may be made. A strip should be cut on the cross about 1 in. wide and placed on the outer side of the material, edge to edge. Run a thread  $\frac{1}{4}$  in. from the edges, turn over to the wrong side, leaving  $\frac{1}{4}$  in. on the right side. Fold the remaining  $\frac{1}{2}$  in., turning it inside, and hem it neatly down. The four thicknesses of fold placed round the edge in this manner produce a good round edge, which is most useful in finishing off the edges of brocade, satin, crêpe-de-chine, and other similar materials, when it is impossible to use an ordinary hem.

Another type of French fold which is useful for the same purpose, and is employed to finish the edges of tunics, frills, etc., is called a French hem, and is made as follows: Run a small tuck on the wrong side of the material as far within the edge as is desired, then roll the tuck downward, turn the raw edge of the tunic up to meet it, and hem or slipstitch down to this.

**FRENCH HONEYSUCKLE.** This is a family of hardy perennial herbaceous plants known botanically as *Hedysarum*. The only species much grown is coronarium, or French honeysuckle. It has

divided leaves with oval leaflets, downy beneath, and spikes of crimson pea-like flowers in summer; height 3 to 4 ft.

The seed may be sown outside in April or May, and the plants put out in autumn where they are to bloom. They will thrive in almost any soil, but require a sunny position. Another species much used is *multijugum*, a shrub or sub-shrub growing 3 to 4 ft high. It flowers in July, bearing flowers purplish red in colour.

**FRENCH MARIGOLD.** A showy half hardy annual (*Tagetes patula*) which is raised from seeds sown under glass in slight warmth in February and March; the seedlings are planted out of doors in May. The dwarf varieties, 9 in., are popular edging plants. There are double and single French marigolds with yellow, orange, and reddish flowers. *Legion of Honour*, yellow and brown, is one of the chief favourites for edging. The tall varieties reach a height of 2 ft.

*French Marigold. A favourite annual for the border.*

**FRENCH NAIL.** This type of wire nail is in general use for rough work. It is circular in section, with a flat head, and is procurable in a wide range of lengths and in many different thicknesses. Sizes in common use range from  $\frac{3}{4}$  in. to 6 in. long. The 1 in. size is particularly handy for fixing beaver and other building boards to the studding. The 3 in. size has many uses in the garden, such as nailing up fencing, while the larger sizes are of value in building construction. *See Nail.*

**FRENCH POLISHING.** This is a process by which a polish is produced on wood. The polish is a solution of gum resins or gums, and its composition varies. Shellac is always the main ingredient and alcohol the solvent. The simplest form of french polish consists of a solution of 6 oz. of shellac in a pint of spirit.

The surface to be treated must first be well coated with polish, and time must be allowed between the rubbings for the polish to settle and dry. At first the main object is to put a shell or covering of polish over the surface, whilst later a glaze is put on the surface thus obtained. It is useless to try and obtain a good

polish on a surface insufficiently covered.

Make a polisher's pad by taking a piece of cotton wool and folding it into a firm pad the shape of an egg, with a point at one end. Cover this with a piece of old linen, not too fine, folding over the pad and gathering the ends up into the palm of the hand. Putt the point well out. Open the pad and pour in the polish from the back; it should never be used on the front. Press lightly on a board or palm of the hand in order to bring the polish through to the front of the pad.

**On New Work.** If the wood is rather porous, give it a coat of wood-filler before polishing. See that the surface to be polished is entirely free from dust. Cover the surface with polish by rubbing gently with the pad, using a circular motion. When the surface is covered, leave a little while to harden.

Should the surface be at all rough, it can be rubbed down with fine powdered pumice used on a rag, but no powder must be left on the surface when polishing is resumed. The pad is replenished with polish from time to time, always putting it in from the back. Continue working in a circular motion until the surface is well covered. If possible, leave it to harden for a short time after each rubbing.

It is usually necessary to body-in, as this process is called, three or four times, leaving a day between each coat. As soon as the work is tacky, leave it until dry otherwise the shell may be pulled off. Never stop in the middle of the work, as that may result in pulling up the polish. Rub down with pumice between each coat.

In finishing off, rub carefully with fine pumice and a drop of oil, working with grain of wood. Give a final coat of polish, using rather a dry pad, and leave to harden for several hours. Take a new piece of cotton wool, and on this pour a very little crystal glaze. Rub all over the object, using a circular motion, and when the pad is almost dry, rub hard until a very bright surface is obtained.

**Repolishing Old Work.** The instructions given above apply to the production of polish on new articles. An old piece of furniture such as the top of a dining-room table is repolished on somewhat similar lines. First mix a cupful of vinegar in a quart of boiling water. Dip a piece of flannel into this and quickly wash over the whole surface of the table to remove any grease. Rub dry and polish it well, using a soft cloth; then rub it down with a piece of sandpaper No. 0 or a rag dipped in pumice powder. If there are any holes or deep marks, fill them with stopping and leave it to dry. Rub down to make it even with the rest of the work, and colour with stain to match the wood.

Brown polish known as button polish is the best to use, as it works well and dries quickly and hard. It can be bought at any oil-shop. Make a pad as explained above, and fill it with the polish. Press on the palm of the hand and work in large circles until the whole surface is covered with figure 8 marks. Keep on going over and over the surface.

Should it feel tacky or inclined to pull up the polish, stop at once and put the job on one side. From time to time continue to body-in until there is a thick coat of polish all over the surface. For table-tops a thin coat is useless, as it will crack at once. Rub the surface over with pumice, but do not scratch it. If it requires more polish, go on bodying-in. Take care to remove all dust or grit.

**Spiriting Off.** This is one of the most difficult jobs for an amateur. It must be done gradually. In working in the polish sometimes a little oil is useful, but avoid using too much, as it smears, and is difficult to get rid of. As the pad needs replenishing, use methylated spirit instead of polish, always putting it in from the back, and employing 1 or 2 drops at a time. Rub a little harder than before, but always in circles or figure 8. When only spirit remains in the pad, if the surface is not sticky, take a clean pad, put a drop of methylated spirit or crystal glaze into it, and rub hard up and down until all smears disappear and the result is a brilliant polish.

Work should be done as far as possible in a warm room. Leave it for 24 hours, and if it has gone dull rub it well again. *See Furniture; Sideboard; Table, etc.*

**FRENCH SEAM.** As it ensures absolute neatness on both the outer and inner sides of a garment, a French seam is widely used, generally on lighter weight materials, in making lingerie, children's frocks, blouses, etc. It may vary from  $\frac{1}{8}$  to  $\frac{1}{4}$  in. in width, according to the material.

A French seam is made by taking the two edges of material to be joined and running a thread on the right side as near the edges as possible, avoiding any chance of fraying. Neaten the edges with a sharp pair of scissors, and turn over to the wrong side. Take the join firmly between the thumb and first finger of both hands and press it down. Run a tacking thread through the pieces of material, far enough from the join to enclose the edges left on the right side, before finally finishing the seam by a machine stitch or running thread.

**FRENCH WINDOW.** For a drawing room, or any other room looking on to a garden or a conservatory, French casement windows extending to the floor level are sometimes preferred. It is essential that they should be exceptionally well-fitting, otherwise the room will be draughty and cold, and they should never be fitted to rooms with a north or north-east aspect. None but thoroughly seasoned wood should be used for the frames of a French window.

It is advisable to make the two casements to open outward. They should be hinged to solid frames, and fitted with rebates in the frames, at the top and bottom as well as the sides, so that they can close tight against each other and against the surrounding framework. To prevent rain or wind from entering it may be necessary to run a strip of rubber down the centre where the casements meet, on the inside. The problem of ventilation can be solved when the room is fairly lofty

by an upper casement hinged horizontally to the top of the main framework and working independently of the vertical casements enclosed by their own frame.

There should be bolts at the top and bottom of one casement and a solid sash-fastening on the other in order to secure it thoroughly. *See Bolt; Casement; Curtains; Window.*

**FRET.** This name is given to any geometrical ornament cut or painted on a flat surface in or on a building. Its most familiar form is the key pattern, derived from the Greeks, which consists of a series of narrow bands set at right angles to one another, so as to form a consecutive geometrical design. There are several variations of this pattern, such as the diamond fret, in which the lines are set diagonally to the top and bottom boundary lines of the decorated space. Fretwork is frequently employed on the outer stonework of buildings where it is desired to relieve the harshness of a bare flat surface. The name fret is also used for the metal plate which closes the opening below a grate. It is often pierced.

*Fret. Variation of Greek key pattern for ornamenting a building.*

#### **FRETWORK: A DECORATIVE HANDICRAFT** Practical Advice on Tools, Materials and Designs

The reader may further be referred to the entries Antofret; Cabinet Making; Chippendale, etc. also to those on the various woods used, e.g. Oak; Sycamore; Walnut.

The term fretwork now has a meaning rather different from that current a few years ago. In place of the elaborate models that were then popular, we have a simpler style in which utility has first consideration. In addition, fretwork has a wider and more important application, owing to the growing popularity of the fret in furniture, and the development of wireless receivers and gramophones, both of which use a fret. Thus the fret has become a decorative motif rather than an end in itself.

*Fretwork. Fig. 1. How the fretsaw should be held.*

*Tension device for tightening the blade.*

**The Tools Required.** The most important tool is the fretsaw frame (Fig. 1). The 16-in. size is recommended, as it is sufficiently large to saw wide pieces of wood without being too heavy. Some form of tension device is an advantage, such as that shown. In regard to the saw blade itself, the No. 2 is suitable for general purposes. Thicker saws than this are used for coarser work, where speed in cutting is desired rather than a fine finish. Smaller saws come in for very thin wood, but are not recommended for ordinary use as they are rather more difficult to control.

An Archimedean drill is used to pierce holes through which the saw can be passed to saw internal frets. Some drills are provided with flyweights to give momentum and facilitate easy running. The actual bit should be a trifle larger than the width of the saw being used. A cutting board will be needed. The wooden one is suggested, as this will not cause any damage to the saw should the latter be run against it. A board 8 in. by 4½ in. is convenient for most purposes. It is held to the table with two small thumbscrews. A glasspaper block is used to clean off the design after the cutting has been completed. This is made of steel and has a flat face covered with a piece of flexible material, to enable it to give to any small inequality in the surface. A set of files is needed to enable the work to be trued up after cutting. These tools are the essential ones. There are others, such as the rule, light hammer, plane, and so forth, which can be obtained as the necessity for them arises.

**Materials.** The wood used in fretwork should be obtained ready planed and glass papered. Such wood has already been brought to even thickness, an important point, because it is essential that joints should fit accurately. Designs are prepared specially to suit standard thicknesses of wood, so that only standard material should be purchased, for preference. Satin walnut is largely used, since it is comparatively cheap, is obtainable in wide widths, and is close in the grain. Oak and mahogany are also employed for better-class designs.

A material which has come to the front in recent years is plywood. This is made up of three or more layers, the centre one running at right angles with those at each side. Owing to this feature plywood is practically as strong in its width as it is in its length, a particular advantage in certain frets because of the rigidity it gives. One drawback is that plywood shows the layers at the edge, but for certain types of work this does not matter. Wireless and gramophone frets should as a rule be cut in plywood; a thickness of 3/16 in. is usually convenient. Decorative frets as applied to furniture can be cut in 1/32 in. or 1/16 in. plywood. As these are stained and polished the layers at the edge do not show.

**Designs.** For ordinary fretwork models finished

designs are obtainable from various suppliers. These are printed full size and require simply to be stuck down on to the wood and the outline cut. In some cases, the home worker may like to prepare his own designs, particularly for frets to be applied to furniture, etc. A convenient method is to use squared paper. A portion of the design (perhaps a quarter, or, in some cases, one-half), can be drawn full size, and the position of the other parts mapped with the assistance of the squares. Tracing paper may be used for copying designs or motifs.

**Pasting Down.** The design, however obtained, has to be applied to the wood to enable the cutting to be done. For this purpose paste should be used in preference to glue, since the latter grips the paper too strongly, making it difficult afterwards to peel off the design. The wood should be pasted rather than the design, because in the latter case the moisture is apt to stretch the paper and so distort the design. A clean cloth rubber should be used to make the design lie flat, working it from centre outwards so that any air bubbles are pushed towards the edges. Fig. 2 shows the process.

*Fretwork. Fig. 2. Use of rubber in laying a design.*

*Fig. 3. Laying a large design with the help of a dowel rod.*

Large designs are sometimes a little difficult to handle. In this case the method shown in Fig. 3 can be adopted. Here the design is rolled round a piece of

dowel, and the fretwood pasted. By placing the dowel at the top it can be rolled forward and the design unrolled. The latter will then lie flat on the wood. This method prevents distortion. Allow the paper to dry thoroughly before beginning the cutting.

**Drilling.** This operation is closely connected with the actual cutting, for the latter depends in a great measure on where the holes are drilled. As a general rule it can be taken that holes should be made near to some projecting piece of ornament, as the saw is usually started at such places. It is not advisable to start the saw at the mid-point of a curve, as when later on the join is made a disconnected appearance usually results. In some cases such a start is unavoidable, for instance, in a circle; the hole in this case is made near the line and the saw carefully taken into the circle in a continuous sweep. Small imperfections of outline can be corrected with the file.

*Fig. 4. Use of the Archimedean drill for piercing holes. Fig. 5. How the glasspaper block is held when cleaning up the finished work.*

Fig. 4 shows the Archimedean drill in use. Note that the wood lies on a flat board; when so supported the drill is not liable to split out the grain when it emerges at the underside. If laid on a table with a rough and uneven top, a small depression in the latter might cause the grain to break away as the drill comes through.

The drill shown has flyweights, which keep the tool rotating whilst the upward stroke with the bobbin is made.

**Using the Fretsaw.** It is most important to hold the

saw upright, a facility which comes only with practice. The work should be examined after it has been cut and any inaccuracies carefully noted. Never attempt to force the saw into the wood; it only results in a broken blade. Keep it working steadily up and down by its own weight. It will then cut quite quickly enough and truly.

When a corner has to be turned the saw should be moved up and down without the slightest forward movement, and should be turned gradually whilst in this position. It will be found that the blade will gradually turn in the required direction. It is better, however, to avoid turning in the corner, because it is liable to rob the design of its sharpness (*see Fig. 6, A*). The illustration shows the unsightly gap at the corner made by the turn. A similar thing has occurred at the point of the leaf, where the outline has become dull and rounded. A better method is shown at Fig. 6, B, where the saw is taken into the corner first along one side and then along the other. In this method the two cuts meet and leave a perfectly sharp corner. At the external corner the saw is taken along one side past the corner. It then describes a little loop and comes back along the other side.

*Fretwork. Fig. 6. A, result of turning saw at corners. B, better method, corners being left sharp and clean.*

A point to bear in mind in all designs is the continuity of line. Where two members of a pattern cross one another, they should appear actually to do so. The eye automatically puts in the joining lines between them. In the same way where one member branches out from another in a continuous curve, the line should be sweeping and continuous. This should be noted especially by fretworkers who prepare their own designs.

**Finishing Off.** If the paste has been used sparingly, it is usually a simple matter to peel off the design. If it shows some resistance, however, it can be damped slightly, using the water sparingly. On no account allow the edges of the work to become wet, as this is liable to raise the grain, which is difficult to smooth afterwards. After the paper has been peeled off as cleanly as possible the whole surface should be cleaned up with glasspaper, using the glasspaper block (Fig. 5). The work should be held down on a flat board during the process. If laid on the bench, any inequality in the

surface of the latter might cause part of the design to stand up, and so catch the block, resulting possibly in a breakage. Quite small pieces of design can be treated in a different manner. The glasspaper itself can be laid on a flat board and the design rubbed upon it.

No finish such as polish or paint should be applied to ordinary fretwork models. It only chokes up the edges. Certain designs are somewhat different because they have no elaborate internal fret. They are comparatively plain, and are intended to be lacquered or painted. Frets to be applied to furniture are also in a different category. These are polished with the rest of the job after they have been applied.

Sometimes a file has to be used for fretwork. Filing, however, should be regarded as a last resource, and on no account should the fretting be done carelessly, with the idea of cleaning it up afterwards with the file. This is simply a waste of time. A legitimate use of the file is in fitting joints. It happens frequently that the design stretches slightly when being laid, with the result that the joints do not fit properly. A few rubs of the file soon put this right.

**Assembling Fretwork.** In a large number of cases glue is used, the most convenient form being the liquid kind in tubes. The nozzle is applied to the join and a little glue squeezed out. When the fret is to be applied to furniture care must be taken not to allow the glue to exude at the edges, because it is difficult to remove cleanly and looks unsightly. A good method is to squeeze out the glue on to a flat board, rubbing it with the fingers to spread it evenly. The fret is placed on this and rubbed up and down so that the back is covered with glue. It can then be placed in position and held down by a flat, weighted board. When necessary to use nails in fretwork it is advisable to drill holes first, unless the nails are very small.

*Fig. 7. Designs for frets particularly suitable for loud-speakers or gramophone cabinets.*

**Types of Designs.** It does not follow that because a design is elaborate it is therefore difficult to cut. In fact, the reverse is often the case, the very intricacy of the pattern hiding any small inaccuracies. The most difficult type of design is that which is built up on a geometrical formation, such as the circle, square, and so on. The eye readily detects any defects in regular shapes, and the smallest inaccuracy is at once apparent in a circle, for example, whereas in intricate floral or leaf work small errors would pass unnoticed. The beginner is advised to choose comparatively simple

designs which are not geometrical in form, and which have no very thin members. Some suggestions for loud-speaker or gramophone frets are given in Fig. 7. As a rule the simpler these are the better. There should be plenty of openings to allow the sound to emerge. Such frets should be cut in 3/16 in. plywood.

*Fretwork. Fig. 8. Effective decoration of furniture with applied frets.*

An imitation of carved work can be obtained by the use of fretwork (Fig. 9). Suitable patterns are those often seen on Jacobean furniture, consisting mostly of interlacing strapwork designs. The design is drawn out in the usual way on paper, and pasted on the wood. The thickness of the wood used depends upon the relief required for the imitation carving. Usually  $\frac{1}{8}$  in. or  $\frac{3}{16}$  in. is about right. The outline being cut, the whole is glued down to the background of the work. To make the effect still more realistic the background in the internal spaces of the frets is given a roughened finish by means of a punch. This does away to a great extent with the appearance of an overlay, and makes the work simulate real carving. The applied fret itself can be carved here and there. For instance, in dealing with interlacing straps certain of the members can be made to appear as if they were beneath others, by just sinking such parts where others cross. The grain of the applied fret must run in the same direction as that of the groundwork.

*Fig. 9. Designs showing how carved work may be imitated by the use of a fretcut overlay.*

**Erinoid and Xylonite.** These substances are somewhat tougher than wood, and a special metal-cutting saw should be used for them. One great advantage of using this type of material is that the surface can be modelled to a certain extent after the cutting has been completed. The job is finished off with glass-paper and a file, and the surface polished with fine pumice powder. Such things as paper knives and small frames can be made from erinoid or ebonite.

**FRIAR'S BALSAM.** This is another name for the compound tincture of benzoin. The dose is a  $\frac{1}{2}$  to 1 fluid dram. Friar's balsam is much used in lung diseases, especially consumption and chronic bronchitis, for its disinfecting action. It has a stimulating effect on the lung tissues. When used as an inhalation, a teaspoonful of the balsam is added to a pint of very hot, but not boiling, water, and the resulting vapour is inhaled. It is a useful dressing for wounds, as it is an efficient antiseptic and also tends to check bleeding. Used in the proportion of one part of balsam to ten parts of water, it also forms a soothing application for cracked lips and rough skin.

**Fricandeau.** A popular dish made from fillet of veal is known by this name. *See Veal.*

**FRICASSÉE.** This is a type of stew, generally white, consisting of meat, game or fish cut into pieces and cooked in sauce.

**Chicken Fricassée.** A fricassée can be made with half a cold boiled chicken. Take the meat from the bones, and put the latter, together with a small onion, into a pan with the liquor in which the chicken was cooked. Cook them well for an hour or more, then strain off the stock. Melt 1 oz. butter in a pan and stir in 1 oz. flour. Add enough stock to make a thick sauce, put in the pieces of chicken and simmer them gently for 30 min. Mix the yolk of an egg with a gill of milk or 3 tablespoonfuls of cream, and add this gradually to the contents of the saucepan. Stir in a teaspoonful of chopped parsley, a little lemon juice, and seasoning to taste. Serve on a hot dish garnished with sprigs of parsley and slices of lemon.

*Fricassée. Breakfast dish made from any white fish.*

**Fish Fricassée.** Any white fish, cooked or uncooked,

may be employed in making a fricassée. To do this, break  $\frac{3}{4}$  lb. fish into flakes and prepare a sauce with  $1\frac{1}{2}$  gills milk, a lump of butter slightly larger than a hen's egg,  $1\frac{1}{2}$  oz. flour, and  $\frac{3}{4}$  pint fish stock. Season this to taste, then add the fish and heat the whole thoroughly, allowing it to cook for a few minutes if the fish is raw. A squeeze of lemon juice may be added just before serving, and a border of potato, together with a little chopped parsley, used as a garnish. *See illus.*

**Rabbit Fricassée.** A brown fricassée of rabbit can be made thus: Take out the inside, cut off the head, and remove the eyes. Wash the head, liver, and heart in cold water, soak them in cold salted water for 15 min., and then put them into a saucepan with a peeled onion and a quart or more of water or stock. Bring them to the boil, remove the scum, add seasoning to taste, and then simmer for 2-3 hours.

Cut the rabbit into joints, wash and dry them, and in the meantime put six rashers of streaky bacon into a saucepan and fry them gently until the fat looks transparent. Then put them on a plate, and to the pan in which they were cooked add  $\frac{1}{4}$  lb. dripping. When this is smoking hot, coat the joints of rabbit with flour, and put them in two or three at a time, frying them until golden brown. Then take them out and keep them hot with the bacon, fry a sliced onion in the fat, stir in one or two dessertspoonfuls of flour, and let it brown. Skim and strain off about  $1\frac{1}{2}$  pints of the stock, add this to the flour, and bring the whole to the boil, keeping it well stirred.

Add a few drops of browning and more seasoning if necessary, put back the rabbit, together with the head, liver, and heart, and cook all gently for  $1\frac{1}{2}$  to 2 hours. Add the bacon about 15 min. before serving. The rabbit should be piled in the centre of a hot dish, with the bacon on top and the gravy poured round. Dice of cooked carrots may be used as a garnish. *See Oyster; Sweetbread.*

**FRIENDLY SOCIETY.** These societies exist for the purpose of enabling persons to insure their lives, to provide funeral expenses or endowments; and to make provision for sickness, unemployment, old age, and various other contingencies.

**Two Types of Society.** Their original constitution and scope have been greatly altered by law and changing industrial conditions, and they now may be classified into two groups, the fraternal orders, such as the Manchester Unity of Oddfellows, and the collecting societies, such as the Liverpool Victoria. The organization of the fraternal orders is to a large extent dependent upon voluntary labour. On the other hand, collecting societies employ paid collectors, who usually call every week upon members for their contributions.

The conditions of membership vary according to the rules of the particular society. Members can insure

death benefits for any sum not exceeding £300, but the sum assured in respect of children is limited by statute to £6 in case of children under 3 years of age, to £10 for children under 6 years of age, and to £15 for children up to 10.

One advantage of membership is the ability to dispose of any sum payable at death, not exceeding £100, by means of a written nomination, which must be registered at the head office of the society. Other benefits obtainable from friendly societies include relief or maintenance during widowhood or distressed circumstances; when travelling in search of employment; or in such circumstances as shipwreck or damage to boats or fishing nets.

Members can also provide, again by weekly payments, for the old age, i.e. any age after 50, and for the sickness, widowhood, orphanage, and old age of their dependents. Other forms of insurance secure the member against loss by fire, up to the value of £15 of the tools used by him at his work.

A member, in addition to his own life assurance, may insure funeral expenses for husband, wife, or child, and in respect of a parent, grandparent, grandchild, brother or sister. Endowments and endowment assurances, subject to limitations laid down by law, can also be effected at varying rates. As ordinary friendly societies have no shareholders, any profits accruing from successful management are distributed amongst the society's members.

Persons who take out a policy from a friendly society should carefully examine the conditions and not sign until they are satisfied. If they are unable, for any reason, to maintain their payments, they are entitled by law to receive some equivalent for the money they have already paid by premiums. *See Insurance.*

**FRIEZE: In Decoration.** This band of plain or decorated space below the cornice is frequently used in a high room with good result. It has a lightening effect when of plaster washed in a pale colour above a dark wallpaper or panelling, and is therefore largely employed in timbered halls and living-rooms. Should a frieze be liked in a low-ceilinged room to give interest to distempered or plain papered walls, a motif frieze can be applied were required.

For friezes surmounting wood panelling some form of relief is popular. This may be either plaster or imitation plaster. As regards the first, exactly the same remarks apply to the frieze as to the ornamental plaster-work of a ceiling. That is to say, the original design is modelled by an artist or from his drawing, a mould is taken, and the result is reproduced as often as may be desired. The slabs or lengths of frieze are transferred from the place of manufacture to the room, and fixed in position on the wall by the same method as ceiling sections.

Imitation plaster friezes in fairly high relief, made of wood-pulp, papier mâché, or asbestos, are also made in sections or panels, and can be obtained from paper manufacturers. They are applied like wallpapers. Relief motifs are obtainable separately, which can be placed on a plain surface as desired. (*See Hall.*) In heraldic

designs these are particularly suitable for oak panelled rooms. It is necessary to bear in mind that small rooms will not stand too high a relief.

An effective frieze for an ordinary room can be made with any good washable distemper. A frieze banding may be used to separate this plain frieze from the wallpaper. Bandings should repeat a definite colour note in the room, such as the fireplace tiles or the ground of the carpet.

*Frieze. Fig. 1. Frieze for hall or dining room. It is in relief plaster work, distempered pale buff, and surmounts oak panelling.*

Before distempering the frieze care should be taken to see that the underlying plaster surface is good; any holes should be stopped with plaster of Paris, finished off with a trowel, and, if necessary, with pumice stone. On a really smooth surface one coat of the distemper will suffice for a plain frieze in any colour that may be desired. Such colour usually matches the ceiling. In certain cottage rooms nothing looks better than a simple frieze washed with deep cream colour. If the plaster work is roughed up before being coloured the frieze is more effective for an oak beamed room.

**Stencilled Friezes.** These are often seen in nursery decoration. With this type of frieze, having chosen the design of nursery rhyme, fairy tale characters or attractive animals, the amateur decorator proceeds to trace it with a blue or red pencil on a sheet of stiff oil paper. This is then affixed to a smooth board and the traced pattern cut out with a sharp penknife. If the pattern is so intricate that the sheet after this operation will not hold together, parts of it can be left uncut, these being subsequently filled in with a brush on the wall surface. The oil paper pattern is fastened in position on the wall with drawing pins and the colour, either distemper or oil, brushed over it. The pattern is moved on to the next space to be decorated, and the process repeated until the entire frieze is finished. Unless this is only partially to be decorated at definitely appointed places, the design selected should be one that fits the spaces to be covered on each wall, and careful preliminary measurements should be made. The design itself should be easily contained in the centre of the oil paper, so that its repetition will be practically mechanical, without the necessity of any further measuring. Stencil designs can be obtained which can

be traced and adjusted on to the oil paper. Charming nursery friezes are also designed by good wallpaper firms. The frieze illustrated in Fig. 2 is made very deep so that its details are easily seen by small children. Surmounting a dado of "black board" it has an added charm for the day nursery. In the modern room decoration is often cut out and applied on a frieze where interest is required and not necessarily all round the room. For instance, a group of figures or a flight of birds will be placed over the fireplace, and perhaps at two corners of the room only. The designs of these groups vary according to the decorative shape required by the space. *See* Anaglypta; Colour; Cornice; Stencilling; Wallpaper.

*Frieze. Fig. 2. Frieze of colour prints for a nursery. It is very deep so that the detail is easily seen by children, and surmounts a blackboard dado.*

**FRIEZE:** The Material. As originally made centuries ago friezes were coarse woollen cloths rendered blanket-like by roughening the surface with wire brushes. A rough face is still a feature of most friezes, which are cloths too heavy for suits, but excellent for overcoats for motoring.

Irish friezes are appreciated for their thickness. The cloth is heavily full after being woven, and it becomes so dense that wind does not blow through.

**FRILL.** This is made of a strip of material cut any width, single or double, the upper edge gathered or pleated on to a garment or band, and the lower edge finished in some way and left to hang loose. Frills in heavier materials are usually cut on the cross and finished with a picot edge or with a bind.

Lace, net, georgette, ninon or any silk or light cotton

material may be used for frilling. The lower edge of the frill may be trimmed in many different ways; a hemstitched border is sometimes used, or a tiny rolled hem or scalloped bind may neaten the edge. Frilling — both plain and pleated—in various colours and materials can be purchased by the yard. The pleated kind is the least practical because the pleats lose their shape when washed.

**FRINGE:** Uses in Furnishing. While fringes for dress are a matter of seasonal fashion, these trimmings have a definite place in decorative furnishing. As period trimmings they belong to the 16th and 17th centuries and the first decade of the 18th century and were greatly used until the reign of Queen Anne for enriching cushions, hangings and upholstery. During the Georgian periods they were not much employed, but appeared again in Victorian times, and are extensively used to-day both as correct period and as modern trimmings for cushions, curtains and pelmets, bedspreads, stools, pouffes and lampshades.

*Beaded fringe.*

*Fringe made by fraying ends of ribbon, linen, etc.*

Fringes look particularly well with Jacobean style chairs, upholstered in green, brown or maroon velvet and further embellished with heavy cords and tassels. Metal fringes were first introduced into England in the reign of Charles II, but straight silk fringes were much employed in the Tudor period, and variegated fringes were seen in early Stuart days. Such trimmings are therefore correct for the settee and chair with twisted oak frame, or for stools and chairs with X legs reproduced from the Tudor style, for William and Mary stools and armchairs with stretchers and turned legs, but seldom for the later 18th century pieces with

cabriole legs, when fringe would have detracted from the embroidered seats then in vogue. Tufted fringe was used on William and Mary chairs. It was secured by small buttons edged with silver wire and trimmed velvet upholstery. As trimmings for candle-shades for use with electric light sconces silk fringes are often employed, and lampshades may be composed of silk fringe shading from pale yellow to orange or from flesh pink to deep rose, sewn in wavy lines on a silk foundation.

Fringes can be bought by the yard in various colours and widths from all drapery stores, and are applied by means of a band which confines the top ends of the fringe. Fringing may also be made on the material itself. When this is done the depth of the fringe must first be decided, and a line of machine-stitching run at that distance from the edge. All the threads parallel with this line must then be pulled out with a needle or pin until the actual stitching is reached. The machine-stitching is not essential, but it helps to prevent the material from fraying. A beaded fringe can be made by cutting a number of threads of even length and threading each of them with the same number of beads. Fasten off the bottom end securely, knotting it so that the beads cannot fall off. The lengths should then be applied at regular intervals to the edge of a lampshade, or other article to be so adorned, or may be sewn to a narrow braid first and then applied. See *Bead; Curtain; Lampshade*.

**FRITILLARY.** The most striking of these is *Fritillaria imperialis*, the crown imperial, which in spring bears drooping yellow or reddish flowers on stout stems 2 feet or so high. The bulbs should be planted 6 inches deep in autumn and left undisturbed for years. The snake's head fritillary (*meleagris*) 8-12 inches, has beautifully chequered blooms in purple, white and other shades of colour in spring: it flourishes in grass or in the rock garden. *Aurea* and *citrina*, with yellow flowers, are two pretty fritillaries for sandy loamy soil in the rock garden. Propagation is by seeds sown as soon as they are ripe or by offsets.

**FRITTER.** Fruit, meat, fish, cheese, eggs, or bread can all be employed to make fritters. Fresh fruit can be used, but meat or fish should be already cooked. Remains of cold meat or fish can be successfully reheated in this way. Hard-boiled eggs should be sliced rather thickly. A good frying batter should be made, and slices of the fruit, meat, eggs etc., dipped into it, then dropped into a pan of very hot, deep fat and fried a golden brown. See *Apple Fritters; Batter; Bread Fritters; Cheese Fritter; Cold Meat; Frying; Orange Fritter*.

**FROG:** Its Garden Utility. The frog should always be welcomed in the garden, and introduced there if he does not come of his own accord. He never touches leaf or flower in the way of food: but in addition to a prodigious consumption of insects of all kinds, he also destroys slugs and earthworms. His soft skin of yellow and brown must be kept moist, and to keep him in a

healthy condition and active it is worth while providing for his comfort by having a patch of long grass in a shady corner of the garden, with a sunk pan of water near by, in which he can soak at intervals.

The frog and the toad are quite easily distinguished. In addition to its brighter and varied colour, the frog is more angular, has longer legs, and the moist skin is perfectly smooth. The toad has a rounded outline, is more portly, and the dry, warty skin is of one dark tint, without spots or bands.

**FROGHOPPER.** Under this popular name are included a number of insects allied to the plant-bugs and aphids, and, like them, subsisting by sucking the juices of plants. The familiar and conspicuous cuckoo spit is formed of surplus fluid, exuded by the immature froghopper and whipped into a froth to protect its tender body. If the froth is blown aside the yellow insect will be seen. In the mature stage it uses its hinder pair of legs for making prodigious leaps, and as a rule escapes capture.

In the earlier stages the insect inflicts great damage on many plants, particularly noticeable on carnations and pinks. Washing with insecticides, such as a solution of nicotine and soft soap in water, is recommended; but the most certain method is to look for the cuckoo-spit and then destroy the insect by pressure of finger and thumb. See *Insecticide*.

**FRONT AXLE:** Of a Motor Car. The front wheels of a car rotate on stub axles which are connected by more, or less vertical pivots to the ends of a fixed or dead—i.e. non-rotating—axle secured to the springs. The axle, in addition to transmitting the weight of the vehicle from the springs to the wheels, has to resist the torque or turning effort imparted to it when the brakes are applied. This torque tends to twist the end parts of the axle, and the circular section now generally adopted for the ends between the spring pad and the stub axle is best adapted to resist such forces. The diagram shows a front axle of the dropped type.

*Front Axle of a Motor Car. Diagram showing a front axle of the dropped type.*

**FROST.** During the winter months the householder has to guard against the action of frost. Should no precaution be taken water is liable to freeze in the pipes, especially during the night, the water supply

may be cut off, and burst pipes will add to the inconvenience. Except when the frost is unusually severe these troubles can generally be prevented by wrapping straw, felt, sacking, or some other material round the pipes, and keeping an oil-stove or other heating apparatus in any room where pipes are exposed to the cold.

**Protecting a Pipe.** External water pipes should be protected with a generous wrapping of straw or felt. An effective method is to box them in with a wooden casing and pack it with straw or hay. An important part to watch is the overflow pipe, which protrudes a few inches from the wall and is very often forgotten. Should it freeze, surplus water cannot get away and flooding may result.

In frosty weather it is as well to shut off the main water supply each evening and to drain the system. The drinking water should come off the rising main, and the supply for the bath, w.c.'s and hot water apparatus is from a storage tank in the roof, fed by the rising main. Usually in addition to the pipe from tank to bath, lavatory basin, etc., there is a separate pipe running to the hot water tank, each having a stop-cock near the cold tank. It may be well temporarily to shut off the bath and w.c. supply when a bad frost is expected, draining the pipes by opening a tap at bath or lavatory basin. The w.c. should be flushed last thing at night, when the flushing cistern will remain empty till the stop-cock at the storage tank is opened again the following morning. If the w.c. water comes from the rising main the supply will have been cut off when the main stop-cock was turned off.

### The Hot Water System

The fire in the kitchen or independent hot water boiler should be banked up at night. Since the cold supply to hot water system has not been shut off, the circulation in the latter will not be interfered with unless the cold water tank freezes. The rising main having been shut off, the cold tank cannot refill, of course, so little or no water should be drawn from the hot supply taps in the circumstances.

If the pipes of the hot water system freeze, as evidenced by the water ceasing to flow from the hot taps, the fire in range or boiler must on no account be lighted until the thaw comes. The water must run quite freely and continuously before it is safe to use the boiler.

The householder should make himself familiar in advance with the run of the pipes and the position of the stop-cocks, so that in emergency he can shut off the main supply at the hydrant box usually situated in the forecourt, or at the additional stop-cock which should be provided inside the house. The latter is a great convenience when fitting a new washer to a leaky tap, etc. A long-handled key will be needed for the outside stop-cock, which is on the pipe usually some two or three feet underground. This should be obtained and placed in a readily accessible position. When shutting off the main supply in frosty weather it is preferable to use the outside stop-cock, as then the whole of the

service pipe can be emptied, and there is no water left in the pipe to freeze. Reference should be made to the diagram given in the article Water Supply.

Should it be impracticable to shut off the main supply to a storage tank or flushing cistern it is desired to empty, the ball-cock may be tied up with string, the latter being fastened to a rafter or to a stick laid across the open top of the tank or cistern. Should there be no stop-cock on the distributing pipe from a tank, it may be possible to plug the outlet with a piece of broomstick having a tapered end.

**Dealing with a Burst Pipe.** When pipes freeze there is always a likelihood of a burst somewhere in the system, and this may not show itself until the thaw. If the burst pipe forms part of the distributing system from the storage tank the appropriate stop-cock near the tank must be turned off. Failing this the taps on the system should be opened to empty the tank as quickly as possible, and the stop-cock on the rising main must be turned off, of course. In emergency the pipe at the burst (on the supply side) may be hammered flat, but this makes subsequent repair more difficult and expensive, as a section of the pipe will have to be cut out and replaced. However, to prevent a flood this measure may be justified. When the pipe has been flattened it should be cut through and the end bent over and hammered tight at the end.

During a spell of severe frosty weather, if the bedrooms of the house are cold or the habit is to sleep with the windows open, a good plan is to remove the water from the basins, jugs or water bottles for the night, as if these freeze they are liable to crack.

**Frost in the Garden.** One of the greatest benefits of frost from the gardener's point of view is the purification and pulverisation of land which follows the freezing of the soil where autumn digging has not been shirked. Frost penetrates and disintegrates the close particles of heavy clods, reducing them to that friable condition so much desired when sowing and planting time comes round, and destroying the pupae of pests which lurk beneath the surface. To ensure the quicker germination of the seeds of alpine plants it is usual to expose the pots of soil in which they are sown to frost and snow by placing them out of doors. During severe frosty weather plants in cold frames should be well protected by mats. *See* Apricot; Frame; Fruit.

**FROST BITE.** This most commonly affects the fingers, the toes, the ears, and the tip of the nose. Children, old people, and alcohol drinkers are the most likely victims.

In the mildest form the skin turns to a dusky red, a soft swelling occurs, and pain may be acute. This is the common chilblain. In a further stage the chilblain becomes a blister, which may break and leave a small ulcer. In still severe degrees gangrene results.

When any part is actually frozen, the circulation must be restored very slowly. The patient must on no

account be taken near a fire nor even into a warm room. Put him in a cool room, and gently rub the frozen part with snow, or with a piece of flannel wet with cold water. As the blood begins to circulate, tingling and pain may be felt. When this occurs the rubbing may be carried out more briskly, the hands of the nurse may be applied to restore warmth, and the patient may be taken into a warmer room.

The sufferer may now be given a small quantity of warm liquid, such as hot milk or tea. If the fingers or the toes become much congested, raise the limb. As soon as the circulation is fairly restored, wrap the part in cotton wool or flannel. *See Chilblain.*

**FROSTED GLASS.** Frosted or ground glass is produced by two essentially different methods. By the first an acid is used to etch away the surface of the glass, and thus render it partially or wholly obscure. The second process consists of grinding the surface with emery and water, thus producing the familiar appearance of frosted or ground glass. A similar result is also obtained by sand-blasting. *See Glass.*

**FROZEN FOOD.** Many kinds of food are frozen for purposes of keeping. If frozen meat is properly cooked and of good quality, it almost equals the home-killed variety.

Meat should never be cooked while the frost remains in it; it must be melted out in cold water before the meat is exposed to the fire. Frozen meat requires longer and slower cooking than home-killed meat.

Freezing has a more deteriorating effect on beef than on mutton and lamb, Canterbury lamb in particular suffering little by the process. All frozen meat shrinks while cooking, and allowance for this should be made when it is bought.

All kinds of game are now preserved by chilling and freezing, which enables this favourite food to be served at table long after the game season is over. Rabbits which have been frozen should be converted into entrées or stews. They should be cooked longer than fresh rabbits, and be made savoury with plenty of vegetables. It is not advisable to roast frozen rabbits. Most poultry makes an excellent food when frozen. The birds, if of really first rate quality when preserved, may be cooked by almost any method employed for fresh poultry.

Fish which is frozen can be kept for weeks and will be quite fit for table, but it should be soaked for some hours in cold water before being cooked.

Milk is sometimes frozen in blocks, especially if intended for use during a long voyage. When thawed it more closely resembles fresh milk, and is invaluable where invalids or young children are concerned. Fruit also can be kept for a considerable time in cold storage. *See Beef; Ice; Mutton; Refrigerator, etc.*

#### FRUIT: ITS FOOD VALUE AND ITS CULTURE

With Details about the Planting of an Orchard  
Further information will be found under the headings Apple; Pear; Plum; Strawberry, etc. See further Grafting; Pruning; also Diet; Food; Jam.

When obtainable in good condition, fruit should be eaten as regularly as any other article of food. The great majority of fruits contain scarcely any tissue-building or energy-producing substances, but they are rich in salts and vegetable acids. The latter undergo changes in the course of digestion and appear ultimately as alkaline carbonates.

**Fruit as Food.** While not contributing material for growth and repair, some fruits are rich, however, in the vitamin which is necessary to a healthy development and existence, and the absence of which from the diet leads to the occurrence of scurvy. Lemons, oranges, and grapes are fruits that may be mentioned in this connexion.

With some exceptions fruits contain from 80 to 90 per cent of water. Fruits containing over 80 per cent of water are practically useless from the nutritive standpoint alone, but they are nevertheless invaluable for the salts that they contain. Their solid contents consist of sugar, salts, chiefly of potash, and cellulose. The nutritive qualities of a fruit depend chiefly on its content of sugar. Dates and figs, prunes and raisins, contain about three-fourths of their weight of sugar, and also from 2 to 4 per cent of protein. Bananas contain more than 20 per cent of sugar, grapes and plums about 15, apples and apricots about 10-12 per cent. The slight percentage of food material in fresh fruit is reduced by cooking.

For children fruit is particularly wholesome, and, as is shown by their craving, it is a really necessary article of diet. The best varieties for children are apples, oranges, grapes, and bananas. Fruit alone cannot nourish a child, but fresh fruit should be a part of a mixed dietary of milk, cereals, eggs, and meat suitable for young children.

Ripe fruits act as a regulator of the system, and provide some of the extra fluid required in hot weather. Lively people may eat stewed fruit with advantage. Grapes are valuable in cases of ailments arising from a too generous diet, and the juice is a wholesome laxative. All fruit is more or less laxative, and good for constipated people, when eaten fasting.

Oranges have been recommended in certain cases to persons of a diabetic tendency; but patients should consult an expert physician before experimenting with sweet fruits.

Watery fruits, such as melons, limes, oranges, and apples, are wholesome thirst quenchers, partly through the water they contain and partly by stimulating the flow of saliva.

Fruit should be eaten only when fully ripe, but not when beginning to decompose. In cities fruit is frequently sold in a very underripe condition. It is then indigestible, and lacks the sugar which forms its chief nutritive matter. In strawberries is found the same acid that is contained in apples. Lemons and oranges contain citric acid. These acids undergo a change in the bodily chemistry, and do not increase the acidity of the

blood.

	Water %	Carbohydrate (sugar)%	Protein %	Acids %

*Fruit. Table showing the average food content of the principal varieties of fruit.*

The best time to eat fruit is about two or three hours after a meal. Immediately after food it very often interferes with digestion.

A person suffering from gastritis or diarrhoea would aggravate his malady by eating fruit. In some people, too, many fruits produce flatulence. Fruit containing many seeds, including strawberries, raspberries, blackberries, figs, and currants, often cause great irritation of the intestine in children and elderly people.

Plums, peaches, and apricots are rather tough, and unsuitable for people of weak digestion. The most digestible kinds are oranges, grapes, grape-fruit, raspberries, and fully ripe apples and pears.

**The Growing of Fruit.** The growing of fruit is a matter of considerable interest, and there are many who wish to have, not merely a few apple, plum, pear, or cherry trees, but a garden or orchard in which a variety of fruit can be grown on scientific and economical lines. Such a garden should include what are known as top trees, i.e. apples, cherries, plums, etc., between which trees bearing soft fruit, as it is called, i.e. currants, gooseberries, raspberries, as well as strawberries, should be planted.

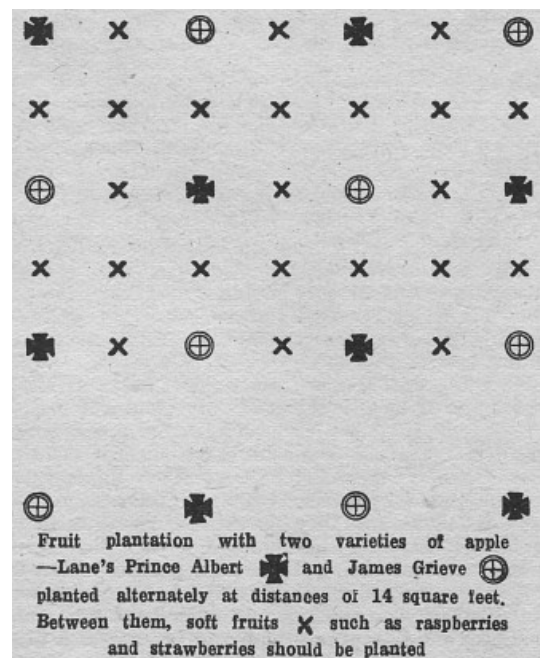

The varieties chosen must be suited for the particular soil; the manner in which the trees are to be trained must be settled beforehand and the plantation must be arranged so that the trees have sufficient space to grow without overcrowding. Top trees take about 20 years to reach their prime; soft fruit trees take a much shorter time.

The land selected for a fruit plantation, if at all exposed to high winds, must be protected by a windbreak. Lombardy poplars are generally used for this purpose. Cuttings about 1 ft. or 1 ft. 6 in. long and 3 ft. apart should be planted along the boundaries of the plantation the same year as the top fruit is planted, and they will have grown into a high hedge by the time the fruit trees begin to bear. If a shelter or hedge of poplar is not considered sufficient, the first row of fruit trees should consist of damsons or plums of the Monarch or Kentish bush variety, which will serve as a second shelter.

Fruit plantations must be properly fenced to prevent damage from hares and rabbits when the trees are young, and pilfering when they begin to bear. The choice of varieties is always difficult. Success is fairly certain if only standard varieties are planted, but it is desirable to make careful inquiries as to which are the most successful in neighbouring plantations, so that the selection can be based upon local knowledge of the soil and its capacities.

Care must be taken that each tree is allowed sufficient space for growth. It is a great mistake to plant trees so closely that when half-grown they have to be pruned very severely, as this leads to a great decrease in the annual yield of fruit.

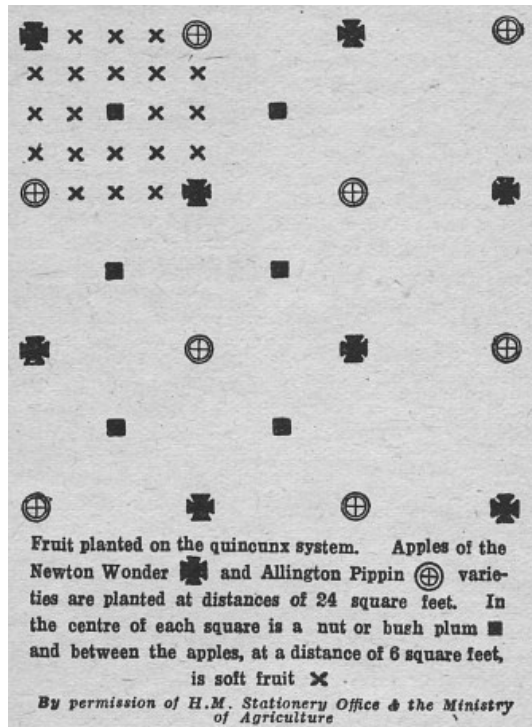

**Four Systems of Planting.** There are in all four systems of planting top fruit trees: square, quincunx, triangular, and cordon. For the square system the land is marked out in a series of squares and the permanent trees are planted in the corners of each square, with fillers and soft fruits in between.

In plantations of this kind thinning is effected in the following manner: The small fruits are grubbed as soon as the permanent trees or fillers require more space, and later on the alternate fillers themselves are removed, thus leaving a tree in the centre of each

square formed by the permanent trees. Finally, when the permanent trees are nearly full grown, the remaining fillers must also be grubbed.

The quincunx method of planting is very like the square system. The plantation is arranged in a similar way, except that a tree is planted in the centre of each square. As a rule, the trees planted in the centre of the square are fillers, but if they are to be retained permanently, an upright variety must be selected so that all chance of overcrowding is avoided. Inter-planting with fillers and soft fruit can be carried out quite as easily as with the square system.

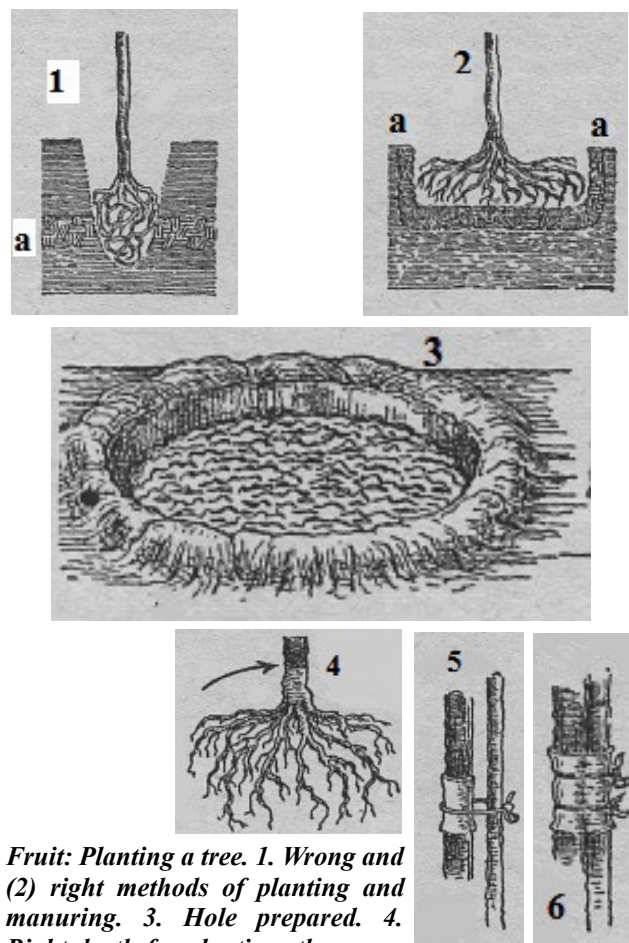

In the case of triangular or hexagonal plantations the trees are planted at the corners of a series of equilateral triangles, and are, therefore, equidistant. Such plantations cannot be thinned satisfactorily, and the system is only suitable for plantations consisting entirely of permanent trees. In the cordon system the trees are planted in rows 6 ft. apart and 2 ft. 6 in. apart in the rows. The direction of the rows should be north and south, and the trees trained at an angle of 45 degrees to the ground inclining to the south.

The following are suggestions for plantations of fruit: Bush apples, for example Lane's Prince Albert and James Grieve, may be planted on the square system, 14 ft. apart. They should be inter-planted with red or black currants or gooseberries at 7 ft. Alternatively Newton Wonder and Lord Derby can be planted at 20 ft. square apart, also on the square, and between them, soft fruits at 5 ft. square. A third scheme for bush apples is Worcester Pearmain and Allington Pippin at 18 ft., inter planted with soft fruits at 6 ft. If half-standard trees are preferred Newton Wonder and Allington Pippin should be planted on a 24 ft. square system. In this case bush apples, pears, plums, or cob nuts can be planted in the centre of each square, and the intermediate land can then be interplanted with soft fruits at 6 ft. square.

Turning to plums and pears, bush plums of the Victoria and Czar variety planted at 14 ft. square make a good plantation. Soft fruits can be planted between them at 7 ft. square. Bush pears of the Conference and Durendeu varieties can be planted at 12 ft. square with soft fruit at 6 ft. between them. A more elaborate scheme is for a mixed plantation of standard trees. Apples of the Bramley Seedling and Lord Derby variety should be planted at 40 ft. on the quincunx plan. Between them bush Czar plums should be interplanted at 20 ft. The intermediate land can be planted with Stirling Castle or Lane's Prince Albert apples as fillers at 10 ft. square or with soft fruits at 5 ft.

Fruit trees may be planted at any time during their dormant period, provided the land is in a dry, friable condition so that the soil can be worked well in amongst the roots and the land can be firmly trodden without puddling it. The best time to plant is in November and early December. If the land is in good form, no application of manure need be made unless interplanting with strawberries, raspberries, or a vegetable crop is contemplated, in which case a normal dressing of 20 tons of dung per acre should be given. The exact position of each tree should be clearly marked with a stick or stake.

*Fruit: Planting a tree. 1. Wrong and (2) right methods of planting and manuring. 3. Hole prepared. 4. Right depth for planting; the arrow shows where the old soil ends. 5. Right method of tying a stake after planting. 6. Tying at a later stage.*

7. Good example of planting and staking. 8. Notched board, useful for planting trees at equal distances.

**Bush Fruit Trees.** Fruit trees may also be grown in pots, and although such cultivation is thoroughly practicable, it is not a profitable proposition without glass. Good specimens should be obtained during the autumn from a nurseryman specialising in established pot-trees. Repotting is a most important factor, being necessary every few years to keep the trees healthy and fruitful. Roots should always be freed of old exhausted soil previous to potting, and clean pots with ample drainage prepared to receive the plants. A layer of broken turf is then placed on top of the crocks and the roots placed in position. Soil must be well distributed, and made very firm with a potting stick. Pots of about twelve inches in diameter are a suitable size. Leave an inch or so between soil and pot-rim for watering. After potting give a thorough soaking.

*Fruit.* Above, seedling Japanese quince and, right, single-stemmed red currant tree, grown in pots (*Our Homes & Gardens*)

Early in the year the trees are placed under glass; a temperature of 40 to 45 degrees is high enough for the first few weeks; this may be increased to 50 to 55 degrees later on. When the trees are in blossom the greenhouse must be ventilated freely.

Pot fruit trees are placed out of doors when the crops have been gathered; they must be in a sunny position,

the pots plunged to the rims in ashes. Careful watering is necessary to ensure that the soil does not become dry. Pruning is done chiefly by disbudding to prevent the growth of superfluous shoots. Apples, plums, cherries, and figs are suitable for this form of culture.

**Removing Fruit Stains.** Before it has time to dry the affected part should be covered with salt and then washed without soap, the alkali in the latter tending to fix a stain rather than to remove it. If the stain is dry, the material should be stretched over a basin and water which is almost boiling poured over the mark. Very delicate fabrics may be treated by spreading them over a piece of blotting-paper and then sponging on the wrong side with hot water. If the mark still remains, moisten it with a little lemon juice and then rinse it with hot water.

Fruit stains on the hands can be removed with olive oil and castor sugar. Mix a little of the sugar and oil to a paste, and then rub this well into the skin. Let it remain for a few minutes before washing the hands in warm soapy water. Obstinate stains may need two or three applications. *See Stain.*

**FRUITADE.** Black or red currants, whortleberries, and raspberries are probably the most suitable fruits for making this drink. Put them into a preserving pan, allowing a quart of water to every pound of fruit. Heat it up, then strain it carefully through a jelly bag and add the juice of 1 lemon and  $\frac{1}{4}$  lb. of sugar to every quart of syrup. Stir the whole until the sugar has dissolved, and, when cold, add a little ice and serve.

Various kinds of syrups useful for flavouring purposes are made in much the same way, except that less water is used. The juice of the fruit is either squeezed out, as in the case of oranges, and then boiled with a little sugar, or extracted by stewing with sugar and a little water, and then boiled up with more sugar. *See Loganberry; Mulberry; Orange; etc.*

**FRUIT SALAD.** This attractive dish is a favourite sweet for parties and also for the dinner table in summer. Fruit salad is made from uncooked fruits, either fresh, canned, or bottled. The more varieties of fruit contained in the salad the better it is. Pineapple chunks form a good foundation. The salad can be served plain or with cream, ice cream, or custard, with chopped nuts or desiccated coconut as a garnish. Tinned fruit salad can be obtained ready mixed for use.

To make the salad of oranges, bananas, and apples, or other comparatively dry fruits, a syrup must be made from sugar and water boiled together and coloured pink with cochineal. The fruit should be sliced, sprinkled with castor sugar, covered over and put aside for an hour or so, and the syrup poured over when cold. A wineglassful of sherry added to the syrup is an improvement. Fruit salad can be served in separate small glasses or in a bowl.

**FRUIT SAUCE.** This sauce can be made from either fresh or bottled fruits. To prepare it, boil together 2 gills of water, 2 breakfastcupfuls of red or black currants, raspberries, or any similar fruit, and sugar to taste. Skim the sauce frequently, and when it thickens strain and serve it with any sweet pudding.

**FRUIT SLICE.** This labour-saving device consists of a special knife which peels and also slices fruit quickly and neatly. Such a knife may also be used for peeling and slicing or chopping vegetables.

**FRUIT TART.** Various kinds of fresh or bottled fruit, used either separately or in conjunction with others, are employed in the making of fruit tarts. Blackberries and apples, raspberries and red currants, and apples and rhubarb are suitable combinations, though any one may be used alone. *See Pastry.*

**FRUIT TRAY: How to Make.** A useful article, frequently in demand, is a fruit storage tray. Convenient sizes are 24 in. by 16 in., 27 in. by 18 in., and for a fairly large size 30 in. by 20 in. American whitewood is very suitable for making one, but birch, beech, white pine, ash, satin walnut, and common deal can be pressed into service, allowing a shade extra for thickness for the last-named kind of wood.

*Fruit Tray. Fig. 1. Tray with recessed blocks, allowing similar trays to be stacked above.*

Fig. 1 shows a useful type of tray. The sides can be 4 in. wide, and are cut to shape to allow a free flow of air to the fruit, at the same time giving hand clearance. Kidney-shaped hand holes are also indicated in the ends. The sides can be nailed together, and are stiffened in the angles by blocks. These can finish  $1\frac{1}{4}$  in. by  $1\frac{1}{4}$  in. by  $4\frac{3}{4}$  in. long, and when in position will recess  $\frac{3}{4}$  in. below the top edge of the frame and project  $1\frac{1}{2}$  in. below it to form toes. The recessing of the blocks will permit of similar trays standing firmly above one another when being stacked. Close up to the blocks, and in the centre, three cross rails, about  $1\frac{3}{4}$  in. by  $\frac{1}{4}$  in., and with the upper edges rounded away, are let in flush with the bottom edge of the frame and screwed. The lath bottom of  $1\frac{1}{4}$  in. by  $\frac{1}{8}$  in. lengths is screwed or nailed to these and to the framing (Fig. 2). The stretcher can be cut in right through, as at A, but is best masked by setting the ends  $\frac{1}{8}$  in. in front face of the framing.

*Fig. 2. Parts of the fruit tray: A side cut away for stretcher.*

**Racks for Trays.** In stacking, the difficulty is always that to get at the lower trays, all the upper ones have to be lifted off. Some form of rack, therefore, has its uses, and that sketched at Fig. 3 is easily put together. Four 5 ft. lengths of 2 in. by 2 in. material will serve for the uprights, with the rails top and bottom of the same material cut to the necessary widths and depths. These are mortised and tenoned together, and an additional rail, 3 in. by 1 in., dovetailed in or screwed at back, can be added for fixing to the wall. The main feature of this design is that each tray will draw out, bearing being obtained by glueing and screwing a  $1\frac{1}{4}$  in. by  $\frac{1}{2}$  in. fillet to the sides of the drawers, so that these can travel on similar fillets of the same width and thickness, screwed horizontally, and at equal heights to the inside of the front and back up-rights to serve as slides. The corner blocks of trays must not in this case project below the bottom. If properly spaced a bray can be inserted between each pair of sliding trays, so that it travels on the edges of the tray immediately below it. Fig. 3 should make these points clear.

*Fig. 3. Back for holding trays, which can be drawn out separately.*

**FRUIT TRIFLE.** This makes an excellent party sweet. Prepare it by splitting a sponge ring into halves, spreading it with apricot jam, and placing the bottom half in a dish. Drain the syrup from a small tin of fruit salad, heat it, and then pour some of it over the sponge in the dish. Put on the top half of the cake, soak it with the remainder of the syrup, and, if liked, also pour over it  $\frac{1}{2}$  gill of sherry. Beat together one whole egg and the yolks of two others, and add to them 1 pint of milk and 1 dessertspoonful of sugar. Pour the custard into a jug, and stand the latter in a saucepan of water over the fire, stirring its contents until they thicken.

*Fruit Trifle. Popular dish for a children's party.*

Add a little vanilla flavouring, and when the custard begins to thicken take it out and leave it to cool. Then pour it round the outside of the sponge ring until it is not quite level with the top of the cake, and leave it to get cold. Heap the fruit salad in the centre of the ring; add a pinch of salt to the whites of the two eggs, and whisk them to a stiff froth. Fold into them a dessertspoonful of castor sugar and shake them all round the top of the sponge cake, leaving some of the fruit in the centre uncovered. If sufficient, shake the remainder over the custard and sprinkle the whole with chopped pistachio nuts.

**FRY.** Such parts of lamb and pork as the liver, heart, etc., are known as fry, and, in the case of pork, also as haslet or harslet. The sweetbread is also included, and in lamb this is considered a great delicacy. The most usual way of preparing such a fry is as follows: Wash and dry it well, removing any uneatable parts. Lay it in a saucepan with cold water to cover it, and a little salt, and dry it and cut it into thin slices, dipping each piece into flour seasoned with salt and pepper. Heat about 2 oz of good dripping in a frying pan, lay in the fry and cook it a rich brown. Take out the pieces and keep them hot while the gravy is made. Into the fat in the pan sprinkle a level tablespoonful of flour, fry this a nut-brown colour, taking care that it does not burn. Pour in  $1\frac{1}{2}$  gills of stock and stir the whole over the fire until it boils. Season carefully, arrange the fry in a hot dish, and strain round the gravy. If liked, a small chopped onion can be fried with the meat. If liver alone is served, garnish with bacon. *See Bacon; Liver; Sweetbread.*

**FRYING.** Frying consists of cooking food in

smoking hot fat or oil. As it is the quickest method of cooking, it is especially useful in an emergency when dishes have to be prepared at a few minutes' notice. Cheap pieces of meat with tough fibres should never be fried, the rapid cooking only serving to make them more tough, hard and indigestible. Fat must reach a far higher degree of heat than does boiling water before food can be successfully fried in it, and should give off a faint blue smoke before the actual frying commences.

There are two methods of frying, the shallow or English method, and the deep or French method. In shallow frying only a small quantity of fat is used, and when one side of the food is cooked it is turned over so that the other side will cook. Deep or French frying requires a deep pan containing enough fat to cover well the food to be fried. French frying is used for rissoles, filleted fish, fish-cakes, etc., and the article to be so cooked is coated with batter, egg, and breadcrumbs or pastry. With both methods the fat must be heated until a blue smoke arises before the food is put in.

Of the two methods, deep frying is the more economical, for though it requires a large amount of fat, the latter, after use, can be strained into a basin and used again, whereas what little remains after shallow frying is usually full of crumbs, etc., and is thrown away. All fried foods should be well drained on kitchen paper before serving and kept very hot, other-wise they will become flabby and indigestible.

**Frying Basket.** When small articles or delicately flavoured and fragile preparations are to be fried, a frying basket is an asset. Made of bars of wire, this basket fits into a metal pan and is used in deep frying. The basket fits down into the hot fat, and, in the case of small articles, when ready all can be lifted out of the fat at once and none are overcooked. Small fish should always be fried in a basket. Fritters, or any preparation that has been dipped in batter, should not be fried in a basket, as the coating sticks to the bars and does not brown and become crisp.

**Frying Pan.** These can be obtained in tin, enamel, iron, steel, and aluminium. The three latter are the best materials, as boiling fat melts the solder of tin and injures the surface of enamel. An iron or steel frying pan is used with a kitchener, and aluminium is the best material to use with a gas cooker.

To clean an iron frying pan, scrape off as much grease as possible, scour it well inside and out, rinse it in hot water, and dry it thoroughly with a dishcloth. If some grease still remains, the pan may be filled with water containing a little soda and the water brought to the boil. Aluminium pans may be cleaned in the same way, except that the soda must be omitted, while frying pans made of enamel should be treated according to the general directions for cleaning enamel.

Electric frying pans, made of heavy spun steel and supported by stands, are useful breakfast-table

appointments. They can be obtained in various sizes, and their chief advantages are that food can be prepared in them more quickly than on a gas-stove or before a fire, and can also be served immediately it is cooked. *See Batter; Breadcrumbs; Fish; Sole; etc.*

**FUCHSIA.** As a native of S. America, the fuchsia is not generally hardy in British gardens except in the S.W. counties. Its graceful habit of growth, its distinct and beautiful pendent blooms, the ease with which it may be cultivated and its adaptability to all conditions, ensure it a place in every greenhouse collection.

*Fuchsia. Two varieties of a graceful and easily cultivated greenhouse and summer bedding plant. Left, single; right, double.*

It may be grown as a pot plant for summer-bedding, or it will develop into a large shrub if tended year after year without being over-pruned. Those who have only used it for greenhouse decoration should experiment with some of the largest specimens and pot them on until they are big enough to occupy a good-sized tub.

Ordinary loamy soil, with a little leaf-mould, decayed manure, and some sand will suit the plants. During the flowering season they should be well watered. In the winter they should be dried off. Cool-house treatment will suit them all through. Before they start into growth in the spring they should be repotted and cut back.

Propagation is simply effected by putting young shoots in sandy soil under glass in August. These cuttings root very freely, especially in a propagator.

In spring the shape of the plant must be decided on. If a standard fuchsia is wanted the plant is allowed to reach the desired height of stem before it is stopped. If a pyramid is wanted the top of the plant should be cut off to ensure the development of side shoots. Magnificent, tall, pyramid-shaped fuchsias can be obtained by carefully stopping and training and by repotting as becomes necessary.

Hedges and large bushes of hardy fuchsias are familiar to all visitors to the south-west and other mild districts of the British Isles. These shrubs will also flourish in colder districts, though there they are often cut to the ground by frost in winter. If a covering of old ashes is placed over the roots in autumn the shrubs will usually start into fresh growth in spring. The best of the hardy fuchsias are *macrostemma*, *Riccartoni*, and *gracilis*. *See Bedding; Greenhouse. Pron. Few-shah.*

*Fuchsia. Method of propagation.*

1. Unsuitable cutting. 2. Sturdy shoot with heel (a). 3. Potted shoot with sand round heel. 4. Several cuttings in single pot; A, sand. 5. Cuttings in glass-covered box. 6. Old plant pruned to furnish side shoots.

**FUDGE.** A sweetmeat that hails from America, fudge is made from white or brown sugar, milk, cream or condensed milk, butter, and flavoured with chocolate, coffee, and vanilla essence.

The ingredients required for chocolate fudge are  $\frac{1}{2}$  lb. brown sugar, 2 tablespoonfuls of butter, 4 tablespoonfuls of chocolate powder, a small tin of unsweetened evaporated milk or a teacupful of milk, or  $\frac{1}{2}$  teacupful each of cream and water, and a little vanilla essence. Mix the chocolate powder with the milk, cream, or evaporated milk to a smooth paste. Melt the butter in an enamel or aluminium saucepan. Add the sugar and chocolate by degrees and boil up gently until a little of the mixture dropped into a cup of cold water hardens when rubbed between the fingers. Remove from the stove and add the vanilla flavouring. Pour the mixture on to a shallow buttered tin and mark it out into squares with a knife before it sets.

Another and cheaper way of making chocolate fudge is by using 4 tablespoonfuls of cocoa powder instead of chocolate.

**Coffee Fudge.** To make this use a teacupful of golden syrup, a breakfastcupful of brown sugar, a small tin of unsweetened, condensed milk, a tablespoonful of butter, and 2 tablespoonfuls of coffee essence. Melt the butter in a saucepan over the fire and add the syrup and the sugar. When these are well blended, add the coffee essence previously mixed with the milk. Boil it all together gently for 15 min., stirring all the time. Remove from the fire and beat the mixture until the sugar begins to crystallize round the sides of the pan. Pour it on to a buttered tin and mark it out with a knife into squares.

*Fudge. American sweetmeat resembling soft toffee, made in various flavourings.*

**FUEL: The Varieties Compared.** The chief fuel burned in the homes of Great Britain is coal of the ordinary or bituminous kind. Other fuels are anthracite and coke, used for special slow combustion stoves and for boilers. In country districts a good deal of wood is used, while in some parts of the country peat is burned. Oil, too, is employed as fuel, while electricity and coal-gas, though not strictly fuels, can be used for warming rooms, heating water, melting metal, and similar purposes. Peat is only found in certain parts of Great Britain, Cheshire, for instance, and owing to its smouldering propensities is only suitable for fires that are not intended to brighten as well as warm a room. There are also patent fuels on the market, but the value of these varies.

Gas fires and cookers and electric heaters and cookers are installed in many homes. In others a system of central heating is arranged, but in all these a certain place is usually left for coal fires, which, although somewhat wasteful, have attractions for so many persons.

Special coke grates are procurable which combine the cheerful glow of the open fire with some of the advantages of the gas fire. The coke is ignited by gas jets at the bottom of the grate, which are turned out after about 20 min., the coke then being well alight. In an ordinary grate, with coal as the main fuel, logs of wood can be burned, and if oak or any other good hardwood is bought it is not unduly expensive. *See—Anthracite; Coal; Coke; Electricity; Gas; Oil; Peat; Wood.*

**FULHAM WARE.** The stoneware produced by

John Dwight at Fulham in the last quarter of the 17th century is highly prized because it marks the beginning of great art in English pottery. Examples of the fine statuettes which he moulded are not often met with.

There was a large output of Fulham ware of more useful types, readily distinguished from the Cologne ware on which it was founded, and this may be collected to advantage. Besides greybeards it includes brown mugs and tankards, sometimes with hunting scenes and Hogarth designs in applied reliefs. There are also flasks and jugs with horizontal ribbing round the neck, simple noggins with little or no decoration, and the like.

This domestic pottery successfully displaced the Flemish Grès ware of the time, and was the forerunner of Staffordshire salt-glaze. Modern Fulham ware is represented by normal types of brown stoneware and other domestic designs. *See Pottery.*

*Fulham Ware (British Museum).*

**FULLER'S EARTH.** This mineral is used as a dusting and cleansing powder, both for clothing and for the skin. In the former case it is efficacious in removing grease from woollen and other fabrics, and enters into the composition of some makes of cloth ball. Fuller's earth is used on the skin, especially when a bland, inert covering is required for an irritated or chafed surface, and is therefore an ingredient in certain soaps and face creams. It is sometimes used for powdering the skins of babies, but when applied as a dressing for the navel or inflamed buttocks of infants it appears to have been followed by tetanus or lockjaw. A powder containing boracic acid is always therefore to be preferred for this purpose. Fuller's earth can also be employed for cleaning floors and other wooden surfaces. *See Boracic Acid; Cloth Ball; Clothes; Face; Stain, etc.*

**FUMED OAK.** Oak can be darkened by subjecting it to the fumes of ammonia. This gives an appearance of age and enriches the colour, though the natural colour of new oak is often preferred when wax polished. Mahogany and some other woods are affected by ammonia fumes, which are an alternative to the use of liquid stain. The sapwood of oak is not affected by ammonia, and where this occurs stain must be used to make the parts match. Some kinds of American oak cannot be fumed. The method is to enclose the work for 12 to 24 hours in a case, cupboard, or small room, with one or more open saucers of liquid ammonia. A packing-case should have strips of paper pasted over joints that are at all open. If one or more panes of glass can be fitted as windows the work can be examined

without opening the case and letting fresh air in. A quick test of the effect ammonia will have on the wood can be made by placing a piece on the open mouth of the ammonia bottle. A trial for a few minutes will show whether the wood can be fumed or not.

Fuming is usually done after the construction of the article is finished, but before the application of varnish or polish.

**FUMIGATION.** The idea that houses require fumigation after illness from some infectious disease is being rapidly dispelled. It is now generally recognized that in the majority of cases infection is spread by contact with a patient suffering with, or recovering from, the infectious disease. Fumigation of rooms after such cases has been discontinued in many large towns and boroughs without any increase of infectious cases, though spraying with disinfectant is carried out instead.

Fumigation of rooms for the purpose of getting rid of household pests is still common, but here again the advent of the modern form of penetrating spray, together with the discovery of suitable insecticides, has largely superseded the use of a gaseous disinfectant as a means of exterminating insects. The fumigation of books, gloves, boots, fancy leather work and dresses and all fabrics which are likely to be ruined by steam disinfection is still carried on. Rooms or other spaces to be fumigated must first be sealed hermetically, and can then be treated adequately by fumigation if desired.

Sulphur or formalin are most often used. Sulphur may be used in the form of crushed rolled sulphur or as sulphur candles. These are obtainable in varying sizes from chemists, and are provided with instructions as to the number required for a given space. Liquid sulphur gas in cylinders may also be used. The room should be kept sealed for at least 24 hours.

Formalin is usually employed in a special apparatus which heats the liquid, causing the gas contained in it to be given off. From 10 to 15 oz. of formalin are required for every 1,000 cubic ft. of space. Another method is to pour 10-15 oz. of formalin on to 5 oz. of potassium permanganate crystals contained in a deep dish. Enough gas is produced to treat 1,000 cubic ft. of space. Formalin may also be used in the solid form of paraform tablets. These heated in a special lamp give off formalin gas, 30 tablets being used for 1,000 cubic ft. of space.

In all methods of formalin fumigation the room should be kept warm and moist, and remain sealed for at least six hours. After fumigation the room should be well aired and thoroughly cleaned.

**Other Uses of Fumigation.** Fumigation is also practised for protecting plants, fruit trees, and the like from the ravages of garden pests. Among those used in this connexion are carbon bisulphide, formalin, and hydrocyanic acid gas. Carbon bisulphide is recommended for use against the apple sawfly, as injections of it will destroy the pupae of the sawfly in the soil. As it is poisonous care should be taken not to inhale it freely.

Fumigation may be used also to destroy rats, but this

is inadvisable where they are in dwelling-houses, and it must be employed with great care wherever food is stored. For burrows in the open carbon bisulphide may be used. A large wad of cotton wool, rags, or similar material should be soaked with the liquid; this should be at once inserted in one of the main burrows, and its outlets and inlets closed up. The liquid evaporates, permeates through the burrows, and asphyxiates the rats. This fumigant is not only poisonous but inflammable. No light, therefore, should be brought near it. Fumigation is also one of the methods employed for destroying wasps, and in a different way for protecting furniture. *See* Disinfection; Furniture; Rat; Spray; Wasp.

**Fumitory.** *See* *Corydalis*.

**FUNERAL: The Arrangements.** When a death takes place, the nearest relative, or someone acting for him or her, must make arrangements for the funeral, which should take place not later than the fourth day from the death of the person.

The first duty is to see that the body is properly laid out, this task being usually performed by a woman. If no one is known, an undertaker will supply one.

The next urgent matters are to notify the death to the registrar, to choose the grave, and to fix a time for the funeral. If a doctor has been in attendance he will give a certificate of death, which should be taken to the registrar for the district, at whose offices the necessary particulars about the deceased, age, etc., are entered. If no doctor has been in attendance, the coroner must be told, and he will arrange for an inquest, if necessary.

An undertaker should be sent for, or visited, and terms arranged with him. Usually, on knowing how many persons he must convey, the place of the burial, and other such matters, he will fix an inclusive fee for carrying out the funeral, including not only the hire of cars and bearers and the purchase of the coffin, but the payments at the cemetery and the fees to the clergyman or minister and others. He must be given the death certificate which has been supplied by the registrar, and which he must show to the officiating clergyman.

The grave should then be chosen by visiting the cemetery or churchyard where the deceased is to be buried. The undertaker will also make this arrangement if requested. In some cases the ground for the grave must be bought outright; in others only an interment fee is charged. Where there is a family vault, notice must be given that it is to be opened. In parish churchyards there is usually some difference made as to fee between parishioners and non-parishioners. The time for the funeral must be fixed, in conjunction with the undertaker, and the invitations sent out.

The service will be conducted by the clergyman or minister attached to the graveyard unless the mourners wish for their own clergyman, in which case they should acquaint the one in charge with their wishes. It is usual also to put a notice of the death in *The Times*,

The Daily Telegraph or the local paper. This may give the time and place of the funeral, and if no flowers are required it should state that fact. Relatives only may be invited, but in other cases invitations are extended to friends. In the case of persons having a large circle of friends it is not uncommon to hold a service, to which all friends are invited, quite apart from the funeral ceremony proper.

**The Funeral Ceremony.** On the day of the funeral the guests arrive at the house just before the time appointed for the procession to leave it. After the coffin has been carried out they will be escorted to the cars, the nearest relatives taking precedence over the more distant ones and over friends. In most cases friends go to the church, but only near relatives to the house.

On reaching the cemetery a service will be held in the church or chapel, and then the mourners will follow the body to the grave, where the burial sentences are recited. The guests may return to the house, where perhaps light refreshments are served. On returning to the house the blinds which were drawn down during the ceremony should be pulled up.

For bodies that are cremated a somewhat different procedure is followed. An undertaker is secured and he will make many of the arrangements, but two doctors must view the body and give their certificates before the ceremony can be carried out. *See* Cremation; Death; Flowers; Mourning; Wreath.

**FUNGICIDE.** A fungicide is a preparation for killing fungus on trees and plants. Two that are recommended for fungus on fruit trees by the Ministry of Agriculture are Bordeaux mixture and lime sulphur at summer strength. Fungicides should always be applied as preventives rather than as remedies, as attacks by fungi develop very rapidly. The best way of preventing an attack is to cover the vulnerable parts of the tree, i.e. leaves, fruit, and young wood, with a fungicide, applied as a very fine spray.

Fruit trees should be sprayed with lime sulphur in February-March before the buds are advanced in growth. Amateurs are advised to purchase lime-sulphur concentrate from horticultural dealers rather than to attempt to make the mixture themselves, and to dilute it according to the directions. Bordeaux mixture is used just before the blossoms open and again as soon as they have fallen. If lime sulphur is used when the trees are in leaf a weaker solution is required or the leaves will be damaged. Spraying black currant bushes with lime sulphur from mid-March to mid-May at fortnightly intervals is the best way to get rid of big bud or black currant mite. Bordeaux mixture can be obtained in concentrated form, and then needs merely to be mixed with water.

Black spot and mildew on rose trees can be controlled by spraying the trees in mid-winter with sulphate of copper, one ounce in three gallons of water, by using Bordeaux mixture in March, and liver of sulphur, one ounce in three gallons of water, occasionally in summer. *See* Bordeaux Mixture; Fruit; Lime Sulphur; Spraying.

**FUNGUS.** This name is applied indiscriminately to parasitic plant diseases that are caused by spores. Fungous diseases such as apple canker, finger and toe disease, are dealt with under their respective headings.

Sometimes poisonous fungi are mistaken for edible mushrooms, with serious consequences. Some varieties are poisonous to all who eat them; others may be harmless to the majority of people and poisonous to a few, owing to some idiosyncrasy. Even edible mushrooms are indigestible, and may cause diarrhoea in delicate persons and children. They decompose rapidly and should always be eaten fresh. When mushrooms are cooked, set aside, and then warmed up again, they may be harmful owing to the development of poison.

It is not easy to distinguish the harmful from the harmless kinds. A Ministry of Agriculture pamphlet points out that certain tests are quite fallacious. For instance, it is widely believed that the contact of poisonous fungi tarnishes a silver spoon, that all fungi which grow on wood are dangerous, and that an edible mushroom may be known by the fact that the skin is easily peeled off. These beliefs are not to be relied upon.

**Poisoning by Fungus.** The symptoms of fungus poisoning may not come on for 10 or 12 hours, or even later; then there may be severe pain in the abdomen, followed by vomiting and diarrhoea. The muscles twitch, the skin becomes cold and clammy, the breathing rapid, the pupils of the eyes dilated and the face pale. In some cases nervous symptoms, headache, giddiness, etc., precede or take the place of those indicating irritation of the stomach and bowels. The heart gradually fails and the patient collapses. The case may run on to coma and end in death.

*The doctor must be sent for at once, and meantime give an emetic. Use whatever is at hand, rather than have any delay.*

A tablespoonful of mustard or two of salt in a large tumbler of tepid water answers admirably. If these are not available, give large draughts of lukewarm water, and tickle the back of the throat with a feather. Follow the emetic with a good dose of castor oil (1 oz. for an adult).

Keep the patient lying down in a warm room, and well covered with blankets. Apply cloths wrung out of hot water, or hot poultices, to the abdomen. Rub the arms and legs vigorously to promote warmth and prevent cramp. Give suitable stimulants, such as hot coffee, hot milk, hot brandy or whisky and water, or a teaspoonful of sal volatile in a wineglassful of water. *See* Brown Rot; Canker; Emetic, Mildew; Mushroom; Poisoning; Toadstool.

## FURS: THEIR VARIETIES AND USES

### The Choice and Care of these Valuable Garments

In this work our readers will find entries on all the popular furs, e.g. Chinchilla; Ermine; Musquash, etc.

The article on Rabbit is also of interest. See further Clothes Moth; Rug, etc.

The term furs includes fur coats of various kinds, necklets, animal ties, wraps, cloaks, eapes and muffs. Fur is also used for making collars and cuffs and for lining coats, gloves, and motoring rugs; another use is for trimmings and edgings, while felt hats are also made of it. Fur rugs, made chiefly from racoon, goatskin, sheepskin and white bear, are used on floors and as hearthrugs. More costly furs may be used for travelling rugs, and leopard, gazelle and wild cat skins are sometimes employed for upholstery.

While the retail price of furs varies somewhat according to fashion, and bargains can be acquired at special and summer sales, certain skins are always highly priced. The value of a fur skin depends upon the colour, texture and durability of the fibres of the underfur, and also upon the pelt. The coats of fur-bearing animals are at their best towards the end of the winter. The sea otter is ranked as a standard for the seven most precious furs; taking the wearing quality of this fur as 100, the other furs compare as follows: Seal, 75; sable, 60; silver or black fox, 40; ermine, 25; white fox, 20; chinchilla, 15.

If the best value is to be obtained, furs should be purchased from a reliable furrier. Imitation skins, so treated as to render them almost indistinguishable from the genuine article, are sold under a variety of names. Some of these skins are hard-wearing and, therefore, economical to buy, but others are apt to develop a worn and shabby appearance with undue rapidity.

Rabbit is used extensively as a substitute for seal, ermine, dyed musquash, sable, beaver, chinchilla, and nutria; goat is frequently made to represent monkey and bear; and marmot to represent sable and mink. Hare replaces sable and various kinds of fox; lamb is treated to look like nutria; nutria is used instead of beaver; while dyed musquash often imitates seal and opossum skunk. Sometimes, too, furs are skilfully topped as a means of disguising their real origin, or to enhance their appearance, as, for instance, when light sable is topped to give it the Russian sable colour. This process consists of brushing the top hair with a colour which imparts richness to the fur, while another device is to insert white hairs in the skin of a cheap fox to give it the appearance of silver fox. Badger hairs are used for "pointing" purposes.

#### Wide Choice of Furs

Furs of the hard-wearing order include astrakhan, badger, beaver, mink, goat, bear, seal, musquash, and skunk, but if grace is desired, then mole, sable, chinchilla, marten, fisher, broadtail, fox, and ermine may be selected. Where cheapness is the main consideration, rabbit, racoon, opossum, fitch, hamster, hare, marmot, Thibet, wallaby, and the smaller wolves are to be recommended.

For women of limited means fur coats should be selected very carefully. In mink or other expensive furs they are outside the usual range of price, but in cheap furs they are now within the reach of almost anyone.

There are still, however, the considerations of the work of the sorter who matches the skins and of the cutter. At a good furrier's both sorter and cutter command high salaries and have acquired their art through long years of training and experience. A satisfactory fur coat cannot be cheaply priced if it is to preserve a good shape and appearance. Poorly sorted skins and badly cut garments of this type look ostentatious and clumsy. The ideal fur coat is warm without being unduly heavy. Hudson seal, which is merely musquash deprived of the top hair, is a skin which makes up into comparatively light coats. It tends to split, however, and is therefore not so hard-wearing as might be desired. When a split occurs, the two edges of the leather should be brought together and oversewn at the back, while if the leather itself has perished a new piece of fur will be required. To carry out these renovations it will be necessary first of all to remove the lining. Where a cheaper coat is required, dyed coney or sheared lamb is chosen. Moleskin coats, while not suited to rough wear, are liked by some women on account of the colour and their supple quality when well made.

Fur buttons to match a fur coat can be made from odd pieces of the pelt sewn over ordinary large buttons and, if necessary, padded with cotton wool. The buttons should be attached to fur coats in this way: Sew a piece of black tape, just wide enough to pass through the shank of the button, along the leather for about 2 in. above where the first button is to be placed. A hole should be pierced for each button, and the shanks slipped through. Then push the tape through each shank and sew it firmly along between each button, finally stitching it for about 2 in. as at the commencement.

In the choice of furs the discerning woman will realize that fur should be chosen to suit her complexion and hair. Luxurious furs are all very well, but it may be that simpler furs suit her far better. Fox, too, is particularly becoming, but it is not durable.

Besides being made up into separate furs and into garments, fur is also used for trimming purposes. On winter coats or wraps of velour cloth and similar materials long-haired furs such as lynx or wolf may be used. Lighter furs, such as the various dyed conies, sheared lamb, foxaline and also sable, ermine and white or grey dyed fox are used to trim summer coats and evening wraps. Fur sets of collar and cuffs can be purchased unlined, and also trimming in various widths by the yard. It is in such sets and trimmings that the retail prices of furs vary most, according to the current fashion, as often these furs are of the cheaper kinds, dyed or shaped to suit the requirements of a particular season and of no lasting value.

While valuable furs which have become old-fashioned in shape are best re-modelled by a furrier, cheaper furs or odd pieces, if care is taken, may be cut at home. If a furrier's knife is not obtainable, a strong, sharp penknife should be used. The fur must be laid on a board with the skin uppermost, and the place where

the incision is to be made marked with chalk. While the cutting is being done, the fur should be held down firmly at each side. To join two pieces, place them together with the fur inside and oversew the edges. Do not draw the stitches too tightly or the fur will pucker.

**Care and Storage.** The care of furs is important, for proper treatment adds considerably to the length of time during which they will remain wearable. Natural furs wear best, because dye has a deleterious effect on the pelt or leather, though in some cases it is so slight as to be almost negligible. On the other hand, dyed furs are practically immune from the ravages of moth. Furs should be kept in the dark and hung up whenever possible. The fur should fall in the natural way, skins such as fox being hung from the head. Before putting on furs shake them vigorously, except in the case of such delicate skins as chinchilla. After wear, repeat the shaking process and go through the fur gently with a metal comb. Fur coats which have been rubbed on the under-sleeves or collars should also be combed after use.

*Fur. Moth-proof wardrobe for storing furs, adapted from a cedarwood cigar cabinet.*

Wet furs should never be dried before a fire. Hang them up, preferably in a draught, and when the moisture has evaporated shake and comb them with care. In addition to occasional sha-kings, the furs should also be beaten with a light cane and subsequently combed in order to keep them free from moth. The presence of the latter can be detected by patches of loose hair. Should these appear the furs are best sent to a furrier, for, though moth is not difficult to keep at bay when proper precautions are taken, it is not easily eradicated once it has actually started its destructive work.

The cleaning of furs may be done either by a professional cleaner or at home, though the former method is to be recommended in the case of valuable skins. Both bran and silver sand, when heated in a dish in the oven, make a good cleaning agent for almost any kind of fur, though sand should not be used on white fur. Either of these should be rubbed into the fur with the fingers, and afterwards brushed or beaten out. White and other light-coloured furs may be treated in the same way with warm powdered magnesia. Frequent cleaning can be avoided by wiping the furs with a damp towel after wear.

Fur hearthrugs require equally careful treatment, for they are quickly attacked by moth. In the summer they tend to make a room look too hot, and should therefore be removed in favour of cooler floor-coverings.

Cold storage facilitates the care of expensive furs during the summer months, and ensures immunity from moth. Furs bought at that time of year from a good furrier are usually stored free of charge till they

are required. Special moth-proof bags are sold in which skins may be hung up while not in use, and are particularly useful in this connexion when the owner is away from home for a long period.

For home storage of furs a useful mothproof wardrobe can be obtained. The illustration shows a cedarwood cabinet adapted for this purpose, but which was originally made for packing cigar-boxes. Cedarwood, when permeated with the smell of the cigars, possesses moth-preventing properties and is of decorative value, either stained or natural. When required for storage of smaller furs, the shelves which originally furnish such cabinets can be retained. If these have been removed, as in the one illustrated, a wardrobe rail can be easily fixed or hooks for fur articles placed in bags to keep them free from dust. Whatever its wood, the cabinet for storage of furs should be absolutely airtight. Furs packed lying down in a chest or trunk may be protected by wrapping them in newspaper, turning the edges over so that they interlock. The chest or cabinet should contain either flaked naphthalene or paradichlorbenzene crystals, 1 lb. to every 10 cubic feet.

**FURMENTY.** This is prepared by boiling 1 quart of milk in a large saucepan over the fire, and putting 2 oz. of stoned raisins and the same quantity of cleaned currants in another pan containing just enough boiling water to cover them. Boil them for 5 min. until they feel soft and are well swollen, then drain off the water and add the fruit to the boiling milk.

Add 1 teacupful of prepared wheat grains, 2 oz. of loaf sugar, and a little nutmeg, and boil all these ingredients for about 20 min. Then take the pan from the fire and let the mixture cool slightly, afterwards straining in 2 well-beaten eggs. Stir the whole again over the fire until it thickens, but do not let it reboil, add a little brandy or home-made wine, and pour the whole into a deep bowl, serving it cold.

In some districts prepared wheat can be bought by the pint at any confectioner's, but when it is not possible to purchase it in this way it can be made at home. Do this by soaking a pint of husked wheat in cold water for 24 hours, then put it, with a pint of clean cold water, in a covered jar in the oven. Bake it slowly till the grains are quite soft, and it is then ready for use.

**FURNACE: How to Construct.** A furnace is used to melt metal for casting, and in the article Casting are given diagrams and instructions for building a useful brick furnace suitable for cast iron or brass. The same article describes a furnace made up from standard fireclay bricks and heated by a gas blow pipe. A gas-fired crucible furnace, working on the injector principle, is shown at Fig. 1. In conjunction with the furnace a foot blower of the type shown in Fig. 2 is employed to furnish the necessary air pressure.

**Muffle Furnace.** A muffle furnace for the

enameller is readily made from fireclay bricks, built up as shown in Fig. 3. The furnace body is strengthened with iron bands, and a long chimney is provided to dispose of the fumes, and to create sufficient draught to cause the fire to burn well and fiercely. All joints must be luted with fireclay, and the whole well baked with the gas burner.

*Furnace. Fig. 1. Gas-fired crucible furnace working on the injector principle.*

*Fig. 2. Foot blower used in conjunction with the furnace to give the necessary air pressure.*

In this style of furnace the door is usually at the end and the flue pipe at the top. The burner is located beneath the furnace, the latter standing on short legs resting on a substantial base of some fireproof material, such as a firebrick or a sheet of asbestos on an iron plate. A hole is cut in the bottom of the furnace to admit the flames of the burner, and a simple damper regulates the amount of air admitted.

Fireclay bricks can be obtained from the ironmonger, who will also be able to procure the clay muffle to go inside furnace, the appropriate type of gas burner (Fletcher Russell & Co.'s) with gas and air regulators, and if desired a chimney with cast iron foot. The gas supply tap and pipe must be large enough to allow full pressure at the nozzle, and for the size indicated a half-inch supply is required. It is advisable to procure the clay muffle first and to make the furnace to suit it. Dimensions inside muffle for the furnace in question might be 4 in. long by 2 in. high by 2 in. wide. For a larger size a  $\frac{5}{8}$  in. supply pipe would be needed, when

muffle might be, say, 9 in. by  $4\frac{1}{2}$  in. by  $5\frac{3}{8}$  in. See Boiler; Casting; Enamelling; Fireclay, etc.

*Furnace. Fig. 3. Diagram showing construction of gas-heated muffle furnace for the amateur enameller.*

**FURNISHED HOUSE.** In London the best letting seasons are in the winter and during the late spring; at holiday resorts, unless also winter resorts, during the summer months. The houses are let furnished from month to month, or for three months or even longer, as the case may be. In July and August, when most people take their holidays, the highest prices are obtained at holiday resorts, but June and September are busy months, while early lets are arranged for May; in some sheltered spots the season lasts into October.

There are two ways of letting a house. The tenant may carry out the business himself either by advertising or by private treaty, thus saving an agent's commission and other incidental expenses. In most cases, however, it is usual to entrust it to an established firm of house agents. The agents charge a small commission on the whole transaction, that is to say, on the total amount eventually realized by the let. They undertake no responsibility for default on the part of the visitor, but any risk is minimized by the stipulation for payment of half the various instalments of rent in advance.

The first step is to enter in the agent's register of houses to let, the rent required, and particulars of the accommodation available. This is intended for the information of visitors on the look-out for houses, who call on the agents and are invited to see if there is anything in the register that will suit their requirements. In this manner the tenant gets in touch with prospective clients, and after that it rests mainly with the principals to come to terms when the premises have been inspected. The final step is the signing of an agreement drawn up by the agents, the cost of which is shared by the parties. Under this agreement the visitor binds himself to take the house for the term and at the rent agreed upon, the tenant paying all rates and taxes.

If any rooms are unfurnished or partly furnished,

which are occupied or used as store rooms, care must be taken to see that they are not included in the number of bedrooms and sitting rooms entered in the agent's book. This is important because if any mistake is made in this respect the tenant may be called upon to furnish the room or make a reduction in the rent.

**Preparing the House.** One of the first considerations in getting a house at a seaside resort ready for a family with children is to arrange it so that it can be easily kept clean. From this point of view linoleum is to be preferred to carpets and rush mats to carpet mats. In case of accident it is always advisable to put away the things that are most valued amongst the household goods, especially silver, china and other valuable ornaments. Unless by special arrangement plate and linen are never included, and they should be carefully put away. Glass, china and blankets are counted as necessities, and reasonable supplies of these should be provided, together with all that is necessary in the way of kitchen utensils. Gas or electric fittings must be in good working order, and the same remark applies to blinds, curtains and door locks and any labour-saving devices.

Where the meter is not on the slot system, the gas company ought to be notified of the change, so that the meter can be read, and the tenant pays for the gas he has consumed up to the date of his departure.

If the garden is any size, and has been well cultivated, the tenant may undertake to see that it is kept in order, and make a charge for his trouble, unless the upkeep of the garden has been included in the rent. It is more usual for the visitor to make his own terms with the gardener, but he is not under any obligation to do so, and the tenant should be careful to stipulate for the upkeep of his garden upon making the agreement. The latter document should also contain a clause forbidding the newcomer to take in lodgers or to sublet the house or any portion of it. *See Agreement; Cottage; Holidays.*

## FURNITURE AND FURNISHING

### Good Taste and Economy in the Equipment of the Home

Other general information on this subject will be found under the headings Colour; Decoration. See also Antique Furniture and articles on the various styles, e.g. Chippendale; Tudor; and those on the rooms and pieces of the home, e.g. Bureau; Chair; Kitchen; Nursery.

While modern furniture is undoubtedly a good choice for small rooms in the average flat that is to be newly equipped throughout, there is still a strong feeling for antique styles in furnishing period houses. The great thing is to choose such styles with a nice appreciation of their suitability to their surroundings. In old days no one worried about period. As new pieces of furniture to meet the current modern need were designed, so they were gratefully acquired by the rich and comfortably settled in the same room with the pieces of former years.

Each acquisition was an event as important as the entire redecoration and refurnishing of a house to day. It is still really far more important to acquire pieces to suit individual needs and to blend colours, shapes, woods and metals harmoniously, than to try to live in the uncomfortable replica of a room only suited to the life of many generations ago. On the other hand there are reasons for selecting certain periods to inspire furnishing schemes, the chief of which is the type of the house. One may possess antique pieces and good reproductions, but while there are so many modern decorative schemes in which such pieces can be pleasantly set, it is far more difficult to reconcile furniture having metal tubing frames and table surfaces of glossy enamel or glass to a Tudor setting, than to utilize successfully a refectory table and oak stools in a modern dining room with painted walls and a rubber tiled floor.

**The Oak Period.** As many small houses of to-day are based on the 16th and 17th century cottage and farmhouse type, it is useful to remember that the oak period in antique furniture coincides roughly with the Tudor and Jacobean periods in architecture, and therefore oak is in harmony with low-pitched ceilings and visible beams, brick fireplaces and casement windows. Those who wish to furnish after the style of the 17th century have to-day two special conditions with which to contend. They cannot own much genuine old furniture of the period, and are likely to feel tied when trying to equip the whole house to correspond, as they cannot be limited to furniture which was sufficient for a household of 300 years ago. They have to remember that in early Jacobean times there was no electricity available, no gas, no sanitary arrangements, and very few carpets.

Some people solve the problem rather wisely by confining one period, such as the Jacobean, to one or two rooms of the house. For instance, a Jacobean hall and even a dining room, in spite of the limited space of to-day, are possible to furnish with some degree of success. A carved oak chest is perfectly at home, and forms a very useful receptacle for rugs and other articles. The Jacobean chair, with its hard wooden seat, almost upright back, and straight legs, is right in the hall, and, when cushioned, quite suitable at the table, but scarcely in a living-room where comfort and ease are demanded. The court cupboard or buffet—both terms are correct—makes a picturesque feature.

The small gate-leg table is more appropriate in the hall than in the dining room, because of its limited top accommodation and inconvenient underframe, which renders it awkward for the legs and feet of diners. An excellent casement window treatment for either Tudor or Stuart period style hall is given in the article on Curtains.

If the dining room is to be furnished in this style, some liberties must be taken. It may have a late 17th century dresser as a sideboard, and the dining table, for the sake of comfort, should be a refectory or an

extending one with centre rail beneath, but built on the lines of the old draw-table. This table, of which there are many made to-day, is quite in keeping with the Jacobean tradition, while being more comfortable and convenient for a small room. It was common in the 16th and early part of the 17th century for diners to sit upon stools placed down the sides of the table. This fashion appears to-day in small dining rooms (q.v.) In larger rooms tall cane-backed chairs usually associated with the period of the Restoration are often seen, upholstered in velvet or tapestry and often with fringe to trim the chair seats. The dining room (and hall) may have a stone-flagged floor to all appearances. In reality it will be made of composition which is quiet to the tread and warm to the feet. Rugs of old Persian designs may enrich this flooring. Parquet is more ordinary with a carpet of Oriental type. In this room no mahogany should be used, for it was not employed in the 17th century.

There is something to be said for the use in such a dining room of definitely modern armchairs and settee upholstered in brown velvet and leather, as they do not clash with anything. Leather was a common material for the finishing of chairs in the 17th century. A piece of furniture that well may be included in an oak room is the bureau; though still existent, specimens are very rare of earlier date than the end of the Stuart period, but the bureau was made of oak in Cromwellian times, and good reproductions are easily obtainable.

**The Walnut Period.** A drawing room furnished in the Jacobean style is not correct, as such a room was unknown at this period. With the arrival of William III and Dutch domestic ideas after the changes of 1688, furniture undoubtedly took upon itself a more comfortable and pleasing aspect. Tall sash windows were used more generally, houses became formal in plan and elevation, rooms squarer, and chairs and tables were made frequently of walnut, and showing graceful curves in their structure. The William and Mary period saw the arrival of the parlour, and the alteration in social habits, particularly the introduction of tea as a popular beverage, influenced furnishing in the direction of leisured grace and comfort. Upholstered chairs, showing very little wood, began to appear, and the grandfather chair and clock are typical of the time. The picture of a room in the William and Mary or Queen Anne period is one of quiet restfulness and homely charm. The walls had broad panels, often of walnut with gilt enrichments, conferring greater dignity than was usually seen with the smaller panels found in Jacobean and Tudor interiors.

Inasmuch as the old parlour suggests general social functions, and not specific use like the dining room, it is the model for the furnishing of the drawing room, or the more gracious type of living-room of to-day. The Queen Anne parlour was eminently serviceable, comfortable, and homely, yet it had a sense of style, and symmetry, which appeals to-day as much as it did then.

The articles suitable for rooms furnished in accordance with the walnut period include a round tea-table, chairs, with and without arms, having seats

covered in needlework or brocade and concave splat backs, a china cabinet, or a niche with fitted shelves each side of the fireplace, a bureau, one or two tabourets or footstools, a chest of drawers, a dresser which is without cupboards, a folding card-table, and a small settee which was practically a double chair, with two splats divided by a smaller one, outwardly flaring arms and six cabriole legs, known as a courting-seat. The whole of this furniture may be in walnut, and a suitable colour for the hangings of a room in which it is placed would be green, though maroon, blue or yellow were often used.

*Furniture. Fig. 1. Group of modern painted furniture showing inspiration from both Queen Anne and Georgian styles, but blended by colour for use in the same room.*

The beds of this period had very tall posts, and they were fitted with voluminous curtains, with shaped lambrequins (festooned drapery) above. The bed itself was low, within a foot or eighteen inches of the ground, and the posts were not highly decorated. Furniture made in cheaper woods was often painted and lacquered. Gilding and inlay were also used. Lacquered leather screens, with six folding panels, were a decorative feature.

Modern versions of such pieces and accessories are often seen to-day. Fig. 1 shows a group of charming painted furniture. The bedside table and chest of drawers show the earlier influence of Queen Anne designs, while the chair, though reminiscent of the later and more classical Adam period, blends happily. The walnut period extended in the main from about 1685 to 1713.

**The Mahogany Period.** Through the discovery of the value of mahogany for furniture making, the 18th century may be said to be dominated by mahogany as far as furniture is concerned. With the commencement of the age of Chippendale, which can fairly be placed

between the end of the first quarter of the 18th century and the commencement of the wars with France (1793), furniture followed in the main the French tradition, becoming lighter and more elaborate in ornamentation.

To possess a home which shows almost throughout inspiration from the mid-Georgian period is simple, for furnishing houses have reproduced Chippendale, Hepplewhite, and Sheraton furniture in vast quantities. On the whole, these reproductions are good in design, and constructed on simple lines, avoiding over-elaboration of carving, and usually selecting the plainer examples as models. Bedrooms, based on those of the late 18th century, often show inspiration from the work of Hepplewhite, and the four-post bed itself, with its fluted columns, is copied. Sanitation, indeed, had not yet arrived at a constant supply of hot and cold water, and the bathroom had yet to make its appearance. But there were small washstands and dressing-tables which combined picturesqueness with that utility and convenience of which to-day we avail ourselves. This bedroom furniture gradually became the Victorian suite, made up of a wardrobe, dressing-chest or dressing-table, with or without a washstand, and one or more single chairs.

A bedroom equipped with furniture of the Hepplewhite or Sheraton period, roughly the last quarter of the 18th century, should avoid the suite, and may properly include, beside the bed itself, a tall-boy, or double chest of drawers, a man's wardrobe, basin stand, folding-topped dressing-table, separate mirror, wing easy chairs, and oddments such as screens and hanging shelves. Until the 19th century it was the custom not to hang dresses, but to lay them flat in drawers. Hence the tall-boy, which gave extensive drawer accommodation, and the wardrobe fitted with trays.

It has taken more than a century to bring the sideboard, in structural essentials, back to what it was originally. In early Georgian days a side-table, it became a complete sideboard with flanking cupboards and centre drawers during the last quarter of the 18th century, and gradually developed in size and importance until in the Victorian age it was almost a domestic altar, and occupied much room. The high back was practically unknown before the reign of William IV, but all through the 19th century it was part of the conventional sideboard.

To-day, in conformity with English period furnishing and also with the best modern ideas, it has shrunk to relatively sensible proportions for the size of rooms.

**The Modern Period.** A great advance has been made in the structure of upholstered chairs and settees, which are more comfortable now than ever before. The principal reason for this is the development of the use of wire springs and mesh and the consequent increase of durability and resilience. These circumstances have also affected the production of the modern mattress, which has made the bed of to-day much more comfortable than before.

Divan beds are favoured because they look decorative in the daytime if attractively covered and

cushioned. Heads are constructed with fittings which serve as bedside tables and bookshelves in accordance with practical ideas of dual purpose furniture for smaller rooms. For furnishing the modern small house various pieces of "double duty" furniture can be obtained, such as a compact sideboard with a writing slab which can be pulled out and is stowed away when not in use, in place of the usual drawers above the cupboards; there is also a dining-table with a sliding top beneath which is accommodation for cutlery in baize-lined partitions. The illustration of a small bureau wall fixture (Fig. 2) depicts a particularly useful and space-saving idea. The chair and mirror also shown are examples of good taste in modern furnishing for small rooms.

*Furniture. Fig. 2. Space-saving bureau wall fixture. The flap folds up and the thickness of the piece is then 3½ in. The flap below conceals space for magazines (Courtesy of Rowley Gallery).*

Very practical built-in furniture is a great feature of modern furnishing. Fig. 3 shows a dining room with a built-in sideboard and a glass cupboard. The table in this illustration cannot be appreciated without the colouring. The glass top could be carried out in various beautiful shades—a sea-green, for instance, with table glass in amethyst and the beautifully designed candlesticks in crystal with a purple line and mauve or silvered candles. The corners of the table are chromium plated, this finish is repeated in the handles of the fixtures and doors. The chairs unexpectedly hark back to a Regency style, but seem quite at home in company with the lace trimmed mats, the china, cutlery and lustre central lighting fixture.

Modern style is essential in the kitchen. In many of the newest abodes it is small, yet replete with all that is required for the business of cooking. Everything that saves labour and unnecessary expenditure of coal, gas, and electric power is in it. Cookers that are convenient and economical; sweepers that excel in the task of cleaning rooms and furniture; cupboards for brushes to hang in; washing machines, square aluminium saucepans which can be packed in the minimum amount of space, and good lighting, all combine to help

the work of the kitchen.

Restraint is shown in the amount of glass, china, and linen with which people set up house nowadays. Sets of breakfast, tea, and dinner china are chosen, all of one pattern, so that the vast number of plates needed with varying designs may be cut down.

*Furniture. Fig. 3. Modern dining room furniture designed for a small flat. The austerity of the fixtures and glass-topped table is softened by beauty of colour and accessories. (Humphrey & Vera Joel)*

Two pairs or one and a half of blankets for each bed, three of sheets and half a dozen pillow-slips, a cotton or silk spread, and a down quilt may be considered a generous allowance in an ordinary house. Towels and household cloth's, as well as these other items, should be of the best quality that can be afforded; cheap ones are false economy.

Glass has, in a great measure, taken the place of silver, because it is more easily cleaned. The use of stainless steel has increased, while chromium plating gives a bright appearance to lighting fittings, mirror frames and hearth furniture. Unnecessary ornaments are avoided.

The nursery is the apex of charm and cheerfulness, and in many homes the best and largest rooms the house provides are dedicated to day and night use for the children. Furniture made of enamelled or of closely grained, unpolished and unstained wood, with rounded corners and handle knobs that cannot hurt the baby on adventure bent, is used. Round the top of the day nursery wall, where they can be seen when not in use, the children's big toys, are placed, instead of being cupboard-bound in an untidy mass. Wardrobes are provided with hooks low enough for the small child to reach, so that the virtue of putting things away directly

after use can be inculcated early in life. Little low chairs and tables are added, and that invaluable item the play pen.

Another particularly well plenished apartment is the modern bathroom, with real or closely imitated washable tiled walls, tables with glass tops, and a floor of rubber tiling or cork parquet.

**The Care of Furniture.** The beautiful appearance which distinguishes really well-kept old furniture is due, in the main, to two circumstances. It has been shielded from rough usage, and it has been regularly cleaned with the familiar preparation called elbow-grease.

The kind of polish used for any wooden furniture is of comparatively small importance, for none of them is effectual without regular use and vigorous application. None of them will achieve its purpose by a liberal allowance and little rubbing. Beeswax and turpentine is a mixture which, though very old-fashioned, is perfectly safe to use on any wood, and in this connexion it should be remembered that it was the only preparation used by scores of housemaids who, through years of labour, produced that delightful patina we admire so much to-day on old furniture. On the other hand, preparations under various names are reliable, provided they are not taken as substitutes for regular rubbing with a linen cloth.

One of the worst marks and most difficult to remove is the circular stain left by carelessly used glasses in which hot liquid has been served, and it is worth remembering that the more brilliant the polish of the table top the more permanent appears to be the mark. The reason for this is that a fine polish is really a very attenuated film or gloss over the surface of the wood. This film is only obtained after an immense amount of labour. Alcohol or hot liquid will destroy it, and in the case of french polish only one method will put the matter right. This is to have the whole of that portion of the table-top glass-papered down and to repolish it afresh. The colour may be restored to varnished or wax-polished surfaces by treating them with linseed oil (q.v.). Ash and deal topped tables, such as those used in kitchens, can always be well scrubbed with soap, sand, and hot water, and the harder they are rubbed the better.

**Blistering of Furniture.** Occasionally inlaid furniture will cockle. That is to say, the thin veneer will come up here and there in a blister, and it cannot be remedied except by a cabinet maker, who may remove the veneer and re-glue it under pressure. This blistering is caused often by furniture standing too near a radiator, or sometimes damp will swell the wood and cause the trouble. It is curiously true that houses heated by radiators are more likely to damage furniture than those heated by the open fire, notwithstanding the variability in temperature arising from the older system. The explanation appears to be that heat from radiators draws the moisture from the

wood, causing it to warp and split. Furniture requires fresh air in England, for the wood is not dried to stand great heat as is the case in hot countries.

A weak solution of oxalic acid will clean leather coverings, but all preparations should be very sparingly used, and leather should not often have anything applied to it, or it is liable to become sticky. Horsehair seats should never be re-covered over the old cover, which should be removed and the stuffing taken out and cleaned before stretching a new covering over.

**FURNITURE BEETLE.** Several species of beetle that in a state of nature reduce to powder the dead, dry branches of trees have taken to the destruction of woodwork in the house—rafters, floorboards, and furniture. They are all very small, longer than broad; their breadth may be judged by the tiny holes which mark their exit from the burrows they eat in the wood whilst in the grub stage. The females search for a crevice in which to lay their minute eggs, and when these hatch the grubs at once begin feeding in the wood. The presence of these pests is usually indicated by a fine powder escaping from the holes in the wood.

*Furniture Beetle.*

*Worm-holes in deal flooring (natural size) made by the furniture beetle. (British Museum of Natural History)*

Remedies are very difficult in application. Dry heat of about 130° F. is perhaps the most certain way to destroy the grubs, and if the article affected is sufficiently small the ordinary gas-cooking oven will serve for the purpose. In the case of fixed woodwork and large furniture the apartment must be made absolutely airtight, when it may be filled with the vapour of carbon disulphide or hydrocyanic acid. The latter is a deadly poison and the former, though less dangerous a poison, will explode on contact with a light. Naphthaline in liquid form may be injected into the holes, but it is a tedious operation if there are many of them; or corrosive sublimate dissolved in methylated spirits may be substituted where the odour of naphthaline is an objection. *See* Antique Furniture; Sideboard; Wood Worm.

### FURNITURE CREAM AND POLISH.

Beeswax and turpentine together form an excellent polish for furniture. Shred the beeswax and add as much turpentine as will dissolve the wax to a moderately thick solution, or, as an alternative, add ½ oz. camphor to a bottle containing a pint of turpentine. Let the latter mixture stand for 24 hours before adding 2 oz. finely shredded beeswax. When this is dissolved

the polish is ready for use. Neither of these polishes should be made on a stove or close to a fire. Paraffin and turpentine or linseed oil, turpentine and methylated spirit mixed in equal quantities, provide other satisfactory polishes.

A good reviver for furniture which has been somewhat neglected is made from ½ pint each turpentine and linseed oil, and ¼ pint each brown vinegar and methylated spirit. Put these ingredients into a bottle, shake them well, and let them form an emulsion before using. *See* Antique Furniture; Spring Cleaning.

**FURRING: In Building.** Furring is the process of nailing small strips of wood to joists, rafters, wall surfaces, or any other part of a building, to form a level surface whereon to fix laths or building boards. The same expression is applied to packing pieces of timber which are employed to bring uneven pieces of carpentry work to a regular surface, as, for example, the packings under joists, to bring the top surfaces level. Short pieces of timber attached to the ends of the rafters of a roof for carrying the eaves beyond the surface of the wall are also known as furrings. Usually furrings are of quite small section, often about 2 in. wide and ¾ in. thick, and in the case of preparing a wall surface for covering with building board it may be necessary to pack out the furring strips so that their faces should be level.

**FUSE: How to Replace.** An electric fuse is a short length of thin wire of an easily fusible metal which is inserted in the electric circuit as a protection against fire. The current causes heating of the lamps or apparatus and also of the wires and cables, but there is no danger under normal circumstances. If, however, an excessive amount of current flows the heating may approach the limit, when danger from fire will result. Being of an easily fusible metal, the fuse reaches melting point earlier than the other parts of the circuit, and thus breaks the circuit, so that no current can flow.

*Fuse-box, showing detachable safety fuse holders.*

Where the cables enter a house two sealed fuse boxes with glass fronts, one for each cable, will be found situated on the company's side

of the meter. These fuses are not to be touched by the consumer. If they happen to fail, he should ring up the company to send and replace them. Next to the meter on the consumer's side comes the main double-pole switch, consisting of two large

tumbler switches connected by a wooden bar so that both work together. After the switch comes a pair of consumer's main fuses, through which the whole house supply passes; next comes a batch of three or more pairs of fuses, each pair carrying the current for a section of the house; and finally there may be a number of smaller fuses, which are often away from the other fuse-gear, and control single rooms.

In the event of the sudden extinction of a group of lights, the first thing to be done is to find and examine the fuse which has gone. If the fuse shows signs of heating and appears simply to have melted, one may suspect the cause to be gradual deterioration of the wire through long use, and a new piece of fuse may be substituted. Should the wire have disappeared, except for some blobs of melted metal, a definite fault on the affected circuit must be looked for before attempting to insert a new fuse. The cause may be a short circuit due to a mistake made in wiring some fitting which has been receiving attention, or perhaps the insulation on a hanging flexible has become frayed, thus allowing the bare wires of the two leads to touch and form a short circuit. After the cause of the trouble has been removed, the house must be entirely isolated by opening the main double-pole switch, when the melted fuse can be replaced by a new one. The ends of the burnt fuse will afford a guide to the proper size.

It is important to use the same size fuse-wire as before when replacing a fuse, as a larger size may be an infringement of the wiring rules approved by the fire insurance company, and thus may even invalidate the fire policy. The operation consists in cutting off a suitable length of fuse-wire and laying it in place with the ends wrapped round the terminal screws, finally securing the ends by screwing down the terminals, but not hard enough to cut the soft fuse-wire. *See Electricity.*

**FUSTIAN.** Although the name is applied to the whole class of heavy corduroys and moleskins, fustian means more specifically the dense, heavy cotton cloth with a smooth, leathery face that is much employed for making labourers' trousers. Drabs and browns are the colours most commonly in use, although others can be obtained. Fustian also makes an excellent material for covering chairs and stools.

**GABARDINE.** Raincoat cloths of various kinds are known as gabardines. Chiefly twill-woven, some of them are plain-weave, and are of cotton, a mixture of wool and cotton or all-wool. Those which are close-textured are best. Fawns, drabs, greys, slate, smoke, and similar self and mixture shades are the predominant colours.

Certain wool cloths of a twill or whipcord character and designed initially for raincoats are employed for dresses and tailor-made costumes.

Gabardine is made chiefly in 54 in. width. White or cream gabardine in heavy weight, either in all wool or with a cotton weft, makes an alternative to flannel for cricket and tennis trousers, and is less liable to shrink.

Before being made into raincoats gabardine is

submitted to a process which causes rain to run off the surface without wetting the cloth. Rainproof gabardine, unlike mackintosh, is not spoiled, but actually improved, by being dried in moderate heat before a fire. Grease and soap are very destructive of this rainproof property. Cotton rainproof gabardine in the best quality, and made from super-combed Sea Island cotton, wears well, but soon becomes dirty in towns.

**GABLE.** Properly speaking, the gable is part of the outside wall, having a triangular form, which rises above the level of the roof line. The gabled roof is the only alternative in an ordinary house to the hipped roof, the latter meaning a roof that is returned round the end of a building. *See Bungalow; House; Roof, etc.*

**GADROON: For Ornament.** This is a fluted ornament. It consists of a flowing reeded form, short for its width and rather oval or egg-shaped. It is often seen on the edges of tables, and is frequent on pieces made by Chippendale. It is also found on articles of silver and Sheffield plate.

*Gadroon. Example at base of a Sheffield-plate candelabra (Courtesy of Chapple & Mantell).*

**GAILLARDIA.** These are very showy annual and perennial plants with large double or single blooms, chiefly in shades of yellow and crimson. The perennial varieties are liable to perish in winter on heavy, clayey land, and it is usual to treat them as bien-nials by sowing seeds every year in June, either out of doors or in boxes of soil in a frame. Cuttings may also be inserted in a frame in August. Except on light or well drained soil it is wise to winter both seedlings and cuttings under glass and to plant them out in May. Some of the finest up-to-date varieties are Mrs. Bateman Brown, Tangerine and Mrs. McKellar. The flowers are long-stemmed and useful for cutting. The annual gaillardias are raised from seeds sown under glass in March, the seedlings being planted out of doors in May. These plants are useless after having flowered. Pron. Gā-lar-di-a.

*Gaillardia. Showy yellow and crimson blooms of gaillardia.*

**GAITERS: How to Knit.**

Gaiters can be had in various materials, as, for example, in leather, black oilskin, and waterproof cloth, but they may also be knitted in wool. Leather gaiters may be cleaned with boot polish, and those of oilskin washed with a cloth

dipped in warm soapy water.

A knitted pair, designed for a child of 2-4 years, can be made according to the following directions. Width is given by means of the expansive rib in which they are worked, and extra length can be added to make them suitable for an older child of 4 to 6 years. The materials required are 3 oz. of 4-ply Beehive Scotch fingering wool, and two No. 10 bone knitting needles. Half a yard of elastic about  $\frac{1}{2}$  in. wide will be required for the straps which go under the instep to keep the gaiters in position. For a larger size use 5-ply fingering and No. 8 bone needles, and knit extra length before shaping for the ankle.

Beginning at the top of the gaiter, cast on 48 stitches. 1st row: Knit 4, \* purl 2, knit 2; repeat from \* to the end of the row. Repeat this row for  $1\frac{1}{2}$  in. for the welt which comes above the knee. Now begin the knee shaping. Knit plain up to the last 12 stitches, then turn and knit back 24 stitches; turn again and knit 23 stitches; turn and knit 22; turn and knit 21. Continue in this way, knitting one stitch less each time until only 12 stitches remain on the last short row. Now turn and knit all the stitches on the needle; turn again and knit first 2 stitches, then purl to within the last 2 stitches, which knit. This completes the knee gusset.

The pattern for the leg begins as follows. 1st row: Knit plain. 2nd row: \* Knit 2, purl 2; repeat from \* to the end of the row. Repeat the last two rows until this fancy rib pattern measures 4 in. long. Here extra length can be knitted for a taller child before shaping the ankle.

*Gaiters. Pair of child's knitted gaiters with knee gusset.*

Shape the leg by decreasing one stitch at each end of every second row until there are only 40 stitches left. To decrease at the beginning of the row, slip the second stitch, knit the third, then pass the slipped stitch over the third stitch. At the end of the needle knit until within three stitches of the end, then knit two stitches together, knit the last stitch. Continue without any further shaping until the gaiter is long enough to reach the ankle (in the gaiter illustrated  $4\frac{3}{4}$  in.), then work the instep. Knit 12 stitches in the rib pattern, then on the next 16 stitches only, knit for  $1\frac{1}{2}$  in.; this makes the instep tab. Fasten off the wool very securely but still keeping the stitches on the needle.

Now go back to the point where the last 12 stitches were knitted before the instep tab was begun, and after the 12 stitches pick up and knit 9 stitches along the side of the instep tab, knit across the 16 instep stitches, pick up 9 stitches on the opposite side of the tab, and knit the remaining 12 ankle stitches. Work six rows on all these stitches in plain knitting, and cast off rather loosely. Press the gaiters on the wrong side, putting a thin damp cloth over the knitting, then sew up the back seam and sew elastic at each side in position so that it will just fit under the instep of the shoe. *See Knitting; Sock; Stocking.*

**GALANTINE.** This cold, glazed dish is prepared from boned meat, poultry, or game.

A good breakfast galantine can be made by removing the skin and gristle from 1 lb. of raw topside of beef and the rind from 6 oz. of raw, streaky bacon. Chop both finely or put them through a mincing machine; then place them in a basin with 6 oz. fresh white bread-crumbs, 2 beaten eggs, and 1 gill of good stock. Season, then pound the mixture gently, either in a mortar or with the end of a rolling-pin. Turn the whole on to a pastry-board, shape it into a roll, tie it up in a floured cloth, and boil it gently for two hours in stock or water flavoured with onions, turnips, carrots, or other root vegetables.

When cooked, lift, and after removing the cloth re-roll it and press it between tins until it is cold. Brush over the top and sides with 2 coatings of glaze, letting the first dry before applying the second. Trim the ends, lay the galantine on a dish, and garnish it with aspic jelly. *See illustration.*

*Galantine of boned meat, an appetising breakfast dish.*

#### Chicken Galantine. To

prepare this, bone one large chicken (*see Boning*) and remove the skins from 6 pork sausages, seasoning the latter with salt, pepper, and grated nutmeg. Cut  $\frac{1}{2}$  lb. ham and 2 hard-boiled eggs into strips, place the boned fowl on a table, and spread a layer of sausage meat all over the flesh. On this lay alternate strips of ham and egg. Cover the whole with more sausage-meat, then roll up the bird from side to side like a roly-poly pudding. Tie it up in a clean pudding cloth, and then put it, together with the bones, in a stockpot half-filled with water. Let the whole simmer for about  $1\frac{1}{2}$  hours, and when it is cooked, re-roll it tightly in the cloth, placing it between two tins or dishes. A good plan is to put heavy weights on the upper one in order to press the meat.

Leave the bird to get cold, and in the meantime prepare a sauce by melting 1 oz. butter, stirring into it 1 oz. flour, and cooking the two over a gentle heat for 5 min. Add  $\frac{1}{2}$  gill milk and  $\frac{1}{2}$  pint of the chicken stock, stir the whole until it boils, and then let it simmer gently for 5 min. Season the sauce carefully with salt and pepper, strain into it 2 teaspoonfuls lemon-juice, and let it cool slightly before adding 4 sheets of gelatine previously dissolved in 1 gill of hot water. Reheat the sauce carefully, put it through a hair sieve, and when it has cooled stir in 1 gill of cream. Then pour it evenly all over the chicken, and leave the whole to set, afterwards placing it on a dish with a border of chopped aspic arranged round the edges. If a cheaper dish is preferred, all milk may be used in place of the cream.

Veal galantine is made in the same way, using the same stuffing, but it is glazed in the same manner as

the beef galantine after pressing.

**Nut Galantine.** A vegetarian breakfast dish is made by shelling and blanching 3 oz. of nuts, skinning them and putting them through the mincing machine. Add  $\frac{1}{2}$  lb. breadcrumbs, or potatoes, a finely minced onion, and a teaspoonful each of chopped parsley and mixed herbs. Season well and bind with white or tomato sauce, and the beaten yolks of two eggs. Make into sausage shape, put into a scalded floured cloth and tie securely, before placing it in boiling water and letting it simmer for  $1\frac{1}{2}$  hours. When done, press and glaze as for beef galantine.

**GALATEA.** Made for nurses' uniforms and house dresses, galateas are strong twill cottons generally striped in blue and white and sometimes in red and white. Hard-twisted yarn and fast colours are employed in the manufacture, and they may be recommended for very hard wear. Pron. Gal-la-tee-a.

**GALBANUM.** This is a gum resin, greenish yellow in colour and with a disagreeable odour. It may be used as an expectorant, in doses of 5 to 15 gr. The compound galbanum pill, also known as the compound pill of assafoetida, as it contains both drugs, is used in hysteria.

**GALEA.** (Goat's Rue). This is a vigorous, hardy, herbaceous perennial which bears bunches of pea-shaped flowers in summer. It flourishes in ordinary soil and is increased by division or by seeds in spring.

Officinalis and Harlandii, pale lilac, and officinalis alba, white, are the chief sorts; they reach a height of about 4 ft. These plants take up a lot of room and therefore are scarcely suitable for small gardens.

*Galea or Goat's Rue, which bears lilac-coloured, pea-shaped flowers in summer.*

**GALL.** This is another name for the bile, the excretion of the liver (q.v.). The name is also used for the excrescences on the oak, *Quercus infectoria*, which is produced by the eggs of an insect.

**Gall Ointment.** This is an astringent ointment made by rubbing up powdered galls with benzoated lard, and is chiefly used for haemorrhoids or piles. When there is pain in this disorder the gall and opium ointment is better. See Piles; Tannic Acid.

**GALLIC ACID.** This substance is found in tea and other vegetable products. It is an astringent and acts like tannic acid, from which it may be obtained by boiling the latter with dilute acids, e.g. sulphuric acid. The dose is 5-15 gr. It has been used for arresting internal bleeding, and is useful for the night sweats of

phthisis, and in chronic diarrhoea, etc. See Tannic Acid.

**GALLON.** This measure of weight is used for beer, milk and other liquids, and for corn. It contains four quarts, and the standard imperial gallon contains 277.274 cubic in. Its weight equals 10 lb. of distilled water.

**Stock Sizes of Cisterns.** The usual stock sizes of galvanized iron cisterns, rectangular in form and open at the top, intended as receptacles for water are as follows:

Gal.	Length	Width	Depth	Gal.	Length	Width	Depth
	ft. in.	ft. in.	ft. in.		ft. in.	ft. in.	ft. in.
20	1 10	1 4	1 4	175	4 0	2 6	2 10
25	2 0	1 4	1 6	200	4 0	2 9	3 0
30	2 0	1 6	1 8	250	5 0	2 9	3 0
40	2 7	1 6	1 8	300	5 6	3 0	3 0
50	2 7	1 7	2 0	400	6 0	3 6	3 2
60	2 8	1 8	2 2	500	6 6	3 8	3 6
70	2 10	1 10	2 2	600	7 0	4 0	3 6
80	3 0	2 0	2 2	700	7 10	4 1	3 7
100	3 0	2 2	2 6	800	7 10	4 8	3 7
125	3 4	2 3	2 9	900	7 10	5 2	3 7
150	3 7	2 5	2 10	1000	7 10	5 9	3 7

**GALL STONE.** The hard, stony mass to which the name of gall stone is given consists of bile pigment, lime salts and cholesterin. It may be the size of an egg or no larger than sand, and the numbers vary from one or two large ones to hundreds of smaller ones. Gall stones, which may occur in the gall bladder or in the bile ducts, are much more common in women than in men, and are rare before middle age. Over-eating, lack of exercise, and abuse of alcohol are common predisposing causes. The active cause is germ infection from the intestine or by way of the blood which sets up chronic catarrh in the gall bladder.

Gall stone colic, or biliary colic, is the intense spasmodic pain occurring when a stone, leaving the gall bladder, passes along the bile passages on its way towards the intestine.

Preventive treatment consists in restricting the diet, insisting on sufficient exercise and keeping the bowels regular with salines, such as Epsom or Glauber's salts, etc. Alkaline mineral water or plain water should be drunk freely. Tight clothing should not be worn.

When an attack of gall stone colic occurs the doctor should be urgently summoned. Hot fomentations over the whole liver region sometimes relieve the pain, and should be tried until the doctor arrives. See Jaundice.

**GALL WEEVIL.** Attacks of the little gall weevil are very common to turnips. Damage is in the form of small whitish swellings, from the size of peas to that of marbles. The eggs of the weevil hatch into small, grey, wrinkled maggots, which

feed on the tissues, making a hollow cavity, in which they lie.

*Gall Weevil. Young turnips galled by the pest. Right, the weevil, much enlarged.*

The pest is worst on light soil, and may become serious on any land if proper rotations are not adopted. Change of site may not avert it entirely,

but will keep it within bounds. Should it threaten to become a chronic nuisance, every old stem of green and every old unused part of the turnip crop should be charred over the garden fire before being dug into the soil.

The piece of ground for next year's crop should be dressed with fresh lime at the rate of two stones per square rod, the substance being left on the surface for a few weeks and then turned into the top spit. As a further precaution, all transplanted greens should be well puddled with wet clay and soot the following year before planting. *See Cabbage; Club Root; Turnip.*

**GALOP.** This dance consists of gliding steps executed with much rapidity. Slide the left foot into the second position and chassé to the left, making a half turn on the ball of the left foot and drawing the right foot up behind. The movement is then repeated with the right foot. The girl's steps are the same, but she begins with the opposite foot to the man's. This is usually taught with 8 chassé, 4 and 2 danced smoothly.

*Galtonia candicans, the hardy Cape Hyacinth, which bears white, bell-shaped flowers in August.*

**GALTONIA.** This is a handsome hardy bulb plant which forms a tuft of large leaves, and in August bears drooping bell-shaped white flowers on a stem about 3 feet high. It is known also as the Cape hyacinth and as

*Hyacinthus candicans.* The bulbs are hardy, thrive in ordinary well tilled and manured soil, and are planted in March, 4 inches deep and 12 inches apart. Sand should be scattered round about the bulbs when planting on heavy land. In cold districts ashes should be placed on the soil above the bulbs in winter.

**GALVANIZED IRON.** Sheets of ordinary iron are treated by galvanizing to resist corrosion, common forms including the corrugated sheets used for covering roofs. Flat or Italian roof sheets are made of galvanized iron with one of the sides turned up to form a weather-

tight joint.

Galvanized iron is handled in a similar way to ordinary black iron, except that for soft soldering the flux should be hydrochloric acid. The soldering iron should not be worked too hot, and the surface of the metal must be thoroughly cleaned with a file or scraper before attempting to solder. It may be welded with the oxy-acetylene blow pipe if the film of zinc on the surface is removed by filing.

**Galvanized Wire.** As a rule, galvanized wire consists of soft iron wire coated with a protective film of zinc, applied by one of the recognized galvanizing processes. Being soft and pliable it can be used for binding metal parts to woodwork. It is made in many sizes, from fine to a rod of substantial thickness.

Fencing wire is generally made of galvanized iron, and No. 8 is the usual size for a single-strand wire. Stranded galvanized wire is used for clothes-lines and fencing, the common size having seven strands and ranging from Nos. 3 to 6 wire gauge. A cwt. of No. 6 contains about 450 yd., a cwt. of No. 3 about 260 yd., and other sizes in proportion. Galvanized barbed wire is generally made of steel, and sold in reels of ½ cwt. or more. Galvanized wire netting in various gauges and meshes is sold in rolls of 50 yd., from 12 in. to 72 in. wide, and from ½ in. to 4 in. mesh the mesh being the size of the spaces between the wires. *See Fence; Gauge; Wire; Wire Netting.*

**GALVANIZING.** The object of galvanizing is to preserve from corrosion articles made of iron and steel. It consists in applying a protective coating of zinc to the surface of the metal, and requires the use of special machinery. For hot galvanizing, the article to be treated is immersed in a bath of molten metal at a temperature of about 1000° F.

Electro-galvanizing is carried on in much the same way as the electro-deposition of copper and other metals. Another method is the dry process, sometimes known as sheradizing. The articles have to be properly cleaned and are then placed in a frame or barrel and heated to about 600° F. The barrel contains a quantity of zinc dust, and as the articles move about in it the dust is deposited upon them and forms a protective coating. The sheradized surface is rather brighter and more silvery than that produced by the ordinary hot galvanizing. Should the amateur worker desire to have his products galvanized, this can be done by sending them to a galvanizing firm through the local builders or ironmongers.

**GAMBLING:** In Law. Contracts by way of gaming or wagering are not enforceable at law. Cheques and other securities given for gaming debts may be stopped or recovered from the person to whom they are given. But if a cheque has been paid the money cannot be recovered; and if a cheque or security comes into the hands of an innocent party the latter can

recover on it. If an agent is employed to make bets and he pays any bets lost for his principal, the latter is not liable to repay him, even though he expressly requested him to pay the winner.

Money lent to pay a betting or gaming debt is not recoverable at law. If A owes B a gaming debt, and B threatens to do something which will bring A into disgrace unless he pays, and A promises that if B will hold his hand for, say, a month he will then pay him, and B agrees to do this, then A must pay at the end of the month. This is because the law regards the forbearance as a fresh consideration. If a betting agent wins for his principal and receives the money from the loser, he is bound to pay the money over to that principal.

It is a criminal offence to send a betting circular to a person under 21. It is also a criminal offence to keep a house or place for the purpose of betting with persons resorting thereto. A house kept as a gambling house is a disorderly house, and both the keeper and the frequenters are liable to penalties. If both parties to a bet deposit the money with a stakeholder, the loser may demand his money back before the stakeholder has actually paid it to the winner.

**GAMBOGE.** This is a reddish-yellow gum resin that acts as a powerful cathartic, producing copious watery motions. It is therefore useful for ridding the body of fluid in dropsy, and may also relieve chronic constipation. It is generally used combined with other drugs in the compound pill of gamboge, but it should not be used except on medical advice.

**GAME: Choice and Cooking.** In choosing game, select birds with firm, thick breasts, smooth legs, short spurs and quill feathers, and feet that are supple and easily broken. The time required for hanging depends upon the weather, the individual tastes of the person for whom the game is being prepared, and also upon the particular type of game concerned. Waterfowl, snipe, and woodcock, for instance, should be cooked while fresh, but most other kinds of game may be hung from between 5 and 10 days, and in some cases for a full fortnight. In damp weather 5 days will probably be found sufficient unless the birds are liked high, while game that is bruised or damaged in any way should be cooked as early as possible.

Hang the birds, unplucked and undrawn and with a piece of string tied tightly round the neck, in a place where there is a constant current of fresh air, and examine them carefully each day. If there are any signs of taint, wash the bird in a strong solution of salt and water to which a little vinegar has been added, and then rinse it in clean, fresh water. When plucking game be careful not to break the skin, and before cooking wipe it inside and out with a cloth wrung out with hot water. Snipe, woodcock, and plover, however, should never be drawn.

Roasting is the most satisfactory way of cooking most young game. To roast, pluck, clean, and truss the birds, tying a slice of fat bacon over the breast of each. Cook them before a clear fire or in a hot oven, the time

depending on the kind of bird, keeping them well basted with butter or good dripping. If the bird has been hanging for a long time, it will require to be cooked thoroughly. Ten minutes before the game is cooked remove the slices of bacon, dredge with flour, baste thoroughly and return to the fire or oven to brown well. Place two or three slices of buttered toast under the birds, so that any gravy which drips from them may be absorbed. Then lay the slices of toast on a hot dish, place the birds on them, and garnish the dish with sprigs of watercress. Hot gravy, bread sauce, and fried potatoes and breadcrumbs should be served as an accompaniment.

**Game Cutlet.** Prepare by melting 1 oz. of butter in a pan over the fire, adding to it  $\frac{1}{2}$  oz. flour and  $\frac{1}{2}$  teaspoonful chopped shallot, and frying these a light brown. Then pour in 1 gill stock, and stir the sauce until it boils. Add  $\frac{1}{2}$  lb. chopped game, free from bone, 2 oz. chopped ham, 1 teaspoonful red-currant jelly,  $\frac{1}{2}$  teaspoonful lemon juice, and the beaten yolk of an egg. Stir the mixture, but do not let it boil or the egg will curdle. Season it carefully and turn it on to a plate to cool.

Next shape it into neat cutlets, roll these in breadcrumbs, then brush them over with beaten egg and again coat them with crumbs. Have ready a pan of hot fat, put in the cutlets, one or two at a time, and fry a golden brown.

**Game Kromeskie.** Mince finely  $\frac{1}{2}$  lb. game, 2 oz. ham, and 8 mushrooms. Melt 1 oz. butter in a small pan, and in it fry 2 small chopped onions, browning them as little as possible. Add these to the game, etc., mix all well together, and season to taste, using enough brown sauce to bind it well. Turn the mixture on to a plate to cool, and then cut some fat bacon into thin slices about 3 in. square.

Put some of the cold game mixture on each slice, roll these into cork shapes, and fasten the ends with matchsticks or small skewers. Dip the kromeskies into frying batter, drop them into boiling fat, and fry them a golden brown, finally draining them on soft paper and garnishing them with fried parsley.

**Game Pie.** A raised game pie is best eaten cold. Instructions for making the pastry are given under the heading Pastry. Chop up finely 1 lb. each of veal and pork, and season them well with salt and pepper and grated nutmeg. Put a layer of this meat all round inside the pastry, and fill in the centre with strips of raw game of any kind. A mixture of different kinds such as grouse, partridge, hare, and pheasant may be used if liked.

The bones should first of all be removed, put into a pan containing cold salted water and a small onion, and left to simmer for about 1 hour. This will provide the stock. In layers with the game put 2 tablespoonfuls of chopped truffles, the same quantity of chopped

mushrooms, and 2 teaspoonfuls of chopped parsley. Cover these layers with some more of the veal and pork mixture, brush the edges of the pastry with a little cold water, and roll out the remainder of the pastry to form a lid. Make a hole in the centre.

Brush this lid over with a little beaten egg, and tie a greased band of paper round the mould to reach 3 or 4 in. above the top. Bake the pie in a moderate oven for 3½-4 hours, then take it out of the mould, and leave it to get nearly cold. Melt a little aspic jelly, add it to ¾ pint of the stock, and strain these into the pie and leave it to grow cold.

**Game Pudding.** Cooked in the following way, old game can be made quite tender: Cut a brace of birds into small joints, and chop up the hearts and livers. Skin 1 lb. of sausages, roll the meat into balls, each about the size of a large marble, and stalk and peel ½ lb. of mushrooms. Make some suet pastry, using ¾ lb. of flour, 6 oz. of chopped suet, a teaspoonful of baking-powder, a small teaspoonful of salt, and water to mix. Cut off a third of the pastry for the lid, roll out the remainder, and with it line a well-greased pudding-basin. Fill this with pieces of bird, sausage balls, and mushrooms, then pour in enough seasoned stock to reach three-quarters of the way up the basin. Wet the edges of the pastry, cover the pudding with the remaining piece rolled out to fit the top, and then press the edges together. Tie a clean pudding-cloth over the top, put the basin into a saucepan of boiling water, and boil its contents for at least 2½ hours.

**Game Salmi.** For a game salmi, first of all roast the birds, and then cut them into joints about the size of the wing of a partridge. Lay the joints on one side while the sauce is being prepared. The drumsticks should be cut off quite close to the flesh of the leg, and put with the trimmings, broken small, into a stewpan, with a slice of fat bacon, an onion, or 3 shallots, prepared and chopped fine, 1 oz. of butter, and a bay leaf tied up with a sprig of parsley.

Fry this briskly for 5 min., then pour over it 1 pint of good flavoured brown stock and a glass of sherry; 3-or 4 mushrooms, prepared and cut fine, are an improvement. Season and boil the stock until the liquor is reduced by one-half, then stir in ½ pint of brown sauce. Let it simmer for ½ hour, skimming off the fat as it rises, then strain it and add a piece of butter the size of a large nut, and a teaspoonful of lemon juice.

Heat the game thoroughly in the sauce without allowing it to boil. Arrange the pieces on a dish in the form of a pyramid, and pour the salmi sauce over and round it. Garnish with croûtons of fried bread and button mushrooms cooked in butter. *See Bread Sauce; Grouse; Gun; Hare; Partridge; Pheasant; Wild Duck; Woodcock, etc.*

**GAME FOWL.** Originally renowned for its righting prowess and now for its unique table qualities, this is one of the most popular of our domestic fowls. It lays a fair-sized white-shelled egg unexcelled for

richness of flavour, while for fullness of breast and fineness of bone it is unequalled by any other breed. Game fowls are divided into two classes, namely, old English and modern, and in addition there are many varieties of each. *See Fowl; Poultry.*

*Game Fowl. Cockerel of one of the most popular domestic breeds. (Courtesy of "The Poultry World.")*

**GAMGEE TISSUE.** This consists of a layer of absorbent cotton wool between layers of gauze. It forms a tidy outer dressing for wounds, and is very suitable for applying a protective jacket to the chest in cases of bronchitis, pneumonia, etc. The jacket is cut into shape for effective application. *See Dressing.*

**Gammon.** Cut of bacon taken from the thighs of the pig. *See Bacon.*

**GANGLION.** A Greek word denoting a tumour under the skin, the term ganglion is used to describe two entirely different things— a swelling attached to tendons and a small collection of nerve cells; the former is an abnormal condition, the latter a normal structural part of the nervous system.

The former is a small swelling, often about the size of a hazel-nut, attached to the tendons on the back of the wrist and occasionally to those of the instep. It consists of a jelly-like substance, and is in fact gelatinous connective tissue which forms beneath the sheath of a tendon, probably as a result of long-continued irritation or strain. Such ganglia are frequently connected with the joints beneath the tendons and are nearly always larger and more extensive than they appear to be from external examination.

They can be safely left alone, but if they cause pain or inconvenience they can be removed by a small operation.

A more serious form is known as a compound ganglion. This is a tuberculous infection of the sheaths of the tendons and most frequently occurs about the tendons on the front of the wrist. A considerable collection of fluid results, which distends the sheaths, and is manifested by swelling above the wrist and in the palm. The most speedy and effective treatment is operative.

**GANGRENE.** The Anglicized form of a Greek word denoting a rodent sore, the term gangrene is applied to a local death of tissue, usually of an extremity, but liable to occur in any organ or part of the body. The changes that are operative in the production of the condition are those that cause

obstruction to the local blood supply. The main artery supplying the part may be torn across, or it may be blocked by an embolus, compressed by an inflammatory mass or tumour, or it may be the seat of slow obliterative changes in its own wall. Burns and frost bite are other causes of gangrene.

Two varieties are recognized, dry and moist, the latter being by far the more dangerous; the parts are cold, swollen, discoloured, and afford an ideal breeding ground for poisonous organisms. Most gangrene is associated, therefore, with very profound symptoms of poisoning and a serious danger to life.

Two chronic diseases are especially prone to lead to gangrene of the extremities—diabetes and arterial degeneration of old age. Gas gangrene is a special form of rapidly spreading gangrene common in warfare. It affects even trivial wounds and causes heavy mortality.

Moist dressings such as fomentations are dangerous and should never be used; their place is to be taken by dry heat and dry antiseptic powders; the limb should be raised on a pillow so as to allow as free an exit as possible for the blood and lymph from the affected area, while by gentle massage the circulation in the more healthy vessels of the limb is encouraged.

**GAPES.** A disease peculiar to young chickens, gapes arises from the presence of gape worms in the windpipe. These cause the chickens to open their mouths as if gaping, and if not removed in time will result in death by suffocation. The worms can generally be dislodged by dipping a long, soft feather in turpentine, gently inserting it into the windpipe, and twisting it round, and then withdrawing it, when the worms will be coughed up by the chicken.

Thorough disinfection of soil, coops, and runs must be resorted to whenever an outbreak of gapes occurs. The plan usually adopted for cleaning the land is to lime it thoroughly and let it lie fallow for two years at least. (Ministry of Agriculture Bulletin, No. 6.) *See Chicken; Poultry.*

**GAPING.** Due to a lack of oxygen in the blood, gaping may result from fatigue or from, sitting in a stuffy room. Gaping is a common symptom in persons who suffer from chronic lung trouble.

## GARAGES AND THEIR CONSTRUCTION

### Housing Large Cars, Small Cars and Motor Cycles

By following the instructions given below the motorist who is handy with a carpenter's tools can easily erect a garage to suit his requirements. Consult the articles *Amateur Carpentry; Asbestos; Cement; Door; Weatherboard*, etc. *See also Bicycle Shed.*

A garage is a necessity to very many householders, for the requirements of modern life demand the use of a motor vehicle, and even if this be nothing more than a motor-cycle or a side-car combination, it is desirable to house it in a sound, dry building.

*Garage. Fig. 1. Garage for motor cycle and side-car. Constructional drawings are given on page 862A.*

Suitable materials of construction are numerous. In brick districts the use of the cheapest grade of brick might prove most economical; where gravel abounds, the walls could be put up in concrete at small cost. There is a wide choice of timber structures and suitable asbestos and other building boards.

The motor-cycle and side-car garage shown in Fig. 1 is made on a timber framework covered with asbestos sheets and roofed with galvanized iron. It is highly desirable to fix the dimensions of the building so that the sheets can be used in their stock sizes. Cutting them is a tedious business, and there is the risk of breaking the sheets; the sizes available can be ascertained from the makers or from the builder's merchants.

The first thing to do is to prepare a plan of the site and of the building, and to mark the leading dimensions, something in the manner of Figs. 1 to 7. The side (Fig. 2) and end frames (Figs. 3 and 4) are then made up from 2 in. square deal, halved at the corners, and well nailed together at these and all joints. Cross braces are essential to provide the requisite stiffness, as the asbestos sheets look to the frame for their support, and do not support the frame to any great extent, as is the case when timber is used.

The floor (Fig. 6) is prepared by nailing 1 in. tongued and grooved boards to 3 in. by 2 in. joists, the underside being treated with creosote or some other preservative. The site is cleared of top soil, and nine little piers of brick or stone placed as shown in Fig. 6 so that they will support the sleeper plates, which are of 4 in. by 2 in. deal. The sleeper plates should be creosoted, and held in place by pegs driven into the ground to keep them from shifting while the floor is placed in position upon them. The floor could be laid in cement concrete, but in this case the expense is considerably greater.

Having placed the floor in position, the walls are erected by setting up one side frame, and supporting it temporarily with a cross batten. The end frame is set up and the corners bolted together. The walls must be plumbed up true with a plumb bob, and the angle set square, testing this with a large straight edge and a

large set square, or by the 3.4.5 angle system. This is done by measuring a distance of 3 ft. along the end wall from the corner, and measuring along the side wall a distance of 4 ft. Mark these places by driving nails into the frames at the exact spots, and when the distance across the angle between them is 5 ft. the corner of the building is square. Adjust the wall frames until the corner is square and then fix them to the floor with two bolts in each section, putting them through the joists. The other side and end frames are then erected, and all corners bolted up tightly.

The ridge board is fixed in position, and the walls covered by nailing the asbestos sheets to the framing, the uprights for the latter having been spaced so that the joints between the sheets come on one of the frames. The bottom of the sheets should come just below the bottom of the floor to protect it from the weather and to allow the water that runs down the walls to drip away and not accumulate under the building. This is one of the reasons for the sleeper plates, as they raise the floor above ground level. The top surfaces of the sleeper plates are improved by nailing a strip of stout roofing felt, or preferably a bitu-minous damp-course, to prevent the damp rising from the ground. Free circulation of air under the floor is essential.

The roof is a simple matter when corrugated iron is used, as the sheets have only to be nailed to the ridge and to the plates or to the top of the wall frames. If preferred, it can be made with boards and covered with a good quality roofing felt or imitation roofing tiles. The interior is all the better for a lining of thin matchboard or 3-ply wood, but this is not absolutely essential. The gable ends are covered with weatherboard, as this is easier to fit than cutting the asbestos sheets. All corners and the joints between the sheets are covered with vertical strips of wood about 4 in. wide and  $\frac{1}{2}$  in. thick, as shown in Fig 7. The doors (Fig. 5) are made of matchboard, ledged with 4 by 1 in. deal, and braced with the same material, provided with a bolt and a stout padlock and hasp.

The whole of the exterior woodwork is creosoted, and the roof coloured with a dark red paint; this had better be done after the building has been erected, as the sheets will have mellowed and will take the paint better. The interior can be lined with matchboard or 3-ply wood; but if this is not done, a skirting board and a striking board should be nailed to the walls to take the thrust of the wheels when the machine is pushed in. An exterior ramp or sloping approach must be made and fixed in place to enable the machine to be pushed in without trouble; these boards should have an easy slope, and be supported on wedge-shaped blocks.

**Weatherboarded Garage.** For housing the average car a garage of the size given in Figs. 8 to 12 is ample. It measures about 14 ft. 6 in. long by about 7 ft. 6 in. inside, and has a head clearance of 6 ft. 4 in. Before starting to build, however, it is a wise precaution not only to measure up the car, but to consider whether a larger car is likely to be purchased.

The building consists virtually of four frameworks forming the walls, and a roofing. The frames are made

up from 3 in. by 2 in. stuff and are covered with weatherboard. Each side is made up as a complete unit in itself, and all four are fixed together with bolts afterwards. This makes the whole collapsible, a great convenience if it is desired to move at any time, and simplifies the erection.

Figs. 9, 10 and 11 give the sides, back and door ends respectively. Cut off the various parts to length, taking care to make each set of parts the same length. A simple form of joint to use is the halved joint: all parts can then be cut off to the overall size and the joint marked out with a gauge. When nailing the frames together test carefully for squareness. A good method of doing this is to place a lath of wood diagonally across the whole and mark the length. When put into the opposite corners it should show the same length. The diagonal struts shown in Fig 9 are added afterwards.

The two ends are made in the same way except that the sloping top part is added after the main square part has been put together. Here again the joints are halved, except at the ends of the top sloping members, which are simply bevelled at the underside and nailed down.

**Erecting the Garage.** The type of flooring the garage is to have must first be determined. Concrete is much used nowadays, and has the advantage of forming a foundation for the whole. If this is used channels must be formed in it to allow the bottom members of the walls to sink in so that there is no projection beneath the door. A ramp can be formed outside, as shown in Fig. 8.

Assistance is necessary when fixing the walls together. They are held by handscrews, and bolt holes are bored through the joining uprights. Pass the bolts in from the outside, and put washers beneath the nuts. It will be noticed from Fig. 9 that an extra sloping roof piece is fixed at the centre. When this has been added a series of long pieces known as purlins are nailed down on to the sloping pieces, as shown in Fig. 12. These are to take the roof boards. The last named should preferably be tongued and grooved. Note that the top ends must be cut off at an angle so that there is a good ridge joint. It is a good plan to cut off one board to length, and then cut all the others to it.

The roofing felt is laid on in long strips running from side to side without a join at the top. At the joints an overlap of about 2 in. should be allowed. To make these waterproof use the special cement supplied by the makers. Clout nails are used to fix the felt, and battens of 2 in. by  $\frac{1}{2}$  in. stuff are nailed down over the joints. When cutting the felt to length an extra allowance of about 2 in. should be made so that it can be turned up underneath at the edges.

Fig. 13 shows how the weather boarding should be fixed. It is added from the bottom upwards, and the nails are driven through the overlap, as shown. Note that the boarding at the sides reaches only to the ends of the side frames. A batten fixed to the edges of the front and back frames has the effect of hiding the ends

Garage: How to construct the garage for a motor cycle and side-car shown in the previous page. Fig. 2. Side frame. Fig. 3. Rear end frame. Fig. 4. Front end frame. Fig. 5. Doors, shown from both outside and inside. Fig. 6. Plan of floor. Fig. 7. Details of corner, showing coverboards.

of the boarding. The decorative battens above the doors are nailed direct over the boarding.

An ordinary casement window framing is made for one side. The framing is screwed or nailed to the sides, and the casements hinged to them. For the doors use tongued and grooved boards secured by a series of cross pieces. Diagonal braces should be added to prevent the whole from sagging. All timber should be creosoted to make it durable. For a good job rebated or matched weatherboard could be used, which would present a flush inside surface.

**Garage in Asbestos Board.** A somewhat lighter garage suitable for the "baby" type of car is given in Fig. 14. The main framework is similar to that in Fig. 8, but the walls are covered with asbestos board instead of weatherboarding. Apart from the size of the car it is to shelter, and the space available for it, one should consider the sizes of asbestos board available before starting on the framework. Otherwise, there may be a good deal of unnecessary waste and labour. The boards are in long panels fixed upright, and the framework has to be so made that the framework uprights coincide with the vertical joints in the boards.

A side framework is given in Fig. 15. This allows for panels 2 ft. wide. If the long sides are made to suit the asbestos boards, the two ends (Figs. 16 and 17) can be made any convenient size, for in any case there is a fair amount of trimming to be done here. A fixed window is provided at the back. The framework for this is made up complete in itself and is fixed in the space for it after the whole job has been erected.

Having completed the four frames for the sides and ends (the joints are halved as before), they are erected in position and bolted together. Either a concrete foundation can be made, or stout wooden sleepers can be laid down. Alternatively, bricks can be set out and the garage mounted upon these. If concrete is not used for the flooring, a framework with boards laid across it must be made up. In size this should just fit inside the walls, and is laid in position before the walls are erected.

Large clout nails are used to fix the asbestos board. Fix the whole in position, trimming them where necessary with an old handsaw. A series of battens of 2 in. by ½ in. stuff can be fixed over all the joints (Fig. 18). These give a decorative touch. It is advisable to stain them before fixing. The roof can be made similarly to that in Fig. 8.

Ledged and braced doors made up with tongued and grooved boards are hinged with strap hinges at the open end. A covering strip is nailed down over the right hand door. The ramp can be a series of stout boards nailed down on to three tapering cross pieces.

Numerous by-laws of local authorities control the building of garages, and in particular the materials of which they may be constructed and their distance from the public street or other building. Building a garage usually increases the rateable value of the premises.

**Hiring a Garage.** Some motor car owners, such as those who live in flats, possess neither a garage nor the

ground on which to erect one. To these owners two courses are open. They can either hire a garage or can keep the car at a public one.

In large cities many lock-up garages have been erected, with rents usually in the neighbourhood of 10s. a week. They are often built in connexion with a public garage, or petrol filling station.

In public garages the charge is so much per week or per month, but this method will be found more expensive than building or hiring a lock-up one. It has, however, some advantages, one being that the requirements for repairs of all kinds are on the spot. Moreover, since it is connected by telephone with the owner's house, the delay in summoning the car will be slight.

**Safety Precautions.** The regulations known as "Statutory Rules and Orders, 1929," relating to the storage and use of petroleum spirit affect the garage owner. Every private garage or other building in which petrol is stored, whether it is contained in the usual two-gallon cans or in the tank of the car or motor cycle, must meet with certain requirements.

It must be effectively ventilated; it must have an entrance direct from the open air; it must be separated from adjacent buildings or from other rooms in the same building by fireproof floors or partitions: and suitable fire extinguishing apparatus must be kept in the storage place or as near to it as is reasonably practicable. The extinguisher carried on the car is no longer considered to suffice for this. As an alternative to a fire extinguisher, a supply of sand or other effective means such as loose fine earth may be kept in a pail ready for use, but sand and earth are much less effective than a chemical fire extinguisher. Water should not be used on any account, since both oil and petrol float on top of the water, which will therefore merely assist in spreading the flames.

If any petroleum spirit is kept in the garage, other than that in the tank of the car, it should always be contained in the proper screw-stoppered cans, and must not be left in an open vessel. The greatest care must always be taken to avoid any fire or naked light being so near any vessel in which the petrol is kept as to be dangerous. It should be remembered that even a particle of red ash dropped from a cigarette may cause a fire when filling the car tank. The fumes from the exhaust of a motor vehicle may contain the highly poisonous gas known as carbon monoxide, produced by imperfect combustion of petrol in the engines.

*If the engine is allowed to run while the car is standing in the garage, the exhaust should be connected to the outer air so that the dangerous fumes do not escape into the building. A further precaution is to open doors or windows in order to ventilate the garage thoroughly.*

## GARDENS AND HOW THEY ARE PLANNED

### *How to Lay Out a Town or Suburban Plot*

Garage. Fig. 8. Weatherboarded garage for an average-sized motor car. Fig. 9. Side frame. Fig. 10. Rear end frame. Fig. 11. Front end, with frame for door. Fig. 12. Fig. 14. Garage for small car, covered with asbestos board. Fig. 15. Side frame. Fig. 16. Framework of door end. Fig. 17. Framework of rear end. Fig. 18. Method of fixing asbestos boards and the battens covering joints.

Here are given three ways of arranging a small garden, together with a plan for a large one. Further information appears under the headings Dutch Garden; Flower Garden and Kitchen Garden. Consult also the succeeding articles Gardener; Garden Furniture; and Gardening; those on Crazy Paving; Digging; Fence; Fixtures; Greenhouse; etc., and, in addition, entries under the names of individual flowers and vegetables.

Planning a garden must be done with method, otherwise mistakes will happen which may entail much labour. To lay down hard and fast rules is not practicable, since one garden may differ entirely from another.

This article does not cater for those who are fortunate enough to possess a large position amid ideal surroundings, but for those whose pleasure is limited to the rectangular plot in town and suburb. The maker of such a garden is usually confronted with a rectangle of ground enclosed by bare wooden fences. With a sheet of paper sectionally ruled, some wooden pegs and string, and ordinary intelligence, the novice may achieve success with his garden.

*Walled formal garden, with paved paths and square beds filled with tall tulips, a different colour in each bed.*

For the purposes of illustration a plot of old meadow land is assumed to be the site available, and its measurements are 68 x 30 ft., a good average size. The requirements are space for flowers, roses, vegetables, a lawn, and, if possible, a little fruit, grown within the limitations defined. With this purpose in view three plots are dealt with, each precisely the same size, but differing in aspect, the respective plots facing approximately north, south, and east.

Fig 1 deals with a plot of the measurements mentioned; it has a northerly aspect when faced from the back of the house, shown by the darkly shaded portion at the bottom of the plan. The first operation may be to locate and erect the trellis about 41 ft. from the house, dividing the flower garden space from that to be devoted to vegetables and fruit; this is shown by the irregular shaded line running between the arch (B) and the small summer-house (C).

It is then advisable to take string and pegs and mark out the borders A, B, and C, their respective length and width being 36 x 5 ft., 31 x 4 ft., and 18 x 2 ft., afterwards pegging out the narrow edging for ferns and iris against the house. Next mark out a rectangle for lawn

and rose-beds measuring 32 x 18 ft., which will leave three footpaths well defined as shown in the plan. The rose-beds A and B measure 21 x 4 ft. and 15 x 4 ft. The skeleton of the flower garden being thus effected, the work may proceed by following the advice on digging, path making, and lawns, given under their respective headings.

*Sunken garden, with grass and crazy paving, that centres round a little lily pond.*

The space for vegetables is necessarily small, but most amateur gardeners like to raise a few fresh vegetables for the household in addition to cultivating flowers, and therefore it will give added interest, as well as some profit, to the general scheme. The diagram is almost self-explanatory, the fences being fronted with a bed of rhubarb, a 12 x 6 ft cool greenhouse A, the space allowed being devoted to a storing shed if preferred, a frame 6 x 4 ft, a row of sweet peas 18 x 4 ft., ample room for loganberries, and a bush apple B. A path 3 ft. wide divides these from the centre plot, and leads directly from the main path of the flower garden to the greenhouse.

It is suggested that cordon fruit trees C, and a second bush apple D, be planted as shown in the sketch, leaving the remainder of the space for vegetables. Quite a useful crop of such vegetables as carrots, turnips, salads, etc., can be grown here, but, if preferred, raspberries, currants, and gooseberries may be planted instead. Potatoes would be profitable during the first season, as these break up new ground admirably. Whatever is chosen should be planted or sown diagonally.

In Fig. 2 the plot is identical in size with that in Fig. 1, but the house faces due south instead of north. This difference in aspect naturally requires a different layout, and the suggested remodelling is shown in the diagram.

The main border A is now placed on the eastern side, not the side with the eastern aspect, which is a very different thing, continuing squarely to the arch B, which leads to the vegetable garden. The path also is transferred to the same side of the plot, the house end enclosing a bed about 16 x 6 ft., which may well be devoted to dwarf roses, with perhaps a weeping

standard in the position shown. Standard roses on the lawn to run parallel with the path would be a pleasing arrangement. The dimensions of the lawn are 26 x 18 ft., and flowering trees or shrubs may be planted with excellent effect at C C.

The greenhouse proposed in Fig. 1 is transposed against the dwelling house, and it is suggested that instead a conservatory would be an agreeable adjunct to the drawing room. In the portion reserved for vegetables and small fruits, dimensions 27 x 17 ft., a shed is conveniently placed at D. while the frame is placed in a more suitable position at E. The trellis screen is now 43 ft. from the house, whilst the sizes of the various beds and borders are: A, 38 x 5 ft.; F, 38 x 4 ft.; G, 14 x 3 ft.; and H, 16 x 3 ft. Bush fruits of various kinds may be planted at J J.

In Fig. 3 an aspect facing due east adds to planning difficulties by reason of the southern side of the garden facing direct north. The diagram, however, makes suggestions which may overcome the drawbacks of aspect. Naturally beds should be confined to the north side, suitable climbers being planted to cover the southern fence as defined in the sketch. The trellis screen and arches A A A are 40 ft. from the house, the length of the main border B being 36 ft.

The bed C is 43 ft. from point to point, and is about double width at the house end. Bed D may be 14 x 3 ft., and border E 19 x 3 ft. Shrubs may be planted at F F, and standard roses at G G G. The vegetable plot is 30 x 24 ft., and positions are given to a greenhouse or shed at H, and frame J. There is also room for a flowering tree, a loganberry against the bottom fence, and a morello cherry against the fence facing due north. Borders which have a north aspect are often a source of trouble and disappointment in small gardens, but the natural shortcomings of such a position may in great part be overcome by judicious attention to suitable plants. Roses recommended are Dundee rambler, Bennett's seedling, Gloire de Dijon, René Andre, and Felicite-et-Perpetue.

A number of hardy plants that will grow successfully in such a position include columbines, various campanulas, lily of the valley, day lilies, irises, Michaelmas daisies, herbaceous phlox, montbretias, golden rod, spiraeas, Solomon's seal and meadow rue, with edging plants of polyanthus, London pride and mossy saxifrages. The soil in a north border should always be well dug, and tendency to sourness dissipated by the free use of lime. Amongst shrubs the flowering currant and laurustinus will be found useful.

In Fig. 4 the lay-out of a more extensive plot is dealt with, its measurements being about 154 ft. by 1.19 ft. This design gives the foundation of a charming garden, which is adaptable to any aspect, and sufficiently elastic to allow for alteration according to individual fancy.

**Garden Law.** Every man is under an obligation to use his property so as not to injure that of his neighbour, and this legal maxim applies as much to the garden as to the house. Most people who have a garden devote more or less attention to its cultivation, although they are not actually bound to do so unless there is a

clause to that effect in their agreement in the case of tenants. But they render themselves liable to be sued for damages if negligence on their part results in injury to adjoining property. Thus if a drain is not kept in proper repair, and it overflows and works havoc in a well-cultivated garden adjoining, the neighbour will be entitled to compensation.

On the other hand, if the owner of the drain can prove that the flooding was caused by a violent downpour of rain and not through any negligence on his part, then he can escape liability. The same principle holds good where a tree is blown down by a storm and damages the flower-beds or the greenhouse in the next garden. But if the tree was old and in an insecure condition, so that it was likely to be blown down, and no attempt had been made to support it, the owner of the greenhouse has a good cause of action.

Whether or not a tenant is responsible for the upkeep of a fence will usually depend on his tenancy agreement. Even if he is bound to his landlord to keep up a fence, this does not mean that his neighbours can compel him to keep it up. So far as they are concerned a man is generally under no duty to fence his ground. Nor is he bound to put up or maintain a fence between his own ground and the highway. If he has no fence, however, he must see that there is nothing dangerous—e.g. a pit—on his ground near the highway which might injure persons who inadvertently came on to his ground from the highway. In general, householders find it prudent to enclose, in part or in whole, their gardens.

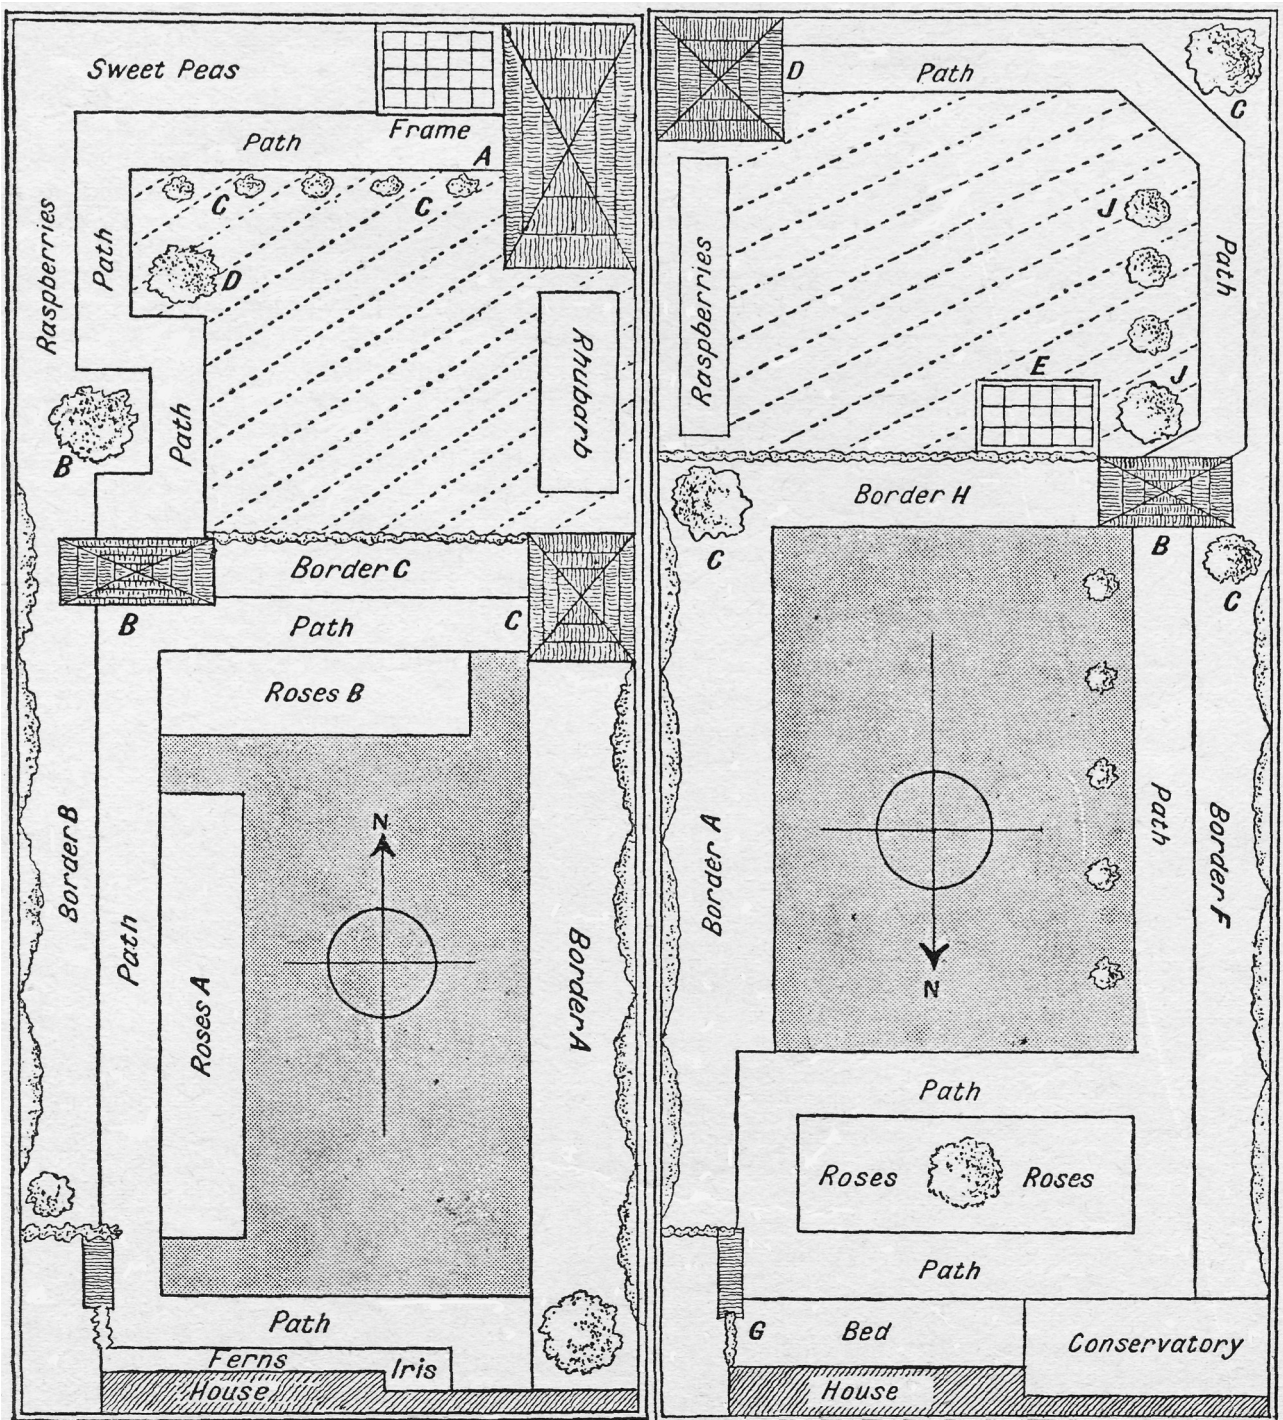

Innumerable legal decisions have been given on the subject of fixtures, and some of these apply to the garden. The old rule is, in effect, that what is once affixed to the soil must not be removed. For example, a tenant who has improved the appearance of his garden by planting an ornamental border of box is not allowed to remove it unless by special agreement with the landlord, and the same rule holds good in regard to trees that have taken root and become established.

But there are exceptions to the old rule of law. Thus, where the tenant is a gardener by occupation, he may take away any trees and shrubs which he planted for business purposes, and even greenhouses or other structures. As a rule, much depends on the terms of the agreement made with the landlord, and it is always advisable at the outset not to forget the garden when settling what fixtures may be removed at the expiration of the tenancy.

A good example of a popular error occurs in regard to fruit trees, for it is often presumed that a tenant is entitled to any fruit which falls into his garden from his neighbour's trees. This, however, is not the law on the subject. In such a case the fruit still belongs to the owner of the trees, who may exercise his right of recaption by recovering it from the adjoining garden if he chooses. The same rule applies to branches lopped from trees which fall into a neighbour's garden. Where

*(Continued in page 932)*

Garden. Figs. 1 and 2. Two methods of laying out a garden plot, the difference in arrangement being due to difference in aspect. In Fig. 1 the aspect is north, while in Fig. 2 it is south.

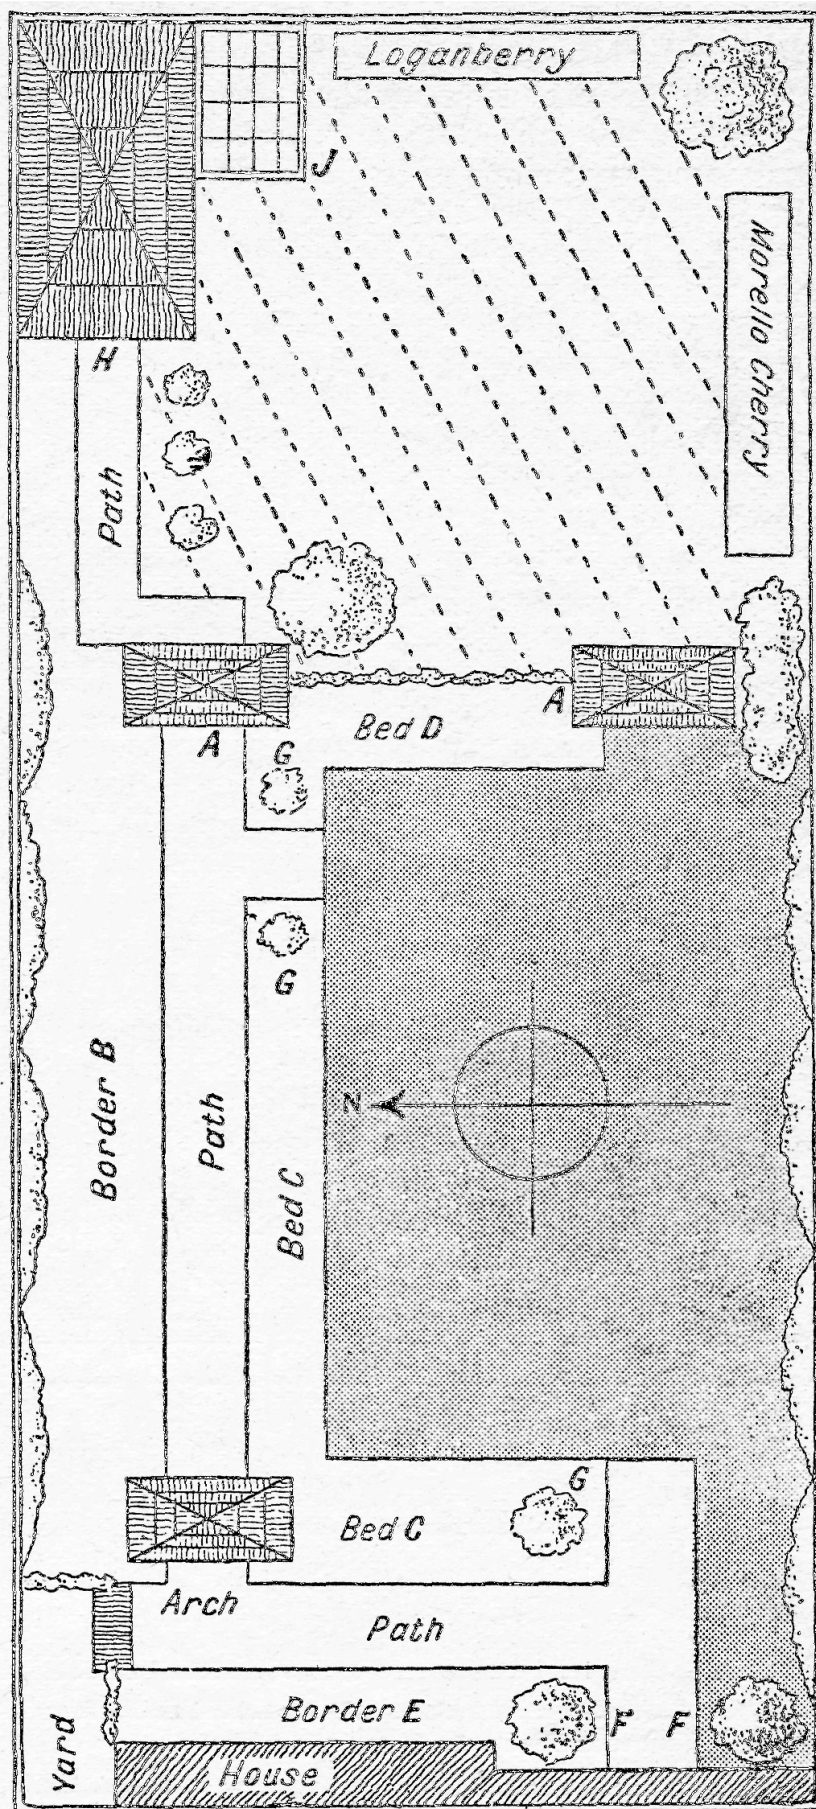

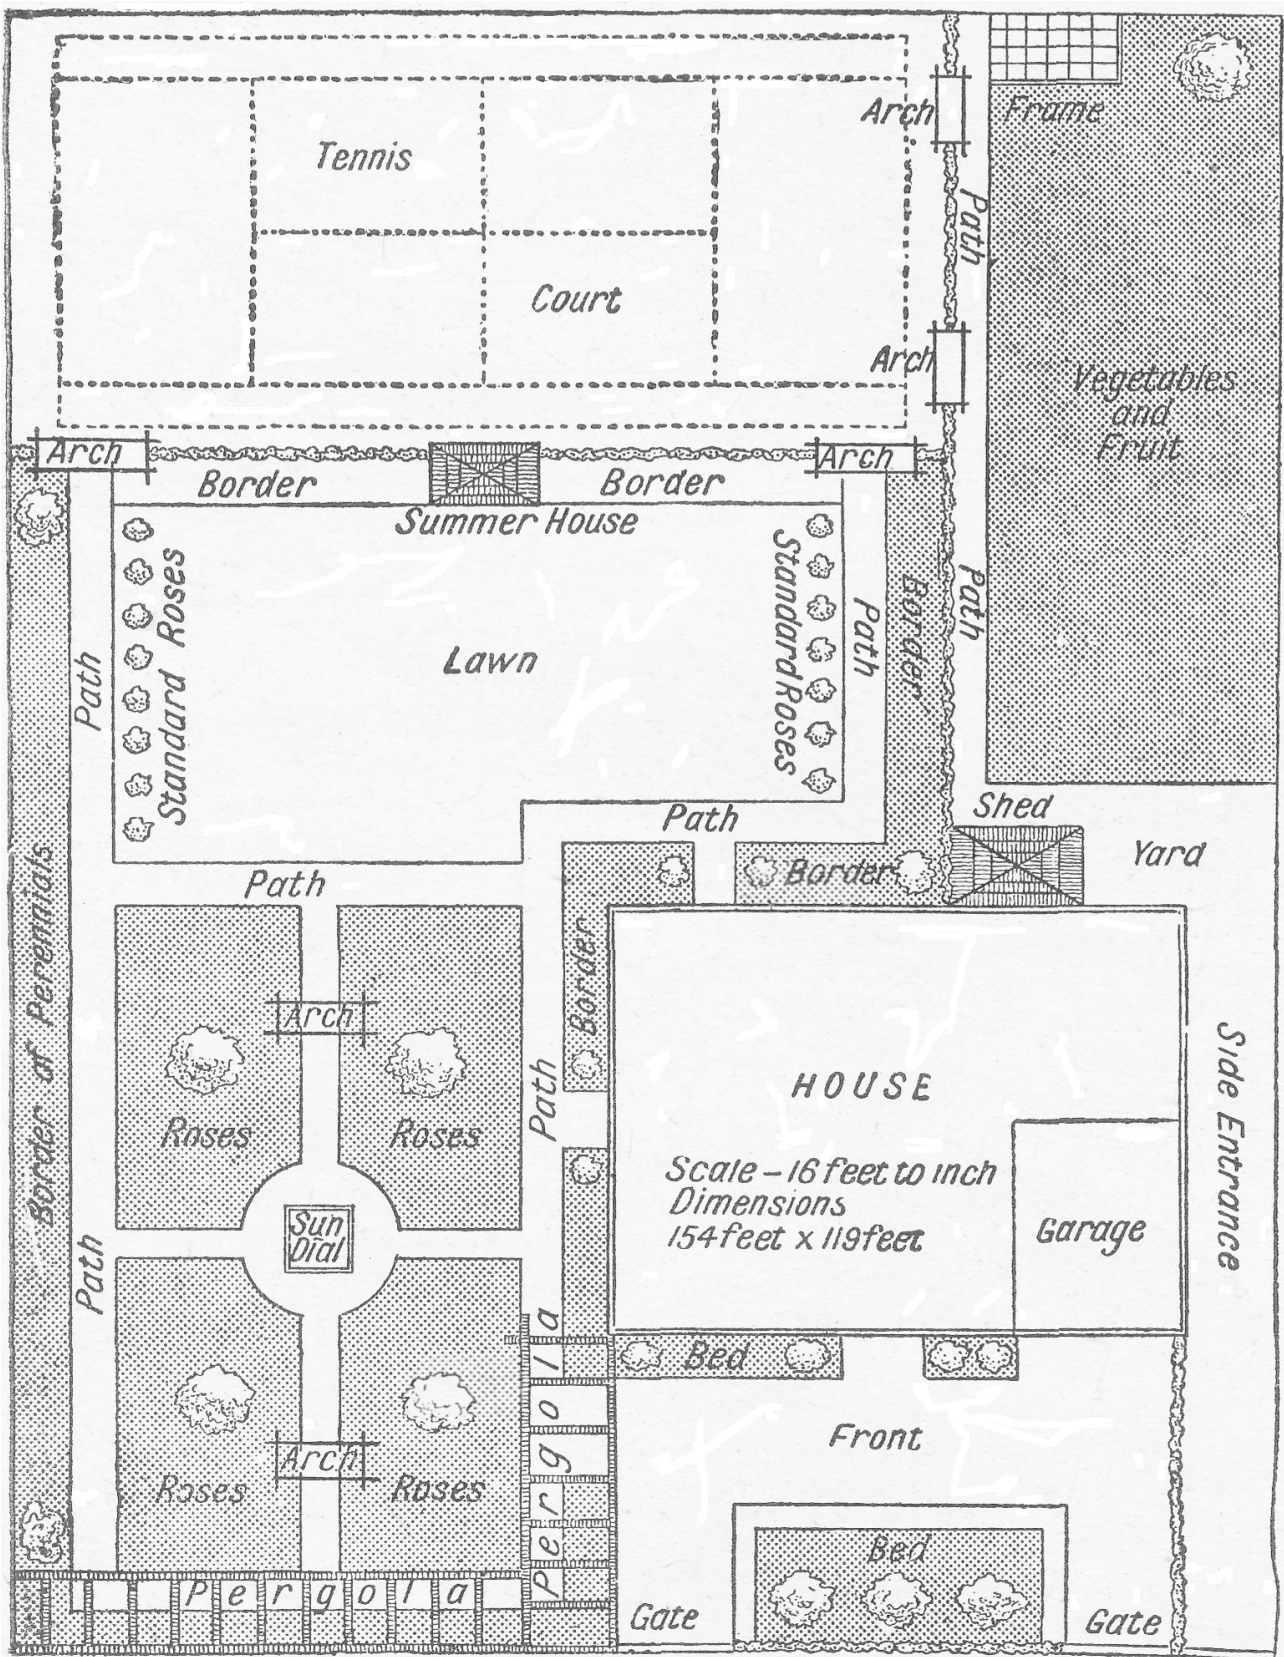

Fig. 3. Another method of laying out the same plot. In this case the garden looks east.

Garden. Fig. 4. Plan of an extensive plot which can be transformed into a charming garden, with tennis court, crazy paths, pergolas and borders.

**GARDEN: EFFECTIVE LAY-OUT FOR A MODERATE-SIZED PLOT.**

This plan makes the garden look larger than it actually is by a judicious dividing up with trellis and pergola. The vegetable garden is on the left, and in the extreme foreground is the tennis court. A well-covered pergola acts as a screen from the road. The wide borders provide plenty of space for herbaceous flowering plants suitable for cutting, an important factor in most middle-class homes, and the long pergola is admirable for roses, either ramblers or climbers.

**GARDEN: TWO SUGGESTIONS FOR SMALLER PLOTS.**

Here we see how the maximum effect may be produced from the minimum space. On the left, a narrow garden with a southerly aspect. Well-stocked borders and a wide arch provide plenty of space for flowers, and there is a small but adequate vegetable garden. Right, a similar garden with a northerly aspect. Here the vegetable garden is fenced off by trellis. Vegetables and fruit bushes are planted diagonally to get as much sun as possible.

branches overhang the next garden, the tenant of the latter is entitled to remove them if he has cause to believe that they interfere in any way with the growth of his plants, but the branches which he has cut off belong to his neighbour, and he must not destroy them without his permission.

Cutting hedges requires to be done with reasonable care, because where a party hedge is badly injured or dies through careless cutting the responsible person may be called upon to make good its value to the owner. Digging which affects the foundations of a party wall involves similar liability. (*See Hedge.*)

Poisonous trees or shrubs growing in a garden have led to legal proceedings when the leaves are eaten with fatal results by a neighbour's dog, a prize rabbit, goat, or other pet. Here the deciding factor is whether the leaves projected into the other man's garden, as in that case responsibility attaches to the owner of the tree or shrub, but not otherwise under ordinary circumstances.

**Garden Chair.** *See Garden Furniture.*

**GARDENER.** A gardener is a man-servant whose duties are to look after the garden, greenhouse, etc. He should, therefore, possess a good practical knowledge of plants, whether for the flower garden or the kitchen garden. He must know when each should be planted, dug up, or transplanted, and his judgement in these and other matters will be frequently tested. His duties include the care of the lawn, while a knowledge of the greenhouse and greenhouse plants is necessary for most gardeners.

Some appreciation of colour is also desirable, as he should be able to lay out flower beds. The number of gardeners kept depends upon the size of the garden. In large ones there will be a head gardener and one or more under-gardeners. The best training for a gardener is to serve in a junior position in a large garden. As the gardener is a servant he must be insured under the National Health Insurance and Unemployment Schemes. The wages of gardeners vary in different districts. The jobbing gardener is usually paid 1/1 per hour. Many persons with small gardens require a gardener for only one or two days a week. Such can be hired at a fixed charge per day or per hour, either from nursery gardeners or privately. No licence is necessary, but in the case of a gardener hired privately one of the employers is responsible for the weekly insurance contributions. For some phases of garden work women gardeners are eminently suited, but obviously are less so than men for the heavier duties. There are in England several institutions where training can be obtained. They, too, must be insured, but no licence is necessary in their case. *See Insurance.*

## GARDEN FURNITURE AND ORNAMENTS

### Practical and Decorative Open-Air Furnishing

For other information of interest in this connexion see the articles on Bird Bath; Cane; Cushion; Hammock; Osier; Summer House; Sundial; Trellis; also Brick; Crazy Paving; etc.

Special furniture and accessories make the garden more enjoyable and healthful during the summer months; well chosen and placed ornaments give it decorative value even when flowers are scarce. The type of furnishing required for the particular garden needs almost as careful choosing as that for the interior of the house. Classical styles in seats and ornaments look well in the formal garden; rustic furniture, and the decorative touch of an old stone trough, or sundial, in the cottage garden; while in the seaside bungalow garden some kind of shelter is usually desirable as a protection against the wind. Here too the most modern type of furniture adds a gay note which suits the otherwise somewhat bare look of a new lay-out. A useful and attractive little osier shelter is shown in Fig. 1. Its roof is weatherproofed on the inside, and two windows admit plenty of light when closed against wind or rain. Revolving floors enabling shelters to face in any desired direction can be supplied.

*Garden Furniture.*  
*Fig. 1. Small but very useful and attractive osier shelter. (Town and Country Associated Industries, Ltd.)*

Many houses, both old and new, have a practical extension into the garden either by means of a veranda, with or without windows which slide back on warm days, or by the simpler means of a bricked or flagged loggia outside the dining room windows, which can be delightfully furnished as shown in Fig. 2. Meals can be taken under shelter here, and yet in the open air. Plenty of folding or cane chairs, cushions, a table large enough for meals, and a hammock-couch, comfortably furnish such a corner. The important points about garden furniture are that it should be light to carry, should stow away into small space when not required, and that any fabric used for it should be durable, damp resistant and bright in colour. Nothing is more de-pressing out of doors than shabby, dingy chairs and cushions. Striped canvas in brilliant colours nearly always looks right, and for painted furniture blues, clear yellows, warm grey and ivory are the best shades from which to choose. In very hot weather for perfect shelter on the lawn from the sun a huge umbrella can be obtained fitted into a table, which when no longer required can be folded and stowed away.

Garden furniture will make a delightful change from the more formal interior of a town sitting room if a balcony or flat roof space can be utilized to provide accommodation for it, and sufficient greenery and

flowers in boxes and tubs introduced in order to create the outdoor feeling.

*Garden Furniture. Fig. 2. An attractively furnished loggia.*

*Fig. 3. Folding table and stools laid for a picnic lunch.*

Strong teak wood is made up into good garden suites, and in it settees, armchairs, chairs and tables are obtainable. A square teak wood table is designed with slotted top so that rain water drains off quickly. Chairs are made in this wood

with footboards to keep the occupants' feet dry. Metal furniture has for a much longer period been recognized as serviceable for outdoor than for indoor use. Folding chairs and tables of this type are made with rounded and shaped leg supports which do not make holes on a lawn. Padded ground cushions with back rests which can be raised when required, and book rests for use with them, are luxurious for lazing or reading. Oilcloth may be employed for the underside of ground cushions; raffia cloth is a good material for garden upholstery. Cretonne-covered mattresses with waterproofed lining and bolster cushions to match provide open-air sleeping accommodation.

A two-tiered wagon which can be wheeled out into the garden with all equipment for luncheon or tea, and converted into a table by touching a knob is a great convenience. Square stools made the same height as armchairs, and loose-cushioned and painted to match, can be used with these to form day beds, or without the extra cushions as convenient low tables. A group of a simple folding table and stools arranged as shown in Fig. 3 makes a pleasant tea or luncheon corner. The constructional details for a suitable folding table have been given in earlier pages.

**Garden Chairs.** Folding chairs for the garden are simple to construct when made of wood and striped canvas.

Fig. 4 shows a light garden armchair. The seat portion is made separately, like an ordinary camp stool, the crossing legs being of wood  $1\frac{1}{2}$  in. x  $\frac{3}{4}$  in. and about 2 ft. 2 in. long, pivoted on pins burred over on

washers. These legs are finished with a stout dowel at top to enter the seat rails, which are  $1\frac{1}{8}$  in. diameter. The canvas is turned in 1 in. at edges and brought over taut to be nailed to the underside of these rails. Height of seat when open can be 1 ft. 4 in. to 1 ft. 6 in.

#### *Garden Furniture.*

*Fig. 5. Useful garden seat and table made from two oak barrels, wax polished or oiled.*

The armchair effect is obtained by separate wing returns, the uprights of which are  $1\frac{3}{4}$  in. x  $\frac{3}{4}$  in. x 2 ft. 4 in. long, and connected at ground by pivots to the cross legs of the stool. The arm rests are 2 in. wide by 1 ft. 3 in. long, or may be increased to 1 ft. 6 in. The three slats in each wing can be 2 in. x  $\frac{1}{2}$  in., and the bottom rail of the wing, entered about 8 in. above ground, can be  $1\frac{3}{4}$  in. x  $\frac{7}{8}$  in., mortised and tenoned to uprights.

The uprights of back can be about 1 ft. 9 in. long, fitted with staples to drop into position in eyes on the back uprights of wing returns, a length of canvas being provided for the back after the back uprights have been connected by  $1\frac{1}{2}$  in. x  $\frac{5}{8}$  in. rails. On removing the back, the wing returns will fold up with the stool between, clips being fitted so that all will pack flat together with the back.

Another type of chair, as shown in Fig. 5, can be made from a barrel. An oak barrel is the best, as this wood when wax polished or oiled looks and lasts well. Such barrels can be purchased inexpensively. The illustration shows how the chair is made; inch timber is used for the seat, and the hoops are either stained a darker shade of brown in the case of an oak barrel, or if the chair is to be painted in a bright colour the hoops look well in black. Fig. 5 also shows an attractive table which is easily constructed from a barrel. Three-ply wood can be used for the middle shelf.

**Garden Seats.** A wooden seat is a practical family piece of garden furniture. It can, if well made and brightly painted and cushioned, be also quite attractive.

Such seats are usually constructed to accommodate three or four persons. For the former a length of 4 ft. 6 in. is necessary between the ends, and for the latter an overall length of 6 ft. 6 in. The seat shown in the sketch, Fig. 9, is intended for four persons, and could be made in painted deal or varnished oak, or, if preferred, teak.

In making the seat, start upon the ends, preparing the front and back legs, and framing in the rails and elbows. The top ends of the front legs should be turned

to the pattern shown at Fig. 15, and the back legs taper above the elbows to 2 in. thick and then swell out again to the full thickness, the shape being as at Fig. 12. Ordinary tenon joints (arranged as at Fig. 13) are used in framing the legs, rails, and elbows together. The front ends of the elbows are finished as shown at Fig. 12, and the seat rails are worked into a thickness of 2 in. in the middle. The front and back seat rails are then tenoned into the legs, each being kept level with the front edges of the legs, and the joints arranged as at Fig. 14. The cross seat rail which is framed between the front and back seat rails (Fig. 11) is intended to support the seat battens in the middle; its top edge is shaped to match the end seat rails.

The top rail is tenoned into the top ends of the back legs, and the back battens are tenoned between this rail and the back seat rail. The battens are spaced an equal distance apart, with the wide batten in the middle, while in the middle and every alternate batten a small heart-shaped opening is cut (Fig. 10). All the joints should be fixed with wood pins, but should first be painted with good lead paint. The seat battens are simply nailed or screwed in position. If made in deal the seat must be well painted, first with a priming coat and afterwards with two coats.

The cutting list given below applies to a 6 ft. seat. For lettering see diagrams.

Fig. 4. Folding armchair made on the principle of a camp stool.

	Long	Wide	Thick
	ft. in.	in.	in.
2 front legs (A)	2 1½	3	3
2 back legs (B)	3 6	3	3
2 bottom rails (C)	1 7	3	3
2 seat rails (D)	1 5	3	3
2 elbows (E)	1 11	3	2
Front seat rail (F)	6 4	4	2
Back seat rail (G)	6 4	4	2
Cross seat rail (H)	1 7	3	2
Top rail (J)	6 4	3	1½
14 back battens (K)	1 9	3	1
Back batten (L)	1 9	6	1
5 seat battens (M)	6 6	2	1

**Garden Ornaments.** An ornamental feature for an enclosed garden, a terrace, or the formal town layout is a stone seat like the one illustrated in Fig. 6. Such a furnishing detail deprives set fashions in bedding of their monotony, and is in keeping with either brickwork or crazy paving, and also with stone vases containing decorative evergreens and the bird bath or sun-dial of classical type. Fig. 7 shows a rustic stone seat suitable for the less formal garden.

Stonework gives a dignified air to any layout, however simple. Quite delightful ornaments are made from old stone troughs and sinks placed on two piles of bricks or on stone pillars to bring them table-high.

Drainage holes having been provided, and a layer of rubble before filling in the soil, rock plants, ferns and mosses may be planted in these sinks with one or two pieces of rock placed to give the outcrop effect.

Garden Furniture. Fig. 6. Garden seat in Portland stone, with moulded ornamental ends. Fig. 7. Simple garden seat made from three pieces of rough stone. (6, courtesy of John P. White & Sons, Ltd.; 7, courtesy of W. H. Gaze & Sons)

Lead vases and ornaments give beautiful accents of colour among greenery. Wrought-iron is effective in the old-world garden of sophisticated, charm. Wrought-iron wall lanterns, gates, antique well heads and triangular rose pillars are all decorative pieces of garden furniture.

Statuary requires particularly careful choosing and setting. Ornaments of this kind can be easily overdone and give a restless, crowded effect. The line of low brick wall, topped by York stone, may be broken by one or two figure or animal pieces of good design. Stone dragons or owls treated in a formally decorative style look effective flanking shallow steps, or guarding a stone seat. Realistic animals and birds do not seem so appropriate for garden ornaments, though obtainable in a variety of designs. Pieces of old stone carvings introduced as reliefs on brick walls have a beautiful effect. Particularly effective for floral decoration on terrace walls are simple vases of stone such as the one shown in Fig. 8.

Pigeon cotes and bird shelters are always interesting. Little thatched bird-tables can be bought ready for placing on poles, and afford endless attraction and opportunity for nature study.

**GARDENIA.** This is a beautiful evergreen flowering shrub for use in the heated greenhouse, bearing rosette-shaped, strongly scented flowers with thick, waxy, white-petals. It was popularised as a buttonhole flower by King Edward VII, but as the habit of wearing buttonholes has to some extent declined, there is little demand for gardenias now, except for the purposes of funeral wreaths. Many people dislike the somewhat overpowering perfume emitted by this flower. The plant requires a humid atmosphere, and a temperature of about 70° F. Equal parts of well-drained loam and peat, with a quarter of decayed manure and a liberal admixture of sand, suit it. It is propagated by inserting the tips of young shoots

in sandy soil in a propagator in spring. If the gardenia is grown in the border of a stove-house, very little difficulty will be experienced so long as the atmosphere

(Continued in page 936)

is kept moist and the foliage is periodically syringed. If mealy-bug and scale put in an appearance, the leaves must be sponged with insecticide.

*Gardenia. Bloom of the white gardenia, a fragrant hot-house flower.*

If no border is available, it is quite a simple matter to grow gardenias in pots. Very little pruning is required. Plants in borders require to be cut back occasionally to keep them within bounds and to preserve their shape. It is well, too, to tie down the lower branches, in order to prevent them from smothering the more prolific wood, which is usually situated in the middle of the bush. *Gardenia florida* is the kind commonly grown. *See Flowers.*

**GARDENING: Some Hints.** The gardener's first necessity is tools, and these should include a good steel spade, a stout four-pronged fork, a clean-toothed rake, a Dutch hoe, a five-clawed cultivator, large and small trowels, a pair of shears, a grass-mower, a birchbroom, pruning shears and knife, an insecticide syringe or sprayer, wheelbarrow, gloves and strong apron, and a garden line. A storing shed should be available wherein all equipment may be kept clean and tidy.

Site and drainage will be the beginning of all work. Digging and trenching must be studied, for earth preparation is the key to success in gardening. Soil composition and the application of suitable manures are other matters for study.

Practical guidance as to the preparation of seed beds, depth of sowing, together with the thinning and planting out of seedlings, may easily be obtained.

Flowers for cultivation make fascinating study for the gardener. The formation of a lawn is not a matter for haphazard undertaking. A well-kept and truly-laid sward, even though it be only a few yards square, must be made on definite principles. The planting of a fruit garden should be undertaken with suitable varieties of apples, plums, pears, etc. Pruning of branches and roots, perhaps grafting for the purpose of propagation also, will call for attention. In due course a greenhouse may be installed and equipped, giving additional interest. Frames and hotbeds also may find place, becoming a centre for early crops and for rearing tiny seedlings. Propagation by seeds and cuttings in greater variety becomes possible where such appliances are available, while the cultivation of choice but tender plants for indoor decoration adds pleasing occupation for gloomy days.

The beginner should early learn to distinguish between insect friends and foes, to become familiar with the best insecticides for the eradication of those that are harmful, to understand the value of spraying trees in season, and to apply suitable remedies for the cure or prevention of fungoid disease. *See Digging; Fungicide; Spraying.*

**GARDEN PARTY.** In Great Britain this form of

summer entertainment is very popular. When it is provided by owners of large houses, people who may be invited only to this one function in the year are glad of an opportunity to see the gardens and also the reception-rooms, which are generally thrown open for the occasion. A tennis or croquet tournament, archery, or a cricket match may form the special attraction, and sometimes a company of pastoral players is engaged. Provision may be made for wet weather in the form of a large tent or marquee with an improvised stage.

In towns a garden party is often an At Home. Wherever the party is given there is music, either a band or a large or small orchestra, and such games as clock golf, croquet, etc. are provided for players, with chairs and seats grouped about. Tea may be served in the house or in a marquee.

A good plan is to have a separate marquee for drinks, ices, fruit, and cream, as people who are taking part in strenuous games appreciate these refreshments at more or less frequent intervals throughout the afternoon. Sometimes all arrangements for refreshments, tents, etc. are put into the hands of a firm of caterers. In the case of a large party this saves a strain on the household staff.

Receptions, concerts, plays by limelight and informal dances are sometimes given at evening garden parties. Semi-evening dress is usual for the women, evening dress for the men. Illuminations for the gardens are generally carried out by a firm of entertainment caterers; brilliant coloured paper lanterns, patterned with boldly stencilled designs, hanging from the trees, are an effective decoration. *See At Home; Ices; Marquee, etc.*

**GARDEN ROLLER.** A roller suitable for a small suburban garden should weigh about 2 cwt.; for large lawns or tennis courts the roller can be 5 or 6 cwt., or even more.

*Garden Roller made from an oil-drum filled with concrete.*

The usual types are made of cast iron, the smaller sizes with solid rollers; the larger have two rollers, and are generally made hollow and may be filled with water or sand to provide the requisite weight.

A good roller should have its edges rounded to avoid cutting lines on the turf. The handle should be balanced and remain upright when the roller is standing, and be available on either side of the roller, as this saves frequent turning. The bearings should be substantial and easily accessible for lubrication, a matter that should not be overlooked, for if the spindle and bearings are kept well oiled, not only will the machine be easier to push, but its life will be doubled. Rollers made of concrete are durable, serviceable, and

less expensive.

**GARDEN SHED.** The shed illustrated is made in sections, so as to be movable, and consists of two side frames, two end frames, and two frames which, when joined together, will make the top. Suitable sizes are suggested on the diagrams, but these may, of course, be modified for special purposes. The upright rails go into the earth at least a foot, and to prevent decay it is advisable to char the portion that is buried. This is better than dipping the ends in tar.

*Garden Shed. The finished shed, with glazed window and plain wood roof.*

*Below, framework, with various joints enlarged.*

Any rough straight-grained timber can be used for the framework, and when the parts are assembled,  $\frac{3}{4}$  in. tongued and grooved flooring boards should be nailed round to complete the work. The top should then be covered with a good roofing felt, and a coat of tar will make a reliable and waterproof roof. The door is not illustrated in detail, consisting only of  $\frac{3}{4}$  in. boards, nailed to three cross-pieces and hinged to the upright by T hinges. It may be braced as shown in the article Door.

The two side frames are mortised and tenoned together where the cross rails meet the uprights, as at the enlarged sketch F, and the centre upright is halved to the cross rails as at E. A simple and quick way of mortising and tenoning rough framing such as this is to take a  $\frac{5}{8}$  in. twist bit and bore out the mortises, leaving the top and bottom of the mortise half-round, as shown at sketch J; the tenoned portion is cut with a tenon saw,

and a rasp is used to work away the corners, as shown. When putting the tenons into the mortises they should be smeared with thick paint, and secured by a couple of nails driven in from the face.

The end frame which will contain the door is also illustrated. The ends are nailed together, the long centre rail being tenoned into the top at A and halved at E; the cross rail B, is tenoned at each end. At G a window may be put in, if desired. The opposite end frame does not require a door, and in this case the rail, B, runs right across the frame, to be mortised and tenoned into the outside rails; while the centre joint, C, is halved together. The side frames are screwed on to the end frames so as to facilitate removal when necessary. The top consists of two frames nailed together, all the joints being halved together, as shown at D. The triangular end pieces are made previous to making the two top frames. The bottom of the shed should be made of old bricks or pieces of stone flag.

**GARGLE:** For Sore Throat. Gargles are not as much used in medicine now as formerly. Their place has largely been taken by sprays, which reach the back of the throat much more effectively. Gargles, however, are sometimes useful for applying drugs to the tonsils, soft palate, and for washing out the mouth. A mouthful of the gargle is taken, and the head is thrown back so that the fluid is held at the back of the throat. Then, without swallowing, the patient gently breathes out from the lungs, the air bubbling through the fluid. Gargles must never be swallowed. A very simple and effective gargle for cleaning and refreshing the throat consists of half a teaspoonful of common salt in a glass of water. This can be used every morning. An astringent gargle for a slightly inflamed or relaxed throat is made as follows:

Spirits of wine	1½ drams
Glycerin of tannic acid	4 drams
Water to make	6 oz.

A soothing gargle compounded from the following prescription is used for irritable sore throat due to dust, heat, etc.

Glycerin of borax	4 drams
Tincture of myrrh	1 dram
Water to make	5 oz.

An antiseptic gargle is often useful in cases of sore throat, especially where the breath is foul. The following may be tried:

Solution of potassium } permanganate B.P. }	20 minims
Water to make	6 oz.

**GARLIC.** A bulb belonging to the onion family, garlic is noted for its pungency both of odour and taste. It is used far more generally upon the Continent than in Great Britain.

For ordinary purposes the bulbs are planted whole, 2 in. deep and 8 in. apart, in rows 9 in. from each other, in February. To obtain exhibition produce the cloves or bulblets must be pulled apart and planted separately. In late summer bulbs should be stored indoors.

**Garnish.** See *Decoration in Cookery*.

**Garret.** See *Attic*.

**GARRYA.** This is an evergreen shrub, 8' to 10ft. high, of which male and female flowers are borne on separate plants. It is the male or catkin-bearing form that is valued chiefly; the long, yellowish-green catkins which appear in early spring are very decorative. This shrub is not very hardy and, except in mild districts, ought to be planted in well drained loamy soil against a sunny wall. Little pruning is needed except to keep the plant shapely; this should be done after the flowers are over. Propagation is by layering in summer or by sowing seeds in a frame in spring. Pron. Gar-re-a.

*Garrya. Catkins of the evergreen shrub.*

## GAS: FOR HEATING AND LIGHTING

### How to Utilize Modern Appliances to the Best Advantage

This article corresponds to the one on Electricity in the Modern Home, and treats the subject in a general but comprehensive way. Gas Cookers are dealt with in the article *Cooker*, and reference should be made also to the one on Hot Water Supply. See further such articles as *Brazing*; *Fuel*; *Qeyser*; *Grate*; *Heating*; *Kitchen*; *Soldering*. *Acetylene* and *Air Gas* may be consulted.

The choice between gas or electricity for the essential services of lighting, heating, cooking and hot water supply is usually dictated by the presence or availability without much expense of one or other of the respective supply mains. When both electricity and gas are laid on, the householder is in the favourable position of being free to employ either or both as he wishes, limiting each to the use for which it is best adapted. For it may not be altogether wise to aim at an "all gas" or "all electric" house, as the case may be; the better way generally is to utilise both services, in conjunction perhaps with solid fuels, the latter being employed for some portion of the heating arrangements. The choice will be governed, too, by the kind of stoves and fuel employed for cooking, and the preliminary remarks in the article *Cooker* may well be studied in this connexion.

There are also, of course, purely economic

considerations. In many districts electricity is expensive, especially in certain rural areas; and the prudent householder, realizing what heavy demands on fuel are necessarily made by the kitchen, will prefer to use gas for cooking and electricity for the comparatively energy-economizing function of lighting. Again, the type of house he occupies may make it preferable to have a gas radiator to warm the hall—to give a certain gentle warmth which other sources of heat in those particular circumstances could not provide so well.

**How Gas is Sold.** For many years after it was first supplied to the public coal gas was used mainly for lighting purposes, and even since the introduction of the electric light, the incandescent mantle, an immense improvement on the old flat-flame burner has enabled it to hold its own as an illuminant with remarkable success.

So long as gas was used chiefly for lighting with flat-flame burners it was essential that it should burn with a self-luminous flame. With the increasing use of gas for heating purposes, and the general adoption of the incandescent mantle, which emits light because it is heated to a high temperature, the tendency became to take heating power or calorific value as the criterion.

This tendency culminated in the Gas Regulation Act of 1920, which introduced a new unit and a new method of charging the consumer. The Act provided that he should pay for the amount of heat represented by the gas he received, so much per therm of 100,000 British Thermal Units, one B.Th.U. being the quantity of heat required to raise the temperature of 1 lb. of water by 1° F. The gas undertakings have to declare the heating value of the gas they supply (so many B.Th.U. per cubic ft.) and to keep to it within close limits.

**The Meter.** The quantity of gas consumed is registered on the meter by several dials, the course taken by the hands being indicated by the numerals. One dial indicates hundreds of cubic ft. of gas up to 1,000; the next dial indicates from 1,000 to 10,000 graduated in thousands; and the third indicates up to 100,000 cubic ft., and is graduated in ten thousands. In larger meters a fourth dial is fitted which records hundred thousands of cubic feet. There is in addition a small dial on the top which has no bearing on the reading, but is used by the gas undertaking for testing purposes (*see Fig. 1*).

Pay no attention to the top dial. Taking the lower dials in their order from left to right, write down the figures shown by the hands. If the hand is between two figures, always write down the lower; if the hand is between 9 and 0 always write down 9. Then add 00 at the end. The index shown in the diagram reads 751,900 cubic ft. If the reading of a month before had been 740,600 the month's gas consumption would have been 11,300 (the difference between these two totals) cubic ft.

Fig. 1. Diagram showing dial of gas meter. It is read from left to right and here shows 751.900 cubic feet.

To convert the gas consumption into Therms multiply by the "declared calorific value of the gas" (generally a figure between 400 and 500 British Thermal Units per cubic ft.; the gas office will tell you exactly what it is for your district) and divide by 100,000 thus: 11,300 cubic ft. =

$$\frac{11,300 \times 450}{100,000} = 50.85 \text{ Therms.}$$

Fig. 2. Diagram showing ventilation system of a modern gas fire. (British Commercial Gas Assocn.)

Generally, in gas appliances, a Bunsen flame is employed, and the gas, before it reaches the burner, is mixed with the volume of air necessary to its combustion. Modern gas appliances are provided with means for making this adjustment, and if the consumer cannot make it for himself he should get his gas supply undertaking to do it for him. No one should continue to use a gas appliance which is not functioning properly, as a defect due to faulty adjustment is speedily remedied by a competent person.

Much gas is wasted by leaving burners alight when they are not wanted. Another source of waste is putting a small kettle or saucepan over a large boiling ring, or turning on the burner too high; a flame that spreads out from under the vessel and up the sides, is merely wasting heat. All vessels used on gas burners should be kept clean and should not be used on coal fires.

Coal gas is perfectly safe so long as it is confined to its supply pipes and is not allowed to escape into the rooms unburnt, but if this condition is not observed it becomes dangerous in two ways. In the first place, when mixed with from 5 to 15 times its volume of air it will explode violently if a light is brought in contact with it. This is the reason why it is unsafe, when a smell of gas is noticed, to search for the leak with a lighted match or candle. In the second place, gas will not support respiration; in other words, a person immersed in it will be suffocated because there is no oxygen in it

for him to breathe. In addition, it contains a poisonous ingredient, carbon monoxide, which, by combining with the haemoglobin in the red corpuscles of the blood, prevents them from carrying out their function of taking up oxygen in the lungs.

**Heating by Gas.** In domestic heating, two different forms of heat are dealt with, radiant, or radiated, heat and convected heat; it is in the proportioning of these that most of the strides have been made in the design and manufacture of modern heating appliances. Radiant heat is heat which is radiated by a hot body in rays. These rays travel out, in straight lines, and do not lose any of their heat until they strike an object which absorbs it. Roughly, the explanation of convection is this: As each particle of the air in contact with the hot body becomes heated, it also becomes lighter in weight than the unheated particles around it. Consequently, it rises and gives place to other particles of air, which also become hot, rise and follow the first. This makes room for a third set of cold air particles, which follows the others. In this way a stream of air issues from the hot surface, carrying heat with it, which it communicates to any cold body in its path.

Radiation to any large extent only takes place from very hot bodies, such as glowing coals, red-hot iron, and incandescent bodies in general.

Fig. 3. A built-in gas fire suitable for a modern sitting room or dining room. The self-lighting mechanism is concealed in the base of the fire. (British Commercial Gas Association)

Fig. 4. A built-in gas fire of the wall panel type suitable for a small bedroom or hall corner. (British Commercial Gas Association)

The greater proportion of the heat given off by the

modern gas fire is in the form of high temperature radiation, the pleasant effects of which are well known. (It was the older type of gas fire, which utilised mainly the principle of convected heat and thus tended to dry up the air in the room, which gave rise to the belief that gas fires were unhealthy.)

Research has improved the design of the radiants used in gas fires so that a larger proportion of energy is given out in the form of infra-red rays that penetrate the skin and warm the blood, so that the heat emitted bears a closer resemblance to that derived from sun rays. The warmth of the modern gas fire, therefore, is in no way prejudicial to health in respect of "stuffiness" or "dry heat."

A gas fire is also a source of room ventilation. In estimating the comfort of any system of heating, the question of ventilation, upon which the humidity of the air and the rate of air movement are dependent, is equally as important as that of the actual heat source. The gas fire, with its controllability, helps to regulate not only the temperature, but the humidity and rate of air movement in the room. Any fire, while alight, changes the air in the room by imperceptibly drawing the used air up the flue and making space for fresh air to filter in through cracks and crannies round window and door; it is possible that the ventilating property of the gas fire gives several complete air changes in an hour.

Gas fires are of two main types, the self-contained and the built-in. The former can be bought in any style or period: so long as an adequate gas supply and flue are available it can be connected up without further adjunct. This type of fire projects slightly out into the apartment.

The built-in type is one in which the body of the fire is let into the chimney breast or mantel, and the front is fitted more or less flush with the surround. It can therefore be placed at any convenient height and in any position in the room in which a flue can be constructed. This type of fire is, in effect, a glowing wall panel, divorced from the stereotyped idea of hearth and fender. It does not need a chimney breast, the flue being formed in the wall by the use of gas flue blocks, but, if fitted in an existing fireplace, the coal grate must be removed and a suitable surround provided. Fig. 3 shows a fire of this kind. Surrounds may be of marble, imitation marble, wood, mirror glass or stainless metal.

The modern gas fire is generally finished in coloured enamel or in a bronze or stainless metal finish, whichever is chosen to harmonise with the room furnishings and decoration. Most fires have automatic ignition. There are three main types of such devices: flint and wheel; electro-catalytic (a platinum filament aided by the current from a small flash-light battery); and cold catalyst.

In selecting a gas fire of suitable size the following method (taken from "Domestic Utilisation of Gas" by Messrs. Smith and Le Fevre) may be useful:

1. Calculate the volume of the room — i.e. the length x breadth x height — in cubic feet. For every 300 cu.ft. provide one radiant.

2. For every 60 sq. ft. of exposed wall, add one radiant.

3. For every 20 sq. ft. of window glass, add one radiant.

*Example:* Room 12x10x10 ft. = 1,200 c. ft., exposed walls 180 sq. ft., window glass 40 sq. ft. Therefore

1200 : 300 = 4 radiants

180 : 60 = 3 radiants

40 : 20 = 2 radiants.

Thus 9 radiants are required. If the calculation indicates a number of radiants that does not coincide with a standard size of fire, the next larger size should be chosen. It should be remembered that the lattice-work type of radiant used in some fires has a gas-rate of approximately 5,000 B.Th.U. per hour, compared to one of 2,250 B.Th.U. with the latest pattern of ordinary upright radiant.

**Gas Radiators.** The independent gas radiator is a flueless heater which is lighted and turned off just as is a gas fire. Appliances of this type are largely air heaters, giving convected heat rather than radiant heat. They are suitable for warming entrance halls, landings, bathrooms and similar parts of the house. There is a number of ornamental designs available, the principle generally being that of a burner enclosed in the base of the appliance, the temperature being controlled in some models by a pre-set automatic device. For use in a garage a special safety type is made in which there is no risk of petrol vapour becoming ignited by the flame.

**Central Heating by Gas.** An automatically controlled gas-fired boiler may be used to heat the hot water for a small or large central heating system. The boiler takes up very little space, and is convenient and economical in use, particular advantages being the freedom from the bother of stoking and the absence of dust associated with any form of solid fuel boiler. A somewhat similar purpose is served by one type of gas air heater; fixed on an outside wall and provided with an air brick at the base; this appliance warms the fresh air that is drawn into the room.

**Lighting Fittings.** As gas is used to light a great number of homes artistic fittings are a matter of importance which has not been neglected by gas undertakings. It is not difficult to obtain fittings to harmonize with any style of decoration. Good bracket and applied wall fittings agree well with modern furnishing. Fig. 5 shows a three-branch chandelier in the modern manner. Glass and chromium relieved by narrow bands of coloured enamel are used on this sitting-room fitting. Fig. 6 is a simpler wall fitting for a bathroom or extra light in a kitchen, passage or scullery. The central sitting room fitting in frosted glass shown in Fig. 7 is of excellently balanced design, while Fig. 8 illustrates the favourite bowl type of ceiling fitting particularly suitable to a dining room.

*Gas: modern lighting fittings. Fig. 5. A gas chandelier finished in chromium, glass and coloured enamel. Fig. 6. Simple wall bracket for bathroom. Fig. 7. Central fitting in frosted glass. Fig. 8. Bowl type of central fitting.*

For kitchen and bathroom use silica shades are recommended, as

they diffuse the light, last well and are not affected by heat. In a large living-room the central fitting can be provided with two or three mantles to afford extra light, as shown in Fig. 5, and in addition wall fittings are an improvement. When a local light only is required such fittings can be used without the central light.

For a hall a lantern lamp is a good choice, with sides of tinted and frosted glass and bottom of clear ribbed glass. The finish of the lantern may be in brass, copper, or egg-shell black. Gas standard lamps, as illustrated in Fig. 8, can be placed where required and attached by a flexible tube with rigid screw to a convenient gas point. They can be obtained either for floor or table purposes and in a variety of designs and finishes.

#### Useful Gas Appliances.

Gas cookers are described in the article Cooker. Other important uses for gas are to operate a refrigerator, and to heat the water for domestic purposes. These are dealt with under Refrigerator and Hot Water Supply respectively. A gas fired boiler is a convenient method of heating a conservatory or small greenhouse. The boiler is placed outside the building in a protecting hutch, so that the products of combustion are excluded. Such a heating installation may be controlled by a thermostat, which automatically regulates the temperature.

*Fig. 9. A gas standard lamp finished in chromium and enamel. (Courtesy, B.C.G.A.)*

The introduction of the gas plug point with bayonet fitting (Fig. 12), has made it possible easily to connect up such an appliance as a gas iron or gas poker (Fig. 13). The latter is used to ignite the coal or coke in a solid-fuel grate, and for this purpose is plugged into a

special gas point. The poker is pushed into the grate and the gas lighted; neither wood nor paper is needed. The act of plugging in the flexible attachment automatically turns on the gas, while the operation is reversed when the connexion is removed from the plug point, the gas supply being automatically turned off. One gas poker may be used in turn to light several fires in different rooms, if, of course, plug points are in existence. There are two main types of gas heated flat iron; in one the appliance is internally heated by a gas burner, and the iron is, of course, connected to the gas supply pipe by a flexible tube. The other type is heated by placing it over a lighted burner on a stand. The latter is placed on the ironing table and is connected when in use to a plug point. Fig. 14 shows a useful fitting for bedroom or dressing room, comprising a burner which may be used for heating either curling irons or a small flat iron, as desired.

*Gas. Fig. 10. Pendant in glass and chromium suitable for hall lighting. Fig. 11 (below): Boiling ring with enamelled drip tray. (British Commercial Gas Association)*

In the summer the disposal of kitchen refuse is sometimes a problem, especially where no coke or coal fired grate or

boiler is used. This difficulty may be overcome by installing a gas heated incinerator, the cost for gas being negligible.

*Fig. 12. Plug point with bayonet fitting.*

#### Gas Mantle.

This term is used to describe a manufactured article used in conjunction with a Bunsen burner for producing an intense light. There are two principal varieties, the upright mantle, used in a vertical position over the gas flame, and the inverted mantle, suspended beneath it.

The mantle should be carefully removed from the cardboard box in which it is packed, placed in position, and ignited by the flame of a match. This burns away the coating, and as soon as the flame has died down the gas may be turned on, and the mantle should give a brilliant light. To ensure this, it is necessary that the mantle should be exactly upright.

The air and gas regulators on the burner should be adjusted until the best result is obtained. In the case of the inverted mantle a similar procedure is adopted, but here the mantle is fixed on a framework of steatite or similar fireproof material, and comprises a ring with three projecting lugs, which are slipped through slots in the bottom of the burner and rest upon little supports made for the purpose. For a small charge many supply companies undertake the maintenance of light fittings, cleaning them periodically and replacing broken mantles, etc.

**Gas Ring or Boiling Burner.** In its older form the gas ring consists of a hollow iron casting. This is in the shape of a pipe leading into a hollow ring, through the top surface of which a series of holes is drilled. The gas, which enters at the end of the pipe farthest from the ring and mixes with air at the inlet, issues through these holes and burns with a blue flame. The gas ring stands on cast-iron feet, and has vertical webs projecting up from the ring, in order to support a vessel. Fig. 11 shows the modern development of the boiling ring. The gas burner is set in a coloured enamel bowl which serves not only as a base, but also to catch any drips or overflowing liquid.

Fig. 13. Gas poker used to ignite coal or coke in a solid fuel grate. Fig. 14. Gas burner for heating curling tongs or a flat iron.

The only adjustments required as a rule with any gas ring are those of the gas pressure and the air. The flames of the jets should be adjusted by the gas pressure regulator so that they are just long enough to play over the full bottom surface of the vessel being heated, and they should never be allowed to lick round its sides. The air should be adjusted so that the cone in the centre of the flame is of a greenish colour, the rest practically colourless, and on no account luminous, otherwise gas will be wasted, the heating power will be too low, and the surface of the heating vessels will become sooty.

The central cone should be short, sharp, and steady, and the flame should hiss a little, while having at the

same time no tendency to backfire when the flame is turned down low. Otherwise the burner is getting too much air. The positions of both the gas pressure regulator and the air regulator should be capable of being fixed by means of a set screw when the final adjustments have been made, so that they do not get out of position when the ring is being used.

**Boiling Water at Will.** Small gas water heaters of the instantaneous type are used to provide the kitchen with its own hot water supply. The latest development in the sink water heater is a similarly shaped appliance (shown in Fig. 15) which will deliver hot, very hot or boiling water, whichever is needed. The three gradations are obtained merely by turning a tap and the appliance is automatic in action, using gas only when hot or boiling water is running. At the setting "Warm"  $1\frac{1}{4}$  gallons at  $90^{\circ}$  F. are delivered each minute; at "Hot," the flow is  $\frac{1}{2}$  gallon a minute at a temperature of about  $150^{\circ}$  F.; while the control set to "Boiling" gives a flow of about  $2\frac{1}{2}$  to 3 pints per minute of boiling water, suitable for tea-making or any other purpose.

### GAS: Poisoning by.

Many deaths are reported every year from suffocation by the breathing in of ordinary illuminating gas. Besides these acute cases, fatal or otherwise, vague illnesses, slight headaches, mental depression, and anaemia often result where a person for hours and days breathes in even tiny quantities of coal gas.

Prominent symptoms in acute poisoning are drowsiness, varying from a slight degree up to the deepest unconsciousness, with a bluish purpling of the complexion, stertorous breathing with puffing out of the lips at each expiration, and perhaps frothing about the mouth.

Remove the patient from the polluted atmosphere, see that the mouth and throat are clear, loosen tight clothing, and, if breathing has stopped or is shallow, carry out artificial respiration. The doctor is to be summoned at once. Even after apparent complete recovery, the patient should remain lying down in bed for at least 48 hours. *See Artificial Respiration.*

**GAS ENGINE.** This is a form of internal combustion engine which uses gas as the fuel. In its commonest form the engine is designed to work on coal gas, but types adapted to other forms of gaseous fuel (e.g. producer gas) are similar in general characteristics, differing only in details of design. Most small gas engines operate on the Otto or four-cycle principle. *See Internal Combustion Engine.*

**GASKET.** This is a thin packing piece of metal, asbestos, rubber, paper, etc., used to make a gas or watertight joint between metal surfaces. The gasket used for the cylinder head of a motor car engine is often formed of a sheet of asbestos between two layers of thin copper. Each side is given a thin coating of gold size. For joints not subject to heat a gasket of thick brown paper coated with grease may be used. *See Motor Car.*

**GASLIGHT PAPER.** Gaslight paper differs from bromide paper (q.v.) in being very much slower, but a gaslight print has much more snap or brilliance than one on bromide paper. The most brilliant prints are given by the so-called vigorous or contrasting grades. There are other grades, usually called normal or portrait, which give softer prints. These are the best to use for negatives which have plenty of contrast and would yield too hard or chalky pictures if printed on the vigorous paper.

The requisites for gaslight printing are simply a supply of developer and fixing bath, and some 10 p.c. solution of potassium bromide. The best developer is that made up with metol and hydroquinone with other chemicals. This developer may be bought ready made up in liquid, powder or tablet form, and is often sold as M.Q.

The 10 p.c. solution of potassium bromide is made by dissolving 1 oz. of this chemical in 9 oz. of water. The fixing solution can be made up with an acid fixing salt, or it may be compounded as described under Fixing.

There are two methods of working. One is to carry out the process in an ordinary lighted room and to handle the paper so that light does not strike it directly, by setting up a screen and carrying out the manipulation of the paper in its shadow.

The other method of working is by bright yellow light. A dark-room lamp with a light yellow glass or paper screen may be used, or a hanging electric bulb simply wrapped in a large sheet of yellow tissue-paper. Gaslight paper may be exposed for any length of time to such light without being fogged.

A sheet of the gaslight paper is put behind the negative in an ordinary printing frame and exposed to light. Daylight is too powerful a light except for very dense negatives. The best light is an electric bulb of

about 40 candle power, or an incandescent burner, with either of which, at about 6 in. distance, the exposure for an average clear negative will be about 15 sec. Different makes of paper vary in speed, but the instructions supplied with each indicate the exposure required.

For development, the sheet of paper is laid, coated side up, in a clean dish an inch or so larger each way than the paper, and 4 oz. of the developer poured evenly over it. If the exposure has been neither too long nor too short, the picture will appear clear and brilliant. With most papers, e.g. Velox, the picture reaches its full depth in an instant; with certain others it develops more slowly, requiring about a minute. With either kind of paper, if exposure has been correct, the picture does not become too dark through remaining for a longer time in the developer. But if exposure has been too short, the picture comes up pale or shows only the shadows. Too much exposure causes the picture to become much too dark and also very flat very quickly. Trial of different times on small pieces of paper will show the correct exposure. If the print which has been given the judged best exposure is still rather greyish in what should be the white parts, e.g. the sky, and also rather weak in the deep shadows instead of a rich black, it is a sign that the developer needs tuning up with a little bromide. Try adding 1 drop of the 10 p.c. bromide solution to 4 oz. of the developer. If not enough, add a further drop, and so on up to about 6 drops. As each print is developed it is rinsed in clean water and put into the fixing bath.

*It is most important that the print should be fully immersed, and that the fixer should, on no account be splashed or carried by the fingers into the developer.*

The best plan is to let the print fall face down on to the fixing solution and push it in with a strip of hardwood or an ebonite print paddle. As prints accumulate in the fixer they must be separated and kept on the move. The stick or paddle allows this to be done without the fingers touching the hypo solution. Prints should remain in the fixer for at least 10 min., but it must not be used for too many, or the later prints will discolour. Twenty ounces will fix about 100  $4\frac{1}{4}$  by 3  $\frac{1}{4}$  prints, but it is best to use it plentifully.

Care should be taken that no part of the surface of the print is exposed to air action for more than a few seconds. Use tweezers for small prints, or a print paddle for keeping larger prints underneath the fixer without wetting the fingers.

After fixing the prints are washed for an hour in water as described under Washing. When washed, prints are hung up, or laid face up on blotting-paper, to dry. They must not be pressed between blotters or dried by heat, for the wet gelatine surface is easily damaged. *See Developer; Developing; Fixing; Metol; Toning; Washing.*

**GAS PIPE: Its Utility.** Gas piping, or gas barrel as it is often known, is made principally in wrought iron and mild steel and sold in long lengths; it is also obtainable in short lengths from about 12 in. upwards.

Flexible metallic gas pipe in sizes from  $\frac{1}{4}$  in. to  $\frac{3}{8}$  in. or more is used for connecting portable gas appliances. Wrought iron gas pipe with stock fittings such as angles, tees, and junctions, is useful to the handyman, as by its aid a variety of articles of everyday utility can be constructed.

Gas pipe is sold according to the nominal diameter, i.e. the  $\frac{1}{2}$  in. gas pipe is nominally of  $\frac{1}{2}$  in. diameter in the bore, or hole through the pipe, but actually measures .825 in. over the top of the threads, or rather more than  $\frac{3}{4}$  in. in diameter. The  $\frac{1}{8}$  in. pipe, which is the smallest iron pipe that is made, measures .382 in., or rather more than  $\frac{3}{8}$  in. in diameter. To avoid confusion it is desirable to specify particularly when purchasing fittings whether they are required to be screwed for iron or brass, remembering that a  $\frac{1}{4}$  in. iron pipe is, practically speaking, equivalent to  $\frac{1}{2}$  in. or  $\frac{5}{8}$  in. brass pipe.

In purchasing iron gas pipe it can be cut and screwed to any desired length. Usually the pipes are supplied screwed at each end and one end fitted with a connecting socket. The short lengths of pipe from 12 in. to  $23\frac{1}{2}$  in. are known as pieces, and above that length as pipes.

Gas Stove. *See* Cooker.

**GASTRIC ULCER.** The lining of the stomach is able, in its normal state, to resist the corrosive, or digestive, action of the gastric juice, but when its vitality is impaired part of the lining is digested off, leaving an acute ulcer. The devitalisation of the lining is almost always due to bacterial poisoning, and this may have a definite origin, such as septic teeth, a diseased appendix or gall bladder, or chronic stagnation of the contents of the large bowel.

Acute ulcers are usually multiple and may occur on any part of the stomach lining. It may chance that an acute ulcer does not heal, becoming chronic and possibly persisting for months or years. This may sometimes be due to coarse, irritating food, but it appears to be definitely associated as a rule with delays in the emptying of the stomach due to spasm of the pylorus. There may be various causes for this, but it is generally believed that excessive smoking may be one of them.

Acute gastric ulcers may be present without causing symptoms. There may, however, be dyspepsia and vomiting of blood. A chronic ulcer causes pain which comes on from a few minutes to one or two hours after eating and is generally relieved by vomiting. There is always blood in the stools.

The treatment of an acute ulcer consists of rest in bed, a bland diet and a free administration of bismuth and alkalies. Chronic ulcers are treated in the same way, but in certain circumstances an operation becomes

necessary. *See* Indigestion; Stomach.

**GASTRITIS.** Inflammation of the lining of the stomach, otherwise gastritis or gastric catarrh, may occur as an acute disorder or may be chronic. Acute gastritis may be caused by overloading the stomach with food; by taking decomposing food, an accident more likely to occur in hot weather; by an alcoholic bout; or by taking some other poison capable of causing irritation.

At the beginning the patient feels dull and depressed and usually suffers from headache. There is fullness in the pit of the stomach, a sense of weight and perhaps pain. Nausea is felt sooner or later and culminates in vomiting. At first the vomited matter consists of undigested food, but later there is much mucus and bile. In children there is diarrhoea, with colicky pains, as a rule.

In the treatment of acute gastritis it is obviously desirable to clear irritating contents out of the stomach, and this may be done in a natural way by the onset of vomiting, which should be encouraged rather than otherwise. By drinking large draughts of tepid water the patient will make the process of vomiting easier and will help to cleanse the stomach. To clear offending substances from the bowel 2 or 3 grains of calomel may be given, to be followed by a dose of salts in the morning.

No food should be given if the vomiting tends to recur, but as much plain water or soda water as is desired. As the symptoms abate, milk in some form should be given. Thereafter, arrowroot or other milk foods are added, and then sweetbreads or steamed white fish. Ordinary food is not resumed for two or three days.

Amongst drugs most used for calming the irritation of the stomach preparations of bismuth take the chief place.

If acute gastritis is at all severe, or even when it is mild if the cause is obscure, treatment should be superintended by a doctor.

Chronic gastritis may follow an attack of the acute disorder, but more frequently begins insidiously. It may be caused by habitual over-indulgence in food or alcohol, in tobacco and, in some parts of the world, in iced drinks. Habitual failure to chew food properly is another cause. Many suffer from the disease from swallowing septic discharges from the teeth, tonsils and adenoids.

The treatment of chronic gastritis cannot be safely prescribed until a careful investigation of the habits and functional condition of other organs besides the stomach permits of a fair estimate of the underlying cause or causes. Sound dietetic habits must be insisted on; alcohol should be discontinued, and if tobacco is used at all it should be very moderately. *See* Indigestion; Stomach.

**GATE.** In its domestic sense a gate refers to the outer entrance to a house, or to the movable part of a

fence or wall. Gates leading to suburban houses are frequently made of cast iron in a stock pattern, but the practice in more modern work is to employ oak or other wood. A design for an entrance gate is illustrated in Fig. 1, the making of which is more or less similar to that for a field gate. The joints are mostly the mortise and tenon, secured by a wooden peg. Staves or pales are nailed on with galvanized iron or copper nails. The field gate illustrated in Fig. 2 is a typical example. Commence by making the stile or upright to which the hinges are fixed; mortise the top bar and then the other bars into it. Prepare the other stile in the same way. The top bar is tapered on the underside as shown, and mortised to take the three upright pieces, noting that two of them come behind the centre line and one in front of it. Next prepare the diagonal member and mortise it into the top bar and into the stile. When fitting the diagonal, arrange for it to carry some of the weight by giving the top bar an initial upward inclination.

Fix the stile, top bar, and diagonal first, then fit the outer stile and horizontal bars, driving them together with a mallet to make sure they are properly home. Secure all these joints with wood pegs properly draw-bored (q.v.). Then fix the uprights, peg them to the top bar, and nail them to the others. The metal work can be purchased ready for use, and only requires bolting in place with coach bolts and nuts.

The hanging of a gate calls for some care if it is not to drop before it has been long in use. The chief requirement is a very secure hanging post. For a carriage gate, if an oak post is used, it should be at least 6 in. square, and 2 ft. in the ground, or more if the soil is light. An oak gate post should be sawn to shape at the top and left in the natural form of a tree stump at the bottom, this part being known as the butt. To set up the post, dig a hole on the side where the gate will be hung. Try the post in place and, when it is all correct, strut it up with temporary battens and pour in sufficient strong concrete to fill the hole; ram it well, and leave it for a day or two to set hard; then drill the holes for the gate nooks, or the pegs on which the hinges turn.

These pegs are bolted in place or, for a light gate, may be driven in with a hammer; they should be so positioned that the gate has a tendency to swing shut of its own accord. The shutting post is fixed in a similar manner, and carries the catch of the latch.

Ornamental gate posts can be made of brickwork or concrete, some very decorative effects being possible with these materials. Those made of brick must have proper concrete foundations; those made of concrete require similar foundations, but may be reinforced with a central bar of iron about  $\frac{3}{4}$  in. diameter. They are usually cast in a wooden mould and can be erected as described for a wooden post.

Many devices have been adopted to hold a gate shut, some of which are illustrated in Fig. 3. They are mostly of iron, wrought or malleable. Means to close a gate automatically include the spring, a weight suspended by a cord running over a pulley on the gate post and attached to the gate. A simple device to accomplish the same result is to adjust the rides so that the upper is

nearer the gate post than the lower ride. Thus the gate will always swing shut. Practically the same effect can be more generally obtained by inclining the top of the gate inwards.

Attention to a gate includes periodical oiling of the hinges and the repainting of all woodwork at least every three years, unless the gate has been treated with wood preservative, when similar material must be used instead of paint. Oak gates that have not been painted can be kept in excellent condition by brushing them with boiled linseed oil. When a gate has worn and sags it can often be corrected by removing the rides and resetting them. (*See next page for diagrams*)

## GATE-LEG TABLES & THEIR MAKING

### With a Useful Model for the Amateur Carpenter

Other articles in this work on various kinds of tables include Afternoon Tea Table; Dining Table; Folding Table, and Kitchen Table. Consult also the entries on Amateur Carpentry; Cabinet Making; Dovetail Joint; Drawer; etc.

The gate-leg table was introduced into England in the 17th century. It developed from the type of table on which the flaps when in use were supported by movable hinges of wood. Instead of these two additional legs were provided which were hinged and could be moved back when the flaps were let down; from their shape they were and are still known as gates.

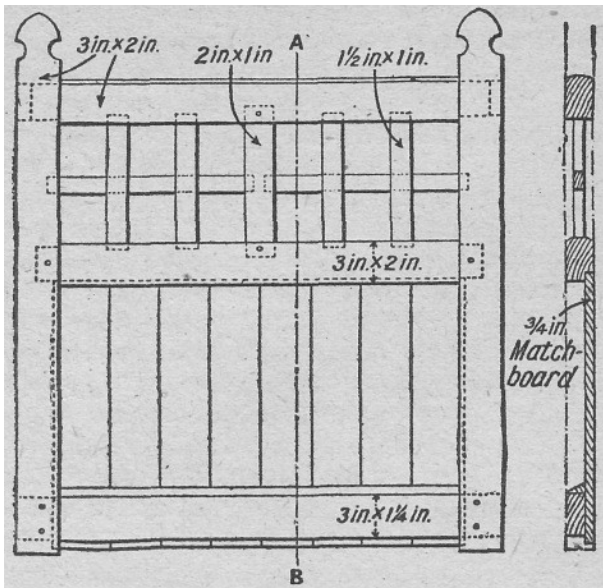

The majority of these tables were of oak and circular or oval in shape with four legs, but others were square or oblong in shape and were fitted with one, two, or four gates. Some tables have drawers at the ends, while others have the turning known as barley sugar on the legs. Such variations are not likely to date earlier than the latter half of the 17th century.

The gate-leg table, especially the round or oval variety, has been much reproduced by modern makers, as it agrees well with oak dining-room and hall furniture and also suits the small rooms of the cottage house.

One authority thus speaks about the age of these pieces: "Their age may be roughly arrived at by a careful examination of the turned members of the legs and, where they occur, of the rails and stretchers. Early ones are coarser in design than the later ones. The turning may be a perfectly simple series of balls one above the other, or a pillar with rudimentary cap and base, and the stretchers heavy and near the ground. These tables were nearly always made of oak, and some of the early ones have carved tops. An early date may be assigned to those examples which show an arcaded pattern at the ends carved between the upper part of the legs."

The type provides a good size of top so that the table can be used for dining purposes, though it is really more convenient as an occasional table in the living-

(Continued in page 947)

Gate. Fig. 1. Diagram showing construction of simple entrance gate. Right, section through gate on line A—B.

room, as it can be closed down to occupy a small space. Another advantage is that a drawer may be fitted without interfering with the movable parts of the piece.

**Making a Table.** Fig. 1 is a table of useful size, measuring 5 ft. by 4 ft. when open, and shutting down to a width of 1 ft. 4 in. It is advisable as a preliminary to set the job out so as to get the right shape for the oval top and the correct arrangement for the turnings. A full-size drawing of the legs must be prepared to take to the turner. Probably a suitable set of legs and swingers, ready turned could be purchased from a local timber merchant, if the turning presented any difficulty. Notice that the legs are all the same shape except the inner legs of the gates, the ends of which have two  $\frac{3}{4}$  in. dowels turned, upon which the gates swing (Fig. 2).

Start by getting out the material for the legs from 2 in. oak; square them up and mark out the mortises for the rails. At the drawer end two rails are put at the top, the upper one being dovetailed (Figs. 3 and 4). A drawer may be put at the other end as well if desired, or altogether omitted, in which case a plain rail similar to those at the sides must be used. When marking out the mortises be careful to see that the inner edges of the top and bottom rails come exactly the same distance apart as the length of the inner gate leg, measuring between the shoulders (Fig. 2). All the rails are then prepared and the tenons cut; the top rails are out of 1 in. stuff and the lower ones of 2 in. squares. A moulding is worked along the top of the lower rails to lighten the appearance, but this may be dispensed with by simply rounding the edges over.

All the joints having been cut and the turnings finished, the two ends and the gates may be glued up and allowed to set. The holes to take the dowels of the gates are bored and the outer legs of the gates cut away as in Fig. 1, so that they close in flat with the side of the table. The side rails may be glued up, fitting in the gates and testing the job for squareness. It will be necessary to join the flaps up in pieces to get the width, and a great deal of waste is obviated by joining them up in accordance with the full-size drawing, so that shorter pieces are used for the outer edge.

In better class work, instead of a square edge being left at the hinging sides (Fig. 7), a rule joint is used, shown in detail in Fig. 5. Fig. 6 is useful in a long table, as it ensures the main top and the flap being always level by reason of the bead fitting into the corresponding cavity. The rule joint, however, is the best, and presents no great difficulty if the essential principle upon which it works is clearly understood.

The curve for the two parts must be struck from exactly the point occupied by the centre of the hinge, and the squares above the hinge and on the flap must run diametrically to the circle thus struck, as shown by the dotted lines in Fig. 5. Plane the wood up true and thickness it and square the edges to form a close joint. Now set a gauge to half of the diameter of the circle and gauge both sides of the top and the underside of the flap. The depth of the square also must be marked. The surplus wood is then cut away and the parts tested together.

Back-flap hinges are used, the knuckles being sunk into the wood to get the required centre. No grease nor any lubricant must be employed until after the job is polished, as grease prevents the stain from taking properly. Before fixing the top, runners and kickers are attached, as shown in Figs. 4 and 8. The drawer is either dovetailed or rebated together. The top is fixed down with screws from the underside, putting them through the rails skew-wise. The table is opened, the top levelled off, and cleaned up, two stops are secured to the underside of the flaps to prevent the gates from opening too far. (See next page for diagrams)

**GATHERING: Of Material.** Large or small puckers in cloth that are made by running a thread through any fullness of material to be reduced, and drawing it in to the required size, are known as gathering. Different weights and kinds of material require different treatment in gathering up the fullness. Thick velours and serges do not gather well, and any surplus fullness should be taken away or pleated, to avoid unnecessary bulk, very little material being left to gather or ease into the band or tighter edge of the material. Most silks gather easily if a thread is run evenly through the fullness  $\frac{1}{4}$  in. from the edge. The smaller the stitch the finer the folds will be when drawn up.

*Gathering.  
Example of  
ordinary form.*

All fine gathering in cotton and linen materials, especially in

making babies' and children's clothes, should be stroked before they are placed into a band or yoke. It is wise to use a double thread for any gathering which is to be stroked, and draw it up tightly, securing it at one end by twisting it round a pin. Take a needle without a very fine point, and, placing it between each tiny fold, draw it swiftly down, making a fine stroke with the point, and drawing the gather under the left thumb. If this is carefully done, each fold will be of uniform size. In hemming down the inner side of the band or yoke on to gathering which has been stroked one stitch should catch each fold.

Rows of gathering 1 in. or less apart are sometimes used as a trimming. It is often effective if used on light material for summer frocks or children's clothes, and forms the preliminary work in smocking (q.v.); a strong or double thread should be used for this purpose.

**GAUGE.** A gauge is an instrument used to compare an object with another of known and accepted

size or form, and generally called the standard. In a wider sense a gauge is a standard of comparison; consequently the word refers both to a gauging instrument, and to the accepted dimensions adopted as a standard.

As an example, take the Birmingham standard wire gauge, generally abbreviated to B.W.G. This is simply a recognized and accepted set of figures defining the diameter of wires, and is also used to define the thickness of some sheet metals. On the other hand, the Birmingham wire gauge is a measuring instrument in the form of a metal plate with holes drilled in it, corresponding in diameter to the standard dimensions of the B.W.G.

The steam gauge and water gauge on a steam boiler indicate in different manners the pressure of steam and the level of water respectively. A rain gauge measures the rainfall in inches of depth, the amount collected in the gauge in a given period being measured by pouring into a graduated glass.

The marking gauge used by carpenters for scribing lines upon a piece of work comprises a wooden bar and a stock made to slide upon the bar, and provided with a thumb screw or a wedge for fixing it. Near to one end the marking pin or scriber is fixed into the bar, and this is used for producing the marks on the work. In use the sliding part is fixed to the bar so that the distance from the face to the scribing pin is exactly the desired distance for the required marks from the working face of the wood. This tool is shown in Fig. 1. A mortise gauge has two independent adjustable scribers, and a cutting gauge has a movable chisel-like blade instead of a scriber.

*Gauge. Fig. 1. Marking gauge used by carpenters for scribing lines upon wood.*

*Fig. 2. Standard wire gauge shown measuring the thickness of a brass bar.*

*Right. Fig. 3. Screw thread gauge.*

A wire gauge (Fig. 2) is a round or oblong plate of metal, preferably nickel-plated, to protect it from rusting. The edge is pierced with a number of slots which terminate in holes somewhat larger in diameter than the width of the slot. The gauging part is the space between the jaws, or the breadth of the slot. In gauging either a piece of sheet metal or a wire, the correct gauge size of the metal may be taken to be that corresponding with the number stamped against the slot into which the material just fits, if in doubt as to the proper size, it is as well to compare by testing with

the gauge sizes next larger and smaller. Similar gauges, known as wire or plate gauges, are used for distinguishing metal up to about  $\frac{1}{4}$  in. in thickness or diameter.

When using an instrument of this type it is important to ascertain the particular kind of gauge being employed, i.e. whether the Imperial standard wire gauge is being used, the Birmingham, or the Stubbs gauge. The Imperial gauge was legally established in 1884. The Birmingham and Stubbs gauges are both in extensive use, the Birmingham being employed chiefly for measuring iron sheets. The absolute dimensions vary with these different gauges. The gauge sizes commonly used are shown in decimals of an inch in the following table, arranged under the heading Birmingham, Imperial standard, and American wire gauges:

No.	B.W.G.	I.S.W.G.	American
16	·065 in.	·064 in.	·05 in.
20	·035 in.	·036 in.	·031 in.
22	·028 in.	·028 in.	·023 in.
24	·022 in.	·022 in.	·0201 in.

The full details can be obtained from any standard text book. As a rough and ready method it may be taken that No. 3 is equivalent to  $\frac{1}{4}$  in.; No. 7,  $\frac{3}{16}$  in.; No. 11,  $\frac{1}{8}$  in.; No. 16,  $\frac{1}{16}$  in.; and No. 22,  $\frac{1}{32}$  in.

A standard twist drill and steel wire gauge is most useful, either in the plain type or giving the imperial standard wire gauge sizes. A combination gauge, showing the standard size of drills, the corresponding tapping size, and also the full thread or clearing size, is also used.

The screw thread or screw pitch gauge (Fig. 3) consists of a number of separate plates secured in a handle, somewhat like a pocket-knife, each separate jaw being fashioned to the correct shape and pitch of the screw thread corresponding with the number and size stamped upon it.

The feeler gauge is used to feel the distance between two objects relatively close together, such as the width of a slot. It has separate blades of hard steel of different thickness, marked with numbers, these being the number of 1 000ths of an inch of thickness. Such gauges are used by inserting a blade or blades into the slot to be measured.

By means of the depth gauge the depth of a hole can be readily ascertained. It has a central measuring rod supported by the stock. To use it, the rod is pushed to the bottom of the hole, and the end of the stock placed upon the outer surface or upon the place from which the depth is to be measured. Some forms have a micrometric adjustment.

Another useful gauge for the amateur mechanic is a sliding caliper. This is made of steel, 6 in. to 10 in. long, the stock being graduated usually in both English and metric measures. One jaw is part of the stock; the other slides along the stock and is fixed by a set screw. A vernier incorporated in the slide enables readings to be taken down to  $\frac{1}{128}$  in. and  $\frac{1}{10}$  mm. respectively.

The jaws are adapted both for inside and outside measurements. *See* Cutting Gauge; Calipers; Wire.

*Gauge. Sliding caliper gauge with vernier, and micrometer adjustment for fine measurements.*

**GAUGED STUFF.** This term is used in plastering work for coarse or fine stuff which has had plaster of Paris mixed with it, thus shortening the period required for setting. One part of plaster of Paris to four parts of coarse or fine stuff may be used, up to equal proportions according to the rapidity with which the material is required to set, and also the strength. For heavy cornices the proportions should not be less than one to three. *See* Coarse Stuff; Fine Stuff; Plastering.

**Gaultheria.** *See* Winter Green.

**GAUZE:** The Fabric. Although the term is applied loosely to light silks and cottons of open texture, gauze has a special meaning founded upon the method by which the fabric is woven. In true gauze the threads are locked in position by being brought round one another. This principle is employed in goods not sold under the name of gauze, e.g. in many Madras curtains, in cellular cloth for underwear, and, partially, in leno fabrics.

In fancy dress, gauze is frequently used to form wings for fairy costumes. Wire gauze, as used for meat-safes and for window shields, is wire woven upon a loom.

**Use in Surgery.** Gauze is extensively employed as a surgical dressing to absorb discharges, or narrow strips may be introduced into a wound to act as a drain, or wounds or cavities may be plugged with it for the arrest of haemorrhage. Gazes impregnated with some chemical antiseptic have distinctive colours. Thus boracic gauze is pink; cyanide of potassium, mauve, etc. *See* Dressing.

**GAZANIA.** This flowering plant, which is unfortunately not hardy in most gardens, makes a gorgeous show in summer in well-drained soil in a sunny position. *Gazania splendens* is the favourite kind; its orange-coloured flowers with dark central ring are 2 to 3 inches across. Propagation is by cuttings inserted in sandy soil in a frame in August; it is unwise to plant the rooted cuttings out of doors until May. Pron. Ga-zā-ni-a.

**GEAR:** Spur and Bevel. Gearing as a means of transmitting power from its source to a given point is

carried out in its commonest form by the spur tooth wheel, of which there are two forms, the involute and the stub. The former is used almost exclusively in Great Britain, while the latter is most favoured by the American engineer. Both types have their technical advantages.

With any form of tooth gearing the drive is positive; therefore, if a wheel of, say, 48 teeth is in mesh with one of 12 teeth, their difference in speed will always be 4 to 1. This means an increase or decrease of the power transmitted according to which wheel is acting as the driver. Should the large wheel be the driver, then the small wheel would only transmit one-quarter of the power expended to drive it. Conversely, if the small wheel is the driver, then the large wheel will transmit four times the power expended to drive it.

By a suitable combination of gears enormous power can be obtained at the sacrifice of speed of the driven end of the train of gears, or a very high speed can be obtained at the driven end at a sacrifice of the power expended. This will be better understood by a reference to Figs. 1 and 2. Two examples in everyday use are the mangle and lawn mower, shown at Figs. 3 and 4.

On referring to Fig. 3, it will be seen that a train of six gears is employed by which to obtain the necessary power called for at the rollers, and operates as follows: The drive commences via the fly wheel through *a* to *b*, thence through *c* to *d*, and then through *e* to *g*. The cog wheel *a*, that is a part of the fly wheel, rotates independently on the extension of the shaft of the bottom roller, shown dotted. The cog wheels *c* and *b* are in one piece, and rotate on the pin *h*. The cog wheels *d* and *e* are also in one piece, and rotate solid with the bottom roller.

A combination on a similar principle is employed for the screw-cutting train of gears on a lathe. The driver is always moun-ted on the end of the man-drel, and the last gear wheel in the train is moun-ted on the end of the lead screw. By varying the combination any desired screw pitch may be cut. Fig. 4 shows the method by which the side wheel type of lawn-mower cutters are driven.

A few of the commonest uses of the spur gear may be mentioned. The change wheels of a screw-cutting lathe; all types of printing machinery and factory machinery; the timing-gear of the internal combustion engine; gear boxes; clocks and watches. In all cases where power is to be transmitted in the same plane the spur gear can be employed.

Two other forms of square-faced gear are the skew or helical gear and the double helical. With the former the angle of the teeth is in one direction only, and, through the medium of the sliding engagement, greater silence in operation is attained, but owing to the side thrust that is created by the tooth angle, an additional thrust bearing must be provided for each wheel employed. Fig. 5 illustrates the skew or helical gear.

The double helical type of gear (Fig. 6) is, next to

worm gearing, probably the most silent gear there is, and with this type, owing to the V-formation of the teeth no side thrust takes place. Where a drive has to turn a corner a bevel or worm gear is employed, and with it the angle of the turn need not be a right angle. The bevel gear is used extensively for machinery and bench drills; one notable application of it is the mechanic's breast drill. As with the spur gear, the bevel gear is also constructed with the teeth set at an angle from the centre of the wheel and known as the helical or skew gear, and double helical gear. Both types are used as the drive for the live axle of a motor car.

The worm gear is invariably employed for a true right-angle drive. The percentage of efficiency is not as high as that of the spur and bevel gears, owing to the large area of sliding contact between the faces of the worm and teeth, but worm gear has the merit of extreme silence in operation. Other forms of gear drive are chain drive, the round, the V and flat section forms of belt transmission, and electric and fluid types.

Of chain gearing probably that of the ordinary pedal bicycle is the most common type in use. It may be noted that with this form the gear ratio is not worked out on quite the same principle as with the other forms of gear, the formula being as follows: Number of teeth on chain wheel multiplied by the diameter in inches of the back wheel, and divided by the number of teeth in the hub chain ring.

The proper functioning of all forms of gearing will depend in a large measure upon the correct meshing of the teeth. One of the worst evils to be avoided is bottoming of the teeth, i.e. the tops of the teeth must not come in contact with the base of the engaging teeth. *See* Bevel Gear, Bicycle. Chain, Clock; Coaster Hub, Differential Gear, Drill; Three-Speed Gear.

## GEARS FOR MOTOR VEHICLES

### Types of Change Speed Gear in Common Use To-day

For further information on this important piece of mechanism consult the articles Bicycle; Differential Gear; Three-Speed Gear. *See also* Live Axle; Motor Car; Motor Cycle.

As understood for motor cars, gear provides up to four forward speeds and one reverse speed. A simple type of three-speed gear is shown in Fig. 1. The four smaller diagrams show the positions of the gear teeth for each speed. The gear shafts are arranged to run in the same plane as the engine, and connected to the clutch and the cardan shaft by means of universal joints. With this arrangement the torque, or drive from the engine, is direct through the gear shaft to the gear wheel.

An example of a four-speed gear box is shown in Fig. 2. The first and second speeds are obtained by a pair of sliding, straight-toothed gear wheels; while, for the third and fourth speeds, dog clutches are used to bring into operation permanently meshed gears of helical tooth formation. The helical gear wheels *a* and *b* on the ends of the countershaft are in permanent mesh respectively with the wheels *c* and *d*, the former being

driven from the engine and the latter running freely on the driven shaft *e*. The sleeve *f* is splined to the driven shaft *e* and, when it is moved to the left, teeth *g* at one end engage corresponding clutch teeth on the side of the gear wheel *c* and give the direct drive or fourth speed. When the sleeve is moved to the right, teeth *h* at the other end engage corresponding internal clutch teeth on the gear wheel *d*, giving the third indirect speed.

The first and second speeds are obtained by sliding the pair of gear wheels, *j*, *k* into mesh with the gear wheels *l*, *m* on the countershaft. The wheels *j*, *k* are splined on the outside of the sleeve *f*. The wheels *j*, *k* and sleeve *f* thus always rotate with the driven shaft *e*. Frequently a "synchro-mesh" arrangement is embodied in the dogs so that the latter are synchronized at the moment of changing gear, thus giving a smooth, silent change.

**Epicyclic Gears.** This type of gear is employed in the transmission system of a few cars, but its chief use lies with the pedal bicycle.

In the epicyclic gear all the pinions are in constant engagement. The mode of operation may be easily understood with the aid of Fig. 3; *a* is a metal ring which carries internal teeth around its periphery; *b* is an ordinary spur-toothed cogwheel keyed to the engine shaft, whilst *c* is a cogwheel, the diameter of which is such as to allow of its engagement with the internal teeth on the ring *a* as well as its engagement with the pinion *b*. The arm, *d*, acts as the bearing for *c*, and is capable of rotating independently of the crankshaft, *f*, from which it takes its support. To obtain the high gear, *a*, *c* and *b* are locked solid by a suitable means, which causes the whole mass of wheels to rotate as solid with the crankshaft, the arm *d* being the driving medium to the transmission.

The second speed is obtained by locking *a*, by means of the band, *e*, and allowing pinion, *c*, with the arm, *d*, free movement; by so doing pinion, *c*, which is being rotated in the opposite direction to the crankshaft pinion, *b*, is through the medium of the stationary ring, *a*, being forced to move slowly with the arm, *d*, in the same direction as the crankshaft pinion, *b*, the arm, *d*, being suitably connected to the transmission, thereby giving the low gear (A, Fig. 3). To obtain the reverse the arm, *d*, is secured stationary, i.e. temporarily disconnected from the transmission, and the ring, *a*, allowed free movement. By so doing the crankshaft pinion, *b*, which operates the pinion, *c*, in a reverse direction, obviously causes the pinion, *c*, to rotate the ring, *a*, on the inner side of which it engages, in the same direction as itself, the ring, *a*, in this case being the driving medium to the transmission. The position of the gears is shown at B (Fig. 3).

A neutral position is obtained by allowing the gear to run free, i.e. the outer ring; *a*, is running free and being driven by the pinion, *c*, which in turn is driven

(*See next page for diagrams, continued in page 953*)

## GEARS

Below. Fig. 2. Diagram showing arrangement of gears in a four-speed gear box.

Above. Fig. 1. Three-speed car type gear box, showing engagement of teeth on the three forward gears and reverse.

Left. Fig. 3. Diagrams illustrating the principle on which the epicyclic gear is worked.

by the crankshaft pinion, *b*, so it follows that unless the outer ring, *a*, is locked by means of the band, *e*, the driving arm, *d*, will remain at rest.

A somewhat different design of epicyclic gear is used in conjunction with the preselector or self-changing principle of operation. The actual changes of gear are effected by the depression of a clutch pedal, but, prior to the operation of the pedal, a small hand lever mounted on the steering column below the hand wheel is moved to select the appropriate gear. In a typical system there are four epicyclic trains of gear, giving four forward speeds and one reverse. By adjusting the hand lever any gear may be pre-selected, to be engaged when desired by first depressing and then releasing the clutch pedal.

Fig. 4. Cone clutch, dogs and splines incorporated in the synchro-mesh mechanism. (Courtesy of "The Autocar")

A synchro-mesh mechanism embodying a cone clutch is shown in Fig. 4. The function of the cone clutch is to synchronise the two rotating parts so that when the teeth come together they are moving at the same speed and the engagement is effected without noise or shock. The principle of the gear-box is not therefore affected—as it is in the self-changing gear, for instance—but the movement of the gears is controlled so that engagement is always preceded by the synchronisation through cone clutches. The most accurate way of regarding the synchro-mesh principle is that of introduction.

The driving shaft of the gear is of normal design, as is the driven shaft. The driven shaft is splined and held at one end in a ball bearing, and at the other in a roller spigot bearing. On the driving shaft is to be found the ordinary gear wheel which meshes with a wheel on the layshaft, and on the driven shaft there is the gear wheel which picks up the drive from the layshaft. In the middle of the driven shaft is a sleeve *c*, fitting into the splines on the shaft and itself splined on the outside, as shown in the diagrams above.

The synchro-mesh mechanism consists in a cone *e*, which is machined on the side of the ordinary gear wheel on the driving shaft. Within the cone is a ring of internal teeth. On the driven shaft is a coned ring, *f*, which projects over the cone *e*, on the driving shaft in exactly the same way as the female member of a cone clutch projects over the male member. When the driver moves the gear lever to top gear a sleeve on the driven shaft is moved up and brings a number of springs, *h*, against the back of the cone. These springs move the

ring up to engage with the cone, the engagement being progressively closed. Synchronisation is thus secured, and a further movement of the gear lever brings into operation the edge *j* of the sleeve, and the resulting pressure forces the clutch hard home and the sleeve splines into the internal teeth of the cone.

So long as the speed of the ring differs from that of the cone the gears cannot be engaged.

Generally speaking, change speed gearing requires little attention beyond keeping the oil at the correct level. All modern gearboxes, like live axle casings, are provided with special filler openings, which are so arranged that the gear box is easily filled to the proper level but cannot be over-filled, since any surplus would overflow from the opening. The filler opening is so placed that the oil is approximately level with the axis of the countershaft. In cold weather, when the oil is thick, the motorist may prefer to fill the gear box from the top, but the plug of the filler opening must then be removed to ensure that the gear box is not over-filled.

An excess of oil may in some cases be a source of much trouble, since it may leak on the one hand into the clutch casing, or may overflow into the torque tube and raise the level in the axle casing to such an extent that oil may leak on to the brake drums.

Most makers advise that the gear box on a new car should be emptied after the first 500 miles, preferably when the car comes in from a run and the oil is therefore warm and liquid. A plug is always provided at the lowest point of the box for this purpose. After the oil has drained out the plug should be re-inserted and the gear box flushed thoroughly with paraffin, or better still with a special thin flushing oil.

**GELATINE: The Substance.** When bones, ligaments, and other connective tissues of animal bodies are boiled in water, a colourless and odourless solution is obtained, and if this is evaporated to dryness, gelatine remains in translucent shreds of a pale yellow colour. When dissolved in warm water and allowed to cool, the liquid is converted into a jelly.

In surgery, gelatine may be used to check bleeding. As a food, gelatine has a certain value in that it can partly replace the proteins, lean meat, egg white, gluten, etc., which are required to replace what is lost in the wear and tear of the body. Gelatine is much used by manufacturing chemists for making capsules, pastilles, and other articles. *See Demulcent.*

**GELATINE: Use in Cookery.** Of the various kinds, sheet or leaf gelatine is the best. It is made in thin, transparent sheets, and will dissolve quickly in water,  $\frac{3}{4}$ -1 oz. being needed for every pint of liquid. Packet gelatine is opaque and yellowish. Of this 1 oz. will stiffen  $1\frac{1}{2}$ -2 pints of water, but it may need soaking for 6 hours.

A third kind, opaque gelatine, is chiefly used for

strengthening stocks and soups. Of this  $\frac{1}{2}$  oz. dissolved in  $\frac{1}{2}$  pint of water, with a teaspoonful of meat extract added, makes a good glaze for a tongue, etc. Powdered gelatine is also greatly used, and is very successful. *See Glaze; Jelly.*

**GENERAL POST.** The name of this game has become proverbial for a complete change round of persons or things. The game can be played by any number of people.

Each player chooses the name of a town, which should be written down by the person who acts as postmaster. One is then blindfolded and stands in the middle, while the others sit down in a circle. The postmaster reads out the names of two of the towns, as, for example: "The post is going from London to Exeter"; or from Liverpool to Edinburgh, etc., and the persons representing those towns have to exchange places, while the blindfolded man tries to catch one.

The blind man continues in the middle until he has caught somebody, though the post may pass successfully many times before he does so. The postmaster should vary the changes as much as possible, sometimes choosing two people at opposite sides of the room, sometimes two who are next to each other. At the words general post all the players have to change their places. A variant of the game is for a player, not blindfolded, to try to gain the place of one of the two persons exchanging seats.

**GENERATOR.** The object of the various kinds of generators is to convert one form of energy into another. As an example, the acetylene generator comprises a vessel containing calcium carbide, another to hold water, and a third to receive the gas, which is generated by the drip of the water on the carbide.

An electrical generator is an apparatus for converting mechanical into electrical energy. The name is generally used in electrical work for a particular type of machine, the alternating current generator; but from the domestic point of view it may be applied also to dynamos generating a continuous current. Occasionally the term generator is applied to a boiler which generates steam, particularly the type known as the flash boiler. *See Acetylene; Dynamo.*

**GENOA CAKE.** To make this cake, wash  $\frac{1}{4}$  lb. sultanas and 2 oz. currants, drain them thoroughly and leave them to dry. Beat  $\frac{1}{2}$  lb. butter or margarine to a cream with 6 oz. granulated sugar, then add 3 eggs, one by one, beating each in well before adding the next. Stir the mixture for 5 min.

*Genoa Cake, decorated with almonds, and wrapped in greased paper as removed from baking tin.*

Mix together

the currants, sultanas, 2 oz. glacé cherries, the same quantity of mixed peel, and  $\frac{1}{2}$  oz. blanched and chopped almonds; then sieve  $\frac{3}{4}$  lb. flour, measure out 1 tablespoonful, and mix this quantity with  $1\frac{1}{2}$  teaspoonfuls baking powder. The remainder of the flour, mixed with the grated rind of a lemon, must be folded alternately with the fruit into the butter, etc.

Stir all together lightly, add a little milk, if necessary, and then stir in the baking powder. Put the whole into a greased cake-tin lined with greased paper and bake it in a moderately hot oven for about  $1\frac{1}{4}$  hours, lessening the heat after the first 20 min. The top of the cake may be decorated with a few blanched and chopped almonds at the same time as the heat is reduced.

**GENOESE PASTRY.** Made either white or coloured, this pastry forms the foundation of many small fancy cakes. To make it, whisk 3 eggs and 4 oz. castor sugar in a basin placed over a pan of hot water until the mixture becomes thick and free from streaks. This should take about 10 min.

Put the basin on the table, continue whisking for a few minutes, and then stir in by degrees 3 oz. Vienna flour and the same quantity of butter. Add the flavouring, then turn the mixture into a shallow baking-tin lined with greased paper, and bake it in a hot oven until it is firm and lightly browned.

**Genoese Biscuits.** To make these, cut some Genoese pastry into crescents and other small fancy shapes, coat them with royal icing, and then leave them in a cool oven until the icing becomes of a pale biscuit tint. When cold the biscuits should be decorated with a few pieces of glace cherries or angelica, and, if liked, a little more

icing. *See Biscuit; Icing.*

*Genoese Biscuits. Small fancy cakes suitable for the afternoon tea table.*

**GENTIAN.** Most of these dwarf Alpine plants are suitable for the rock garden, and some of them thrive in the mixed border. The drug gentian is obtained from the root of *G. lutea*, with yellow, spotted flowers in July; height up to 4 ft. The interior of the root, like the flower, is yellow.

*Gentian. The beautiful blue trumpet-shaped flowers of Gentiana acaulis, a favourite plant for the rock garden.*

*Gentiana acaulis* is a most beautiful but capricious plant, which frequently will not thrive under conditions which might be expected to favour it. It likes well-drained stony loam, a sunny place, and must be

watered freely in early summer. The blue flowers are large and tubular, and are borne on very short stems.

*Gentiana verna* is a lovely miniature kind for the rock garden; it is most likely to flourish in gritty loamy soil in a sunny place, and needs an abundance of water in early summer. *Decumbens* and *septemfida* are two other beautiful gentians which thrive in deep sandy loamy soil if kept moist in spring and early summer. *Sino-ornata* is splendid and easily grown in leaf mould.

*Andrewsii*, 18 in. high, and *asclepiadea*, 2 ft. high, are more vigorous plants suitable for well-drained loamy soil in partial shade. *Lutea* is a distinctive plant with large leaves and stems 2 to 3 ft. high, bearing whorls of yellow flowers in summer; this thrives in ordinary loamy soil.

Many gentians are unreliable and shortlived under cultivation, and it is usual to raise them from seeds every few years in order to maintain a healthy stock. It is advisable to sow the seeds as soon as they are ripe in pots of gritty soil, and to expose the pots to snow and frost in winter; this practice will be found useful in order to quicken germination of the seeds in spring.

**Uses of the Drug.** The drug is obtained from the root of the yellow gentian, found in Europe and America. Its chief characteristic is its extremely bitter taste, and it is largely used in bitter tonics and digestive mixtures. Its action is closely similar to that of *calumba* (q.v.) The doses of the different preparations are: extract of gentian, 2-8 gr.; compound infusion of gentian,  $\frac{1}{2}$ -1 fluid oz.; compound tincture of gentian,  $\frac{1}{2}$ -1 fluid dram. *See* Border; Rock Garden. Pron. Jen-shan.

**GEORGETTE.** Crêpe georgette was the name originally of a silk made from very tightly twisted raw silk both in warp and weft. The surface is crêpe-like and lustreless, crisp and hard to the touch. The goods are self-coloured and dyed in all shades. Though thin and semi-transparent, in good qualities, georgettes are excellent silks for wear. When re-dyeing, allowance has to be made for the hardness, and extra time allowed for penetration. Cotton georgette is a good cotton crêpe, which washes well and does not always require ironing.

Georgette garments are inclined to shrink during the wash, and almost invariably do so when dyed. It is usually possible, however, to pull them into the original shape during the ironing process when the fabric is still damp.

**GEORGIAN STYLE.** This term refers to styles in architecture and furnishing which flourished in the period covered by the reigns of the four Georges, i.e. from 1714 to 1830. The term neo-Georgian is sometimes used for styles designed during the reign of George V.

The Georgian style proper was essentially a vernacular one as opposed to the more formal variation of Renaissance architecture applied to public buildings and the mansions of the great. It is also the basis of a great part of our garden suburb building.

The old Georgian style can be studied best in certain

residential terraces of London. Westminster and Bloomsbury are full of examples of the earlier and later Georgian houses. It is peculiarly adapted to the terrace house, Smith Square, Westminster, Bedford Row, Holborn, Cheyne Row, Chelsea, and Church Row, Hampstead, may be cited as examples of treatment in which the Georgian architect delighted. Red brick, with or without stone dressings, was almost universally employed, and the dark rich tone of this is one of the most attractive features of these old houses.

*Georgian style. Exterior of an 18th century red brick house by Sir Robert Lorimer. This style is distinguished for its simplicity, dignity and repose. (Courtesy of Country Life)*

The roofs are invariably hipped, i.e. they slope upward and backward from the walls on all four sides. They were not brought down to form overhanging eaves, but were stopped behind the walls, and there was often a low brick parapet or a pediment on the front of the house. At the beginning of the 18th century the division between roof and walls was generally a heavy wooden cornice. This disappears in the Georgian house, a red brick moulded cornice being substituted a little below the parapet. The roof was often pierced with dormer windows, as shown in the first illustration. At first the roofing material was red tiles, but these afterwards gave way to slates, especially on town or city houses.

Our fine example shows that the central feature of the facade was the doorway. This was generally of wood in the earlier examples, stone being employed later, and was often covered as seen here by a fine hood and supported on either side by classical columns or pilasters with their correct entablature. Porches were rarely used.

In these houses a great deal of inventive talent was lavished on the hood and the doorway generally, the intention being to contrast this feature so rich in detail with the sedateness of the rest of the front. A fairly substantial string course marked the storeys of the house and separated the rows of windows from each other.

The windows were always of the sash variety, tall and narrow, with wide frames flush with the brickwork, the sashes themselves being divided by glazing bars into several rectangular frames. The frames were painted white. It was usual particularly in twin or terrace houses to build a basement storey, the entrance floor being raised a little above the ground level. Hence there was the opportunity of a flight of stone steps up to the front door, and these steps were often, in the more pretentious mansions, extended in a sweeping curve on either side as they approached the pavement.

**Interior Decoration.** Throughout this century the tendency was towards lighter construction, inside and outside. Just as the glazing bars of the tall window became less solid, so the constructive decoration of the interior grew less massive.

The Georgian staircase, for instance, is easily distinguishable from its predecessor. The string or support of the stairway was stepped so as to show the end of each stair, instead of being, as formerly, a long, solid entablature. This expressed the main idea of the Georgian staircase makers, that the stairway was a continuous series of steps from floor to floor. Pedestals at the foot of the stairway, which in Jacobean architecture were heavily carved, became little more important than the balusters. The handrail was thinner.

Chimney-pieces grew altogether lighter in construction, until they culminated in the daintiness of the Adam period. Panelled walls continued as the basis of the decoration, but the panels were simpler and shallower, and were often in carved pine or were painted in white or cream. It is noteworthy that the same panelling was used throughout the house. The only assertive decorations were the ceiling cornices and the superstructures to overmantels, doors and windows. Wrought-iron work was very largely used, and this ministered to the craving, for light construction. Necessarily there are to be found in some purely Georgian houses Queen Anne and even Jacobean features, but overlapping is inevitable in any architectural period, and the Georgian atmosphere is less mistakable than most.

Our second illustration shows a mid-Georgian drawing room with richly ornamented ceiling and broken pediments crowning the larger door and the chimney-piece. The panels are simple in well designed contrast to the cornice decorated with dentils and classical motives. The furniture is of the Chippendale period with side tables enriched with fretted ornament and chairs with pierced splats of carved ribbon patterns. The writing table is an example of the French taste then in vogue with its delicate ormolu decoration. The Georgian dog grate, serpentine fender and Oriental hearthrug are furnishing points of interest.

*Georgian Style. Mid-Georgian drawing room with characteristic panelled walls, richly ornamented ceiling and pediments over the door and chimney-piece. The furniture is of the Chippendale period. (Courtesy of Country Life)*

An important development in connexion with Georgian interior decoration was the use of wallpapers.

Several factories in London after the first half of the 18th century produced printed and coloured papers in Chinese designs, and as the classical styles became the vogue with the work of the Adam brothers and continued till the end of the Georgian period, designs introducing classical landscapes with temples and statues were popular.

Modern adapters of the style sometimes dispense with some of its most beautiful details. One does not often see a neo-Georgian house with a parapet or a pediment. There is a preference for over-hanging eaves, and only a few modern houses can carry the tall windows of the old-time terrace house. A profusion of artistic wrought-iron work is financially impossible in most cases. But the vitality of the style is proved by deviations that may be made in details without the sacrifice of its general content. *See* Adam Style; Bedroom; Chippendale Style; Fireplace; Furniture; Glass; Hepplewhite Style; Regency Style; Sheraton Style; Silver.

**GERANIUM.** The true geraniums are hardy perennials suitable for the flower border and the rock garden. The zonal pelargonium, a popular flower for summer bedding, and commonly though erroneously called geranium, is a tender South American plant which does not withstand the winter in this country. It is described under pelargonium (q.v.).

*Geranium grandiflorum, a hardy plant with violet-blue flowers in summer. See below.*

The hardy geraniums suitable for the flower border flourish in ordinary soil and are increased by division in autumn or spring and by seeds sown in boxes of soil in a frame in April. All are summer-flowering. The best of the vigorous border kinds are armenum, 2½ ft., crimson purple; Endressi, 15 in., rose pink; grandiflorum, 12-15 in., violet-blue; and ibericum, 18-24 in., violet-blue.

Geranium argenteum, 4 in., grey leaves and rose-coloured flowers; cinereum 4 in., grey leaves and pink flowers; and lancastriense, 3 in., rose colour, are suitable for the rock garden where they thrive in sunny places and well drained sandy soil. Geranium pratense is the common crowfoot which grows wild in Britain.

**GERBERA.** This beautiful summer-flowering perennial from South Africa, commonly known as the Transvaal daisy or gerbera, rarely succeeds out of doors in Britain, unless grown in a well drained sandy soil in a warm sheltered position. It belongs to the daisy order and bears very showy flowers, carried singly on stout stems about 1 ft. long; in the newest varieties the flowers are of various shades of red, orange red, salmon, and rose. The typical kind is Gerbera

Jamesonii, with bright red or scarlet flowers.

The best way to grow the Transvaal daisy is to plant in a sunny border at the foot of a heated greenhouse or in a bed of soil in a sunny frame: it may also be grown in pots under glass. A compost of loam, leaf-mould and sand is suitable. Propagation is by division of the plants in spring or by seeds sown under glass in March.

**GERMAN MEASLES.** The symptoms of German measles, also known as rubella, resembles those of measles, but the disease is much less contagious. The microbe has not been discovered. The incubation period is about 14 days. The infection probably spreads from person to person on the breath, skin scales, and clothing.

An attack may be ushered in by feeling of chilliness, running of the nose, sore throat, headache, pains in the back and legs, and some feverishness. The glands of the neck generally swell a little, and a red eruption may be seen in the throat. On the first or second day a pinkish-red rash appears on the face and neck, and then spreads down over the body. It lasts from three to five days as a rule. The neck glands remain enlarged, and occasionally those of the armpits and groin become a little swollen.

It is best to put the patient to bed and keep him there until the rash fades. Give him light, digestible food, and if there is any constipation give a mild aperient such as half teaspoonful of confection of senna.

Keep the patient from mixing with other children for 8 or 10 days after the appearance of the rash, and until all catarrhal symptoms in the nose and throat have disappeared. Children who have been exposed to infection should be in quarantine for 20 days. *See Infectious Diseases; Notification; Measles.*

**GERMAN SILVER.** German silver is known under several different names, among which are nickel silver, Nevada silver, electrum, and others. It is an alloy of copper, nickel, and zinc, the composition varying. The best quality is composed of two parts of copper, one of nickel, and one of zinc. This grade is more difficult to work but possesses a fine polishing surface, and is used to imitate real silver.

The metal can be easily worked, rolled, hammered or drawn; ease of working depends upon the proportions of the alloy, a higher percentage of copper generally making it softer. While fairly hard, tough, and not easily corroded, it becomes slightly tarnished if long exposed to the air. It can easily be soldered. *See Metal Work; Soldering.*

**GERMAN WHIST.** This variety of ordinary whist is played by two persons. The players cut for deal, the lower cut being the winner. Here the ace counts as the lowest card. The winner of the cut then deals out alternately 13 cards to himself and 13 to his opponent. He turns up the next card to show what are trumps and leaves the rest of the pack on the table.

The player who has not dealt then leads, and play is as at whist. Players must follow suit if they can; if not, they can play a trump card, which is superior to those

in all other suits. The winner of the first trick takes the exposed card into his hand and the loser takes the next from the pack. They repeat this after every trick, and so have always 13 cards in hand until the pack is exhausted. When the thirteenth trick has been made the winner leads one of the cards in his hand and play continues until all have been played out, trumps being as before. The tricks won by each player are then counted.

## GESO WORK IN VARIOUS FORMS

### Modern Uses for this Decorative Handicraft

For related information consult the articles on Italian Renaissance Work; Lacquer Work; Leather Work and Stencilling. See also other ornamental crafts, including Lampshades; Pattern Printing, etc.

Gesso is a form of applied decoration. The material that is employed consists of a pasty substance compounded chiefly of plaster of Paris and glue. It was used for ornament in relief, and is found frequently on the frames of Queen Anne mirrors, on chairs, and other furniture of that period. The woodwork was overlaid with gesso in a decorative design and then gilded, which produced the ornate character of the gilt

furniture of the late 17th and early 18th centuries.

1. Rolling paste in the hands to form a ball.

2. Shaping the leaves or petals.

3. Using the modeller to make veins in leaves or for other delicate work.

When used for high relief gesso powder is unsatisfactory in wear, and for such work barbola paste has taken its place, as it can be easily modelled owing to its plastic nature, and when dry it is quite hard. The box illustrated in Fig. 4 is an example of modern gesso work in low relief; the mirror frame and bowl, Figs. 6 and 7, are ornamented in barbola work. The latter is particularly effective when used for decorating painted and gilded cane furniture. The former is the foundation paste for slightly raised lacquer work designs.

The wooden box for handkerchiefs (Fig. 4) is first rubbed down with sandpaper and then painted white before being coloured the desired shade with transparent lacquer. When this is quite dry make a tracing of the size of the top of the box, and design something suitable. Conventional work of the type shown is the most effective. Trace this on to the box by turning the pencil side on to the wood and going over the back with a fairly hard pencil; but should the design be incorrect when reversed, go over the back of the design with an H.B. pencil, lay this side next the wood, and trace off with a harder pencil, it is better to make the design on tracing paper, as if much is rubbed out on the box it becomes greasy and the colours work badly. The border of a conventional floral embroidery design can be well adapted from a transfer on to tracing paper.

Mix some gesso powder into a creamy paste with water. Apply this to the design with a brush and avoid going over the edge. Care is necessary, as the gesso paste should be modelled a little and applied in the direction it is to lie. Each leaf should be modelled separately and the roses worked in a circular direction. Several coats of gesso may be used, but not very thickly, as it looks rough when dry. Any unevenness can be rubbed down gently with sandpaper.

When the gesso is quite hard it can be coloured with barbola colours. Allow these to dry and then varnish with Barbola varnish. Articles can be obtained with the raised work on them and are then easily finished in colours. The real fascination of the work, however, lies in the modelling.

*Gesso. Fig. 4. Handkerchief box, with border of leaves and flowers.*

#### Barbola Decoration.

Experimental outfits for barbola work can be obtained for 3s. 6d. Varnish, paste, gesso powder, tubes of colours, bronze powders, brushes and tools can all be obtained as required in a good art department. Barbola can be applied in many ways, one of the most effective being for mirrors. Procure a wooden mirror-frame, sandpaper it, then coat it over with quick drying lacquer or stain. Select a suitable design to trace or copy.

*Fig. 5. Tools used for delicate modelling in Gesso work.*

Model groups of fruit or flowers, using barbola paste, and stick them to the wood, using a paste made from the barbola to which water and a little powdered glue have been added. It is important to allow the modelled work to become absolutely dry and hard before attempting to paint it.

*Gesso. Fig. 6. Coloured table wreath or mirror frame.*

In modelling use a little gesso powder on the hands, as the paste will work more easily and will not show the marks of the skin. Avoid labouring the work. Take out the amount of paste required and roll it in the hands, Fig. 1. Should it be desired to form an apple or similar fruit, roll it into a ball, and when the correct shape has been obtained put it on a piece of glass or board, and finish off with a barbola modelling tool, Fig. 5. Avoid handling too much. Press in the top to make the eye and round the sides. Then turn carefully and round the other end, and arrange the stalk. For this make a rather thin roll. Make a hole with the pointed tool, push the stalk into it, and hold it firmly; then take the ordinary modeller and smooth round the top. To fix the apple on a bowl or mirror, make one side flat, so that there is a good surface for the paste.

*Fig. 7. Bowl painted in coloured lacquers.*

Mix a little barbola paste in a tiny wooden bowl, using a few drops of water and a little powdered glue for heavy work. Smear this over the portions of the work which it is desired to affix, and press on to the object, using a tool as far as possible. When it is all quite dry colour it, using barbola colours or, if these are not available, matt water-colours. Bright, pure colours are the most effective. Try rather large fruit and flowers first, as they are easier and do not tend to overcrowd the work.

As the work dries, touch it up where necessary. When all the colours are dry and there is no risk that the paste will shrink, varnish all over with clear varnish. The wreath, shown in Fig. 6, is an equally suitable design for a mirror frame or, in a small size, for an applied decoration to ornament a waste-paper basket or linen basket in cane. A charming effect is gained by leaving some of the flowers silver or gold.

To decorate the bowl shown in Fig. 7, it must first of all be coloured, using for this purpose either quickly-drying lacquer or barbola colour, which is varnished when dry. While the bowl is drying, model the fruit and flowers which are required for decoration. To make the bowl waterproof it is a good plan to coat the inside with gold size, using a large, soft brush.

Having modelled the apple, leave it on a small board to harden, and then model the leaves. To do this roll the paste into a ball, then press it flat and form the shape of a leaf. The sides of the leaf should be held in the two hands and pulled gently towards the worker. This applies to rose petals, as shown in Fig. 2. The modelling tool is then used to finish off delicate hollows, veins of leaves and curled edges (Fig. 3).

**Coloured Bronze Powders.** Another modern form

of gesso work is executed chiefly in gold and silver and applied on a lacquered background. Its particular charm lies in its lustrous effects produced by using coloured bronze powders. It is used for ornamenting many kinds of household articles, among them candlesticks, mirrors and powder boxes, and is a form of work that affords many opportunities for the skilful modeller. A liquid medium is sold for use with bronze colours, which are obtainable in glass tubes.

Examples of this kind of work are illustrated in Fig. 8. On the left is a powder bowl of papier mache, on which is modelled the head and bust of a dancer. The bowl itself is lacquered a shade of petunia red, and petals of the paste are arranged round the dancer's waist and at the edges of the bowl to represent a billowy skirt. The figure should be done in the ordinary manner with barbola paste, and must be affixed to the bowl before it is dry, as the body must be shaped to the lid of the bowl. Then the long petals forming the rest of the decoration should be modelled and placed in position. In this work the modelling tools should be used as much as possible to avoid handling the finished product, and care should be taken to make the surface rough before sticking on the modelled paste. When the work is quite dry, gild the figure, and the tops of the leaves, and then make the undersides of the leaves silver. To put on these colours use gold and silver bronze powder, and a good washable medium, which should be applied with a soft brush.

*Fig. 8. Powder pot and covered bowl decorated with bronze colours on barbola. The handles are in the form of a dancer's head and an open rose.*

For the smaller covered bowl, decorated with a rose, the petals must first be modelled and placed in position, using the modelling tools as much as possible. (See Figs. 2, 3.) A few of the petals should be made rather thin to form a centre. Round this centre fix the rest of the petals, pulling them into position, and turning over the edges of some of them. When the rose is finished, put it on a small board, and touch it up with the modeller. It is advisable to finish this before the paste gets hard.

The bowl itself must then be lacquered deep blue. When it is dry scrape the top and place the rose in its position. Then make a few leaves and arrange them round the rose. Next gild the rose, and colour the leaves green, using bright green bronze powder. As soon as this is dry, transparent lacquer can be used, a little scarlet for the centre of the rose, then orange, with yellow for the outer petals. Finally the leaves should be coloured with green lacquer.

**GEUM**(Avens). These are splendid hardy border plants, some of which will bloom throughout the summer months if the faded flowers and the old stems

are cut off. The two best are Lady Stratheden, yellow, and Mrs. Bradshaw, scarlet; both bloom from May to September. Other showy varieties with a shorter flowering season are Orangeman, orange colour, and Fire Opal, orange-red. All these are about 2 ft. high when in bloom. Borisii, 1 ft., has orange-scarlet flowers. *Geum montanum*. 6 in., and reptans, 8 to 10 in., have yellow flowers in abundance in spring, and are suitable for the rock garden.

## GEYSER: FOR INSTANTANEOUS WATER HEATING

### Types for Local or Multi-point Service

Related articles include those on Bath; Cistern; Gas; Hot Water; Water Supply.

The geyser is now commonly known as the instantaneous heater, to distinguish it from other heaters of the storage type. Geysers are made to burn any fuel, but only those burning coal gas are dealt with here, since the principles on which they all work are the same.

The working is as follows: Cold water enters the heater and passes through a system of chambers and/or tubes and in its passage it takes up heat developed by the gas burned in the lower part of the apparatus. Ultimately it emerges from the geyser as hot water, the temperature of which is dependent upon the rate at which the water is allowed to flow. Water at any temperature from tepid to scalding can be obtained.

Broadly, these appliances are divided into two classes namely, those which supply hot water to only one point (as, for instance, a bath, hand-basin or sink) (Fig. 1), and those which supply several points, e.g. a bath, hand-basin and sink on the same supply pipe (Fig. 2).

*Geyser. Fig. 1 (left): Geyser for the bath, with automatic valve and swing-out burner. Fig. 2 (right): Automatic water-heater for multi-point service. (British Commercial Gas Association)*

In both types the flow of gas and the flow of water are made automatically dependent on each other, so that gas is consumed only while the water is flowing.

Sometimes this inter-dependence of gas flow and water flow is ensured by a special gas valve which is actually operated by the water—the gas is

automatically turned down when the water is turned off—and sometimes interlocking taps are used in such a way that the gas cannot be turned on until the water valve is opened.

The amount of gas required to make a bath naturally depends upon the temperature of the cold water, the temperature of the bath water and the amount of hot water required. If the cold water is 60° F. and the hot water is required to be 100° F., then roughly 1 c. ft. of gas (calorific value 500) would be needed for each gallon of water heated. If a temperature rise of more than 40° F. is required, then a proportionately larger quantity of gas would be needed, and vice versa.

A bath of water may consist of 20 to 30 gallons.

Geysers using gas can be obtained in a variety of elegant finishes, including chromium plate and enamel. Their heating powers range from 2 to 4 gallons per minute.

In choosing a geyser, the size is determined in terms of the number of gallons of water to be heated per minute. As the geyser is only capable of imparting a certain quantity of heat to the water in a given time, it follows that the temperature of the water flowing out of the geyser will depend upon the rate at which it is flowing. If very hot (or even boiling) water is required, the water tap must be turned on very slightly, so as to allow only a very small stream of water to flow. If, on the other hand, the water is required to be only moderately warm, the tap may be turned full on.

The size of a geyser to fill a cast-iron bath with hot water at, say, 98° F. in a quarter of an hour or so would be one delivering 2 gallons a min. for a 5 ft. bath, 3 gallons a min. for a 5 ft. 6 in. bath, and for a larger bath a 4 gallons a min. geyser would be necessary. Roughly speaking, again, it may be assumed that a 2 gallons a min. geyser will boil water at the rate of about 2 quarts a min., a 3 gallons a min. geyser at 3 quarts a min., a 10 gallons a min. geyser at 10 quarts a min., and so on.

**Fitting a Geyser.** The geyser, being an instantaneous water heater, has a high gas consumption during the short time it is on. Its fixing should be carried out only by gas undertakings or responsible firms of hot water engineers, as it is essential that the work should be properly done, that the necessary flue should be provided with an efficient baffle, and that the gas and water supplies and the meter should be adequate in size.

In new houses where a bath geyser is to be installed, a properly built independent brick or cast concrete chimney, terminating above the ridge of the roof, should be provided wherever possible. The flue from the baffle should be let into the chimney, and the end suitably protected from falling mortar. Where, as is generally the case, no chimney is available, the flue leaving the baffle may be dealt with in one of the following ways: (a) it may be carried through the wall or roof to end in a suitable terminal; (b) if a well-ventilated roof space is available, the flue may be led up to terminate in this, adequate precaution against fire being taken by cutting away laths for the passage of the flue pipe and asbestos packing, and by the protection of

exposed woodwork with sheet iron or asbestos compound.

The terminal illustrated in Fig. 3 is an excellent one for use on the flues of geysers where the flue pipe has to be taken through a wall. Its purpose is to induce an updraught in the presence of a wind which would otherwise cause downblow; to present a neater appearance than the older type of terminal, and to prevent birds entering and making a nest. The terminals are made in various sizes and are available in sheet metal or asbestos compound. The metal ones are used in connexion with window boards, and should be mounted flush with the outside wall. The asbestos ones are mounted flush against the wall, the shank being cemented into the wall itself.

*Fig. 3. Terminal for a geyser flue pipe which is taken through a wall.*

**Ventilation.** No gas-heated bath geyser should be fitted in a room without a window, and the window should be capable of being opened—preferably at the top. Where gas-heated geysers are fitted in small bathrooms, it is important that special provision should be made for the ventilation of the room, apart from that provided by the flue equipment of the geyser. The special ventilation can best be provided by the fitting of a 9 in. by 9 in. airbrick in an outer wall of the bathroom. If an ordinary air-brick is fitted, a deflecting board should be fixed over the brick on the room side, to protect the person using the bath from draughts. The smaller the room in which the geyser is fixed, the greater the need for special means of ventilation.

**Safety Precautions.** A cause of accidents has been the production of explosions due to the application of a match to the gas jet after it has been fully turned on for some time. This is easily avoided by following the instructions issued by the makers; but one or two general points must be attended to. Never turn on a gas tap until you have a lighted match in your hand ready to apply to the issuing gas.

When selecting a geyser, insist upon having one with either an automatic valve or interlocking gas and water taps. If the geyser is of the type in which the burner withdraws from the heating chamber, never light the burner when it is inside the chamber. Always withdraw it first and apply a light to it outside. In most modern geysers of this type, the gas is not fully turned on until the burner is inserted beneath the geyser, so that only a small amount of gas is liberated when the burner is outside. If the geyser is of the type in which the flow of water automatically turns on the gas and cuts it off when it ceases, do not turn on the water without lighting the pilot jet. If the pilot jet is alight and in position, no explosion can possibly ensue when the gas

is automatically turned on. There is also a form of electric geyser for bathroom use, which yields hot water almost instantaneously, but has not achieved the popularity of gas geysers.

**GHERKIN.** Although it is, strictly speaking, the name of a dwarf-fruited variety of cucumber, *Cucumis sativus*, the term gherkin is generally applied to immature and discarded cucumbers of all kinds that are used for pickling and other purposes. The true gherkin can be grown in the open air from seedlings raised in pots in March on a hotbed, and transferred in June to well-manured ground.

**How to Cook.** Gherkins have various uses in cookery, and are excellent when pickled. They should be left to soak for 3 or 4 days in salt water, then dried and put into a clean jar. Pour into a saucepan enough vinegar to cover the gherkins, allowing to each quart of vinegar 1 oz. of allspice and ½ oz. of ginger. Let these boil for 10 min., then pour it over the gherkins, cover the jar with a plate, and leave it overnight at the side of the fire. In the morning drain off the vinegar, re-boil it, and pour it over the gherkins again. When cold cover the jar with a bladder. The pickle will be ready for use in about six weeks. *See* Cucumber.

**GIANT FENNEL.** The scientific name of these graceful plants, with umbrella-like effect of foliage, is *Ferula*. They are attractive in the spring in the wild garden, but are also remarkable in the summer and autumn, when the branching, flowering shoots reach a height of about 8 ft., and bear innumerable yellow blossoms. The giant fennels should be raised from seed, as they are not easily divided or moved with success. Of several species, *F. tingitana* and *F. communis* are those which respond most readily to the culture of the wild garden.

**GIBLET: How to Cook.** The giblets of a chicken, duck, goose, or other bird consist of the head, heart, liver, gizzard, neck, feet, and the joints of the wings. They are usually employed in the making of stock, soup, and pies, but may also be stewed. In stewing, wash and scald two sets of goose giblets, skinning the feet and removing the beak and the inside bag of the gizzard. Cut all into small pieces, and stew them until they are tender in enough water to cover them, seasoning them with salt, pepper, a minced shallot, and a little mace.

Then strain off the stock, and in a separate pan melt a lump of butter about the size of a hen's egg, stirring into it about 1 dessertspoonful of flour. When these are lightly browned, add the stock from the giblets and stir the whole until it boils. Put in the giblets, heat them up thoroughly and then serve.

**Giblet Pie.** The giblets of a goose or a pair of ducks, some short pastry, and one or two slices of slightly salted breast of pork are the ingredients required to make giblet pie. Clean and scald thoroughly the head,

gizzard, liver, legs, the ends of the wings, and the neck, and stew them gently in a little water for about 2 hours. Add 2 or 3 onions, black pepper, a lump of butter, and a little salt, parsley, sweet marjoram and thyme. When the giblets are tender take them from the fire to grow cold, then strain off the stock and remove any excess of fat. Line a pie-dish with short crust, moisten the latter with beaten egg, and place the pork at the bottom, putting the giblets on top. Pour in a little broth. Cover the pie with more pastry, and bake it in a moderate oven for about 1½ hours, pouring in a little more stock before serving. *See* Fowl; Soup.

**Giddiness.** *See* Dizziness.

**GILDING.** The process known as gilding consists in coating the surface of an object with an adhesive and applying to it a very thin film of gold leaf. When dry it appears as a solid gold surface. The usual method is to apply gold leaf or metallic powder, the best results being always obtained with gold leaf.

The tools required are the gilder's knife and cushion. The knife has a thin, narrow blade like a table-knife. The cushion is a board about 6 in. square, the upper surface padded with flannel and covered with wash-leather; three sides are shrouded with thin card to protect the gold leaf from the wind. The underside has a loop so that it can be held with the thumb and supported by the fingers of the left hand. The cushion is used to support the sheet of gold leaf and to facilitate the cutting operations.

The gold leaf is obtained in books containing about 25 leaves approximately 3 in. square, each sheet separated by a piece of thin tissue-paper. The knife is used to cut the gold leaf; it must be kept perfectly clean and free from the slightest trace of grease. The blade must never be touched with the fingers, but must be wiped from time to time with a piece of clean rag. A gilder's tip, a long camel-hair brush, is employed to transfer the gold leaf from the cushion to the work. Two or three camel and hog hair brushes will be useful for applying the size and manipulating the gold.

Gilder's gold size can be obtained ready for use, a small bottle covering a considerable amount of work. Suppose that the work is already cleaned and prepared. The gold size is brushed over the part to be gilded, and it is absolutely essential that it should be applied thinly and evenly: if there are little mounds of size on one part of the work, and scarcely covered portions on another, the result will be failure. The next step is to protect the work so that no dust can settle upon it.

The size should be fit to receive the gold after 12 hours, but no hard and fast rule can be laid down as to the right time to apply the gold leaf. If the size is wet, it will work through the gold leaf and result in a muddy appearance; if too dry, the gold will not adhere properly. It is best to make some trials on an odd piece of work and to learn by experience. When the size is judged to be in good condition a little of the gold leaf is

laid on with the gilder's tip, and pressed down lightly with a pad of cotton wool covered with soft linen. The surface of the gold is then brushed over with a soft hog-hair brush, and if the gold remains in position and appears bright and lustrous, all is well.

An actual piece of work can now be undertaken by taking a leaf of the gold and, with the aid of the knife, laying it upon the cushion. Do not touch the leaf with the hands, as any grease will spoil the contact. A strip of the requisite width is cut off with the knife, picked up with the tip and applied to the previously sized work, pressing it into place and brushing over the surface of the gold, the process being continued until the whole is completed. A sheet of clean white paper should be laid underneath to collect any gold powder that falls. After being left in a warm, dry place for a couple of days, the work is finished with ormolu size, a varnish of shellac and elemi, or gamboge, which can be bought ready for use.

**Regilding a Frame.** To prepare a gilt frame for regilding, after removing the picture the gilt work is washed in a weak solution of soda, in lukewarm water, rinsed with clean cold water, and thoroughly dried. Any cracks should be made good with a putty composed of whiting, yellow chrome, and size. When this is dry, paint the frame with a mixture of whiting and a red or yellow pigment to make a rich yellow-gold colour. Mix this with size to the consistency of thin paint, then strain it through a piece of muslin, and while it is still warm brush it on to the frame. After it is dry give it a coat of size, and the gilding may then be proceeded with.

Most frames are gilded in several different ways, and comprise a burnished portion, a matt portion, and modelled parts that have to be done with gold size. The burnishing is done with burnishers generally made of agate or bone. The frame is brushed over with gilder's burnishing size the consistency of thick paint, spread evenly, allowed to dry, and rubbed down with old sandpaper until it is perfectly smooth. It is then dusted and another coat applied. This is allowed to dry and rubbed down as before, after which the work is brushed to remove all dust.

The gold leaf is applied by wetting a part of the frame with water size, laying the gold upon it and blowing gently upon it to force it into contact with the work. If any cracks appear, or there are any portions deficient in gold, damp the parts and apply another piece of leaf. After this it is burnished by rubbing it with a burnisher until a brilliant polish is imparted. Matt gilding is accomplished in the same way, or by the use of gold size, but is finished off by sizing the surface with a mixture of gamboge and size. An alternate method of finish is to paint the whole of the frame with scalding hot isinglass water, coloured with a little saffron or other similar colour. *See Mirror.*

**GILIA.** Most of the gilies are hardy annuals which bloom in summer from seeds sown out of doors in April; they may be raised under glass in March and planted out in May. They grow 12 to 18 inches high.

The best are capitata, lavender; nivalis, white; tricolor, lavender and white; and tricolor rosea, rose colour. The finest of all is *Gilia coronopifolia*, which is often grown as a biennial and raised from seeds under glass in June to provide flowering plants the next year; it will, however, bloom in summer from seeds sown under glass in warmth in February. The brilliant rose-scarlet flowers are on stems 2 to 3 ft. high. Pron. Jil'i-a.

*Gilia. Delicate blooms and leaves of a dainty hardy annual.*

**Gill.** Measure of capacity. It is the fourth part of a pint.

**GILLYFLOWER.** This is the old English name for carnation. It is sometimes applied to wallflowers and stocks. *See Carnation; Wallflower.*

**GIMLET.** This is a woodworker's tool used for boring small holes, generally prior to inserting a screw. It comprises a handle, and a steel rod pointed at one end, with a tapering screw thread of variable pitch. It is used by pressing it upon the work and rotating the handle in the manner illustrated.

*Gimlet. How this woodworker's tool should be held when in use.*

The rotation of the gimlet causes it to screw its way into the wood, and should cut the wood after it has entered a short distance. It should be kept clean and bright, with the edges of the cutting thread quite sharp, as a blunt gimlet, choked up with chips, will split the wood. A bell-hanger's gimlet is made with a long shaft, sometimes 3 ft. in length. The extremity is formed like an ordinary gimlet, but the blade is larger in diameter than the remainder of the stock. It is employed for boring holes through thick joists, or at a considerable distance, and will be found useful in making holes through which to pass electric bell wires. *See Amateur Carpentry; Boring.*

**GIMP.** Flat ornamental edging used as a finish in upholstery is the commonest form of gimp, and usually it is of a looped formation. Gimps are quickly and cheaply made by machine to match the colourings of chairs, settees, or cloth curtains, and can be had to order. Looped yarn for use in knitting shawls receives the name of gimp from the presence of little loops or curls upon its surface. In lace the gimp thread is a braid or cord used to thicken or outline the pattern. Fancy braids for trimming are sometimes known as gimps.

**GIN.** Gin is made from maize and barley flavoured

with juniper berries. There are several varieties. Old Tom has a small percentage of sugar; dry or unsweetened gin has none. Plymouth gin is said to be the purest: genièvre, well known in various European countries, is made from corn.

Gin does not improve much with age. It should be of white colour, unlike old Hollands, which is of straw colour. Gin and bitters is a favourite appetiser, and gin forms the basis of many cocktails, such as gin fizz, gin julep, gin sling, gin smash, and many others. Sloe gin can be made at home with the juice of sloe berries. *See* Cocktail; Sloe Gin.

**GINGER.** Ginger is much used in cookery as a powder, when it is known as ground ginger, as preserved ginger in syrup, or as whole ginger. The last-named is also termed root or stem ginger, and the pieces are a pale buff colour, tough and fibrous. Whole ginger is usually bruised, i.e. well beaten with a rolling pin or similar article, so that the flavour is more easily extracted.

Ground or whole, it is best to buy ginger in small quantities, as it soon loses its pungency. Preserved ginger is sold in jars of varying sizes. Its main use is in the form of dessert, but, like ground ginger, it is also employed in the making of cakes, puddings, etc. The syrup in which it is preserved is used for flavouring purposes.

**Medicinal Uses.** The most important constituent of ginger is an aromatic volatile oil which gives it its well known flavour. Ginger is chiefly used in medicine, dose 5 to 15 grains for its stomachic and carminative effects. It is also a common flavouring agent. Ordinary preparations are the syrup of ginger, dose  $\frac{1}{2}$  to 1 dram, and the tincture of ginger,  $\frac{1}{2}$  to 1 dram. Tincture of ginger is an old-fashioned and sometimes efficacious remedy for flatulence. *See* Flatulence; Indigestion.

**GINGER ALE.** Except that extract of ginger is used in place of the root, ginger ale is made on similar lines to ginger beer, but with the addition of bitter flavours. These include one or more of the following: tincture of capsicum (cayenne pepper), gentian, cardamom seeds, tincture of cinnamon, camomile, oil of rose, or geranium, etc. Sufficient caramel is added to give a golden colour. These materials are added after cooling and before fermentation.

**GINGER BEER.** This beer can be made from ginger root and pure cane sugar alone, but the addition of one or two other ingredients is an improvement. The simplest method for brewing it at home is the following: assuming the copper holds 5 gallons, a wooden tub of the same capacity is required. Get the copper quite clean and free from grease, but do not scour it bright. Fill it with water and bring the water to the boil.

While this is heating weigh 8 oz. of ginger root and crush it by putting it in a linen bag and pounding it with a hammer on a stone. Directly the water boils add the crushed ginger root and draw away from the fire so

as to stop boiling. Let it stand for three hours, covered to keep the heat in, and stir occasionally.

Put 5 lb. white granulated sugar in the tub, then strain through muslin the hot ginger root liquid from the copper on to this sugar, and stir it till dissolved; cover the tub, and when the liquid is quite cold bottle it. In about three weeks the ginger beer should be brisk with gas and ready to drink. If it is wanted sooner, 3 oz. fresh brewer's yeast may be stirred into the tub directly the ginger beer is cold, and bottling done 24 hours later. The beverage will be ready to drink in a couple of days.

**GINGER BISCUIT.** Ginger biscuits are made by sieving together  $\frac{1}{2}$  lb. flour,  $\frac{1}{2}$  teaspoonful ground ginger and  $\frac{1}{4}$  teaspoonful bicarbonate of soda and the same of salt. Rub into these  $2\frac{1}{2}$  oz. butter and mix to a stiff paste with golden syrup. Knead the paste together, roll it out on a floured board to the thickness of  $\frac{1}{4}$  in. Cut it into round biscuits and bake in a moderate oven for 15 minutes. *See* Biscuit.

Gingerbread. *See* Cake.

**GINGER CANDY.** To make ginger candy, put into a pan over the fire 12 oz. sugar and  $\frac{1}{4}$  pint of cold water, and when the former is dissolved add 2 oz. glucose and a lump of butter about the size of a walnut. Boil these to  $240^{\circ}$ , then add a small  $\frac{1}{2}$  teacupful of preserved ginger in syrup, about 6 drops of gingerine or any ginger flavouring, and a dessertspoonful of ginger syrup. Stir the whole gently and continue boiling and stirring until it has reached  $248^{\circ}$ .

Pour the mixture into a basin previously rinsed in cold water and leave it for 5 min., then stir it with a wooden spoon until it is thick and creamy. Cover it with wax paper and a thick towel, let it stand for about 20 min., then knead it thoroughly with a spatula and the hands, finally patting it out between candy bars set on wax paper. When set it may be cut into cubes or any other shape desired.

*Ginger Candy, a delicious and wholesome sweetmeat.*

**GINGERNUT.** To make these, take 1 lb. soft flour into which has been sifted  $\frac{1}{2}$  teaspoonful bicarbonate of soda and the same quantity of cream of tartar. To this flour is added  $1\frac{1}{2}$  oz. butter or other good fat,  $2\frac{1}{2}$  oz. castor sugar, 1 teaspoonful ground ginger, and  $\frac{1}{2}$  a teaspoonful powdered mixed spice. A stiff dough should be made with about 6 oz. warmed

golden syrup. Roll this out about  $\frac{1}{8}$  in. thick, and cut with small plain

cutter. The biscuits spread a little, so must be placed slightly apart on the sheet. This should be slightly greased, and then sprayed with a little water before the biscuits are placed on it. Bake them in a moderate oven for 12-14 min. They are soft when finished, but harden on cooling. *See Biscuit.*

**GINGER PUDDING.** A steamed ginger pudding can be made in the following way: Mix together  $\frac{1}{2}$  lb. flour, 2 teaspoonfuls ground ginger,  $\frac{1}{4}$  teaspoonful carbonate of soda,  $\frac{1}{2}$  lb. chopped suet, 2 oz. candied peel cut into small pieces,  $\frac{1}{2}$  lb. breadcrumbs, and  $\frac{1}{4}$  lb. Demerara sugar. Warm 2 tablespoonfuls golden syrup and pour it into the centre of the dry ingredients, mixing the whole together with a little milk and water to a wet consistency.

Beat the mixture well before turning it into a greased basin covered with greased paper, not a pudding cloth; then stand it in a saucepan half-full of boiling water and steam it for  $2\frac{1}{2}$ -3 hours. Serve the pudding on a hot dish, with hot custard, if liked. This is sufficient for six persons.

**GINGER ROCK CAKE.** Small ginger rock cakes are made by sieving together  $\frac{3}{4}$  lb. flour, 1 teaspoonful ground ginger,  $\frac{1}{4}$  teaspoonful powdered cinnamon, and  $\frac{1}{2}$  level teaspoonful of bicarbonate of soda. Rub into these 7 oz. of margarine; then add 6 oz. white sugar, and a teaspoonful caraway seeds.

Mix these ingredients to a stiff paste with a beaten egg and, if necessary, a little milk. Grease a baking-sheet and drop the mixture on to it in small, rough heaps, leaving a space between each. Blanch 1 oz. almonds, stick one on the top of each heap, and then bake the cakes in a hot oven for 15 to 20 min.

**GINGER SAUCE.** A good ginger sauce can be made by heating  $\frac{1}{2}$  pint milk in a small pan over the fire and in the meantime mixing the yolks of 2 eggs and the white of one in a basin containing about  $\frac{3}{4}$  oz. sugar. When the milk is hot, pour it on to the contents of the basin, stirring all the time, and mix thoroughly. Return to the pan and stir it until it thickens without boiling. Just before it boils pour the sauce into a basin and add sufficient ground ginger to taste.

Ginger Snaps. *See Brandy Snap.*

**GINGER WINE.** Ginger wine is made by boiling together for  $\frac{1}{2}$  hour  $3\frac{1}{2}$  gallons of water, 12 lb. sugar,  $\frac{1}{4}$  lb. good bruised ginger, and the thinly peeled rinds of 6 large lemons. Put the whole when lukewarm into a clean, dry cask, with the juice of the lemons and  $\frac{1}{2}$  lb. sultana raisins. Then add 1 tablespoonful of thick yeast, and stir the wine daily for 10 days. When it has ceased to ferment, add 1 oz. isinglass and a pint of brandy;

bung the wine closely, and bottle in two months.

**GINGHAM.** Long a favourite for children's dresses, house and summer frocks, aprons and overalls, gingham is a cotton fabric made principally in check designs. The patterns range from simple block checks up to elaborate plaids in two or three colours. The cloth normally is finished pure, or with very little loading. The pattern is not printed, but woven from yarn usually dyed in fast colours. The general effect is bright and clean-looking.

The advantages of gingham led to its use in other spheres; for instance, as breakfast cloths, curtains for kitchen or cottage casement windows.

Coloured checks are sufficiently showy in themselves, but an original touch can be added by cross-stitching simple designs upon some of the white chequerings. To ornament every white square is to invite an overcrowded appearance, and it is advisable to select squares at intervals for treatment in one or two colours; or a plain border in white or to match the colour of the check may be embroidered with the design. For example, a daffodil yellow check gingham cloth could have a 6 in. white linen border with a cross-stitch design in the yellow. When washing gingham which has faded, add a little vinegar to the last rinsing water. This will help to revive the original colour. *See Embroidery.*

**GINSENG.** This is a plant of the genus *Aralia*, from the root of which a drug is extracted. That obtained from the wild plant is regarded as better than that obtained from the cultivated one, and the older the root the better the quality, so it is believed. The drug, which is slightly bitter and aromatic to the taste, was formerly believed to possess wonderful medicinal powers, but the existence of these is now doubted. It is, however, widely drunk in China as a specific for all manner of bodily ailments.

**GIRANDOLE.** This is a branched candlestick used for a cluster of lights. They are usually ornamented, the design being frequently made to imitate bunches of flowers. *See Candelabrum; Candlestick.*

**GIRDER.** A girder is a principal and horizontal beam of wood, or more generally of iron or steel, which rests upon supports at either end or at different positions throughout its length, to support a load. The load may be distributed along its entire length or at different points throughout its unsupported length.

As a general rule girders are formed in what is known as the I shape, that is, in the form of the letter I, with flanges at the top and bottom, these being slightly thicker in section than the web or upright piece which connects them. The modern girder usually is composed of special steel, and when rolled from one solid bar is known as a rolled steel joist. In engineering practice a girder means a compound structure forming a beam to receive a vertical load. It is made up of several pieces,

which are riveted together at the joints.

**GIRDLE** or Griddle. This cooking utensil consists of a circular piece of iron, about 12 in. in diameter, spanned by a strong metal handle. It is used in the making of girdle cakes, etc. The girdle is greased and heated over the fire, the dough being dropped on it when it is hot.

**Girdle Cake.** These light teacakes, also known as Scotch pancakes or drop scones, are made with batter and cooked on a girdle. To make them, beat together an egg and 4 tablespoonfuls of milk, add a pinch of salt and, if liked, a pinch of sugar. Sift in enough self-raising flour to make the whole into a batter stiff enough to drop, not run, from the spoon. More flour or more milk should be added until this consistency is attained.

*Girdle Cake. Dish of the teacakes also known as Scotch pancakes or drop scones.*

Beat the batter well, then grease the girdle and heat it over the fire. When it is hot, drop spoonfuls of batter on to it, so that they will form neat rounds about  $\frac{1}{2}$  in. thick. When brown on one side (and they will take a very short time to cook), turn them over. This will make about 18 small scones. If there is no girdle in the house a frying-pan can be used, but great care is then needed to see that the cakes do not burn. They can be eaten either hot or cold, and require plenty of butter.

**GLADIOLUS.** An indispensable garden flower, this is in full beauty in late July, August and September. Varieties of the early flowering type grown in pots under glass bloom in late spring and early summer.

In recent years new types and innumerable new varieties of gladioli have been raised, and among them are many beautiful flowers. There are two distinct types of late summer-flowering gladioli, the large flowered, and the primulinus or small flowered. The recent astonishing progress in popular favour of this flower dates from the introduction of the yellow *Gladiolus primulinus* from the vicinity of the Zambesi Falls early in the 20th century; its flowers are small and of hooded shape, and the growth is slender.

By crossbreeding between this species and varieties of the large-flowered gladioli a remarkable new race has been obtained which has slender, graceful growth and medium-sized flowers of remarkable and varied colouring—yellow, orange, salmon, primrose, apricot, rose, and other tints. Meanwhile the range of colour of the large-flowered gladioli has also been extended, and modern varieties have particularly fine spikes of bloom—one spike may bear seventeen or more flowers.

Both types are invaluable for garden display and for cutting. If the spikes are cut when the lowest flowers are out the others will open in water indoors. It would

serve no useful purpose to give the names of varieties, for they are innumerable, and many similar ones have different names. They are fully described in the growers' catalogues.

*Gladiolus. The primulinus type, which bears small flowers in many brilliant colours.*

The cultivation of the gladiolus is a simple matter. The corms or roots are planted in March or April, 2 in. deep and 6 to 8 in. apart, in well dug soil enriched with decayed manure; it is worth while adding leaf-mould and sand to clayey ground. Ashes from the garden bonfire are also beneficial. Gladioli look especially well in groups in the herbaceous border or in flower beds carpeted with dwarf white alyssum or other low growing plants. In October, when the leaves begin to turn yellow the plants are lifted, and placed under cover for a week or two; dead leaves and soil are then removed and the corms are stored in paper bags in a frostproof place for the winter ready for planting in spring. By setting corms at intervals of 10 days from early March until mid-April a succession of bloom is assured.

The corms of early-flowering gladioli are potted in autumn, kept in a cold frame for 6 or 8 weeks and then placed in the greenhouse. A temperature of 50 degrees is high enough. Favourite varieties are Colvillei, The Bride, white; Blushing Bride, blush; and Salmon Queen, salmon.

Gladioli are propagated by seeds sown in a 10 in. deep box of soil placed under glass in March or out of doors in April; the seedlings should not be disturbed until the leaves have died down in autumn. If planted on a reserve bed the following spring some of them will bloom in summer, others may not do so until the next year.

**GLADWYN.** This is the name given to one of the iris family of flowers, *Iris foetidissima*. It is a native iris, with greenish flowers, about 2 ft. in height, and is remarkable for the bright red seeds which make their appearance after the flowering period is over. It likes a moist soil. *See Iris.*

**GLAND.** Literally meaning acorn, this name is given to a collection of specialized cells which manufacture certain substances needed by the body. Some discharge their fluid through a duct, and others, the ductless glands or endocrines, pass it directly into the blood. Glands are of many different kinds and are of great importance in the maintenance of the health of the body. (Continued in page 968)

**GLADIOLI: CHOICE VARIETIES OF THIS FLOWERING BULB**  
*General instructions for Gladioli culture are given at heading Gladiolus.*

**GHERKIN CROÛTES.** Gherkin Croûtes are made by frying in butter 6 rounds of bread about the size of a florin until a golden brown. Chop white of 1 hard boiled egg. Rub yolk smoothly into 2 teaspoonfuls butter. Season. Spread layer on each croûte. Cut 4 pickled gherkins into strips and arrange in lattice pattern on top, trimming off projecting ends with scissors. Arrange chopped white of egg in narrow border round edge of each croûte

*Ginger Soufflé*

**GERMAN BISCUITS.** For German Biscuits sieve 4 oz. flour, rubbing in 2 oz. butter and adding 1 oz. castor sugar. Knead to smooth paste, form into ball and roll out to about  $\frac{1}{4}$  in. in thickness. Stamp out rounds; bake in slow oven until they are pale biscuit. When cold, spread layer of red currant jelly on one side of half the number of biscuits, cover with remainder, and pour white icing over each. Finish with half a glacé cherry

*Gherkin Croûtes* *German Biscuits*

*Game Cutlets*

*Game Kromesies*

*Gooseberry & Cherry Custard*

*Game Scallops*

*Game Salad* *Gooseberry Huff Cap*

**GAME SALAD.** Any cooked game can be used for Game Salad. Remove bones from meat, season, and cut into dice. Cut round slice from top of a custard marrow and scoop out inside. Prepare 2 lettuces and 1 endive, using only white part of latter, and pull into small pieces. Peel half a small cucumber and cut into strips like matches. Peel a tomato and cut into slices. Mix about  $\frac{2}{3}$  of the salad with a little mayonnaise, put a layer in the marrow, then pile up the game. Cover with remainder of salad. Serve some mayonnaise sauce separately

*Gurnet Baked*

**GOOSEBERRY HUFF CAP.** For Gooseberry Huff Cap, trim 1 qt. green gooseberries. Put in jar with 2 oz. lump sugar and cook till soft. Boil 6 oz. lump sugar with 1 gill water until thick, then rub gooseberries through sieve, add the syrup to the pulp with whites of 3 eggs stiffly whipped. Whisk all together until frothy. Cut off top of Madeira or sponge cake; hollow out inside until only a case remains. Soak case slightly with wine or custard. Heap fruit into the case and decorate the whole with 1 oz. sweet blanched almonds cut into long shreds

## 'G' RECIPES: A SELECTION SHOWN IN ACTUAL COLOUR

**Ginger Soufflé.** Beat up yolks of 2 eggs and mix with  $1\frac{1}{2}$  gills milk. Pour into jug placed in saucepan of water over fire., stir until thick, then leave to cool. Whisk  $1\frac{1}{2}$  gills cream until thick, add half to cold custard, mix lightly and add 3 oz. preserved ginger (diced) and 2 dessertspoonfuls castor sugar. Whisk 2 egg whites to stiff froth and fold in. Strain in  $\frac{1}{2}$  oz. French leaf gelatine previously dissolved in  $\frac{1}{2}$  gill ginger syrup. Stir all over ice until thick, then pour into soufflé case. When set decorate top with remainder of whipped cream, small lump of ginger and piece of angelica. **Gooseberry and Cherry Custard.** Dissolve  $\frac{1}{2}$  pt. packet cherry jelly in hot water and leave to set. Boil 3 oz. Demerara sugar in 1 gill water for 5 min. Add  $\frac{1}{2}$  lb. stalked cherries. Simmer for 10 min., and add  $1\frac{1}{2}$  pt. trimmed gooseberries. Simmer until fruit is tender. Put in glass dish, and cover with  $1\frac{1}{2}$  pt. cool custard. When cold, chop the jelly and arrange on custard. **Game Scallops** are made with cold game chopped, flavoured, mixed with browned breadcrumbs and enough thick brown gravy to moisten well, baked in scallops in quick oven.

Lymphatic glands are widely distributed over the body. They consist of masses of lymphoid tissue in connexion with the lymph vessels which collect used-up fluid from the tissues and carry it back to the blood. They act as filters, stopping in some degree various poisonous matters on their way to the blood.

Inflammation and enlargement of lymphatic glands (lymphadenitis) is a common consequence of any irritating matter which reaches them through the lymph vessels. A wound in the hand may thus cause swelling of the glands in the armpit, or a wound in the foot or leg of those in the groin.

One form is inflammation of the lymph glands of the neck, due to their invasion by the tubercle bacillus, and commonly known as "glands in the neck." A child with a constant cold in the head is liable to develop tuberculous glands of the neck. Eczema of the scalp, suppuration in the ear, decayed teeth, may all set up irritation of these glands and favour their infection by the tubercle bacillus. Treatment should be directed to the cause. *See* Glandular Fever; Mumps; Tuberculosis.

**GLANDERS.** Also known as farcy, this infectious disease of the horse, ass, and mule is communicable to other animals, including man. It is due to a germ known as the bacillus Mallei. When the nasal cavity is affected the condition is known as glanders, but when the lymphatics are involved, and there are nodules under the skin, it becomes farcy, the nodules consisting of the farcy buds.

Coachmen, stablemen, and others who have to do with horses are the persons most likely to contract the disease, and the danger is increased if they have cuts or abrasions about the hands. Anyone suffering from the disease can convey it to another.

The site of infection becomes red and inflamed, and the inflammation spreads along the lymphatics to the nearest lymphatic glands, which become swollen and painful. There is fever and the patient feels ill. He may pass rapidly into the typhoid state, and his condition will look like the form of blood poisoning known as pyaemia. Commonly there is a purulent discharge from the nose.

**GLANDULAR FEVER.** Children are affected chiefly by this infectious disease, which sometimes appears as an epidemic, attacking all or most of those in the house or in a school.

The neck becomes painful, the glands of the neck enlarge, and some of them may become as large as an egg. Occasionally the glands in the armpits and in the groin enlarge. The temperature may rise to 103° or 104°. Early in the second week the fever disappears; and there may be diarrhoea. The swollen glands then slowly return to their normal size, but may remain enlarged for weeks or months. The usual treatment for this disease is to apply hot fomentations to the glands two or three times daily.

## GLASS AND GLAZING

### Choice, Cutting and Uses of Glass in House and Garden

This article deals with glass as used for windows and general constructional work. It is followed by one on Glass Ware, while other entries related to the subject are Leaded Light; Mirror; Picture Framing; Window.

See also Conservatory; Frame; Putty etc.

At a casual glance all sheet glass may appear to be of substantially two forms, plain or transparent, and obscure or rippled, but there are in fact many kinds of sheet glass, with various properties rendering them suitable for specific purposes. Ordinary sheet glass is made in three varieties, known as crown, sheet, and plate glass.

Crown glass is made by blowing the glass in such a way that it ultimately forms a sheet with a boss, or bull's eye, in the centre. This method is not often practised nowadays, but the bull's eyes are valued for their decorative use in windows, doors of cabinets, and other positions. Ordinary sheet glass, such as that used for windows, is made in tubular form, cut, flattened, and afterwards annealed. The usual size is up to 12 to 16 sq. ft. in area, while the weight varies according to thickness from 15 to 42 oz. per superficial foot.

By the area of the glass is meant the number of square feet it contains, and by the weight in oz. is meant the approximate weight of a piece of glass exactly 1 ft. sq., that is, 21 oz. glass means that 1 sq. ft. of it would weigh 21 oz. Thickness and weight vary with different manufacturers, as does the grade or quality. Approximately, 15 oz. glass is a little over 1/16 in. thick, and 21 oz. glass about 1/10 in., while 42 oz. glass is about 1/5 in.

### Sheet and Plate Glass

The objection to sheet glass is that it always imparts a wavy, or broken appearance to the objects seen through it. For ordinary window purposes this may not be an objection, especially if a first-grade sheet glass be used, but for good class work, or in windows where the view should be unimpaired, polished plate glass should be used. Sheet glass can be purchased at so much per sq. ft. from picture-frame makers, or from builders' merchants, or ironmongers. This method is suitable when only a small quantity is required, as the sheets are cut to the size specified.

If a quantity of glass is required, a case or box may be purchased, which usually contains 200 or 300 ft. of glass, that is, a sufficient number of pieces of glass to cover an area of 200 or 300 sq. ft. as the case may be. The sizes of the pieces and their thickness might either be uniform, as, for example, so many pieces of a certain size and all, say, 21 oz.; or it is sometimes possible to buy a mixed case, containing two or three different sizes, or varying in thickness. Many stock sizes are available, and particulars can generally be obtained from the local builders' merchant.

This method of purchasing glass is particularly economical for such constructions as greenhouses and garden frames, where quantities of glass of uniform width can be used, and if the nearest stock-sized glass

be ascertained before fixing the bars in new work, it will be found to save considerable expense for glass-cutting. As regards thickness, sheet glass of 15 oz. should only be used for small frames or for little panes in windows; 21 oz. glass is generally recognized as the thinnest that should be used, and if the window is of any size, such as a sliding sash, a heavier glass is preferable.

Plate glass is made by casting, grinding, smoothing and polishing. Hence it is uniform in texture and thickness, and the objects seen through it are not distorted in any way. It is made in various thicknesses from 3/16 in. upwards, and up to 100 sq. ft. or more in area. It is purchased according to fractional sizes, that is 3/16, 1/4, 3/8 in. etc., in thickness. Plate glass is used extensively as a covering for the tops of dressing-tables and other places where a clean surface is needed. The edges should be ground and polished, and, if necessary, holes drilled near the corners for fixing the glass in place.

Plate glass can be bent by the makers to various shapes such as are required for the curved ends of a cabinet or other furniture, or for a window, but as a rule the amateur should avoid bent glass as it is very difficult to bring it to the exact curvature desired. For small areas, up to about 2 or 3 sq. ft., 3/16 in. plate glass is satisfactory, but polished plate glass is generally about 1/4 in. in thickness.

**Fancy Glass.** Of the fancy or patterned glasses, those known as the rolled plate are perhaps the most useful to the amateur, and are made in different patterns, some quite ornate and others softly waved and subdued in texture. They are used in partitions or places where light is needed but vision is to be obstructed. Prismatic glass diffuses light and gives better internal illumination; it is used for lighting basements and other dark parts of buildings. Coloured glass is generally in the form of ordinary sheet glass.

Of the special glasses, those made with wire netting embedded in the centre and known as wired and cast, rolled, or polished glass, according to their method of manufacture, are about 1/4 in. thick, and are used for roofs, windows and doors. They cannot be cut with a diamond in the ordinary way, and therefore are partly burglar-proof. They are also to a large extent fire-resisting.

Another kind of glass is made up of several layers cemented together. It is used for all purposes where glass is liable to fracture, e.g. a motor car wind screen. The material will resist heavy blows without splintering.

A proprietary glass which passes the health giving ultra violet rays is coming into common use for windows in houses, offices, and factories. Its use entails only a comparatively small outlay to the houseowner.

When purchasing sheet glass to fit into a specific size frame, it is customary to make an allowance for the roughness of the edge of the glass, the amount of this allowance being determined by the width of the rebate in the frame. For example, if the frame is 24 in. wide and has a rebate in it, say 1/2 in. wide, thus leaving a

sight opening of 23 in., the glass should be ordered as 23 5/8 in. in width. It is advisable to inform the dealer of the purpose for which the glass is required.

**Cutting Glass.** The cutting of glass is carried out with a diamond pointed tool, or with a hard steel glass cutter. The former is expensive to buy, and requires considerable skill to manipulate in an effective manner. The steel cutters comprise a wooden handle with a steel end-piece or block fitted with a small circular plate carrying two or three small steel wheels, one of which projects beyond the end of the head and does the cutting. When it gets blunt the screw holding the circular plate is loosened and a fresh wheel brought into position by partially revolving the circular plate and again screwing it up tight.

*Glass Cutting. Fig. 1. How to hold the diamond.*

*Fig. 2. Bench arrangement of battens and nails for guiding the cutter and making square cuts.*

*Fig. 3. Breaking away the glass with pliers.*

*Fig. 4. How to cut a hollow, curved piece of glass. Note criss-cross cuts and use of diamond to tap out the pieces.*

To use either of these cutters they should be held in the right hand in the manner shown in Fig. 1, with the handle between the first and second fingers and the thumb behind them. The diamond is set at a certain angle in the end of a steel block, pivoted on the handle and free to move through about 45°; this is to facilitate the cutting of intricate shapes and to allow a certain amount of latitude when cutting long straight lines. The particular angle at which the diamond must be held varies with each individual stone, and must be learned by experience, the best cutting angle being judged by the sound. When cutting properly the sound should have a ripping quality; when the diamond is wrongly held it is more like a scratch. The tool is usually held in a nearly upright position.

For ordinary use in the home the wheel cutter answers all requirements and will stand more rough treatment than a diamond. As an example, if a new pane is wanted for a window, and it is to be cut from a piece of odd glass, lay this on a firm flat table-top on which has been placed a piece of thick cloth, and place

a steel or wood straight-edge on one side of the glass. Bringing sufficient pressure to bear on the cutter, draw it once across the glass, guiding it by the straight-edge. If the glass is thin it will sever easily if turned upside down with the line of the cut resting on the edge of the table, or upon a clean straight batten, and the surplus glass pressed down. The end can now be cut, guiding the cutter with a set square, or preferably a glazier's tee square: the opposite end and remaining side are then cut. When placing the straight-edge as a guide for the cutter, be careful to allow for the thickness of the cutter block, otherwise the glass will not be the proper size.

The cutting of glass to fancy shapes, such as those needed in leaded light work, is rather more difficult. One method is by preparing a full-size drawing of each piece of glass, then drawing a parallel line on each side of the outline. The distance between the outer lines represents the thickness of the heart of the lead, and consequently the true shape for each piece of glass; it is to these lines that the glass is cut. Another method is to cut a set of thin cardboard patterns to the exact shapes of the glass, and to employ them as templates.

A simple device for cutting diamond or other panes is illustrated in Fig. 2, and comprises a lath of thin wood nailed to the bench. Two nails are partly driven into the bench at right angles, or at any required angle; the edge of the piece of glass is rested against these. Two other nails are also driven into the bench and a straight-edge laid against them, this acting as a guide for the cutter. The method is effective when several pieces of the same size are wanted, as it avoids the need for repeated measurements. Circles are generally cut with a special tool known as a circular glass cutter. It has a central pivot, adjustable arm, and a wheel or diamond.

When cutting curves the outside curve will come away easily, but a notch, or interior curve, will have to be cut across and across, and the parts removed one by one somewhat as shown in Fig. 4. To separate the glass when cut to curved forms, tapping is necessary. This consists in striking the back of the plate of glass with the block of the cutter, carefully following the line of the cut. Steady tapping is important, and if the glass has been properly cut the fracture will run along it at each tap. Any ragged edges can be trued up by grozing, a process consisting chiefly in biting off the ragged edges by means of a pair of pliers, using the jaws to squeeze or bite the edge of the glass as shown in Fig. 3.

Finally, the worker in glass should remember a few simple rules. The glass should be supported on a really flat surface such as a drawing-board. If much cutting is to be done the board should be ruled with two sets of lines, 1/4 in. apart at right angles, to divide it into a number of squares. This will save marking when the glass has to be cut on the square. When cutting properly the diamond makes a soft sound and leaves an almost invisible scratch, while a large rough scratch shows a bad cut. A cut should be started and finished at the very edges. Extra thick glass should be tapped on the side away from the cut.

**Glazing Windows.** In the case of a broken pane in a window the first thing to do is to remove the broken glass by gentle tapping and lifting out the fragments. If

the glass has been fitted by a wooden bead, it must be unscrewed or prized out of its place with a chisel. Most windows, however, are secured by putty. This is best removed with a hacking knife, as shown in Fig. 5. The work must be done thoroughly: if any lumps of old hard putty are left in the frame, they will strain the glass and ultimately make it crack.

If the frame is shrunk and the putty exhibits small cracks, it should be removed by inserting the end of the blade into the cracks and levering the putty out. In exceptional cases it will have to be chipped, by tapping the back of the blade with a small hammer. As this work proceeds, remove the fragments of glass, taking care that those on the top part of the window do not fall out instead, and cut the hands. If working on a first-floor window care must be taken that fragments of glass do not fall on anyone beneath.

When all the old putty has been removed, the rebate must be measured. This should be done at the top and bottom and at both sides, in case the window-frame is not perfectly rectangular. A piece of glass may now be cut, slightly less than these sizes; in most cases about 1/8 in. less will be correct. The putty must be worked up, softening it by rolling it between the palms of the hands until it is quite plastic. If it shows a tendency to crumble, moisten it with a few drops of linseed oil, and again roll it between the hands.

*Glass . How to glaze a window. Fig. 5. Hacking out old putty with the hack knife. Fig. 6. Applying a uniform layer of new putty all round the frame. Fig. 7. Method of inserting glass pane, with one hand each side.*

Place some of the putty into the corners of the rebate, and apply it with the finger and thumb to a uniform thickness all the way around the frame, as shown in Fig. 6. The glass is then placed on to the bottom part of the frame (Fig. 7), pressed in closely, and pushed into place, pressing it all round the edges into close contact with the putty. It may be further secured with the aid of a few brads driven into the framework with the heads just touching the glass. A pellet of putty is then pressed into the corners between the glass and the frame, and consolidated by forcing it hard up against the two with the aid of a putty-knife.

The remainder of the rebate is then filled, and to get a neat finish the knife is used with long sweeping strokes, if possible from end to end of the window, held at an angle to the glass, and with the blade flat on the edge of the frame, to act as a guide for the knife. This

should remove any surplus putty. The inside of the frame should be inspected, and all surplus putty should be removed with the putty-knife or glazing knife. This latter is somewhat thicker in the blade, but otherwise similar in shape to a putty-knife. Any surplus putty adhering to the glass or the frame must be scraped off, the whole dusted over and the glass left clean.

In fitting glass to new woodwork, the latter must be painted prior to applying the putty, or the putty will be liable to flake and fall out soon after it has set hard. In the case of a repair, the putty should be painted to match the existing woodwork as soon as it is dry, say 24 hours or so after its application. Where the glass has to be fitted to a frame and secured by a bead, the same proceeding is followed except that the putty is often omitted. The edge of the glass should be painted a dull black before inserting it into the frame.

Metal framed windows are glazed and treated in the same way as those with wooden frames.

**GLASS PAPER:** How to Use. Sheets of paper covered with glue and coated with powdered glass, sand or other abrasive are known as glass paper, or sand paper. They are made in many grades, the finest ranging from No. 0 to F2, medium No. M2 to S2, and the coarsest No. 2 1/2 to No. 3. Glass paper is used to work up a smooth surface on woodwork, and to assist in the shaping of curved surfaces; as for example when making a handrail, the top is rounded off by the plane, and the flats or ridges rubbed down with glass paper. Painted surfaces are prepared with glass paper prior to the application of fresh paint, as well as between each coat of paint. Glass paper is employed for some of the finishing processes in leather work and also on fibre, or any other material of a similar nature.

*Glass Paper.  
How to use a  
rubber of  
glass paper.*

In using glass paper, a piece of suitable size should be cut neatly to shape and folded round a block of cork, wood or other suitable material. The ordinary block is a flat piece of cork about 1 in. thick, 5 in. long, and 3 in. wide. The proper method of use on a flat surface is shown in the illustration, the movement of the hand being in a series of circles combined with a forward motion, the result being that it traverses the whole surface.

For finer work the rubbing is in a straight line with the grain of the wood, as, although the action of rubbing across the grain tends to produce a true surface, the scratch marks are more pronounced. For curved work the rubber may be hollow or otherwise shaped to assist in producing the desired shape as quickly as possible. When glass paper has to be used on small holes, it should be wrapped round a circular piece

of wood, a lead pencil, or the blade of a gouge.

The best grade of paper to use on any particular job will depend upon the style of finish and the nature of the material; but in general a rough grade such as No. 1 1/2 or 2 will be used to commence with, following this with a medium grade like No. M2, and finishing with the finest. It should be noted that a worn piece of paper is better to use than a new piece, as it does not scratch so deeply and produces a better result, being more mellow and pliable and not so harsh in action. Worn paper is always to be preferred for rubbing down coats of paint or varnish.

### **GLASS WARE: FOR USE AND ORNAMENT** **Beautiful Antique and Modern Household Pieces**

This article first deals with collecting glass as a hobby, then with modern household sets and pieces, followed by a section on the care and repair of glass, and finally with detailed instructions for painting on glass. The entries on separate articles such as Decanter; Finger Bowl; Vase; Wineglass, should be consulted, and also those on Flowers; Table Laying.

The glasses used in the 17th century were light and thin, never quite pure white nor of brilliant lustre. They were mainly either of Venetian make adapted to English patterns or were made in England by Venetian workers or under Venetian influences. Towards the end of the century the English makers discovered or introduced a stronger kind of glass.

In the early part of the 18th century, glasses with narrow funnels and bowls with round bases were in use. These were succeeded by pieces with drawn trumpet shaped bowls and thinnish stems, and a little later appeared the glass with a plain bowl on a straight stem, which stem soon became quite a long one. These long-stemmed glasses, made sometimes with one small knob in the stem, appear to have been the commonest type for tavern use during the second half of the 18th century, although those with wide funnels were employed side by side with them. A knob is a rounded protuberance.

There were other kinds of glass that have value or interest for the collector. Prominent among such is glass made especially for the Jacobites after 1688 and during the 18th century, used for drinking at their gatherings. Examples of these are shown in Fig. 1. Most of these glasses are engraved, the engraving taking the form of reference to the Stuart family; for instance, the word *Fiat*, and various emblems such as the star, the rose with two buds, the oak leaf, and the thistle, associated with the royal exiles.

Of kindred origin are the glasses made in honour of William III and the battle of the Boyne. These date mainly from the middle of the 18th century, but were reproduced after that time. The earliest of them are decorated with a portrait of the king, either as a bust or as a full figure on horseback. Other glasses are adorned with the words of a toast in honour of King

William, words of contempt for his enemies being added in some cases.

*Glass Ware. Fig. 1. Jacobite Glass. Those at either end are engraved with a rose and rosebuds, emblematic of the Stuart cause, with oak leaf at back and motto Fiat. Centre-right, also engraved with rose and rosebuds. Centre-left, engraved with picture of the Young Pretender encircled with a laurel wreath, while behind are roses, a thistle and a star. ( By permission of the Director. Victoria and Albert Museum, S. Kensington)*

In addition to these there are a number of special glasses that appeal to collectors, on account of their beauty or rarity, or both. Prominent among these are the ale glasses which were used for drinking ale or beer in the 17th century. One variety had very wide-mouthed funnels, ribbed or plain, with short stems and large conical feet with wilted edges. Others took the form of goblets on shortish stems; these were of ribbed or plain glass, with square bases to the bowls. Some of them, it is interesting to learn, were provided with lids, the reason being that in those days beer was often drunk when hot. The ordinary ale glass held rather less than half a pint, but some were larger.

Cider glasses, which came into use in the middle of the 18th century, are very rare, and therefore good specimens are valuable. The bowls of these are usually straight sided, almost rectangular in shape. Some of them are finely engraved, the design shown being usually apples, apple-trees, or cider barrels. Their size varied considerably. Mead glasses are equally rare. Here the bowl is generally incurved and it stands on a short, strong stem. They were usually made in coloured glass.

*Fig. 2. Hogarth Glass. Eighteenth century trumpet shape glass with buttonlike stem.*

Another special kind of glass was introduced about 1700 to hold punch. The earliest used for this purpose appear to have been narrow funnel glasses with a slight collar. Afterwards stemless glasses of the type immortalized by Hogarth and named after him were used for this drink (see Fig.

2). Later, tall glasses with extremely small bowls and thin stems came into use for punch, and these remained in favour until nearly the end of the 18th century.

The art of glass cutting, rarely practised before 1740, was brought from London to Stourbridge about 1743, where glass melting had been established a century earlier by French Huguenots. Here it quickly developed the distinctive artistry for which British glass is renowned. The peculiar quality of the metal (as glass-making material is called) was due to oxide of lead instead of lime. Lead used in the correct percentage imparts a much greater brilliance to the glass by improving the colour purity and increasing the light refraction. In old Irish glass the large percentage of lead oxide was responsible for the bluish tint and metallic lustre, which, though admired and sought after to-day, was reckoned by the makers to be a fault.

**Wine Glasses.** The five main periods in the history of English wine glasses are illustrated in Fig 3: baluster stems dating from 1680; the simpler knopped and plain stems from 1730; the transparent air twists in their many artistic and diverse variations starting about 1740 and extending to 1760-1770, the opaque white spiral stems from 1750-1760: and lastly the cut or faceted stems, early examples of which are occasionally met with, but which generally were not in vogue until 1780. These extended to 1800 and a little later, glasses made after this date ceasing to be of interest to the collector proper.

*Glass Ware. Fig. 3. Specimens of five main periods of English drinking glasses. Left to right: 1. Baluster stem. 2. Plain stem. 3. Air twist. 4. Enamel or opaque twist. 5. Faceted stem. (Courtesy of Cecil Davis)*

The five main types of bowls found in wine glasses are shown in Fig. 4. They are drawn trumpet; bell; straight sided; ogee; and double ogee. Changes in these shapes frequently occur, and Fig. 5 illustrates six examples of Georgian variations of the main types.

A good plan in collecting is to commence by getting typical examples of the various periods. When each main period is illustrated, progress can be made by representing each characteristic shape in the bowl of the glass. Endless forms of specialization will suggest themselves. If it is out of the question to excel in each section, much pleasure can be obtained by taking a certain type, such as double ogee glasses, and by paying special attention to the particular form, and embracing every opportunity of adding specimens that show some different feature, in time a section may be completed illustrating the evolution of the type from its earliest inception.

A collection of the many varieties of the opaque twist wine glasses is an interesting pursuit. Combinations of these stems are very numerous, many of which are of great beauty in their film-like threads. Duplicates should be avoided, and it is nearly always necessary to conduct a weeding-out operation as experience shows the weak points of some of the earlier purchases.

*Glass Ware. Fig. 4. Five main types of bowls. Left to right: 1. Drawn Trumpet. 2. Bell. 3. Straight-sided. 4. Ogee. 5. Double ogee. No. 1 also illustrates the domed foot and No. 5 the folded foot. (Courtesy of Cecil Davis)*

*Fig. 5. Six specimens from sets of Georgian wine glasses, showing examples of plain and faceted stems and varied types of bowls.*

*Glass Ware. Fig. 6. Examples of early Irish cut glass belonging to the best period.*

**Old Irish Glass.** About 1770 the Irish specimens of steel-blue metal so much sought after were made, and this represents the finest period in cut glass. Stately chandeliers and table candelabra made their appearance about this time, and these, with the salad or fruit bowls, constitute the rare specimens. Fig. 6 shows two fruit bowls, with pedestal bases, that on the right being of the elegant boat shape. The jug with its square foot is also of beautiful Irish cut glass. The square foot came into fashion about 1780.

It must be borne in mind that the Irish makers were endeavouring to get rid of the fine bluish metal that collectors of to-day eagerly seek, and to substitute white metal of greater brilliancy. This they succeeded in doing about 1815, when the glittering step-cut pieces were first made. This glass was almost metallic in its brilliance, and the object of this manner of cutting may

have been to simulate silverware on the table. After this date, English and Irish metal and designs are very similar, and it is impossible to assert definitely the nationality of such pieces. The tendency was to increase the detail of cutting. Thus the bolder diamond cutting gave place to strawberry diamonds and fine and close cutting, as shown in Fig. 7. In 1850 glass had to a great extent lost its simplicity of outline, and in the Great Exhibition held in London in 1851 the glass wares of Bohemia and the European Continent were closely copied in a style lacking in artistic insight.

*Fig. 7. Water and cream jugs, showing the later diamond cutting of about 1820.*

With regard to the early pieces, great care has to be exercised, for even in the early days continental copies of fine Irish glass were made, and they are still copied, and sent over to trap the unwary. The early factories copied each other, and, except for the rare examples that are impressed on the base with the name of the maker and factory, no one is able to assert positively the source of production.

**Old Coloured Glass.** Amongst other varieties of old glass, the self-coloured Bristol blue, amber, and purple glass commends itself to some, as well as the many shapes in small early cream jugs, bowls, etc. Freak pieces in the shape of boots, hats, bellows, weather glasses, miniature animals, puzzle glasses, etc., appeal to those who wish to collect curiosities. The splashed and striped Nailsea is of interest to those who like colour, and a cabinet of the quaint wine flasks makes a room gay even on a dull November day, for the blues, pinks, and purples are of the brightest. The two Nailsea factories near Bristol were famous for bottles, jugs and crown window glass. They are not recorded to have made flint glass at Nailsea.

*Fig. 8. Bristol opaque glass candlestick enamelled in colours.*

The beautiful opaque white Bristol glass of early period is made of such density that at first sight one imagines the piece to be of porcelain. An example of a candlestick is shown in Fig. 8. The finest specimens are decorated in the Chinese fashion with figures, flowers, etc., in brilliant enamels reminiscent of oriental art. Millefiori glass paperweights are a study in themselves. The rare ones are the dated examples. The dates invariably found are 1847, 1848, and 1849, and these

particular examples show quaint animal decorations. These were made at Bristol, and many artistic specimens in festooned patterns of great variety occur. Larger specimens showing less originality of design were made at Stourbridge, as were also ink-bottles.

**Cameo Glass.** Another variety of glass which is increasingly popular is the cameo glass, invented in England by Apsley Pellatt in 1819. Portraits and other decorations composed of china clay are encrusted in panels, on the sides and in the interiors of decanters, vases, plaques, etc., and these medallions present a brilliant surface, which is, moreover, impervious to the effects of age and wear. A selection of these pieces is shown in Fig. 9. Similar cameo pieces were made in contemporary times by the French and Bohemians, but the English specimens are the finer in quality, and with their silvery appearance at once attract attention; the larger and more important specimens of these are usually of English make.

*Glass Ware. Fig. 9. Examples of the Apsley Pellatt cameo-incrusted glass. Top row, left to right: 1. Cut-glass spirit decanter and stopper with white cameo portrait of Robert Burns. 2. Cut-glass tumbler with inset of French Legion of Honour in coloured enamels. 3. Plain glass scent bottle with portrait of George III. 4. Moulded glass tumbler with inset of cock in coloured enamels. Bottom row, left to right: 1. Cut-glass plaque with portrait inset. 2. Cut-glass paper-weight with white cameo inset of Madonna and Child. 3. Ruby glass tumbler with white armorial inset. 4. Cut-glass patch box with portrait inset. (Courtesy of Cecil Davis)*

French examples of the Legion of Honour and other Orders are to be found in enamelled colours encrusted in the glass in the same manner.

**Modern Glass.** For the household quite inexpensive modern glass can be ornamental as well as useful. This applies to carafes, tumblers, jugs and fruit dishes and also to oven ware, which is made in good shapes and

looks attractive on the luncheon or dinner table. With sunk handles in the lids, to save oven space, a variety of sizes and a guarantee of two years these glass casseroles and entrée dishes are becoming very popular.

Sets of table glass vary in size, but are usually made for six or twelve persons. The ordinary set will consist of tumblers, five kinds of wine glasses for sherry, claret, hock, champagne, and port, liqueur glasses, and finger bowls. In addition, decanters, two or four, may be included, and smaller ones for liqueurs. Some sets include custard glasses, a pickle jar, honey jar, salad bowl, celery glass, grapefruit glasses, water jug, and ice plates, while others may consist of fewer pieces, the types of wine glass being perhaps reduced to three. The liqueur glasses and decanters are often distinct from the other table glass.

Sets of six coloured tumblers with jug to match are obtainable for lemonade, and many charming designs are to be had in cocktail shakers and glasses. Venetian glass is also attractive for dessert use. Crystal flower vases and dishes always look beautiful on the table. Cut glass does not lend itself to idle ornament. It looks far better in use, and very good effects are obtained by substituting glass for silver or china dishes on a well-polished dining table or fine white cloth. Some beautiful cut glass pieces of a modern table service are shown in Fig. 10. Good cut glass gives forth a clear ringing sound when tapped.

*Glass Ware. Fig. 10. Some beautiful pieces of modern English hand-cut crystal table service. (Courtesy of Webb & Corbett)*

When buying coloured table glass in separate lots, but for use together, care should be taken that the pieces chosen are of the same tone. Opaque coloured glass is made in brilliant colours, but lacks some of the decorative quality of the clear metal. Black glass for candlesticks and dessert dishes looks effective on certain tables of modern type, while the Georgian styles of water and wine glasses in hand-cut crystal clear glass harmonize well when used with reproductions of Chelsea, Worcester and Spode china. Whole sets of glasses from large goblets to liqueurs are reproduced in the Georgian styles of the two examples

seen respectively on the extreme left and right of Fig. 5. Champagne glasses are frequently made in these shapes instead of in the former shallow style. Practical consideration is shown in making stems of strong design.

**Caring for Glass.** To clean glass it should be washed in warm, soapy water, rinsed in cold water, and left to drain before being dried and polished with a special cloth. For cleaning glass water bottles and flower vases, a tablespoonful each of vinegar and salt and some warm water may be used. The bottle or vase should be allowed to stand for some hours, shaken occasionally, and finally rinsed with cold water. Crushed egg-shells and a little shredded soap may also be used. Cut-glass which has become very dirty is best washed in warm, soapy water to which a few drops of ammonia have been added, and then scrubbed with a small brush. If washing blue is added to the water it gives to glass a brilliant sparkle. Linen is the best material to use for a glass cloth, though any smooth and absorbent cotton fabric will do for this purpose. A glass cloth is quite useless for polishing purposes once it gets damp.

To prevent breakage when pouring hot liquid into a glass jug or other vessel, put in a spoon or heat the glass beforehand.

When glass dishes, salad bowls, wine glasses, vases, etc., get broken, they should be mended without delay. If the pieces are left to lie about for some time, the edges become chipped and damaged, and it is very difficult to mend them satisfactorily. The broken surfaces should be carefully washed and dried, and the pieces placed in a cool oven or before the fire, so that they will be dry and hot before they are cemented.

In the case of a vase that is washed only occasionally, or wine glasses or salad bowls that can be washed in cold water, any china cement can be used for mending; but if the article has to be placed in boiling or very hot water, the only possible cement is that made with white lead or flake white, which is white lead in a pure and grit-free form. This cement is not affected by water, either hot or cold, or by changes of temperature. The white lead is obtainable at any oil and colour shop, and the flake white from an artist's colourman.

The lead is spread evenly over the broken surface in order to cover every angle and crevice. The two surfaces are then pressed firmly together, squeezing out any excess cement. The more thoroughly this is done the less the line of repair shows on drying. Only a very fine film of cement should be left, just sufficient to hold the pieces together. Any excess must be removed before it hardens.

Two other cements are useful, but they will not stand very hot water. One is composed of a little white of egg mixed with enough plaster of Paris to make a thin cream, and spread on the broken surfaces before it can harden. Another cement consists of 1 oz. of gum acacia dissolved in water, strained, and mixed with as much plaster of Paris as will make a thin cream. Both these cements must be sparingly used, and well pressed out when the broken surfaces are joined together. The mended article must be put in a safe place for the

cement to set, two or three days being allowed for the completion of the process. Sometimes the weight of the broken pieces of glass keeps them in position. Failing this, two or three elastic bands can be used, and the article tied up with tape.

**Painting on Glass Ware.** Painting on glass is a hobby in which artistic training is not necessary, though where talent is possessed it can be well employed by originating beautiful designs. Fig. 11 shows a lovely example of a Persian beaker dating from the 14th century. Such oriental birds can be copied, or form the inspiration for some beautiful modern designs. Vases, flower bowls, dessert services, cocktail sets, and similar articles can be ornamented according to individual taste in designs.

*Fig. 11. Persian glass beaker dating from the 14th century, decorated with paintings in Oriental designs. (From the Eumorfopoulos Collection)*

If the articles to be decorated are chosen with fairly large openings, a pattern or design, a picture or drawing cut from a magazine, etc., can easily be inserted and pasted or even held on the inside, and the outline copied on the outside of the glass. Designs may be traced from copies on to tracing paper and affixed to the back of the glass, as shown in Fig. 12. The body of the design can be filled in according to personal taste and the colour scheme desired. The copy is washed off after the painting has been completed. In all cases the surface to be painted must first be cleansed thoroughly to remove any possible traces of grease. This can be done by washing it in warm soapy water and, after rinsing in cold water and drying, by lightly sponging with methylated spirit and allowing to stand for a few minutes. Many plain glass articles can be purchased at a sixpenny store. These will serve to make experiments on with various designs and methods of colouring. Glass painting colours and brushes can be obtained at a good artists' colourman.

*Glass Ware: decoration by painting. Fig. 12. The plate is painted on its underside and the sundae glass on its outer surface, a transfer being pasted on the other side of the glass and the design traced with a fine brush.*

No other preparation of the surface is necessary, and the colours are supplied in bottles or tubes ready mixed for direct application. These colours possess great

brilliancy and, at the same time, a high degree of transparency. Very little colour need be used to obtain the best results. The design is outlined in black first before filling in with the flat colours.

A No. 1 sable hair brush should be used for this. The colouring may be executed with a No. 3 squirrel hair brush. Where shading is necessary, the colour must be put on quickly. The paler shades are applied first, the darker being superimposed before the first colour is dry. Articles painted in this method dry almost immediately, and can be washed after a few days in warm water and a mild soap without harm. Soda must not be used.

*Fig. 13. The finished articles, the designs being outlined in pale green and filled in with blue, green, and a little red for the dragon's head.*

Should the first colour be allowed to dry, a hard line results. It is better to finish off a bird, animal, or flower separately rather than try to do a group at once. Simple designs are best, as there is less chance of overcrowding the effect. The colours should be lightly put on, or the transparent effect will be marred. A speck of dust or hair from a brush will spoil the work unless removed instantly with the point of a pin.

*Fig. 14. Simple design of lemons and green leaves for a lemonade set.*

A very simple form of glass painting without brushes, which can be done by children and is a delightful indoor pastime, is executed with an Instanta outfit consisting of tubes of colours and rubber stamps with different designs. The latter are charged with colour and pressed on to the glass object which it is wished to

decorate. Flowers and leaves can be arranged to form groups or borders.

**GLAUBER'S SALTS.** The chief constituent of many of the aperient natural waters is sodium sulphate or Glauber's salts. They form a useful purgative for chronic constipation, particularly in persons of a gouty tendency, being taken in a small glass of warm water before breakfast. Glauber's salts are often prescribed as a purgative for sufferers from liver troubles, particularly gall-stones. The dose is  $\frac{1}{2}$  to 2 drams, where repeated doses are to be taken;  $\frac{1}{4}$  to  $\frac{1}{2}$  oz. when prescribed as a single dose. Effervescent sodium sulphate may be taken in doses of 60 gr. or more.

**GLAUCOMA.** Commonest after middle-age, this disease is one in which the natural fluid within the eye accumulates, raising the intra-ocular tension and so stretching the coats of the eye. The disease may come on gradually, without pain, but with a loss of visional acuteness. On the other hand glaucoma may be found as an acute condition. Warning may be given of its imminence by a rapid loss of power to read small type, and by the appearance of coloured halos round lights, combined with dimness of vision. An immediate operation is necessary. *See Eye.*

**GLAZE.** Meat glaze is very strong meat stock, boiled down until it resembles melted glue. It is used when rewarmed to give a shiny and savoury exterior to galantines, cold roast poultry or game, or to brush over raised pies. A small piece of glaze added to soups and sauces adds greatly to their colour and flavour. If stored in pots and kept in a dry cool place, glaze will keep for long, though an equally good way of preserving it consists of pouring a little warmed clarified butter or mutton fat on the surface and allowing it to set. To prepare glaze, put the strained stock into a saucepan, and boil it quickly till only about a quarter of it is left. In the meantime keep it well skimmed. When it has cooled slightly, pour the glue-like liquid into a clean pot and leave it till it is cold and hard. Eight quarts of stock will yield about  $\frac{1}{2}$  pint of glaze.

Glaze for Vienna bread is made by boiling about  $\frac{1}{2}$  gill of milk with a piece of butter the size of a walnut. This liquid is then brushed over the bread and dried off for a moment in the oven. Sugar-glaze for buns, etc., is made by boiling 1 tablespoonful of white sugar with 3 tablespoonfuls of water for 2 or 3 min. It should then be brushed over the baked buns and dried off in the oven.

To make egg glaze for pies, sausage rolls, meat patties, etc., beat a raw egg well, add 3 teaspoonfuls of cold water or milk, and brush over the surface of the pastry before baking it. *See Bread; Galantine, etc.*

**GLAZING:** In Upholstery. Glaze of the right kind helps to prolong the life of certain fabrics, e.g. chintz and window blinds, by reducing their liability to

hold dirt, thereby avoiding frequent washing. Glazing stiffens chintz, and is effected in course of manufacture by the use of heavy calendar rollers under a pressure of many tons.

Machines fitted with a flint polishing tool are used by dry-cleaning firms to rub a polish on loose chair covers. To apply similar pressure by hand would be exceedingly laborious; the more practical method is to use heavy, heated irons, after starching the material with the addition of starch glaze. The latter can be made with three parts paraffin wax and two parts stearin, melted together, and this is boiled in with the starch, or applied lightly to the article with a cloth before starching.

Glaze that is produced solely by heat and pressure without the aid of starch disappears on exposure to moist air.

**GLOBE AMARANTH.** A half hardy annual with "everlasting" flowers of various colours, most suitable for cultivation in pots in the greenhouse. The botanical name is *Gomphrena globosa*. Seeds are sown in warmth under glass in February-March; the seedlings are potted singly in small pots and subsequently into others 5 inches wide in a compost of loam, leaf-mould and sand. If the flowers are cut before fully open they last well and are useful for vases indoors in winter.

**Globe Artichoke.** See Artichoke.

**GLOBE DAISY.** Known botanically as *Globularia*, this small genus of shrubs and herbs is suitable for the border and the rock garden in light loamy soil. The species usually grown are *cordifolia*, a trailing dwarf shrub; *nana*, a low trailer; *nudicaulis*, herbaceous, 6 in. high (*alba*, a white variety); and *trichosantha*, glaucous, 6 in. high, herbaceous. All have rounded heads of blue or purple-blue flowers. Propagation is by division in September or by sowing seeds in a frame in spring. See illus. below.

*Globe Daisy. Blue flowers of one of the varieties suitable for the rock garden.*

**Globe Flower.** See Trollius.

**GLOBE THISTLE.** This is an attractive hardy

plant with grey-green spiny leaves and round heads of thistle-like summer flowers of a shade of blue. They are easily grown in ordinary soil in a sunny position. One of the best is *Echinops ritro*, 3 feet high. The globe thistles are increased by division and by root cuttings in autumn or by sowing seeds out of doors in April.

*Globe Thistle. Blue flowers and grey-green leaves of Echinops ritro, a favourite herbaceous border plant.*

**GLORIOSA.** This genus consists of handsome hothouse bulbous plants belonging to the order Liliaceae. The best and most noteworthy, *G. superba*, known as the Malabar glory lily, is a very showy climbing plant which bears orange-red flowers in summer. The bulbs are planted in spring in large pots filled with a compost of loam, peat, and sand. Warm, moist conditions are necessary to encourage free growth. As the leaves fall, watering must be discontinued gradually; in winter the soil should be kept dry. Propagation is by seeds or by removing small offset bulbs. See Bulb; Flower Garden.

**Glory of the Snow.** This is another name which is given to the flowering bulb known as *chionodoxa* (q.v.).

**GLORY PEA.** Also known as *clianthus* or the parrot beak flower, the glory pea thrives under cold greenhouse treatment in a compost of loam, peat and sand, and is useful as a basket plant. *Dampieri*, the best known species, may be raised from seed or cuttings under glass in spring. It is not an easy plant to manage. *Puniceus*, which bears crimson blooms, is also very showy. It is nearly hardy, but the best results are generally obtained when it is protected by glass.

**GLOUCESTER CHEESE.** Gloucester cheese, one of the principal British varieties, is milder than Cheshire cheese and for toasting purposes is one of the best. In shape flat and circular, it weighs from about 22 lb. upward. Double Gloucester is made of the whole milk; single Gloucester is made of skimmed milk, or milk deprived of half its cream. See Cheese.

**GLOUCESTER PUDDING.** These little batter puddings are made by creaming together  $\frac{1}{4}$  lb. each of butter and sugar and two eggs. To these ingredients add 5 or 6 blanched and pounded bitter almonds and 3  $\frac{1}{2}$ -4 oz. of fine flour. Beat all to a light batter; then pour it into some cups, half filling them, and bake the puddings in a good oven for about 25 min. They should be served with a sauce made thus: Melt a lump of

butter about the size of a small egg in a saucepan over the fire, mixing in smoothly half a tablespoonful of flour. Move the pan to the side of the fire before adding a little less than a breakfastcupful of water; then replace it, and stir its contents until they are boiling. Put in a heaped tablespoonful of sugar and  $\frac{1}{2}$  gill or a little more sherry, and continue boiling for a few minutes before serving.

#### GLOVES: FOR MEN, WOMEN AND CHILDREN How to Choose, Repair and Make Them

In conjunction with this article, such entries as Chamois Leather; Dry Cleaning; Knitting; Leather; Mending may usefully be consulted.

Leather gloves are made from a variety of skins, including kid, goat, sheep, lamb, reindeer, antelope, etc. Kid skin finished on the hair or grain side is known as dressed kid, and that finished on the flesh side is called undressed kid. Cape gloves was a term at one time applied exclusively to articles made from skins imported from South Africa, but it is now generally applied to all gloves with a nappa finish. Suède is leather dressed on the flesh side, and mocha is a finish imparted to the hair or grain side, the grain being removed. Chamois is a leather usually from a split sheep skin specially dressed with oil, and makes a glove which is comfortable, and economical because of its washing properties.

**Men's Gloves.** Styles in men's gloves change very little from season to season, and there is little ornamentation. For everyday wear the most useful and economical ones are of suède, chamois, and doeskin. These are, as a rule, fastened with one button or one fastener, and some makes are silk lined. More expensive gloves made in the same styles are of deer-skin, buckskin, reindeer, and similar materials. For winter wear there are deerskin and Cape gloves lined either with wool or fur. Others are of beaver lined with coney. Some have elastic or sac wrists, others fasten with a strap.

For motoring and flying the gauntlet type is favoured. These are of goatskin bark, tan, nutria, coney, and other materials, and are usually lined with wool. Tan of one kind or other is popular, and some have double palm and fingers where the friction of the driving wheel is felt. For country and sports, knitted hunting string or thick cotton gloves are sometimes worn.

In purchasing gloves, attention should be paid to quality as well as price, for a sound glove made from reliable skins, and with the best sewings, cannot be obtained at the price at which many cheap varieties are offered. Inferior gloves may split the first time they are put on.

**Women's and Children's Gloves.** Fashions in women's gloves change frequently, but usually the alteration is limited to some new form of decoration. White kid gloves, for instance, are sometimes

ornamented with stitching in black, while a similar contrast is achieved with white on black or navy blue gloves. Fabric gloves are used for women's and children's wear, made in all colours and varying qualities, the best quality sometimes being hardly distinguishable from suède.

Gloves of this kind are not so warm for children as those of wool, but they wear reasonably well. Mocha suède gloves, plain, fringed or edged with fur, and those of dark-coloured kid, are popular, while for children's sports and school wear woollen gloves are most usual. The mode of fastening women's gloves varies according to whether they are for evening or day wear. Those for the former are usually 12, 16 or 20 button length and are fastened with 3 buttons, while the latter usually have gauntlet or sac wrists with short lengths of elastic on to which the wrist portion of the glove is gathered.

Babies' gloves are knitted so that the fingers are all in one piece and the thumb only is allowed a separate place. This allows free movement of the hands, and also dispenses with the difficulty of making a very small child put his fingers in the right stalls. These gloves are usually worked with a series of holes at the wrist, through which ribbon can be threaded for tying.

**Care Of Gloves.** When putting on new gloves they should not be pulled violently at the wrists, but worked on gradually finger by finger. A glove stretcher may be used if necessary. In removing the glove the same care should be observed in drawing it off the fingers and thumb, with the use of as little force as possible.

Suède and kid gloves when soiled are best treated with petrol, while stains on silk, woollen or cotton gloves will generally yield to ordinary washing. Petrol cleaning should not be attempted except in the open air or in a room without a fire or other naked light. If the suède gloves are white or of any delicate shade, the petrol should be perfectly clean and not used beforehand for any other purpose. Pour the petrol into two bowls, placing the gloves in the first to soak for a few minutes. Then put them on the hands, and, in the case of long gloves, draw them well up the wrists and arms.

Rub them together as though washing the hands and rub the finger-tips of one hand against the palm of the other. Pay special attention to any badly soiled parts, and when all marks have been removed peel off the gloves, squeeze them well, and then rinse them in the second bowl of petrol. Squeeze out the petrol, pull the gloves gently into shape and hang them up to dry. Dark coloured suède or kid gloves may be cleaned in the same petrol, but dark brown or grey doeskin or reindeer gloves generally require double treatment before they become thoroughly clean.

If a dry process is preferred, the gloves should be rubbed with a mixture of equal parts of finely powdered alum and fuller's earth. If, however, they are of white kid or suède, French chalk should be substituted for the fuller's earth. After applying the

powder, leave the gloves for an hour or more, then brush and shake them well. A final application of warm bran or oatmeal should be given. White or light coloured kid gloves may also be cleaned with a piece of soft white india-rubber. Put the gloves on the hands and, commencing with the fingers, rub the leather well with the eraser. If the surface of the rubber becomes dirty in the process, rub it over new blotting paper until it is clean.

When splits occur in kid, suède, or wash-leather gloves, it is useless to stitch the leather together in the usual way, as this will only tighten the skin and cause it to split again. The most satisfactory repair is achieved by working round the hole with a buttonhole stitch, using silk of the same shade as the glove. When this is done, commence a second round, working this time into the loops of the first round of stitches, and continue the operation until the hole is filled. This mend is almost unnoticeable.

Discarded gloves may be worn to protect the hands while housework is in progress, or the fingers may be used as finger stalls in cases of cuts, gatherings, etc. Two pieces of tape should be sewn on to the ends and tied to keep the covering secure. Odd bits of old chamois gloves may be stitched together to form a pad for cleaning silver.

**Making Gloves.** A glove for placing pieces of coal on the fire can be cut from black velvet or velveteen. To make, place the hand on a piece of paper and draw round it very roughly. A separate thumb covering is allowed, but the fingers are cut in one as for a baby's glove. Allow a generous margin when cutting the material and use one thickness for the back of the glove, and two for the inside. Seam the cut edges together and bind them with tape.

*Glove. Fig. 1. Woman's chamois leather gloves of an easy fitting, pull-on shape.*

The skin gloves which are illustrated in Fig. 1 are of white washable chamois. The beginner should experiment with an ordinary window leather to get the correct way

of cutting and fitting in the thumb and finger gussets.

*Fig. 2. Outline of patterns needed for the chamois leather gloves.*

Besides the skin a leather-cutter's knife is required, a glove needle (which is three-sided), flax thread, and a pattern such as that shown in Fig. 2, which can be cut from a pair of old nappa gloves. Drawing pins with glass or cork heads are also

required. A leather-worker's punch is an addition to the set, if it is decided to have a fancy gauntlet. A skin 12 in. wide by 20 in. long will cut a pair of gloves sizes 6½ to 7, and a larger skin that will cut two pairs is an economy, as the gussets can be cut from odd corners. Examine the skin when buying, and see that there are no thin places that will break into holes when worn. Thongs are cut from a round piece of leather in circles and should measure about ⅛ in. wide for glove trimmings.

To cut, place the pattern on the skin in such a position that the stretch of the glove will be across the hand. Fasten the pattern down with drawing pins so that each piece is quite taut, or the skin will move in cutting. There are six pieces, and they should all be placed on the skin before deciding to cut, so that the best position can be judged for cutting without waste, and to get the main part of the glove on the thickest part of the skin, the gussets being cut from the edges of the leather. Cut the straight lines and between the fingers with the knife, but the tips of the fingers and the thumb gusset can be cut more easily with a sharp pair of embroidery scissors. When the six pieces for the right hand are cut, number them as shown.

The stitch used is known as jab-stitch or stabbing, and is worked so that the cut edges of the skin are on the right side of the glove. This makes a strong edge and one that is easy to mend if the thread wears. To jab-stitch, place the two edges of skin together and push the needle right through the two pieces, push back again about ⅛ in. away. This is shown in the illustration (Fig. 7) with the glover's needle in position. Begin to sew at point No. 3, on to 2 and then 1 (Fig. 2), follow right round the thumb and hand, setting this part in very carefully so that there are no puckers on one side, and continue the process right round to point No. 4.

*Fig. 7. Stabbing or jabbing stitch used in glove-making.*

To sew the first finger begin at the point marked with an asterisk and sew round the curved top. Take the finger strip marked 1 and 2, place this in position so that the outward curve at the centre, which is marked 3, points to the back of the hand and the end marked 1 at the tip of the first finger. It will be noticed that each one of these strips is a different shape, and it is important to number them according to the fingers against which they will fit. In some gloves these

strips are cut straight, with curves at the ends for the tips of the fingers, but the centre curve shown gives a better fit, with much spring and much longer life to the glove.

Sew along both sides of the gusset to the point marked 2, which fits against the top of the middle or second finger. Join the other strips between the second and third and third and fourth fingers in the same manner, the final point, marked 4 coming at the top of the little finger. Now sew down the outside of the little finger, down the side to where the gusset comes in. Place the gusset in position, and sew along one side of that to the palm of the glove, and along the opposite side of the gusset to the back of the glove.

The back of the glove has three very tiny tucks oversewn with black flax thread, or three lines of running-stitches (the centre one longer than the two side ones) can be worked down each of the three strips. Measure off the scallops with a sixpence or other small coin, pencilling round one half of it, and cut out with embroidery scissors, then punch a hole in the centre of each scallop. If a straight edge is preferred, punch holes all round about  $\frac{1}{4}$  in. apart, and thread with thongs of the leather, carrying this decoration right round the glove and up the sides of the gusset. It should be borne in mind that it is not necessary to sew the sides of the gloves below the wrists if it is decided to thong them.

**Gauntlet Gloves.** In making women's gauntlet gloves, such as those shown in Fig. 3, it is a good plan to cut patterns for two hands, as it is much easier to fit them on the selected skin. Good quality chamois, doeskin, suède, and French gloving suède are all suitable. They vary in price, but home-made gloves are much cheaper than bought ones, and are not difficult to make with some practice if the directions are carefully followed.

Choose a skin of a size that will cut the pattern without much waste. Before putting down the patterns finally, hold the leather up to the light, and mark all tiny holes or thin places with a pencil. Avoid these when cutting out the gloves. The next point is to determine the right way to use the skin. Stretch it carefully in both directions, and arrange that the way which gives the most is across the hand, otherwise the gloves will be tight across the hand and will neither fit nor wear well.

Lay the skin face downward on a hard surface, arrange the patterns, and go round the outside first. Then lift up the fingers, one after the other, so as to mark down the side of the next finger to the one lifted up. Tailor's chalk is best for all dark colours, but for chamois a soft lead pencil may be used.

Fig. 3. Woman's suède gauntlet gloves.

If there is only one pattern, reverse it for the other hand. Always try and get a good piece of skin for the thumbs, and see that the leather stretches across them. Do not forget to reverse the pattern for the second thumb. Fig. 4, shows the shapes

of the pieces needed.

Fig. 4. Right, pattern for making woman's gauntlet gloves; left, similar pattern for man's goatskin gloves shown in the next page.

Three gusset pieces are required for each hand, half a dozen small diamond-shaped gussets for the base of the fingers, and two long gussets for the front of the glove.

Take one thumb, fold the tops together, and stitch, using twist. Follow the directions given in making a man's glove. Stitch in the gusset in the same way, but instead of a strap insert a piece of elastic from 2 dots on the pattern to the corresponding 2 dots. Trim off the top of the glove when the gusset is fixed. Turn up round the bottom about  $\frac{1}{4}$  in., stick it down with a little gum paste, and press it. Then cut holes round the hem thus made, using a thonging punch. Thread some thongs from the same skin, as shown in Fig. 5.

Fig. 5. Thongs for gauntlet glove. Dotted lines show direction of thong on back of skin. This trimming starts in centre of gusset.

**Man's Winter Gloves.** A pair of man's gloves in goatskin with fur cuffs, size 8, is illustrated in Fig. 6. Cut out as explained for a woman's glove. The pieces needed are shown in Fig. 4, left. The stitching up the back must be done first. This consists of three rows of stab-stitch, below the fingers (Fig. 7).

Fold the leather and commence sewing from the top. The tiny ridge of leather made by sewing the two pieces together must be as small as possible, and the lines must be kept even. The line between the first and second finger should be about  $3\frac{3}{8}$  in. long, that between the second and third  $3\frac{1}{2}$  in., and the last one 3 in. Always avoid unpicking. If the work does not look very flat, press it by leaving it between some books.

*Glove. Fig. 6. Men's goatskin gloves, patterns for cutting which are shown in Fig. 4.*

Sew up the seam of the thumb as far as the bottom of the short side. Do not fasten off, but leave the thread hanging. Place point C on the glove to point C on the thumb and sew together seam CD.

Continue the seam to B, and then on to about 1½ in. down the side of the thumb. Unthread the needle as before. Now thread the needle with the first end left at C, join seam CA and continue 1½ in. down the side of the thumb. Fit the remainder of the thumbhole and thumb by placing the edges together, taking great care not to stretch either edge. Should the thumb seem too large, as is usually the case, trim off the hole, but on no account cut anything off the thumb. Do this very gradually until the thumb fits well. Continue sewing together, and when ready to fasten off pull the loose end through to the back, also the one which is being worked, and tie the ends together.

Sew the small shaped gussets into the bottoms of each pair of finger gussets, taking care that the point comes exactly in the point between them. Then sew the gussets marked 1 and 2 into the glove, the small gusset to be towards the inside of the hand. Begin sewing on the back at the point up the first finger to about 1 in. from the top. Trim off the gusset at the top until it fits the middle of the top of the finger, continue stitching to the end of the seam. Push the needle through the inside to the top of the gusset and stitch the other side down to the base. It is important to make sure that the point O on the pattern comes exactly to the point of the fingers.

Do the other fingers in the same way, but continue down the outer side of the fourth finger about 7 in. Insert the end of the strap fastening between the back and front of the hand. Stitch it to the back, and then continue the seam to the end. Trim off any surplus. Fix the steel bar to the small strap of leather by slipping it over the end and folding the two ends together. Stitch close to the bar and fix it to the glove. Put in the front gusset. Begin sewing at the bottom and work to the point up one side, then from the point to the bottom of the other side. Make the bottom even by turning off any unnecessary pieces of leather.

To put the fur inside the cuffs, cut a piece of fur 3 in. wide and long enough to go round the bottom of the glove, noting that the fur is to brush downward. Place the fur side towards the outside of the glove and stitch firmly all round the edge. Oversew the two ends of the fur together. Turn the top of the glove back sufficiently, so that the fur can be turned over, and slipstitch the other end inside the glove. Do not take the stitches through on the right side. The fixing of the press-studs to the strap remains to be done. Fit the lower half of the stud at the O mark shown on the strap. Then put the strap through the bar and fix the top half to the end of the strap with the top side of the press-stud underneath, so that when the end is brought over to meet the lower half the stud will shut properly.

Be careful to put the strap through the bar before fixing the stud top, as this will not go through afterwards. Use good stout glazed thread or fine twist for sewing, and do not use too long a piece of silk. The edges are put together and sewn with stab-stitch, which is simply pushing the needle down through the two pieces of leather and bringing it up again,, making a tiny stitch. It is not possible to run gloves together.

**Knitted Gloves.** The pair of man's gloves, one of which is shown in Fig. 8, were knitted with a fairly heavy wool, and are for a size equal to No. 9 in kid. For smaller sizes use No. 13 steel needles instead of those given. The materials required are 4 oz. of 3-ply super wheeling yarn, which is better for warmth, wear and general masculine purposes, and a set of four No. 11 steel knitting needles. Cast 52 stitches on the three needles altogether, in the proportion of 18 on each of two needles and 16 on the third; working in rounds of double rib—that is, knitting two stitches and purling two stitches alternately all round, until 36 rounds are worked for the wrist. Here the hand begins and ten rounds are knitted in plain knitting, after which the gusset for the thumb is begun.

*Fig. 8. Knitted glove for a man.*

To begin the thumb, purl one stitch, then increase one stitch (by knitting through the loop just underneath the next stitch, then knitting that stitch), knit 2, increase once in the next stitch as before, purl one stitch, and knit to the end of the round. The two purred stitches mark the outside of the thumb. \* Knit two rounds in plain knitting, but purling the two stitches that were purred in the previous round. In the next round increase once on the inside of each of the two purred stitches, then knit plain to the end of the round. Repeat from \* until there are 20 stitches between the two purred stitches. Knit two more rounds without increasing, then in the next round knit the purred stitch, pass the next 20 stitches on a safety pin, and leave them for the thumb. Cast on five stitches after the last knitted stitch, then follow on the other stitches and finish the round. Work 14 more rounds for the top part of the hand that comes above the thumb.

### How to Knit the Fingers

Here the fingers begin. For the first finger take the five stitches cast on at the back of the thumb, two to the left of them and seven to the right, leaving the rest of the hand stitches on a piece of string, with the open ends towards the first finger, in order that the stitches can be slipped off for the succeeding fingers. Cast on six stitches, then on these 20 stitches knit 25 rounds.

Decrease once at the beginning of each needle by knitting together the second and third stitches. Knit three rounds without decreasing, do another decrease round, then three rounds without decreasing, another decrease round and one more round, decreasing one stitch only in the round, when there should be 10 stitches left. Place these so that there are five stitches on each needle, and one needle behind the other, then graft the stitches together as instructed under knitting. Cut off the wool and darn in the end on the wrong side of the glove.

For the middle finger take six stitches from the left end of the string (palm side of the glove), pick up and knit six loops at the bottom of the first finger, then take off and knit seven stitches from the opposite end of the string, which comes at the back of the hand, and cast on four stitches to come between the fingers, making 23 stitches altogether. Knit one round, knitting together the first and second of the six stitches at the bottom of the first finger, and the fifth and sixth of these stitches. On the remaining stitches knit 28 rounds then finish off the top like the first finger, decreasing until there are only 10 stitches left, and graft them together.

For the third finger take six stitches from the palm end of the thread, pick up and knit four loops at the foot of the second finger, take seven stitches from the opposite end of the thread and cast on three stitches, 20 stitches altogether. On these stitches knit 25 rounds, then finish off the top like the first finger. For the little finger take the remaining 13 stitches and pick up four loops at the side of the third finger, making 17 altogether. Knit 20 rounds, and finish off the top like the other fingers.

The thumb can now be finished, so take the stitches off the safety pin and pass them on the needles. Pick up five loops where the stitches were cast on at the back of the thumb, and knit one round on all these stitches. In the next round knit together the second and third of the five cast-on stitches. \* Knit one round plain, then decrease again over the two knitted together in the last round, then finish the round. Repeat from \* once. On the remaining stitches knit 18 rounds, then finish off the top of the thumb like the fingers.

The left-hand glove is worked exactly the same until the first finger is reached. Here take two stitches to the right of the five cast on behind the thumb, and seven to the left of these stitches. This will reverse the hand, and the rest of the fingers are taken off in the order given for the right hand.

**A Baby's Gloves.** The knitted gloves shown in Fig. 9 have a thumb piece and the bag shape only for all the fingers.

*Fig. 9. Baby's gloves with crochet chain for securing up the sleeves.*

The materials required are 1 oz. of 4-ply Beehive Scotch fingering wool in white and a small quantity, about  $\frac{1}{4}$  oz., of pale blue silversheen for the edge of the

wrist and top of bag, and the surplus for the crochet chain. Use No. 10 steel knitting needles, and work at a tension of about 7 stitches to the inch in width; the wrist portion will measure nearly  $3\frac{1}{2}$  in. wide when measured flat across the double portion, 3 in. across the palm, and 8 in. long from the wrist to the top of the finger portion. A No. 10 bone crochet hook is also required, and 1 yard of narrow ribbon to match the silversheen.

With the white fingering cast 45 stitches on the three needles in the proportion of 16 on each of two needles and 13 on the third. The 1st round is knitted plain. 2nd round: \* purl two stitches together, purl two single stitches, wool round the needle and back to front again to make a stitch, purl 1, wool round the needle, purl 2, purl 2 together; repeat from \* all round. There should be five patterns in the round. The 3rd round is knitted plain, and the fourth is similar to the second.

Repeat the third and fourth rounds once, and knit the 7th to 11th rounds all plain. Repeat from the second to the 11th rounds twice, then knit one round plain, increasing three stitches in the round at equal distances apart by knitting in the front and back of each of three stitches. Work 16 rounds in plain knitting but without any shaping.

In the next round make the ribbon holes for the wrist as follows: \* knit one, bring the wool to the front of the needle so that it will pass over the needle when knitting the next stitch, then knit the next two stitches together; repeat from \* all round. In the next round the wool that was passed over the needle will be knitted in the ordinary way, thus making a stitch and so forming the hole.

To form the hand, work 12 rounds in plain knitting; then divide the stitches for the thumb as follows: knit the first stitch, slip the next eight stitches on a safety pin, and leave them until the hand is finished; cast on two stitches and knit the rest of the round. Knit 16 rounds on these stitches for the hand, then begin to decrease to shape the top. For the 17th round, knit 1, knit 2 together, knit 15, knit 2 together, knit 2, knit 2 together, knit 15, knit 2 together, knit 1; and for the 18th, knit 1, knit 2 together, knit 13, knit 2 together, knit 2, knit 2 together, knit 13, knit 2 together, knit 1. Continue decreasing in this manner until only 18 stitches remain. Cast off the stitches and, with the silversheen crochet the top together, using a No. 10 bone crochet hook.

The thumb is made by taking up the stitches that were left on the safety pin, dividing them on to two needles, and with a third needle knitting up three stitches under the two cast-on stitches. Work 12 rounds in plain knitting, then knit 2 together until all the stitches are worked off, and with the silver-sheen work 1 double crochet into each stitch at the top of the gauntlet. Work the second mitten exactly the same as the first, as they are interchangeable on each hand.

**GLOWWORM.** Where the glowworm appears in the garden, usually on a grassy bank, it should be permitted to remain, for as a grub it feeds entirely

upon snails. The male somewhat resembles in form the common wayside beetles known as soldiers and sailors; the wingless female, the chief light giver, differs little in appearance from the grub. As a rule, she climbs a grass stem at night to make her light more visible to the flying male. The latter often flies into open windows where there is a light. Attempts to establish the glowworms in gardens are often made, but are doomed to failure unless the snail pest is already there.

**GLOXINIA: How to Grow.** With bell like flowers of innumerable colours and shades, the gloxinias are a family of very beautiful greenhouse or stove-flowering plants. They are tuberous perennials, but are usually raised in the first instance from seed. The seed, which is very small, should be sprinkled in well-drained pans or boxes of light, sandy soil with which a little leaf-mould is mixed. January and February are suitable months for sowing.

*Gloxinia. Blooms of several varieties of this beautiful greenhouse plant.*

In an ordinary greenhouse heat, say of 55° to 60°, the seed will germinate in less than a month, and as soon as the young plants, which grow rapidly, are large enough to handle they should be pricked out. A change from a 3 in. pot to one of larger size will be all that is required. Ordinary potting soil of loam and leaf-mould will suit them admirably. They will flower in summer.

After the flowers are over gloxinias should be dried off gradually by giving decreased supplies of water and finally keeping the soil dry in winter: the pots containing the roots must remain under the glass safe from frost. In early spring the tubers should be taken out, repotted, and started into fresh growth. Gloxinias must be shaded from strong sunshine. During the summer months they need little or no artificial warmth.

Gloxinia tubers are not much good after the second or third year, but attempts may be made to perpetuate favourite sorts by cutting half-way through the mid-rib of one or more healthy leaves, when the flowering season is over, and pegging them down to a sandy surface-soil with pegs or hairpins. In the course of time tubers will form at the bases of the wounds, and new plants thus procured may be grown in the ordinary way.

**GLUCOSE.** Grapes and other sweet fruits contain the colourless syrup known as glucose or grape sugar. It is found in the human body, in the blood and lymph, and in medicine it is added to nutrient enemata, being readily absorbed. Glucose is prepared artificially from starch, dextrin and cane-sugar. It is used in brewing, confectionery and jam making. *See Diet; Food; Jam; Sugar.*

**GLUE: How to Prepare.** Glue is an adhesive preparation, often in the form of impure gelatine, obtained by boiling down animal substances such as skin, horns and hoofs. It is mostly either of the cake type, such as Scotch glue, or purchased in a tube, generally in the form of a patent preparation. Fish glue is sold in convenient form in a tin or tube. Various grades are available. Casein glue employed by bookbinders, is made by dissolving casein in a solution of borax. Dutch, Flanders or Cologne glue is a pale, strong adhesive bleached with chloride of lime. Elastic or flexible glue is obtained by combining glue with a preparation of glycerin, glucose, etc.

*Glue. Fig. 1. Applying glue to two surfaces simultaneously. Fig. 2. Rubbing the two edges of joint together. Fig. 3. Cramping up the joint; two hammers are used to drive wedges home.*

The preparation of Scotch glue is simple, but unless carried out properly results in partial failure. The glue is purchased in the form of rectangular blocks about 6 in. square, and one of these should be loosely wrapped in a piece of old paper, and broken into small pieces with a hammer. The contents of the paper are placed in the inner vessel of the glue-pot, covered with cold water, and left to soak for 24 hours at least. The glue-pot is then placed on a slow fire, gently brought to boiling point, and left to simmer until its contents are completely dissolved and ready for use.

Glue should be dissolved by gentle heating; if it is allowed to boil for any length of time it will darken, and much of the strength will be lost, and the same applies to reheating. It is, therefore, prudent to mix only such a quantity as will be used up without delay. Never put new glue in a pot containing old hard pieces; the pot should be cleaned out, and fresh glue made as required.

The glueing up of the parts is best carried out in a warm room, the surfaces to be united being warmed, and the adhesive applied sparingly but thoroughly (Fig. 1) to both surfaces. The two parts are pressed gently together, as in Fig. 2, to squeeze out all surplus

glue and exclude air bubbles; the ultimate strength of the joint depending upon the closeness of contact between the two pieces of wood. If this is properly done the joint will never come apart under ordinary uses. Repeated testings have shown that the wood itself will splinter before the joint will give way.

Another point is to provide means for cramping the parts together (Fig. 3), as the joint should be kept in firm contact until the glue sets hard, and 24 hours is none too long for this essential process. In some cases it is necessary to unite pieces of wood in such a manner that they can be parted without difficulty. This is accomplished by placing a piece of thin brown paper between the faces of the wood while the joint is made. When it is to be severed, the paper can be split and the surfaces cleaned up with a plane, and finally glued together. This class of glue-joint is in considerable demand for curved work, when several pieces have to be shaped, and for some reason separated, before the final completion of the work.

When any considerable area has to be covered a short stiff brush may be used, but on delicate work it is better to apply the glue with a thin stick of wood shaved at the ends to form a sort of knife blade.

Patent adhesives, such as the various liquid glues, are convenient for repair work and small jobs, being applied direct to the joint faces. They should be pressed close and cramped, although they set hard in a few hours. Similar remarks apply to most of the fish glues. A glue for metal may be made from fish glue and carefully prepared flour paste in equal proportions.

**GLUTEN.** When mixed with water gluten has a gluey consistency, from which its name is derived. Gluten or vegetable albumen is one of the constituents of most cereals. It can be obtained by kneading flour with half its weight of water till it is stiff and then continuing the kneading under running water, which washes out the starch.

Wheat flour contains about 12 per cent of gluten, and it is to this quantity together with the elastic nature of gluten in the flour that bread owes much of its light and spongy texture. The grains of other cereals, such as oats, rye, barley, that are deficient in gluten, will not by themselves yield a light, porous loaf. Gluten is sometimes used by itself, or with only a very small quantity of starch, for making gluten bread, or gluten biscuits used in diabetes. *See Bread; Food.*

**GLYCERIN.** Obtained from fats, glycerin is a colourless, thickish, transparent fluid which readily dissolves other substances, and does not turn rancid or evaporate. Consequently it is often used as a means of applying other drugs to skin surfaces, or mucous membranes. It is also commonly included for its soothing qualities as an ingredient of throat lotions.

Common glycerin preparations are glycerin of boracic acid, sometimes called boroglyceride, for fomentations; glycerin of alum; glycerin of tannic acid, a useful astringent preparation; glycerin suppositories, etc. A characteristic quality of glycerin is its power of absorbing water from any moist surface with which it

comes in contact.

When mixed with an equal part of plain water or rose-water, glycerin forms a good application for chapped hands and helps to keep the skin white and soft. Used pure it is generally too irritating. Perspiring feet may be rubbed with glycerin and then sprinkled with borax with excellent results. Shoes that are to be put away temporarily should be rubbed with a cloth dipped in glycerin. This will make the leather soft and pliable and prevent cracks.

**GNAT.** The mosquito family of insects are also called gnats. Many species of this family, which breeds on stagnant water, carry malaria, and others carry yellow fever, dengue and filariasis. They are blood-sucking insects and they introduce infection in the act of biting. The common English gnat carries nothing. The irritation following bites may be treated by applying solutions of ammonia, bicarbonate of soda, or permanganate of potash. *See Mosquito.*

**GOAT.** As a profitable animal costing little to keep, or simply as a children's pet, the goat can be strongly recommended. It can be kept where a cow would starve, and its milk possesses high dietetic qualities. A goat takes up little space, and the stall of a disused stable will accommodate two or three. For breeding purposes a male goat should be hired. Goats first come in season at a few months old, but 18 months is soon enough to put them to a male. To breed from a goat earlier ruins the milk yield.

A goat-keeper, unless he has ample space, should kill the kids when they are born, that is to say, if he keeps a goat for her milk, for the young will take it all; and, unless of very good pedigree, kids do not pay to rear. The flesh in flavour is very like veal. The milk yield of a goat varies greatly. An animal that will give four quarts when in full profit is a remarkably good milker, two quarts being nearer the average. Milking should be done regularly twice a day, and the bag thoroughly stripped.

The best food for goats in winter, when they have to be kept indoors, consists of leaves, grass, vegetables, and a little hay and corn. Out of doors they can subsist on a hedgerow, eating grass and leaves which would otherwise be wasted; and all through the spring and summer, if there is plenty of such food for them, they need not cost a penny for their keep. They should, however, have some concentrated food if they are milking. Anyone owning a heavy milker of a good strain will find it pays to feed the animal well in winter, stall feeding, as for cows, on hay, crushed or whole oats, bran and cracked maize.

A goat can very rarely be allowed its liberty owing to its fondness for barking trees and the inquisitive disposition it manifests towards everything it can reach. It is, therefore, customary to tether it on a rope or chain with a swivel attached to a stout iron pin driven into the ground, moving it to fresh ground every

day, or even several times a day. Goats are very hardy. The only thing likely to upset them is a surfeit of wet greens. They have aversion to damp and heavy winds, and in wet weather should be confined to their stall and given a little hay.

**Goat's Milk.** Goat's milk is an exceedingly nourishing and valuable food for infants which cannot receive their natural nourishment. Both the protein and the fat are greater than in cow's milk but there is less sugar than in human milk. An important recommendation for goat's milk is that these animals do not suffer from tuberculosis. For very young infants goat's milk is too strong. If given at all it should be well diluted with water. For growing children it is an excellent and nutritious food.

The following notes are taken from Advisory Leaflet No. 118 issued by the Ministry of Agriculture:

Goat's milk is as sweet and palatable as cow's milk, richer in cream, and more easily digested. Butter made from it is white, and may be coloured with annatto. Soft and hard cheeses of excellent quality can be made from the milk. Two points to note in milking are that it should be done at regular intervals and done quickly, as the goat becomes impatient if the operation is delayed. The milk should be strained through a clean butter-cloth and stored in a cool place. All utensils must be kept scrupulously clean by scalding with boiling water, and the hands should always be washed before milking.

**Feeding the Goats.** For feeding purposes the best receptacle is a metal pail. Variety of food is essential, but there should be no waste. Food of any sort should never be placed on the ground, as the goat will refuse to touch it if it is in the least soiled or tainted. Cabbages and similar green food should be hung up by the roots. Hedge clippings, garden produce of all kinds, acorns, roots, weeds such as dandelions, sow thistles, and docks are all eaten by goats; but everything must be perfectly clean and sweet, or they will reject it. Milking goats may have two or three handfuls of corn or cake daily, and when the lactation period extends through the late autumn or winter months, some concentrated food such as grain, meal, or cake is necessary if a satisfactory milk yield is to be obtained. Mangolds and swedes may be given, cut in half and placed in the manger, or sliced or pulped and sprinkled with bran or middlings. Good, sweet hay should form the staple food for winter.

Dyed goat fur is a cheap and popular substitute for bearskin. It is used largely for trimmings, white Thibet goat providing an attractive decoration for evening wraps and cloaks. *See Fur.*

**GOAT MOTH.** The caterpillars of the goat-moth bore galleries in the stems of many trees, and render the wood of little or no use for practical purposes. The odour of the caterpillars and their burrows has been compared to that of the goat. The moth, which flies at night, is large and plump, the female being 1½ inches long or more, with saw-like antennae, brown wings mottled with grey and black, whitish rings on the abdomen. The caterpillar measures up to 4 in. in

length, and more than 100 have sometimes been taken from one stem.

**Goat Moth.** *The caterpillars attack tree stems by boring, thus rendering the wood useless.*

Trees which are badly attacked and are of no great value should be cut down and the larvae destroyed. When a tree is only slightly attacked, or when it is of special value for shade or ornamental purposes, the following methods of destroying the pest are recommended for ordinary garden purposes by the Ministry of Agriculture. Small quantities of carbon bisulphide may be injected into the holes in the trunk, or small pieces of potassium or sodium cyanide may be pushed into the holes. Whichever poison is used the holes must be thoroughly blocked with clay immediately after the operation is completed.

**Goat's Beard.** *See Spiraea.*

**Goat's Rue.** This is a variant name for the perennial better known as the galega (q. v.).

**GO BANG.** This indoor game is played by two or four persons. The requisites are a board marked like a chessboard into 400 squares, 20 along each side, and 400 pieces, each 100 being a different colour. They are divided between the players, each taking 100 or 200 as the case may be. The pieces are all outside the board at the start, and each player in turn puts one on to any square he likes, provided it is unoccupied. The object of the game is to get five pieces in a straight line, straight in any direction, and the player who succeeds in doing this first wins.

A variant of the game is to place the pieces on the board in turn as in the previous game, and to endeavour to surround an opponent's piece with them. The piece which is surrounded is then taken from the board. The game continues until all the pieces have been placed on the board, and the player who has then surrounded the larger number wins. Go Bang is also played on a board of 361 squares, 19 along each side. In this case 362 counters, or men, are used.

**GODETIA.** One of the most beautiful hardy annuals; seeds are sown out of doors in spring where the plants are to bloom in summer. If sown in pots in September and grown in a slightly heated greenhouse they will flower in spring under glass. There are

innumerable tall and dwarf varieties with single or double flowers. The former are sold chiefly by colour. Of the latter varieties the Azalea-flowered, Lady Albemarle and Duchess of Albany are some of the best for the garden.

*Godetia. Flowers of this easily grown hardy annual.*

**GODPARENT.** Alternatively known as sponsors, these are the persons who, when a child is baptized, make certain promises on its behalf and undertake that it shall be taught the Christian faith. Godparents exist in the Church of England, the Roman Catholic Church and the Lutheran Church, but not among the Presbyterians, Wesleyans, and other bodies. The Church of England ordains that each male child shall have at least two godfathers and one godmother, and each female child two godmothers and one godfather.

**GOFFERING.** This is a laundry process, applied as a finish to lace, cambric, and embroidery frills and producing a fluted effect. It is used mainly for frilled pillowcases and muslin curtains, servants' caps and apron borders.

The goffering irons are made in various sizes for coarse or fine needs, ranging between wide cambric and embroidery frills to tiny Valenciennes or other lace borders gathered, insufficiently full for goffering. The irons must be kept very clean and must not be used too hot. On the other hand, if not hot enough they will not produce the fluting. The temperature should be tested with clean white paper.

In practice one arm of the iron is slipped under the material and the other is brought over the top, pressure and a slight turn to the right producing the required result. Frills that are set in groups of pleats need ironing instead of goffering. *See* Laundry.

*Goffering Irons.*

#### **GOITRE: Cause and Cure.**

Derbyshire neck, or goitre is an enlargement of the thyroid gland. It is commoner among women than among men, and cases have been associated with the

drinking of limestone water. The patient should remove to another district if this is feasible. Otherwise all drinking water must be boiled, as the disease is due perhaps to some poison or germ in the water.

The development of a simple goitre has some relation to the supply of iodine to the tissues of the body. The secretion of the thyroid gland contains an organic preparation of iodine, and the most obvious explanation of a simple goitre is that it represents an increased effort to maintain or increase the supply of iodine to the tissues. One method of preventing the disease is to give small doses of iodine regularly. The administration of thyroid extract has proved successful in some cases, but this powerful drug should never be used except under medical observation. *See* Exophthalmic Goitre; Gland.

**GOLD: Marks and Qualities.** It is compulsory for certain articles of gold to bear a hall-mark if they are manufactured and offered for sale in the United Kingdom. The chief marks of the Goldsmiths' Hall for gold wares made in England is a lion followed by other letters or marks representing the particular year in which the hall-mark was applied, and the initials or registered trade mark of the firm responsible for the manufacture of the article. The principal marks of the Birmingham Assay Office are an anchor followed by the marks which indicate the quality, the year of manufacture, and the maker.

The different qualities of gold that are hallmarked are 9 carat, 15 carat, and 18 carat. They are distinguished by the figures on the articles, as follows:

18 carat gold	.750
15 carat „	.625
9carat „	.375

The higher qualities of gold are considerably softer, consequently articles which have to withstand hard wear are best made in the lower qualities. A 9 carat or 15 carat gold watch albert will wear considerably longer than one of 18 carat or 22 carat. In regard to gold cigarette cases these will wear better in 9 carat than in 18 carat.

When disposing of old gold it will be found useful in calculating the price per oz, that ought to be obtained to take the average price of gold at 3/6 or 3/9 per carat, and multiply this amount by the quality of the gold, 9 carat, 15 carat, 18 carat, or 22 carat, as the case may be. For example, old 18 carat gold ought to realize 18 times 3/6 or 3/9, according to the market price. A small loss has to be incurred in the melting of old gold by the refiners.

Gold jewelry of the quality 15 carats and upwards will wear a soft yellow colour throughout, but lower qualities are usually gilded. When new, these are the same colour as 15 carat or 18 carat, but after being in wear the gilding will wear off and the gold will have more of a reddish tint or bright copper colour. This is not in any way detrimental, but it frequently causes the

owner to conclude that the article is not real gold. In the alloying of lower qualities of gold the base metal has the effect of making it a reddish yellow colour, and it frequently happens that the colour of 9 carat gold appears like bright copper before it is gilded and polished.

For cleaning gold there is nothing better than a paste of water and ordinary powdered rouge. This is brushed on to the article, or if the ornament has a smooth surface the paste can be applied with an ordinary leather. A bright polish is obtained quickly. If any of the paste remains it can be removed with a damp brush. No moist rouge paste should ever be allowed to come in contact with any stones such as pearls, turquoises, etc., which might be set in an article of jewelry; nor should any water or moisture be applied to any such articles, as this would discolour pearls or turquoises. For cleaning gold, jewelry, or ornaments set with stones other than diamonds, it is essential that a stiff brush with dry powdered chalk should be used. *See Brooch; Carat; Jewelry; Ring.*

**GOLDEN BUCK.** Cheese and poached eggs are the main ingredients in this American recipe. To make it, put  $\frac{1}{2}$  pint of milk into an enamelled saucepan over the fire, and when it boils add  $\frac{1}{2}$  lb. of grated cheese,  $\frac{1}{2}$  teaspoonful of salt, and  $\frac{1}{4}$  of pepper. Stir the whole until the cheese has melted, and with it coat 6 rounds of hot buttered toast. Place a poached egg on the top of each, dust them with a little pepper, and serve them at once.

**GOLDEN DROP.** The name of golden drop is borne by a small family of hardy perennials known technically as *Onosma*. They are excellent for the rock garden in thoroughly drained sandy loam, and may be propagated by seed or by cuttings. The plants should be covered in winter with pieces of glass, raised 2 or 3 in. above the plants by wire pegs. The favourite kind is *Onosma taurica* (echioides), 8-10 in., with golden yellow flowers in summer.

Golden drop is also the name of one of the best known varieties of plum. *See Plum.*

**GOLDEN EYE.** There are about a dozen British species of the delicate four-winged insect variously known as golden eye, lacewing-fly, and stink-fly, but they bear so close a likeness one to another that the differences are evident only to experts. In the larval stage they feed entirely upon other insects, and these are usually some species of aphids or their near relations, which they suck dry, certain species piling up the empty skins on their back.

The eggs on their hair-like stalks may be seen standing like a cluster of pins on a rose-leaf, and should be respected always. Each larva accounts for many aphids every day, as a few minutes' observation of its method will demonstrate. At the end of its service it spins an egg-shaped cocoon in which it passes the winter; emerging next spring as an active pupa, it at once assumes the winged form. All the species should

be treated as friends.

**Golden Feather.** *See Feverfew.*

**GOLDEN FERN.** So called because the undersides of the fronds are covered with a golden, powdery substance. *Gymnogramme* is the chief kind. *See Fern; Gymnogramme.*

**GOLDEN PUDDING.** Wash  $\frac{1}{4}$  lb sultanas, dry them thoroughly in a cloth, and remove the stalks. Mix  $\frac{1}{2}$  a level teaspoonful of bicarbonate of soda with 6 oz. flour, and sieve them into a basin. To these add 6 oz. breadcrumbs, 6 oz. chopped suet, the fruit and a little grated nutmeg, and mix all well.

Whisk together a beaten egg and 6 oz. golden syrup and stir them into the dry ingredients, with sufficient milk and water to make a fairly soft dough. Turn this into a greased basin, cover it with a greased paper and a floured pudding cloth, and steam it for  $2\frac{1}{2}$ -3 hours.

**GOLDEN ROD.** A vigorous, hardy, herbaceous perennial which bears showy yellow flowers in late summer and early autumn. It flourishes in ordinary soil, in sunny or shady places, and spreads quickly. Propagation is effected by division either in autumn or spring. The best is *solidago Golden Wings*. 5 feet high.

*Golden Rod. Flower sprays of a hardy perennial which is suited to a large garden.*

**GOLDEN SAUCE.**

This sauce is made by boiling together for 5 min. 1 gill golden syrup,  $\frac{1}{2}$  gill water, and a tablespoonful of lemon juice.

**GOLDEN WEDDING.** This term is applied to the completion by both parties of 50 years of married life. Custom decrees that presents given on such occasions shall be of gold.

**GOLD FISH.** As a rule this beautiful carp is kept in a relatively small glass bowl, where its lidless eyes cannot escape from the constant glare of sunlight or electric light, and where it is expected to thrive with little or no food. It should be kept only in ornamental ponds or in aquaria proportioned to its size, with growing water plants which will afford it shade and partial food. Other food may include bloodworms, very small earthworms, and crumbled biscuit. Any unconsumed food should be removed. If gold fish are kept in a pond the latter should have some protection from

frost in winter, a few boards laid across one end being usually sufficient. *See Aquarium.*

**GOLD LACE.** Fancy gold lace made in a manner similar to silk or cotton lace has been used as a trimming since ancient times, and there are periodical revivals of fashion for the article. Such lace need not be thrown away when tarnished. The original colour can often be restored by brushing the lace gently with a soft brush dipped in methylated spirit; the work is made much easier by first tacking the lace down upon calico.

An alternative method of freshening gold or gold and silk lace is to soak it overnight in weak acetic acid or even in white vinegar. The lace should then be gently washed in tepid water with plenty of good soap, and it may be dried by pressing it lightly between soft cotton cloths. If it is desired to stiffen the lace after washing, a dip into a weak solution of clear white gum arabic will give satisfactory results.

**GOLD-TAIL MOTH.** In the southern and middle districts of England the caterpillars of the gold-tail moth are a pest. Feeding naturally upon hawthorn and various forest trees, they show a fondness also for pear, apple and plum trees, likewise roses. The moth is a beautiful creature, with pure white satiny wings which, in the female, have a spread of  $1\frac{3}{4}$  in. The male is smaller and his forewings have a black spot, sometimes two spots, near the hind margin.

The body ends in a fluffy tuft of yellow, which the female uses for thatching her batch of eggs. These are laid in July or August, and soon hatch; the young caterpillars spin a web at the forking of two twigs in which they rest for the winter. In spring they come out to feed. They are black in colour with a bright red stripe along the back divided by a thin black line: and there are tufts of fine black and grey hairs. Late in May it spins a cocoon. The moth emerges in July or the end of June.

The gold-tail moth should be looked for in July, when it will be found resting quietly all day on leaves. The winter nests of the caterpillars, usually not far apart, may be seen on the bare twigs, and the awakened caterpillars may be seen sunning themselves on these nests in spring. Hand-picking and destruction is employed in either case.

The very similar brown-tail moth is restricted in Britain almost to coast districts in Kent and Sussex. *See Insecticide.*

**GOLF, MIDGET.** Within recent years great interest has been developed in so-called Midget Golf, which strictly is not a game of golf at all and bears only the remotest relationship to golf proper. In America particularly Midget Golf had assumed by 1930 the proportions of a national craze and millions of money were invested in Midget Golf courses for public entertainment. The game consists entirely of hitting an ordinary golf ball with an ordinary putter into a variety of holes, the approach to which is made difficult by all sorts of ingenious contrivances.

To those unfamiliar with the game the illustrations which we give will explain it sufficiently. In most cases the ball is driven up a short incline, passes through a small opening, thence down into the scoring hole, usually placed in a difficult position. The complete set of holes may be either 9 or 18, the 5 which we illustrate being selected from a set of 9. The obstacles can be laid down in any large room or on a turf lawn and the player has only to putt the ball into the hole as best he can. The one that takes the lowest number of strokes at each hole and has the lowest aggregate of strokes for the course is the winner.

Many manufacturers have put on the market ingenious Midget Golf sets either constructed of wood or in the cheaper variety of stout strawboards, painted and decorated attractively. Such sets can be obtained at all sorts of prices, but any handyman can construct them quite successfully for himself, and persons of inventive mind can very quickly improvise a set suitable for indoor use, as there is no limit to the devices for making entry to each hole difficult.

Much amusement and a good deal of exhilaration can be obtained from playing at Midget Golf, which is not to be confounded with Miniature Golf. The latter term describes those small golf courses often to be found associated with residential country hotels. They are laid out like ordinary golf courses, but designed for approaching the green by means of a mashie, and they are, of course, outside the consideration of the ordinary householder, who at most is likely to be able to turn some portion of his garden into a temporary Midget golf course fitted with obstacle holes somewhat on the lines of those here illustrated. *See Clock Golf.*

*Golf: the Midget game. Five pieces, selected from a set of nine, showing various hazard in this amusing game. Midget golf*

*can be played either indoors or on a lawn. (Courtesy of A. W. Gamage, Ltd.)*

**GOLOSHES.** Waterproof rubber shoes made to wear over ordinary boots or shoes in wet weather are known as goloshes. Their chief feature is that they have

no fastenings, but their elastic tendency allows them to be pulled over the shoe, to which they fit closely. They can be obtained in various sizes, and are hard-wearing if treated with care, and require only an occasional rubbing with a damp flannel to keep them clean. *See Rubber.*

**GONG:** For Household Use. There is one principal type of gong, and from it most of the existing varieties have developed. A round, smooth piece of metal is hung in or to a frame, and is provided with a beater, for which there is a resting place somewhere on the piece. The beater takes the form of a stick or bar, having a ball of some soft material, covered with leather or cloth, at the end that is used for striking.

One type of gong hangs in a heavy frame of oak or other hardwood; the frame, a square one, standing on the ground. A variant of this has an iron frame, while other metals may be used for them. Smaller gongs of the same type are made to stand on tables or other elevations, and are also suitable for use in the dining room.

**GONORRHOEA.** This disease is very contagious, and may be contracted indirectly from towels, sponges, clothing, etc. Symptoms usually appear on the third or fourth day after exposure to infection, though it may be rather earlier, or not for 7 or 8 days. The result of the widespread misconception as to the seriousness of the disorder is that too frequently proper medical advice is not obtained, or if a doctor is consulted his directions are not carried out properly. No person who contracts the disease should be content until his doctor, after appropriate tests, is able to assure him that he is clear of infection. Vaccines have proved very beneficial in some of the cases of joint affection.

**GOOD KING HENRY.** The useful vegetable (chenopodium) popularly known as Good King Henry has various localized names, including wild spinach and perennial goose foot. The plant has two uses, as spinach by gathering its leaves, or as asparagus by earthing up the shoots.

Seed may be sown 1 in. deep in drills 18 in. apart during April, thinning seedlings out to 9 in. in May. *See Asparagus.*

**GOOSE.** Anyone owning grass land or living near a common will find it profitable to keep geese, as, being persistent grazers, they need little else in the way of food. Swimming water is desirable when breeding.

Their housing is quite a simple matter, any shed or outbuilding sufficing so long as the roof and walls are sound and the floor dry. The floor must be covered with rough-cut litter to form bedding material. The goose usually lays its eggs in rough nests in the corners of its house, the bird following her wild protective instinct by covering her egg with litter when she vacates the nest after laying. In breeding, well-grown geese are usually mated with a well-matured gander, and hatching may either be effected by a goose or a hen. The former, which will only sit on the nest she is accustomed to lay

in, may be entrusted with from 10 to 12 eggs, but if a hen is used she will not be able to cover more than four. The period of incubation varies from 28 to 30 days.

Goslings are the easiest to rear of all poultry. Their first food should consist of hard-boiled egg, chopped up finely and mixed with biscuit meal, to which a little water or skim milk is added to moisten it. After a couple of days the egg may be discontinued and the birds placed upon a cheaper and plainer diet.

Wheat is a most useful food for goslings, but it should be given scalded, not raw. A good method is to scald it for some hours, drying it off with ground oats or barley-meal. Ground oats, barley-meal, and toppings are all useful foods, either singly or mixed in equal proportions. When the goslings are eight to ten weeks old whole grain may be given, preferably wheat, and some bone-meal should be added to the food. Green food, too, is necessary until they can forage for themselves.

To fatten geese for Christmas they should be confined about a month beforehand to a shed, preferably one with an open front covered with wire netting, and fed liberally on a diet consisting of barley-meal or Sussex ground oats for soft food and barley or other good grain at night, greenstuff being supplied liberally. The goose is a long-lived bird, not arriving at maturity until its third year, and often reaching the age of thirty, but its period of usefulness does not extend beyond eight years.

Geese will continue to produce eggs profitably until an advanced age, and instances are known of geese 19 years old which still continued to lay an average of 55 eggs each per year. For hatching purposes the eggs of mature birds are more reliable than those of young stock.

**How to Cook.** The best way of cooking a goose is to roast it; but geese are also braised. To roast one, prepare it as for duck, singe it thoroughly, and then fill it from the tail end with sage and onion stuffing. Fold the skin over the opening and keep it in place with a small skewer. Turn the flap of skin at the neck under the body and fasten that in a similar manner. Truss it in the same way as a duck, tie a piece of greased paper over the breast, and roast it before a clear fire or in a quick oven, keeping it well basted. About ½ hour before the bird is cooked take off the paper so that the breast may brown. A medium-sized bird should take from 1½—2 hours. When it is ready for serving, take out all the skewers, lift it on to a hot dish, and hand with it some good gravy and apple sauce.

To braise a goose, prepare and truss the bird as for roasting, and dust it over with a little flour. Melt 2 oz. margarine or bacon fat in a saucepan, and when it is hot put in the goose and brown it all over. Add a carrot, 1 or 2 sticks of celery, a sliced onion, a bunch of herbs, 1 gill white wine, 10 peppercorns, and a little salt, and cook the whole for a few minutes until the

wine is reduced by half. Pour in enough stock to cover half of the goose, and cook over slow heat.

*Goose. Left, goose of the Emden breed, very popular in England. Right, dark grey Toulouse goose.*

The time taken in cooking depends upon the age and size of the bird, but from 2-2½ hours is usually required. Baste the goose occasionally with the stock, and when it is ready turn it on to a hot dish. Pour the liquid into a smaller pan, reduce it, and when it is of a rich brown colour skim it, pour a little round the goose, and serve the remainder in a sauceboat. Apple or cranberry sauce should accompany braised goose. *See Carving; Duck; Fowl; Poultry.*

**GOOSE: The Game.** Known as the royal game of goose, this is sometimes called the race game. To play it the figure of a goose should be drawn upon a piece of paper and divided into 63 sections, which are numbered. If desired, any other number can be chosen, but 63 is the usual figure. A draught-board or any piece of paper can be used instead of a goose. A pair of dice and a dice box are also necessary, but no particular number of players is needed.

Each player has a counter. In turn each rattles the dice, and according to the number thrown he moves his counter along the goose. The object of the game consists in exactly reaching the 63rd partition, and the player who does this first wins. For instance, if a player has reached the 56th partition he must throw 7 to finish. If he throws more, e.g. 9, he must go back 2, and this continues until he secures the number that carries him exactly into the 63rd division.

### GOOSEBERRIES FROM GARDEN TO TABLE The Cultivation and Cooking of this Useful Fruit

For other information on the subject of fruit culture the reader is referred to the articles *Fruit; Grafting; Kitchen Garden Pruning*; and those on other fruits, e.g. *Apple Currant*. See further *Bottling; Insecticide; Jam; Spraying*; and the entries on *Magpie Moth* and other pests.

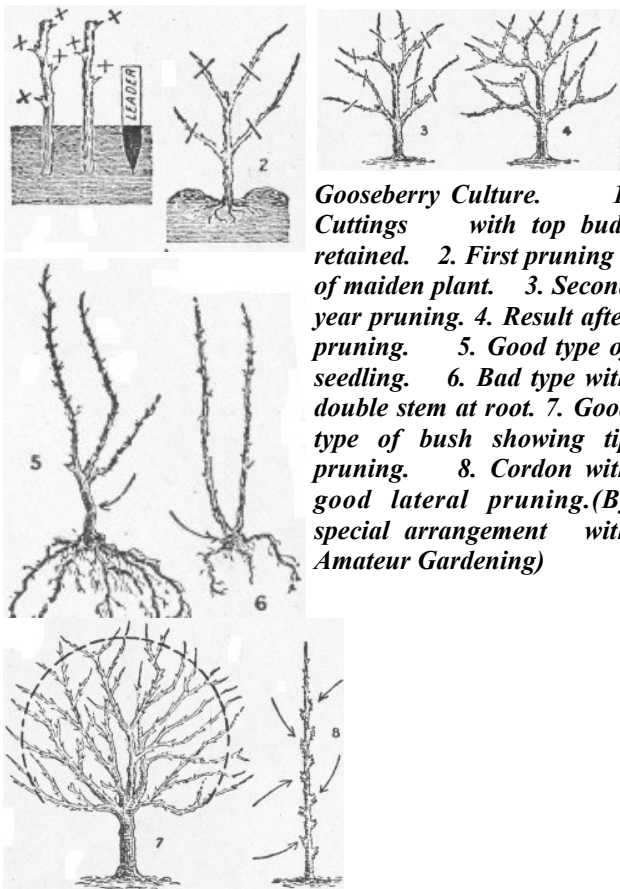

This is the most useful of the bush fruits, for under fair treatment it crops well and regularly, and the fruits are valuable both when green and ripe. Botanically it

belongs to the same genus or plant group as the currants (*ribes*); its botanical name is *Ribes grossularia*.

The gooseberry nourishes in ordinary well-tilled land which is kept in a fertile state by adequate manuring. The bush form is the most profitable, but the single, double and treble cordons are useful for planting alongside a walk in the kitchen garden; they bear exceptionally fine fruits in limited numbers, and in addition the bushes are easily and conveniently managed.

The best time to plant is in November, but planting may be done at any time in mild weather between October and mid-March. The bushes ought to be set at 5 feet apart each way. The uppermost roots need not be covered with more than 2 or 3 inches of soil. An annual top-dressing of stable or farmyard manure in February is beneficial.

Pruning is an important detail of management. Amateurs often make the mistake of pruning the bushes too severely, with the result that growth is vigorous but the crops are poor. Pruning should take the form of thinning out rather than severe cutting back. The branches ought to be so far apart that the hand can be passed between them conveniently, and to ensure this it is necessary to cut out shoots that tend to crowd the main branches. Parts of the old branches can often be cut out with advantage to make room for young shoots.

*Gooseberry Culture. 1. Cuttings with top buds retained. 2. First pruning of maiden plant. 3. Second year pruning. 4. Result after pruning. 5. Good type of seedling. 6. Bad type with double stem at root. 7. Good type of bush showing tip pruning. 8. Cordon with good lateral pruning. (By special arrangement with Amateur Gardening)*

The tips of the branches ought to be cut off, and branches which are so low down that the fruits would

be spoilt by soil splashed up during rainy weather should be removed. The ideal gooseberry bush is one with a stem 8 or 9 inches high. After thinning out is finished the remaining side shoots should be shortened to within two buds of the base of the past summer's growth. It is usual to deter the pruning of gooseberry bushes and cordons until towards the end of February, because the buds are so liable to be damaged by birds. In many gardens it is in fact necessary to net the bushes. Scattering a mixture of soot and lime over the branches affords some protection, so also does the practice of tying the branches loosely together.

The pruning of cordon gooseberries is perfectly simple, for it consists merely in shortening the side shoots to within two buds of the base of the past summer's growth. The leading shoots, those which extend the branches, are pruned so as to leave about 8 inches of the past year's growth.

Cuttings provide a simple way of increasing gooseberries; pieces of the previous summer's shoots 8 to 10 inches long are inserted out of doors in October or November, a small straight-backed trench is dug out, sand is scattered along the bottom and the cuttings are set at 6 inches apart, at least half each cutting being beneath the soil. All except three or four buds at the tops of the cuttings should be cut out.

These are some of the best varieties, of goose berries with large fruits: Red: Crown Bob, Lancashire Lad, Whinham's Industry; Green: Plunder; White: Careless, Shiner. Yellow: Keepsake, Leveller. With small fruits: Red Ironmonger (first-rate for jam), Keen's Seedling, Warrington; Green: Langley Gage, Green Gascoigne; Yellow: Golden Gem, Yellow Sulphur; White: Whitesmith.

*Gooseberry. Fruit of Criterion variety.*

**How to Cook.** In cookery, the gooseberry is employed in a variety of ways, pie-making, stewing, and bottling being among the most common. It is used for making jam, wine, chutney, and many different kinds of sweets, including compotes, jellies, flans, puddings, etc. The amount of sugar required depends almost entirely upon the kind of gooseberries used, green, unripe ones naturally demanding more than the riper fruit. Directions for bottling gooseberries will be found in the general article on fruit bottling; goosebeny recipes are dealt with under their respective headings.

Gooseberries for use as dessert may be either red or golden, the latter being generally preferred. There are hairy and smooth, varying from the size of a cherry to that of a small plum. For all ordinary cooking purposes, unripe green gooseberries are undoubtedly the best sorts to employ.

To stew gooseberries, top and tail them and wash them if necessary, then put them into an enamelled saucepan with 3 tablespoonfuls of sugar to every pint of the fruit, and just cover them with water. Let them boil gently until tender but unbroken, and serve them, hot or cold, with custard.

**Gooseberry Amber.** This sweet is made by melting 2 oz. of butter in a saucepan over the fire, and then adding to it 1 lb. of trimmed and washed gooseberries and  $\frac{1}{4}$  lb. castor sugar. Let these cook gently until the fruit is reduced to a soft, thick mass, then stir in 1 oz. breadcrumbs previously rubbed through a wire sieve and beat in well the yolks of 3 eggs. Turn the whole in a buttered pie-dish.

Bake the mixture in a moderate oven for about  $\frac{1}{2}$  hour or until it seems set, then beat up the whites of the eggs to a very stiff froth, adding lightly to them 3 level tablespoonfuls of castor sugar and a few drops of vanilla essence. Heap this meringue roughly all over the top, and sprinkle a little more castor sugar over all. Put the dish in the coolest part of the oven, and let it remain there until its contents are crisp and pale brown in colour. Serve the sweet at once.

**Gooseberry Chutney.** Gooseberry chutney is made by chopping finely about 1 quart green gooseberries,  $\frac{3}{4}$  lb. stoned raisins and 6 oz. onion. Put these into an enamel pan, with  $\frac{1}{2}$  lb. brown sugar, 2 tablespoonfuls mustard seed, 1 quart vinegar,  $\frac{1}{2}$  saltspoonful turmeric. 1 good pinch cayenne, 1 tablespoonful ground ginger, and 2 small tablespoonfuls salt; then heat the whole slowly, and keep it boiling gently but steadily for 1 hour.

The chutney may be strained through a coarse sieve or left unstrained, and when cold should be put into clean, dry jars, and corked and tied down tightly. It improves if kept for a time.

**Gooseberry Cream.** To make this sweet, take about 1 lb. or  $1\frac{1}{2}$  lb. gooseberries, top and tail them, and put them into a saucepan with  $\frac{1}{2}$  pint water and 4 oz. castor sugar. When the fruit is soft rub it through a hair sieve and add a squeeze of lemon juice. Then melt  $\frac{1}{4}$  oz. gelatine in two tablespoonfuls of water and stir this into the gooseberry purée. When this is quite cold, whip  $\frac{1}{2}$  pint cream and mix it lightly in. Colour with a little green colouring and put into a mould to set.

**Gooseberry Fool.** Top and tail 2 lb. gooseberries, wash them in cold water, then put them in a pan with  $\frac{3}{4}$  lb. sugar and 1 gill of water. Boil gently, and if the saucepan gets too dry, add a little more water, but as little as possible. When the gooseberries are soft rub them through a wire sieve and measure the pulp. To each pint allow  $\frac{1}{2}$  pint boiled custard. Mix pulp and custard well together, sweeten to taste, and serve it in a glass dish or in custard glasses, with whipped cream on

top. Either cream or milk can be mixed with the gooseberries in place of custard.

**Gooseberry Jam.** To every pound of green fruit used in making this jam allow the same quantity of sugar and  $\frac{1}{2}$  pint of water. Put the sugar and water into a pan over the fire, and boil them for  $\frac{1}{4}$  hour; then skim the syrup and add the gooseberries. Let the whole simmer gently for about  $\frac{3}{4}$  hour, stirring all the time, and then test the jam on a plate. When it is done, pour it into jars and tie them down immediately.

**Gooseberry Jelly.** To make this, take two quarts of green gooseberries, which should be washed, topped and stalked. Two quarts will make a pint of juice, so if more is required more goose berries can be taken. Put them in a preserving pan and just cover them with cold water. Bring them to the boil and simmer them until they are broken and pulpy, when they should be strained through a jelly bag or a clean cloth tied on to the legs of an inverted chair. After this has been done, they should be left to drip overnight into a bowl.

The juice should be measured and put into a clean jar with 1 lb. of loaf sugar to each pint. Stir it until the sugar has melted; then boil it fast for about 20 minutes, until the jelly sets when tested. Keep it well skimmed, afterwards putting it into small pots, which should be covered in the same way as jam jars.

**Gooseberry Pudding.** A boiled gooseberry pudding large enough for 5 persons can be made by sieving together  $\frac{1}{2}$  lb of flour,  $\frac{1}{2}$  teaspoonful of baking-powder, and a little less than that quantity of salt. Then add 4 oz. of finely chopped beef suet and mix the whole to a stiff paste with some cold water. Cut off two-thirds of the pastry, roll it out, and with it line a greased pudding basin. Wash about 1 pint of gooseberries, then top and tail them.

When the basin is half-full of fruit, add 2 or 3 tablespoonfuls of brown sugar, then put in the remainder of the gooseberries, and lastly enough water to half-fill the basin. Roll out the remaining piece of pastry to fit the top of the basin, wet the edges, and then press them together. Cover the pudding with a scalded and floured pudding-cloth, then put the basin in a pan containing plenty of fast-boiling water. Let it boil steadily for 2 hours, adding more boiling water when necessary. When the pudding is cooked, lift the basin out of the pan and let it stand for a minute or two after removing the cloth, so that the steam may escape: then serve it on a hot dish.

**GOOSEBERRY CLUSTER CUP.** This is a disease that affects gooseberry bushes; the fungus forms bright orange patches on the leaves and fruit. The most satisfactory method of arresting its spread is by collecting and burning infected leaves and fruit.

**GOOSEBERRY MILDEW.** The gooseberry plant is attacked by two distinct mildews, the European and the American. The former occasionally attacks red

currant bushes.

The most obvious differences between the two may be summed up as follows: Whereas in the European mildew the fungus occurs as a very delicate mould or mildew on the leaves, the American mildew forms a dense white woolly mould which, though found on the leaves, attacks chiefly the shoots and berries. As the growth of the American mildew continues, the white stage gives place to a light brown woolly phase, and finally to a thin dark brown felted mat, which is very conspicuous on the berries and shoots. This condition is never found in European mildew.

The American mildew is a much more serious danger to the fruit-grower. There are two principal lines of treatment against it: spraying, to prevent and to destroy the white or summer state; and tipping, to eliminate the brown or second stage.

For spring and summer spraying lime-sulphur is the most convenient and satisfactory substance. The strength usually employed is 1 gallon of lime-sulphur to 29 gallons of water. Three, or at least two, sprayings should be given, the first about the first week in April, the others at intervals of three or four weeks.

Tipping consists in the cutting away in autumn of all shoots which show signs of the presence of mildew; they must be burnt. The ground under diseased bushes should be dug over in winter in order to bury the winter spores, and if only a few bushes are grown dead and fallen diseased leaves must be burnt.

It is illegal to sell gooseberry or currant bushes affected with the disease, but the bushes may be sold after notification if all the diseased shoots are cut away. Much of this information is taken from Leaflet 273, published by the Ministry of Agriculture. *See Spraying.*

**GOOSEBERRY MOTH.** This pest, more commonly known as the magpie moth, is very destructive. It is only seen at night, as a rule, and can be easily identified by its creamy body and wings prettily marked with black and white. The parent moth deposits its eggs on both gooseberry and currant bushes, and these hatch out into voracious looper caterpillars, which are spotted black and creamy yellow, and about 1 in. long.

*Gooseberry Moth. Pest destructive to gooseberry bushes. Right, caterpillars attacking young leaves.*

Remedies are forking a generous dressing of fresh lime and soot into the top soil around the bushes in winter, applying a winter wash to the trees at the same time, together with hand-picking of the caterpillars. *See Caterpillar; Fruit.*

Gooseberry Culture. 1. Cuttings with top buds retained. 2. First pruning of maiden plant. 3. Second year pruning. 4. Result after pruning. 5. Good type of seedling. 6. Bad type with double stem at root. 7. Good type of bush showing tip pruning. 8. Cordon with good lateral pruning. (*By special arrangement with Amateur Gardening*)

**GOOSEBERRY SAWFLY.** The sawfly caterpillars devour the leaves and, in a bad attack, strip the bushes completely.

The adult sawflies first appear in April and May. Eggs are laid on the gooseberry leaves, and when the caterpillars are hatched they feed on the leaves. The two methods recommended by the Ministry of Agriculture and Fisheries (Leaflet 30) are hand-picking and spraying. Hand-picking is the simplest method in the case of a few bushes, but it must be done before the colonies of young larvae have scattered over the bush. Some prefer to pick the leaves on which the eggs have been laid.

*Gooseberry Sawfly. Larvae of a destructive insect pest which attacks gooseberry and currant bushes. Right, female adult fly.*

Spraying is thoroughly effective; the chief difficulty lies in the fact that the best washes are poisonous. Lead arsenate, 1 oz. in 1 gallon of water, may be used in the case of an early attack, where it can be applied before the gooseberries have flowered and also after the fruit has been gathered. Hellebore, when fresh, and nicotine are also effective and, though poisonous, do not retain their poisonous qualities for long. They may therefore be used with safety if an interval of three weeks be allowed between the dates of spraying and packing. *See Insecticide; Spraying.*

**GORE.** A gore is a triangular piece of material sewn into a garment to enlarge the lower part when the material is not wide enough to cut the full width required in one piece. These gores are usually added to the lower ends of side seams.

**GORGONZOLA CHEESE.** This is the name of a highly esteemed and exceedingly nutritious Italian cheese, considered by some to be superior to Stilton, which it slightly resembles. It is a round, flat, broad cheese, which when cut should be of a deep yellowish cream colour, with rich green veinings.

**GOSS PORCELAIN.** The china produced by W. H. Goss was made at Stoke-upon-Trent about 1860. The name is sometimes used inaccurately to indicate the products of other heraldic potteries as well. The Goss name is usually but not invariably present, and on more ambitious pieces a rising falcon is used as a mark.

**GOUDA CHEESE.** Flat, with rounded edges, Gouda differs from Edam or Dutch cheese in shape and also in colour, being of a dusky yellow. Its weight varies

from 3 to 15 lb., and some are larger.

**GOUGE.** A gouge is a curved chisel, the blade being curved transversely so as to be trough shaped instead of flat. Paring gouges are ground internally, and are intended for hand planing of grooves. Firmer gouges are ground externally and are used for scooping out timber into hollows. Gouges are made in various widths, but a  $\frac{5}{8}$  in. firmer gouge is a useful size. *See Firmer Gouge.*

*Gouge. Left to right, paring gouge, firmer gouge, front bent carver's gouge, curved gouge.*

**GOURD.** These are deciduous climbing and trailing plants, bearing large fruits of diverse shapes; they are useful for rapidly covering arches, trellises, poles and open fences. They vary from less than 1 oz. in weight to the huge snake cucumber over 4 ft. in. length. Gourds may be grown on raised beds like marrows. The seed is sown in a greenhouse or frame in March, and the seedlings are hardened off and planted out in June in rich soil.

The following list of varieties suggests the many quaintly shaped and marked specimens which can be grown: Turk's cap, bishop's hat, serpent, gooseberry, Hercules' club, gorilla, siphon, half moon, giant's punchbowl. These are large fruiting kinds. Among the smaller sorts are gourds resembling fig, cricket ball, thumb, cherry, hen's egg, pear, bottle and orange. *See Pumpkin.*

*Gourd. Calabash gourd growing in a greenhouse. (Courtesy of Amateur Gardening)*

**GOUT.** Gout is a disorder of metabolism in which uric acid accumulates in the blood and tissues and causes various manifestations.

The tendency to gout is often inherited and may be transmitted through females who show no sign of the disease themselves. Other causes are an excessive consumption of rich food and of wines. A regular and copious consumption of malt liquor, even when the

food supply is spare, results in what is called poor man's gout. Sedentary habits predispose, especially in conjunction with other causes.

An acute attack of gout is due to the deposition of crystals of biurate of sodium in the cartilages of a joint. A poor circulation in the part, some slight injury or something similar may be the exciting factor, but the excess of uric acid in the blood and tissues, which is the essential feature of gout, alone makes the attack possible. The painful joint should be treated by heat in some form; cold applications are dangerous. The best drug for relieving the pain is colchicum, either the wine or the tincture, in doses of 20 to 30 minims every four hours, until the pain ceases; but colchicum should only be used on medical advice, as it may cause depression. Water or gruel containing potassium bicarbonate should be drunk freely. On the night of the attack it is as well to take a mercurial purge, say 3 or 4 grains of calomel, and follow this up with a dose of Epsom salts in the morning. The diet should be restricted to milk and barley water unless other directions are given.

In chronic gout more joints are affected and there is a greater tendency to deposits in the soft parts about the joints and elsewhere, such deposits, or tophi, sometimes ulcerating through the skin. Because of their white, chalky appearance these deposits are sometimes called chalk-stones; they do not, however, consist of chalk, but of sodium urate. In chronic gout there is a tendency to arteriosclerosis. The patient often has a sallow complexion and suffers from dyspepsia.

A person who is of the gouty habit should be moderate in eating, avoiding fats and rich food, meat extracts, sauces, liver, kidney and sweetbreads, and restricting red meat, starchy foods and sugar. Fresh fruit and vegetables may be taken, but, as a rule, tomatoes, cucumber, rhubarb, bananas, gooseberries, currants and strawberries are unsuitable. Potatoes may generally be allowed. Asparagus and beans and other pulses should be taken in small quantities only. Alcohol is best avoided altogether. Water should be taken freely.

An active open-air life should be adopted. Clothing should be warm and the skin should be kept active by regular baths and brisk friction with a towel.

When attacks have occurred, or there are manifestations of irregular gout, it may be worth while to have a spa treatment at Bath, Buxton, Harrogate, Aix-les-Bains, Contrexéville, Karlsbad, Homburg or elsewhere.

**GOVERNESS.** A nursery governess is one who gives the children simple instruction in addition to looking after them generally. Nursery governesses are almost always resident, but other governesses may be either resident or daily. Sometimes two or more families combine to engage a governess for their children. Most governesses are expected to supervise the children's recreation or some of it, but the extent and nature of this duty should be clearly stated on engagement.

Unless she is able to secure exemption, a governess must be insured under the national health insurance scheme. Governesses can be engaged through the

advertisement columns of the newspapers and through some of the teaching agencies in London and elsewhere. Nursery governesses can be secured sometimes through the ordinary registry offices. The remuneration, which varies considerably according to duties and capabilities, is usually paid by the month. *See Insurance.*

**GOVERNOR: Of an Engine.** This is a device for maintaining a constant speed of rotation of the crankshaft under variable loads. It derives its motion from some rotating part of the engine, and is so devised that when the speed of the engine increases the governor reduces the power supply, and augments it when the speed decreases. They are used on gas, oil, and petrol engines as well as upon steam engines.

*Governor for regulating the speed of an engine.*

Most governors for steam engines follow the original ball governor of James Watt, and a diagram of a modern example is given. *S* is a vertical shaft, rotated by means of bevel gearing, and a belt from some convenient part of the engine. Four links, *L L L L*, connect two metal balls, *B B*, with the top of *S* and with a weight, *W*, able to move freely up and down *S*. When the engine speed increases beyond that at which the governor is set to function, the fly-balls, *B B*, swing out, raise the weight, *W*, and a collar connected by lever *D* to the throttle, and close or partly close the throttle, thus cutting off the supply of steam and reducing the engine speed.

The governor fitted to a clockwork mechanism (e.g. a gramophone motor), brings a friction brake into operation when the fly weights swing out, thus checking the speed.

**GRAFTING: For the Gardener.** This useful gardening operation is best carried out late in March and in April, during mild, dull weather, when the sap is running freely. The graft or scion is a piece of branch of the previous summer's growth cut from a tree of the variety it is desired to perpetuate; the stock is the tree on which the graft or scion is inserted.

Grafting depends for its success on fixing a scion on the stock in such a way that the cambium layers (the seat of growth), which lie immediately beneath the bark, are in contact. It is necessary that the scions or grafts be in a less advanced state of growth than the stock and to ensure this it is usual to cut them off the trees in winter, tie them in small bundles, and half bury them in the soil of a shady border.

There are various forms of grafting. Crown or rind

grafting is the most useful, for it enables the gardener to refurnish old trees of worthless varieties with fresh branches of good varieties.

**Whip Grafting.** 1. Stock suitably prepared: *a*, correct cut; *b*, seat for tongue of scion. 2. Scion: *a*, tongue. 3. Stock and scion fitted together. 4. Same bound together. 5. Whole covered with grafting wax.

**Grafting. Method of crown grafting.**

1. Tree preparation at *a*.

2. Scions: *a*, correct; *b* and *c*, badly prepared. 3. How scions are inserted. 4. Scions bound in position.

6. Section showing raffia binding under wax

5. Final binding with grafting wax.

The branches of the old tree are cut back to within 12 to 18 inches of the base in March. The grafts or scions (cut in winter from a tree of the variety it is wished to increase) should be 8 inches or so long and cut so that each one tapers to a point at the base. Three or four grafts may be inserted in each large branch. The bark of the latter is slit to the same depth as the tapering part of the scion, and is lifted to allow the scion to be pushed down behind it. The scions are then made secure with raffia, and covered with grafting wax or puddled clay to exclude the air. Any shoots which develop on the stock (the branches of the old tree) should be cut off. When, in summer, the grafts or scions

begin to grow, they should be supported with thin sticks to prevent their being blown out in windy weather.

When both stock and scion are of approximately the same width saddle grafting is usually practised. The top of the stock is cut in the form of a wedge and the base of the scion is cut so that it fits over it exactly. The work is completed by tying and covering with grafting wax or clay.

**Grafting Wax.** Wax used for grafting purposes can be bought from seedsmen and others, but if desired it can be made at home from the following recipe:

Tallow	1 part
Beeswax	2 parts
Resin	4 „

These should be melted together and the liquid painted over all the cuts with a brush while it is still hot. *See Apple; Rose.*

**GRAIN: The Measure.** This measure of weight is chiefly used by chemists, although it is also found in avoirdupois and troy weights. In apothecaries weight 20 grains make one scruple, and in avoirdupois weight 7,000 grains go to the lb. The ounce in apothecaries' and troy weights consists of 480 grains.

**GRAIN: In Wood.** The term grain refers generally to the character and size of the growth rings of timber. Beautiful grain is more naturally inherent in some woods than others; some woods depend for their figuring upon the annual rings, others upon the medullary rays, others again upon the juncture of a branch to the trunk.

**Grain.** Fig 1, section of a log showing growth rings and medullary rays.

Fig. 1 represents the section of a log. Every year a growing tree adds a fresh layer to the outside, thus forming a series of concentric rings by which it is usually possible to tell the age of the tree. The outer part or sap-wood is in many woods of a lighter colour and is much more liable to shrink than the heart wood, as it is softer, and contains more moisture. The medullary rays radiating from the centre carry nutriment and occur in every wood but are not always visible; in oak or beech they show strongly, when cut, in the form of white layers which are termed the silver grain, as in Fig. 2. If the ends of a sawn oak log be examined, they can be seen in the form of narrow white lines.

**Fig. 2. Medullary rays showing as white layers.**

The boards should be cut parallel to these rays. Fig. 4 shows a few methods of cutting in this way. D giving the maximum amount of figuring, but it will be obvious that a certain amount of waste occurs between the cuts, so that figured oak is always more expensive than plain. The latter (Fig 3) is cut as in Fig 5. by which method there is no waste: the centre board only will be figured. Fig. 6 shows the difference between two boards cut from the same tree in different places.

Fig. 3. Grain of plain oak.  
Fig. 4. Methods of cutting parallel to rays. Fig. 5. Cutting without waste.

Fig. 6. Difference in grain of two boards from same tree. Fig. 7. Undulations in wood from which a straight board is cut. Fig. 8. Cutting tangentially to rings. Fig. 9. Board cut through fiddle-back mahogany.

A tree never grows perfectly straight, so that when the log is converted into boards the undulations in the direction of the grain occur in the thickness of the wood by reason of the board being cut in a straight line. (Fig. 7) This is the reason why, when planing a piece of wood, parts of it will tear up when planed in a certain direction. These waves or undulations occur with greater frequency in some woods than others. In pine they are sometimes hardly apparent, and in oak are generally large in proportion: in mahogany and sycamore they may appear as fiddle-back. This consists of a series of minute waves in close formation and when polished shows alternate light and dark streaks running across the grain. Fig. 9 shows a board cut through fiddle-back mahogany.

#### How Curl Grain is Obtained

Another well-known variety of grain is that known as curl, which is obtained by cutting the tree at the juncture of a branch. The main direction of the curl usually is curved, and when veneers are cut the two adjoining leaves are almost identical, so that the most beautiful effects are obtainable by matching them. These curls are seldom cut into solid boards, partly because of their comparative rarity and cost, and partly owing to the fact that they are liable to twist and warp, the grain running in almost every direction.

Burrs, burr walnut for instance, are the result of a cut being made through a growth or excrescence produced on certain kinds of trees. These growths are usually the outcome of the attack of fungi and result in the appearance of innumerable small shoots, the whole sometimes growing to a considerable size and yielding large leaves of veneer. They are also to be found on the stumps of coppiced trees.

When a pine log is cut as in Fig. 5 the centre plank does not contain the best figuring, as the rings appear at each side in the form of narrow parallel lines of alternate light and dark stripes. In the outer planks the stripes are wider and have a V-shaped formation, the beauty of which is enhanced by the natural irregularity of growth. A method of cutting for work requiring an attractive appearance is shown in Fig. 8 in which every plank runs tangentially to the rings.

Fig. 10

Fig. 10. Shrinking tendency in a sawn log.

The question of cutting is important for other reasons besides that of figuring. Fig. 10 shows the natural shrinking tendency of a sawn log, so that for work requiring an absolutely reliable surface, only those running diametrically should be used. D, in Fig. 4, is the ideal cutting for this purpose, and as in oak the silver grain is also in evidence, the method is wholly desirable. See Mahogany; Oak Wood. Woodcarving.

#### GRAINING AND MARBLING

##### Suggestions for the Artistic Treatment of Wood Work

This article describes the surface treatment of white woods to simulate oak and other hardwood; it contains also a section on simple marbling. See also Wood and the articles on other forms of ornamentation, e.g. Enamelling; French Polishing; Lacquer; Painting; Varnish.

The process of reproducing the colour and appearance of natural wood by a manipulation of paint in superimposed layers is known as graining, the grain being produced on the paint while it is still wet. Marbling is the corresponding process to simulate marble.

Graining is essentially an art, results being good or bad according to individual ability; success can come only with experience. The essential requirement is that the grainer himself shall be familiar with the

appearance of the natural wood.

The tools required include painters' brushes and combs. The latter are made of steel in various widths, and with varying numbers of teeth to the inch, usually from 6 to 15; others are made of leather, bone and other flexible materials. Old hairdressers' combs may be pressed into service. Leather combs can be made at home from a piece of stout leather, the teeth being cut to shape with a pocket knife. Several sorts of brushes are needed, including a selection of overgrainers, mottlers, and shaders. A first-class badger hair softener is required and should be about 3½ in. wide. A few camel hair, sable, and fitch brushes are necessary for the veining and similar work, together with a bone thumb-plate and a quantity of clean rag.

**Imitating Oak Grain.** The commonest form of graining is that which represents oak, ordinary deal doors being treated in this way. The ground is first prepared by stopping, priming, and undercoating, as if for ordinary paintwork; then the ground colour is applied. The tint must be the lightest that is to show on the finished work. The grounds will be composed of white lead, or other equally good white, stained with yellow ochre, or chrome, applied as ordinary paint, and finished with a slight gloss. The graining colour may be obtained by a mixture of raw umber or other colour, and should contain plenty of driers. It is brushed thoroughly into the door, after the previous coat is quite hard, and should not be applied thickly, but must be worked well in.

*Graining: two stages in preparing a figured oak panel. Left, straight grain worked on the prepared ground. Right, breaking up grain with fine steel comb.*

Apply the graining colour to one of the panels only at the start, having previously studied the style of graining to be copied. Supposing it to be light figured oak, this will require a coarse leather comb to produce the straight part of the grain. Then, next to this, the grain is worked in with a medium toothed steel comb; the combing with this tool is carried about half-way across, producing a series of lines wide apart at the outside and closer at the middle of the panel. With a fine steel comb work over the whole of the surface, with a slightly wavy motion, so as to break up the original straight lines, as the untouched side of the panel is reached, the pressure

on the comb should decrease, and thus subdue the graining. Combing should start at the top and continue in one unbroken stroke to the bottom, keeping an even pressure on the comb, and using the whole width of it. The figure has now to be worked with the aid of a rag wrapped round the thumb, or by the use of the thumb plate, which is wrapped up and used like the finger tip. Perfect mastery of the thumb plate is necessary, using the broad part of the blade to wipe out the highest lights, and the narrow edge to work in the half lights and the finer markings. Treat all of the panels in a similar manner, but vary the grain. The rails and stiles are then grained, but will not call for much figure work as the wood is generally straighter in grain. The badger is used to soften the edges of the graining, and the mottler to soften the veins and to give a more woody appearance to the work. Fine veining can be worked with the veining fitch.

**Knots and Surface Markings.** The final proceeding is the overgraining and shading, the pigment is ground in water, the colour is spread on a palette and diluted with beer. The overgrainer is dipped in beer and the pigment worked into it. The brush ought to work itself into two or three parts; if it does not, it should be combed or worked with the fingers. The colour is applied with a continuous motion from top to bottom. Before the colour is dry work over it with the badger to break up the hard lines. Knots and other surface markings are worked in with the sable pencils and fitches, the whole idea of this part of the work being to enrich the colouring and improve the appearance. A little black or blue can be used sparingly. When the graining is complete the whole surface of the door is varnished.

*Graining: final stages in preparing a figured oak panel. Left, working in the figure with thumb plate. Right, finishing off and softening with the mottler.*

Finely-grained woods may be represented without combs, using brushes only. The grounds are prepared, and the graining colours diluted with beer, the graining

being accomplished with hog hair mottlers, large sash tools, and the fitches and sable pencils. A piece of wash-leather, a sponge and some rag are of assistance, and two or more colours may have to be worked together. The brushes are worked more or less dry, to remove the unwanted colour, as a comb.

Bird's eye maple is grained with the brush, a command of the mottler being necessary. This brush is held so that the bristles separate and break up the straight end; it is held nearly upright, and wiped over the work so that it removes the colour in an undulating manner. Mahogany and walnut require the mottler for the graining colour: the breadth of the veins is varied by altering the pressure of the fingers on the bristles.

**Use Of Transfers.** Graining by means of transfers is a much cheaper method than hand graining, as the one sheet will give several copies of the design.

The transfer is cut slightly larger than the actual size required, placed face downward on a clean dry table, and the back well damped with a half-wet sponge. The paper is allowed to soak for 3 or 4 min. until the graining print begins to have a glossy appearance. The surface of the material to be grained should be damped evenly by means of a sponge and brush, and the transfer placed face downward on the moistened surface, the back being rubbed evenly by the brush. The paper is removed, and a soft paint-brush, or softener, passed over the surface while the latter is still damp.

**Marbling.** The processes of marbling are similar to those that are employed in graining, but as marble is a solid substance the colours employed in its representation must be opaque, and most of the effects have to be obtained by a manipulation of the brush. Two of the finishing stages in the process are illustrated.

*Graining: Stages in marbling wood. Left, wiping the veins with a thumb rag. Right, completing with a feather dipped in colour.*

The ground is worked up and the colourings applied to the surface, the harshness subdued with the badger, and fine veinings worked in with the sable and fitches. The colours may be ordinary artists' colours in collapsible tubes, thinned with turpentine and linseed oil. The colours can be flattened and worked to

represent some classes of marble by rubbing them over lightly with a fine rag moistened with linseed oil.

There are many varieties of marble with numerous colourings and surface veinings, all of which can be reproduced after a preliminary study of the natural material, or of reliable coloured photographic reproductions. The amateur is advised to give a sufficient consideration to them until their appearance becomes quite familiar, and then to attempt the actual work on a trial piece of smooth board.

Marbled work should be finished by varnishing with a clear varnish, as a coloured varnish will never look well; the finished surface must be free from any suggestion of brush marks.

**GRAMME.** A gramme, or gram, is the unit of weight in the metric or decimal system. One gramme is equal to 15.432 grains troy. *See Metric System.*

### **GRAMOPHONES: THEIR CHOICE AND CARE** **Mechanical and Electrical Methods of Sound** **Reproduction Explained.**

This article deals with the various types of instrument and the accessories. A section on Radio-gramophones is followed by one on the construction of a console type cabinet. Consult also the article on Pick-up.

Gramophones may be divided into three main groups according to the style of case or cabinet: portable models, table instruments, and floor cabinets. The method of sound reproduction may be (a) mechanical, or (b) electrical. In the former the movement of the needle as it travels over the track on the record imparts vibration to the metal or mica diaphragm of the sound box; the diaphragm in turn sets up oscillations of varying frequency in the column of air in tone-arm and horn, so that sound-waves are produced. In the electrical pick-up the needle movements produce electrical impulses of varying value in a circuit comprising a low-frequency amplifier and loud speaker.

The mechanism which causes the turntable to rotate may be a clockwork one or an electric motor. To test the quality of a gramophone motor it should be released at varying speeds, with a record on the turntable. A good motor is one which runs evenly, strongly, and without noise. By even running is implied the quality of revolving the turn-table steadily, without jars and tremors; a strong-running motor is one that works vigorously, as though pushing against restraint. A good motor attains the desired speed quickly, and maintains that speed consistently without slackening appreciably towards the end of the spring. The sound box should always be tested by playing a varied selection of records, such as a march, a tenor solo, and an instrumental disk. The results from these records will demonstrate the range and power of the apparatus.

A floor cabinet, apart from its value as a musical

instrument, forms a pleasing addition to the furniture of a room. Both cabinet work and internal fittings require close attention, so that a model may not be purchased in which the quality of the mechanism is sacrificed to provide a handsome exterior. There is no danger of this if one of the well-advertised makes of instruments is chosen.

**Types Of Motor.** A good type of double-spring motor is shown in Fig. 1, the chief parts being indicated as follows: A, main spindle; B, regulating disk and governor; C, winding spindle; D, spring cases; E, winding ratchet. A motor such as this will play the two sides of a 12-in. record with a single winding.

*Gramophone. Fig. 1. Garrard double-spring motor suitable for any gramophone. It is tested to play two sides of a 12-inch record at one winding.*

In many gramophones an electric motor is substituted for one of the usual clockwork type. Connexion is established very simply by plugging in to an electric-light or power socket. Two kinds of electric motor are illustrated, the universal and the inductively driven. The first is suitable for all voltages from 100 to 250, either A.C. or D.C. The second will run on alternating current only, and is supplied for 100-130 or 200-250 volts. Both comprise an automatic stop. The inductively driven motor has no commutator or brushes, and is thus free from sparking, which, in a radio-gramophone, might be liable to cause interference with reproduction.

Whatever style or quality of gramophone an owner may possess, it needs a certain amount of care if it is to do its work efficiently. In particular, the motor requires regular attention, otherwise it may knock, break down, or at least fail to revolve the turntable correctly. The motor should be oiled and cleaned at regular intervals, according to the quantity of work it has to do. The following procedure is recommended where a motor is in need of a thorough cleaning, which, in many cases, is due to the old oil in the spring-boxes becoming dirty and viscid.

Remove the motor from the case by releasing the turntable and the motor-board screws, the spring having first been allowed to run right down. The spring-box or boxes are placed intact in a vessel containing either paraffin, benzine or petrol, to remove all the old lubricant. If benzine or petrol be used, the operation should not be carried on near naked lights, and is best performed in the open air. If the spring-boxes are allowed to soak for about 24 hours, very little of the former lubricant will be left in the coils of the springs. Meanwhile, the other parts of the motor should be cleaned with a paraffin rag.

Then wipe all the parts as dry as possible, using a clean,

non-fluffy cloth. Following this, the spring-boxes are filled with a compound of vaseline and graphite, which may be purchased in a collapsible tube. The easiest way to introduce the compound into the boxes is by raising the cogged plates. The other parts of the motor are treated with a good oil of medium thickness. Light oil should be used for the governor bearings and heavy grease for the cogs. The springs should on no account be removed from their boxes for the purpose of cleaning, except by those who are thoroughly experienced, as it is a difficult task to get them back. When the motor has been assembled and returned to the case, it should be given a good run before the instrument is played, to allow the lubricant to be well distributed.

*Fig. 2. Example of a Garrard induction electric motor for use with A.C. mains. Fig. 3. Garrard Universal motor suitable for A.C. or D.C.*

**The Sound Box.** This part of the apparatus is almost

entirely responsible for the quality of the music, which is reproduced through the vibrations of the diaphragm, usually made of mica or metal. The box, although simple in construction, is necessarily a delicate article, and accordingly it needs careful handling. It should not, for example, be left on the machine when not in use. A good quality sound box rarely needs any adjustments, and if protected from dust, knocks, and harsh treatment generally, it will give good service for a considerable number of years.

Apart from tone, the characteristics of a good box are that the diaphragm is insulated with gaskets, or rings, of good quality rubber; the back of the box fits closely, while the adjustment of the small bar which is attached to the diaphragm is exact, so that the bar does not press upon, nor pull away from, the diaphragm.

*Fig. 4. His Master's Voice table model. Fig. 5, H. M. V. portable model, very useful for out of doors. Fig. 6. H. M. V. acoustic gramophone.*

**Care of Records.** The average record will play quite 100 times without showing appreciable signs of wear. A dustproof case is recommended, as, if records are left exposed to the air when not in use, dust fills the delicate tracks and may destroy the fine tones in reproduction. A flat camel-hair brush also may be employed. It is advisable to brush the baize of the turntable before commencing to play; this baize is a dust-trap which is often overlooked.

Records should be guarded from sudden changes of temperature. The disks should not be left exposed to the direct rays of the sun or within range of the heat of a fire, or they may warp. The turntable should be allowed to reach full speed before the needle is placed on the record, otherwise the first tracks on the rim may become roughened.

**Correct Speed.** The speed at which records are played has a distinct bearing on the quality of the music, and whenever possible a disk should be played at the speed at which it was recorded. In many cases, this speed is noted on the record itself; in others, it will be found mentioned in the catalogue of the firm concerned. Where the speed is not noted anywhere, 78 revolutions per minute is exactly right for modern recordings.

An automatic stop device is incorporated in some motors, and is also obtainable as a separate unit to be fixed to the motor board. It operates in conjunction with a spiral or elliptical "run-off" or finishing groove on the record.

Fibre needles may be recommended to those who like music with a soft, mellow tone. Fibres have the further advantage that they do not wear out the records as metal needles do. Steel needles afford greater satisfaction than fibre ones to those who like loud, brilliant music. Metal needles, excepting the specially prepared, semi-permanent varieties, should never be used more than once.

*Gramophone. Fig. 7. Left: close-up view of its control board, showing automatic record-changer, pick-up, tuning-scale, short wave guide, electric clock, etc.*

### Radio-Gramophones.

These instruments are combined wireless receivers and electrical gramophones, designed either for battery or mains operation. The equipment normally comprises one or more stages of screen-grid high-frequency

amplification, and a detector followed by a low-frequency magnifier. A switch is provided whereby the electrical pick-up can be brought into circuit when required, the apparatus then becoming a straightforward electrical gramophone.

Briefly the method of operation is as follows: With the switch in the position for "radio" the high-frequency stage or stages and the detector are connected by way of the low-frequency magnifier to a sensitive moving-coil loud speaker, the receiver then being employed for the reception of broadcasting in the usual manner. When the switch is placed in the "gramophone" position the high-frequency amplifier is disconnected, and the pick-up is connected in circuit with the low-frequency magnifier of the instrument.

The movements of the pick-up needle in traversing the grooves in the record set up small voltages which are afterwards amplified by the low-frequency magnifier to a strength sufficient to operate the loud speaker.

In the case of "all-mains" radio-gramophones the turntable motor is usually electrically driven, and the total current consumed is comparatively small. Electrical gramophones which incorporate a moving-coil loud speaker possess definite advantages over other types. There are also electric record-players which can be plugged into an existing radio receiver with excellent results.

*Gramophone. Fig. 8. Console gramophone cabinet. Fig. 9. Assembling the main framework. Fig. 10. Sliding the front fret into position. Fig. 11. The horn being fitted into the centre compartment beneath motor board.*

**Easily-made Console Cabinet.** The light cabinet gramophone illustrated in Fig. 8 is constructed from a parcel of "ready to assemble" materials sold by dealers in accessories for home handicrafts. The home worker with few tools and limited time or opportunity for cabinet work, or one who doubts his ability to prepare

his own timber, will find this type of parcel convenient. The idea is applied also to many useful and ornamental articles of furniture, such as bedroom suites, tables, cabinets, etc.

Accessories for the gramophone include a tone-arm, sound box, and horn. Some form of motor will of course be needed, and suitable types are illustrated on page 1003. A good sound box should be purchased, since the performance of the instrument is dependent primarily on this part of the apparatus. The tone-arm also should be chosen with discrimination, and needs to be fitted carefully. It should move quite easily across the record and must be free from shake or joggle. The internal horn may be built up from plywood, but it pays to purchase a scientifically-designed metal amplifier, which is a tapering horn up to 8 or 9 ft. long, folded upon itself to fit into the small compass of the cabinet. Great volume and pure undistorted reproduction are given by this type. The accessories can be had from most local dealers, or the constructor could write to the firm mentioned above for particulars.

All the parts for making the gramophone have been prepared, the surfaces cleaned up and the joints cut. This leaves the amateur merely the work of glueing up and finishing. The main structure is put together with dowelled joints. The first step is to insert dowels in all the holes in the ends of the rails. The rails can then be regarded as having tenons. To simplify the assembling it is advisable to put the two sides together independently, and allow the glue to set before adding the front and back rails. An advantage of this method is that it enables one to treat the sides as complete units, and avoids the necessity of dealing with many joints in one operation.

Fig. 9 shows the two complete sides being put together by the addition of the front and back rails. When the glueing up is finished the work should be tested for squareness, except where the parts are sufficiently wide themselves to ensure the whole being square. A cramp (q.v.) is extremely useful when glueing up, as it ensures tight joints and enables the work to be held firmly whilst the nails are driven in. It is sometimes necessary to put in nails to strengthen the joints, e.g. where wide rails are used with single dowels. The nails then prevent the rails from twisting. Panels and front fret fit in the grooves in the legs. These grooves are outside the rails, so that the panels can be slid in after the main carcass has been put together. Fig. 10 shows the front being put in place.

The bottom rests on the rails, the corners being cut to fit around the legs. Partitions are provided to separate the motor and trumpet space from the record space at the sides. The back is nailed on. The lid consists of an edging made up from moulding, mitred together. A rebate is formed in the top edges, and the top fits in this. An idea of the interior arrangement is given in Fig. 11, which shows the trumpet being placed in the centre compartment. The motor board rests upon the interior divisions. Holes have to be cut in this to enable the motor and other components to be fixed. Their shape and positions depend, of course, upon the motor and

components used. A suitable motor, with all the necessary fittings, may be obtained from a gramophone dealer.

**GRANDFATHER CHAIR.** This term is applied to a type of antique easy chair found dating from the 17th century, and also associated with Sheraton and Chippendale. In the form in which it is now known this chair was evolved from the one that was provided with ear guards as a protection against draughts. They were made of oak and high, narrow back and turned stretcher connecting the turned legs. Later some were made without stretchers, having cabriole legs.

*Grandfather Chair. Chippendale mahogany wing chair covered with tapestry. (Courtesy of Waring & Gillow, Ltd.)*

Grandfather chairs made in Queen Anne's time and style, when this type of chair was at its best, have the graceful curvilinear treatment so frequently found on pieces of that period. At this time they were made mainly of walnut. *See* Armchair: Chair.

## GRANDFATHER CLOCKS: THEIR CASES & WORKS

For Collector, Cabinet Maker and Mechanic

This contribution deals with the subject from the three points of view enumerated above. For related information see Clock; Pendulum, and the various articles dealing with woodworking.

Long-case clocks, or grandfather clocks, as they are called, were first made in England in the early years of the reign of Charles II. The earliest existing ones date from soon after 1660, and those who possess a specimen of earlier date than 1700 are fortunate. Oak was the material first used for the clock case, but soon walnut came into favour for them, and some of the finest examples are in that wood. Marquetry was introduced into some of the earliest pieces, and there are beautiful clocks decorated in that way in the Victoria and Albert Museum and in other collections, both public and private. In some pieces the marquetry is arranged in panels.

The objects of these clocks was to take the swing of the pendulum, which varied a great deal in length, what were called royal pendulums being up to 65 in. long. The earliest long-case clocks went for a day or rather more, i.e. from 24 to 30 hours; but when the royal pendulum appeared, eight-day clocks began to be made, and have remained popular.

It is common to find the dials of early grandfather clocks furnished only with an hour hand, though the

minute hand was introduced about the year 1690. Clocks about this period which have both are invariably of good make and finish. The single hand was sufficient for clock makers who produced ordinary utility work for at least 100 years after the introduction of the long case.

Most of these early clocks had square dials of rather small dimensions, from 9 to 11 in. across. Early in the 18th century an arched top was made, and this coincided with the form of the enclosing case, for grandfather clocks of the reign of Queen Anne had commonly an arched moulding. The arched top to the door of the case also appeared in the early part of the 18th century, and in some early cases a bull's-eye of glass was put into the door to show the pendulum swinging to and fro behind it, as seen in No. 3 below.

A grandfather clock of the period of William III and Mary would be likely to have elaborate inlaid decoration in the door panel, and also in the base. This form of ornamental enrichment was brought from Holland, and commonly consisted of a conventional rendering of tulips, birds, seaweed, and scrolls. Twisted columns flanking the dial indicate a period about 1700 or slightly earlier.

*Grandfather Clock. Left to right: 1. Early 18th cent. red lacquer clock, decorated with Chinese figures, chased brass dial. 2. Late 18th cent. clock with canted corners, crossbanded with manogany, painted dial. 3. Queen Anne clock in walnut case, inlaid with floral marquetry, chased brass dial. ( Courtesy of Gill & Reigate. Ltd.)*

Many cases of grandfather clocks were lacquered from about the reign of Queen Anne, i.e. from 1702 to well on in the 18th. century. Straw coloured lacquer is very rare, red is more frequently seen, and black is commonest. All have Oriental devices in gold. An example is shown in the first illustration.

Chippendale long-case clocks were usually of mahogany and often carved, but his best work was not elaborate, though applied fretwork was seen in spandrils above the arched dial. The horn-shaped top

to the hood is considered typical, and the pillars of the front corners of the case are fluted, often having bases and caps of metal. Sheraton designed long-case clocks with delicate columns standing free of the main structure at each side of the dial; the ornamentation is usually of graceful inlaid work. The introduction of cheap American clocks in the 19th century resulted in the practical extinction of the grandfather clock, except as antiques.

**The Mechanism.** Figs. 1 and 2 show the back and front of the earliest type of grandfather clock, which requires winding every day, a single weight, A, serving both for the going and the striking. In the illustration the two trains of wheels are side by side, but they also may be arranged one behind the other, the striking train being at the back. In some clocks an endless chain is used as shown, and in others a loose mesh rope. Attached to both main-wheel arbors is a deep grooved pulley B with steel spikes set at equal distances, to which the chain or rope grips; the weight hanging on a pulley C supplies the motive power to both trains. The winding is done by the chain or rope. The pulley on the striking mainwheel is loose, with a click attached which works on the arms of the wheel. When the weight is pulling, the click butts against the arm, so pulling the wheel round.

*Grandfather Clock. Figs. 1 and 2. Back and front of earliest type of clock, requiring daily winding. (Courtesy of J. W. Benson. Ltd.)*

There is no centre wheel and pinion in these clocks. The wheels for carrying the hands are geared up to the mainwheel arbor, forming a compound motion work. A large wheel D attached to the mainwheel arbor works into a smaller one (behind G), which carries the minute hand, the protruding square for the latter being lettered E. On the top of the large wheel D is fixed another small wheel, F; this gears into large wheel, G that carries the hour hand, the combination of the four wheels making a 12—1 ratio.

The striking mechanism, in this case, is a locking plate, that is, a disk geared up to make one revolution in 12 hours, and divided off into varying spaces to mark the number of blows to be struck (H). The pins for raising the hammer are driven into the web of the main-wheel J. There are 13 of them, and 78 blows are struck in 12 hours, a ratio of 6-1 from the main-wheel to the locking place.

Pivoted between the plates is a detent K; fixed to it is a short arm which catches on a pin in the wheel geared next to the mainwheel, and locks the striking train. On one end of this is a lever L, which as the hour approaches is raised by a projection on the minute wheel. This lifts the inside lever clear of the locking pin and sets the train in motion, but it is held again in check by a portion of the lever until the minute hand reaches the hour, when the lever drops and the train is free to proceed. The part of the lever in question passes through a slot in the plate (M).

On the back of the detent K is fixed another lever N, which operates on the locking plate. When the striking train is at rest this lever is in one of the slots P. When the clock starts to strike it is lifted out, and as the clocking plate moves forward it holds the lever up until it reaches the next of the slots, which by their varying distances apart regulate the number of blows to be struck when the lever N reaches the slot the lever falls, thus locking the train.

**Eight-day Movement.** In the clock that keeps going for eight days, two weights are used, with gut lines in the older clocks and wire lines in the more modern. One of the latter is illustrated in Figs. 3 and 4, showing back and front respectively. Reference to the eight-day bracket clock movement illustrated under the heading Clocks will show that the grandfather clock differs from the former mainly in that the motive power is derived from weights instead of springs. The timekeeping mechanism and that which operates the striking gear are similar to those of the English bracket clock.

Attached to the mainwheel arbor is a grooved drum A, on to which the line is coiled when the clock is wound up. This is worked with a click and ratchet B, the latter cut on the edge of the drum and the click and spring fastened to the mainwheel C. The winding is done by a key fitting on to the squared part of the arbor D.

The figures show a modern clock movement striking hours and half-hours on a gong. The half-hour striking is controlled by a lever E, which works on a cam on the minute wheel F. At the hour it raises the lever clear of the pin G, and at the half-hour lowers it so that the rack can only use one tooth, striking one blow. There is also a lever H operated by means of an index J on the dial, which shuts off the striking work by holding up the rack at the pin G.

Many clocks are fitted with a calendar showing the day of the month, sometimes by a pointer on the dial; more often there is a slot in the dial through which the date shows, being marked on a circular slide. This slide is operated by a wheel geared into the hour

wheel and making one revolution in 24 hours. On the wheel is a pin or nib that moves the slide.

*Grandfather Clock. Figs. 3 and 4. Back and front views of eight-day clock, showing mechanism. To left of Fig. 3 is the pendulum. (Courtesy of J. W. Benson, Ltd.)*

The phases of the moon are shown on some clocks. The moon is painted or engraved on a toothed disk, which works behind the dial, part of which is cut away to show the phases. There are usually two moons on the

disk, so that as one disappears behind the dial on one side the other starts to rise on the other side, one revolution of the disk giving the period of two moons. Other types of clock chime on gongs, while some play a selection of tunes.

**Making a Clock Case.** A grandfather clock case can be made by the amateur who has some skill in cabinet work. Oak is the correct wood for the Jacobean style of case here illustrated (Figs. 5 to 11), but its choice for the highest class of work has been rare. Oak inlaid with mahogany or walnut and ebony bandings is often met with and, at a later date, kingwood, tulipwood and other fancy woods were introduced. Oak is also found veneered with walnut. Maple and sycamore are sometimes met with, in addition to

rosewood, pearwood and ebony. Oak inlaid ebony and ivory dice or herring-bone if the detail is small, has a very neat effect. A quartered oak treatment with diamond centre is also good.

The shaft or pendulum case may be put in hand for a start, and some attention should be given to the jointing in order to assure a good stiff case, as the part sometimes has to withstand a considerable dead weight strain. The worker should select his movement before cutting the case sides or settling the major dimensions, which depend on the type of mechanism, length of drop for weights, swing of pendulum, etc.

*Grandfather Clock. Fig. 5. Jacobean style clock case in oak. Fig. 6. Upper part. Fig. 7. Mouldings used.*

The length varies, and it is possible to make a dwarf size grandfather clock to finish about 5 ft. high. In the present case the shaft may be made 3 ft. 6 in. long between A, Fig. 6, and B, Fig. 9, with a depth of  $7\frac{1}{2}$  in. The width of the shaft will be governed by the swing of pendulum, a bare clearance being all that is necessary. An average width is about 12 in. to 14 in. The moulding which caps the shaft is built up to a height of  $2\frac{3}{4}$  in., an enlarged section being indicated at Fig. 7 d. For the shaft the material should finish  $\frac{3}{4}$  in. thick for sides and  $\frac{3}{4}$  in. or  $\frac{7}{8}$  in. thick for the front framing.

*Figs. 8 and 9. Section and elevation of lower part.*

*Fig. 10. Alternative door. Fig. 11. Working details. (By arrangement with Evans Bros., Ltd, London)*

A plan given at Fig. 11 f indicates the sides as rebated for the back to enter flush, or this may be merely screwed to the sides with brass round-headed screws, after bevelling away the edges for finish. The back is continued upwards behind the hood, the latter sliding into position and resting on the moulding which caps the shaft. The sides of the shaft are usually housed into a front framing, as on plan, and glue-blocked neatly in the angles behind. The top rail of front framing, upon which the capping mould is mounted, can be  $4\frac{3}{4}$  in. wide, and the bottom rail, which continues well down into the base below mould B, as shown in elevation diagram at Fig. 8. about 8 in. wide. Both are mortised into uprights, from  $1\frac{1}{2}$  in. to 2 in. wide.

The door, as Fig. 5, and shown enlarged at Figs 6 and 9, has an external break at top and bottom, with moulded edge. It can be made as in the section. Fig. 7 b, of  $\frac{1}{2}$  in. net thickness, with an overlapping facing of  $\frac{1}{4}$  in. net thickness to form a rebate, and shut over the case front framing. This mould is necessarily shallow, and must be very cleanly worked. It would, in another manner, be possible to rebate in a wider section mould, as in Fig. 7 c, on solid  $\frac{3}{4}$  in. material, and afterwards rebate the door to close on to a front framing rebated to correspond. A central diamond, bevelled away to form four facets from a piece  $\frac{1}{2}$  in. thick, is mounted on a panel of  $\frac{1}{16}$  in. thickness, to be glued and fixed in position on door with needle points.

An alternative front is seen at Fig. 10, the central panel, which forms the door, having a shaped and moulded heading. This must be sufficiently wide to give fair access to the pendulum, and is rebated (as Fig. 7 b) to shut on to the panelled front. Special hinges for clocks are made with wide flanges after the manner of Fig. 11 c and d.

The surbase, as Fig., 5, shows 1 ft. 8 in. high over mould B. An enlarged section of this mould is seen at Fig. 8 e, the section being  $2\frac{1}{2}$  in. high and the

projection about  $1\frac{1}{4}$  in., making the width of surbase 1 ft. 4 in. full. The front is framed up of 3 in. by  $\frac{3}{4}$  in. stiles and top rail, and has an applied rectangular panel, with ovolo-moulded edges, fixed to overlap the opening. A sunk panel could be fitted if preferred. The bottom rail should be sufficiently wide to reach the ground, about  $7\frac{1}{2}$  in., the surbase being built out from the shaft sides, which also continue to the ground.

A double plinth 6 in. high is shown, with ovolo mould round each break,  $\frac{1}{2}$  in. material being used. A section to enlarged scale of the surbase is given at Fig. 8. It should be noted that the shaft sides are tied by the cross rail behind the front of surbase, and a similar rail at back, in addition to a bottom rail front and back, into which the case bottom is grooved and blocked under. Finishing depth of surbase is  $9\frac{3}{8}$  in., and at ground the dimensions are  $10\frac{3}{8}$  in. for the plinth.

The finishing height for the hood, with a 10 in. dial as shown, is 1 ft. 6 in., and width would be about 1 ft. 4 in. An enlarged front elevation is seen at Fig. 6, but, as already suggested, the movement had best be obtained before putting the clock case in hand. The hood portion should project sufficiently beyond the door to allow for the columns. Twist columns are shown, and these will require neatly carving up, as they cannot be turned in the ordinary lathe. Plain columns (as Fig. 11 *a*) can be substituted if the twists present undue difficulty, but the effect will be appreciably less quaint. The columns may either be planted on door front to open with it, or can be fixed on pilasters so that the door can open between the columns.

The front and sides of the hood are preferably tongued together of  $\frac{3}{4}$  in. material, or, in an inferior manner, may be merely glued and blocked together. In blocking, it is best to use sound and well-fitting pine blocks, always cut with the grain to agree with the parts they are to hold. The end of the hood may have a column at the back of the return (as at Fig. 11 *a*), or can finish plain, as Fig. 5, with the end opening glazed. The front opening is the same size as the diameter of the dial (10 in. by 10 in.), with a  $1\frac{1}{2}$  in. framing surround moulded  $\frac{1}{4}$  in. ovolo. The columns are of  $1\frac{1}{2}$  in. by  $1\frac{1}{2}$  in. material. The door will shut upon a similar frame of  $\frac{1}{2}$  in. thickness, well secured in position by glue blocks behind. The cornice mould can be  $2\frac{1}{8}$  in. high, and, with the frieze will finish a full  $4\frac{1}{2}$  in. high to the enlarged section Fig. 7 *a*. The carving on frieze is of simple gouge detail with a  $3\frac{1}{2}$  in. bevelled panel applied in centre as a break.

In mounting the movement, this is supported on a seat board or shelf indicated at Fig. 11, *b* and *e*. It is fixed across the upper extremities of the shaft sides, and must be cut out for the pendulum and weight lines. Often an old movement will have the seat board attached, which can be used as a template for marking out another. The movement is held to the board by a couple of hook bolts passing over the pillars of the movement and through the board, where they are secured by nuts. Such bolts can easily be made from

stout wire and a screw thread cut on one end.

The capping at top of shaft forms a ledge upon which the hood slides when pushed home in position. A dustboard should be rebated into the top of the cornice. Scrolled detail could be carved on the frieze in place of the flutes shown, or the frieze could be left plain if nicely finished and not too wide. The Jacobean colour is a rich nut-brown, and might be finished with a rubbed treatment.

**GRANITE.** On account of its hardness and durability and its excellent appearance granite is one of the most valuable building materials. It is used extensively in road-making and engineering works as well as in the construction of houses, pillars, tombstones, memorial columns and for many other purposes.

Granite chippings or sand, mixed with Portland cement in the proportion of one of cement to six of granite powder, is useful in repairing a damaged part of a granite face. The same or some similar mixture is employed in the preparation of granolithic concrete, and finishes with a hard and durable surface, the colour of which will be determined by that of the granite used as the aggregate. *See Cement; Concrete.*

**GRAPE.** The grape is one of the most nourishing and wholesome of fruits. In illness it is cooling and refreshing. The content of nourishing sugar is very high in ripe grapes, ranging from 10 p.c. in some varieties to 30 p.c. in the richer kinds. This compares with an average of 2 p.c. in plums, 6 p.c. in strawberries, and 8 p.c. in oranges. The grape contains  $\frac{1}{2}$  p.c. of tartaric acid, as compared with 1 p.c. in apples and oranges and strawberries. The acid is combined with potash, and has a slight laxative effect; it also stimulates the kidneys.

In Switzerland the grape cure is a long-established method of treating corpulence, bronchial catarrh, obstinate constipation, and catarrh of the intestine. The patient eats from 2 to 8 lb. of grapes per day between meals.

Dessert grapes may be either black or white in colour, many varieties of both being grown, and vary greatly in size, the large ones being the best. The skin should be soft and the seeds few in number. Muscat of Alexandria has the finest flavour. A good bunch of grapes is very thick at one end, and tapers evenly to a point.

*Grape. Bunch of the pale variety known as Muscat of Alexandria.*

**Cooking Grapes.** Small green grapes are most used in cooking. To get rid of the tough skin, dip the grapes for a moment into very hot water, after which it will be found to peel off easily. The amount of sugar required depends upon the kind of grape

used, and their ripeness. In early summer, when the bunches on the vines are thinned out, tiny unripe grapes are often on the market. These can be stewed, or made in pies, but as they are very sour plenty of sugar will be required.

Only sound grapes should be pickled, a simple method being to remove the stalks from the fruit and then put it into a clean jar. Cover the grapes with white wine vinegar; then tie them down with a bladder and store them for four or five weeks in a cool, dry place.

**Grape Jelly.** Black grapes are best for jelly-making purposes if a pretty colour is desired, but green ones also give excellent results. Wash and stalk 2 quarts of grapes, then put them into a pan and bruise them gently over a very low heat until the juice flows freely. Strain without pressing the whole through a piece of muslin, passing the juice through two or three times to clear it. Then measure it, put it into a clean pan, and boil it for 20 min., skimming it if necessary. Add  $\frac{3}{4}$  lb. loaf sugar to every pint of juice, stir the whole until this has dissolved, and then boil it rapidly until it will set when tested on a plate. Put the jelly into jars, then cover and tie it down.

**Grape Tartlet.** These are made by lining some greased patty tins with short crust pastry, filling them with rice to prevent the pastry from rising, and then baking them until they are lightly browned. In the meantime, make a syrup of sugar and water, making allowances for the fact that ripe grapes are naturally sweet. Flavour the syrup with a little sherry, then peel and stone the grapes, add them to the syrup, and cook the whole for 2 or 3 min. Take the rice out of the tartlet cases and fill them with the grapes and syrup, putting a little whipped cream on top of each. *See* Dessert; Vine.

**Grape Scissors.** Scissors suitable for cutting grapes are a useful accessory to the dessert service. The best are of silver, and good specimens of the 18th century are in existence. Some of these are beautiful examples of moulded work and chasing. A steel blade will be found inset in some pieces. To-day grape scissors are usually made to match the knives and forks used at dessert. *See* Scissors.

**GRAPE FRUIT** or Shaddock. Grape fruit, which is procurable during most months of the year, is at its best as a breakfast fruit, to be eaten before the meal, and should be prepared in the following manner: First of all it is cut in half horizontally, using a special cutter or grape fruit knife. The pithy centre is cut out and the pips removed, and finally the knife is passed round between the rind and the juicy fruit, and the latter cut into pieces of a convenient size.

Grape fruit is served in special glasses which can be cheaply purchased. Pointed grape fruit spoons are best used when eating this fruit, and can be obtained in sets. *See* Breakfast; Diet; Glass; Marmalade.

**GRAPE HYACINTH.** The popular name of muscari, a hardy bulb which bears somewhat grape-

like clusters of flowers on stems 6 or 8 inches high in spring. It is very beautiful when massed in the shrubbery or rock garden; it makes a charming picture if planted beneath the golden bell shrub (forsythia), for both bloom together. Grape hyacinths flourish in ordinary soil in sunny or slightly shady places; as the bulbs start to grow early they ought to be planted in September, 3 inches deep and about 4 inches apart. The finest of all is one named Heavenly Blue, a variety of *Muscari conicum*; the flowers are bright blue. *Botryoides* is another favourite, with blue flowers; there are white varieties of this and of *conicum*. *Moschatum flavum* is yellow; *monstrosum* bears large inflorescences of pale blue flowers.

*Grape Hyacinth. Grape-like flower clusters of this hardy bulb.*

**Grape Sugar.** *See* Glucose.

**GRAPHITE:** As a Lubricant. Graphite is a form of carbon, very dark and soft, being one of the softest of minerals. It is employed in the manufacture of electrodes, pencils of the better class, and paint, also for making crucibles and for foundry facings, where the heat is intense; but its chief use is as a lubricant.

For this latter purpose the graphite should be of a very fine grade, so that it can enter between bearing surfaces without clogging, and be able to float in the oil film between the bearing surfaces. The grade should vary according to the thickness of the oil, a coarser grade being used with greases and extra thick oils. Under the names of blacklead and plumbago graphite is employed with oil in lubricating slow-moving heavy bearings, especially cast-iron bearings, as it helps to smooth the surface of the porous metal. The best proportion appears to be a 4 per cent mixture by weight of oil and graphite.

Various branded and proprietary mixtures of graphite lubricants are on the market and suitable for use on cycle chains, for lubricating motor vehicle and other bearings, and in this form is convenient for domestic use. *See* Bearing; Lubricant, etc.

**GRASS:** For the Garden. For garden cultivation there are many sorts of grasses which are raised as easily as hardy annual flowers, and can be gathered and dried for ornamental purposes. The following table shows the principal sorts with their height in feet, all being annuals except the last six, which are perennials:

Agrostis elegans (Cloud grass)	1
„ laxiflora „ „	1
„ nebulosa „ „	1½
* „ pulchella „ „	1¾
Anthoxanthum gracile (Vernal)	¾
Avena sterilis (Animated oat)	1½
Briza gracilis (Quaking grass)	¾
* „ maxima „ „	1
Brizopyrum siculum (Spike grass)	¾
Bromus brizaeformis (Brome grass)	1
Chloris barbata	1
„ elegans	1
* Chrysurus aureus (Golden spike)	½
Coix lachryma (Job's tears)	1½
* Eragrostis elegans (Love grass)	1
* Hordeum jubatum (Squirrel-tail)	1½
* Lagurus ovatus (Hare's-tail)	1½
Pennisetum longistylum	1½
* Arundo conspicua (Silver reed)	5
Elymus arenarius (Lyme grass)	1
Erianthus Ravennae (Woolly beard)	1½
* Gynierium argenteum (Pampas grass)	8
Panicum altissimum (Tall witch grass)	3
* Stipa pennata (Feather grass)	2

Of the 24 varieties in the above list 9 are starred as a special selection, 6 of which are annuals and 3 perennials, including Pampas grass. These are the choicest and in most cases also the easiest to grow. Pampas grass (q.v.) is a conspicuous and beautiful object in autumn. Pennisetum longistylum is really a perennial, but generally receives the same treatment as an annual. Most of the ornamental grasses succeed under the same treatment as hardy annuals, sowing in rows or clumps in well-prepared soil outdoors in the early part of April.

*Grass. Example of a beautiful and decorative annual grass worth cultivating in a border. (Courtesy of James MacDonald, Harpenden)*

Most growers of ornamental grasses want to preserve some of them for vases and table decorations in winter, perhaps intermixed with everlasting flowers. If so, care should be taken to gather them before the seed is ripe. As soon as the flowers have developed, the stems should be cut, because if left till they begin to drop they will not be durable. The stems should be laid out in a dry room for a few days. These grasses may readily be dyed any desired colour for ornamental purposes. *See* Garden; Lawn.

**GRASS CLOTH.** Grass cloth is made from the long unspun fibres of a plant of the nettle species. Light, fine and silky, but plain, it is a rarity and valuable, deserving of care, although its strength

enables it to resist hard treatment. Unlike cotton or linen, it does not contract when it is wetted.

The same fibre of which grass cloth is made is spun and woven in Europe, and sold under the name of ramie or China grass. Often suggested as a substitute for linen, it finds its chief use in incandescent gas mantles, which are knitted from the spun yarn, and then impregnated with minerals.

**GRASS OF PARNASSUS.** The best known member of this genus is *Parnassia palustris*, a small plant with angular stems, each carrying one heart-shaped stemless leaf and solitary, white, green-veined flowers in summer. It is found on the moors, and is an excellent subject for the bog garden or the rockery, where it should be given a peaty compost.

### GRATES: TYPES FOR VARIOUS ROOMS Efficiency and Decorative Values of Kitchen and Sitting Room Types.

All matters concerning domestic heating are dealt with in this work, and the reader should consult the articles on Adam Style; Central Heating; Chimney Piece; Electricity; Fireplace; Gas. See also Cooker; Flue; Fuel; Hot Water Supply; Range, etc.

The beginning of the grate proper occurred when a basket made of iron was placed in between the two dogs in order to catch falling pieces of burning wood and allow a sufficient air supply to reach them for the wood to burn out completely to ashes without smouldering. This form of dog grate or basket grate is still used for burning logs. Figs. 1 and 2 show two examples, as supplied by the Falkirk Iron Company. The small brackets on the front of the dogs are provided for carrying the spits, or long rods of iron, upon which joints of meat are spitted for roasting. The basket underneath can also be used to hold the twigs and smaller logs used for lighting up the large logs in the first instance. Such a type of grate can also be used for burning coal, and is best suited for country houses with large fireplace recesses and an adequate supply of timber logs.

*Grate. Fig. 1. Light pattern wrought iron basket grate. Fig. 2. Wrought iron basket grate in a heavy pattern. Fig. 3. Jacobean dog grate with cast iron bars and knobs. (Courtesy of Falkirk Iron Co., Ltd.)*

Grate. Fig. 4. Section and plan of a barless slow combustion grate (heaped fire).

The immediate development of the basket grate was still a dog grate, but the fire basket itself took

the form of an oblong box with a solid back and sides, and an iron grating at the bottom of the fire, with horizontal iron bars running along the front. A modern stove of this type, built in the style of the Jacobean period, but with the back and sides of the fire-box lined with firebricks, is shown in Fig. 3. There has been a marked tendency to return to the period form of stove, not only in the case of coal grates, but also with gas-fires and electric heaters, and dog grates of almost any period may be obtained for the use of any fuel.

Grate. Fig. 5. Plan and section of the Dipper sunk grate with raised hearth.

Fig. 6. View of the barless grate shown sectionally above.

Fig. 7. Pyramid fire with independent tile fireplace, suitable for a bedroom.

(5 and 6. Courtesy of Teale Fireplace Co., Ltd., 7, Well Fire & Foundry Co., Ltd.)

The majority of sitting-room grates are now formed on the slow-combustion principle, and have no bars. In some there is no bottom grate, and the fire burns directly upon a solid block of fireclay. The firebed is often of the well type, sunk below the hearth level. The back and sides, made of specially prepared firebrick, retain the heat and act as an added source of

radiation. A barless slow-combustion grate of the kind known as the heaped fire is shown in plan and elevation at Fig. 4, a picture of the grate as set into a fireplace being given in the article Fireplace.

Grate. Figs. 8 and 9. Convertible grate which normally burns solid fuel, especially coke, but which can readily be adapted to gas.

This utilizes the simplest application of the principle of slow combustion, in the form of a metal plate which fits tightly around the front of the grate, and fills in the opening between the bottom grating, which carries the coals, and the hearth itself. It keeps the space under the firegrate hot and heats up the entering air before it reaches the glowing coals. When pushed close up to the grate the plate prevents practically any air from passing into the fire from underneath. In this grate the fire-grating is unattached to the surrounding firebrick. It may be removed entirely during the summer, and be replaced by flowers or any other form of decoration. In other slow-combustion grates the front plate is fretted, and a slide allows the ventilation to be adjusted. Another type of grate is illustrated in Figs. 5 and 6. The fire can be ignited by gas, and in summer may be replaced by an insert gas fire.

In Fig. 7 a "Pyramid" slow-combustion grate is shown, in conjunction with a neat, tiled fireplace which is suitable for a bedroom. This type of fireplace is made in many colourings and in a variety of styles. Figs. 8 and 9 illustrate a convertible grate which normally burns solid fuel, but can readily be converted to gas for occasional use. It is specially designed for coke

burning, having a damper which can be lowered to start the fire. A gas poker connected to a nearby plug-point is used to kindle the coke. For summer months the "insert" gas fire is put in and connected to the supply pipe. Fig. 10 shows a permanent gas-coke fire.

*Fig. 10. A gas-coke grate. Quickly lit by gas, which is turned off when the fire is well alight burns evenly without smoke or soot.*

*(British Commercial Gas Association)*

An attractive sitting-room grate which presents a cheerful appearance and permits a fair amount of cooking to be done is the solo-

oven grate. It comprises a high-pressure hot-water boiler and an oven. Pots or pans may be placed on the hob plate. The ventilating fret, when lifted out and placed on the hob in front of fire, accommodates two extra saucepans for boiling. The handles for the controlling dampers are on the canopy.

**Grate Polish.** A useful grate polish can be made as follows: Take a cake of blacklead and the same weight in bluestone crystals and mix both to a cream with warm water. When the mixture is cold apply it to the grate with a brush. When the fire is lighted the copper in the bluestone will bake in the blacklead and so form a permanent polish. It should be rubbed from time to time with a soft cloth. Users of this polish should remember that both the black-lead and the bluestone are poisonous.

Another good grate polish is made by mixing  $\frac{1}{4}$  lb. of black-lead with a teacupful of vinegar. Apply this in the usual way and polish with a dry brush. For polished grates, use a paste made from 1 oz. soft soap and 2 oz. emery powder. Lay this on the steel and rub it with a dry wash-leather.

**GRATER.** In its simplest form, a grater is a small piece of tin through which holes have been pierced, close together, leaving jagged edges. The article to be grated is rubbed up and down the rough surface. Bread, nutmeg, lemon, and cheese graters are those most commonly used, and frequently the three latter are combined in one. In a cheese grater the holes are larger, and smooth edged, having a sharp lip at the base. Graters should be washed in very hot water and dried at once on a soft cloth, as if once allowed to get rusty they are difficult to clean. *See* Cheese; Lemon; Nutmeg.

**GRAVEL:** Its Various Uses. Gravel, or small stones rounded and smoothed by the action of water,

either in rivers or the sea, is used largely in building construction as well as for making garden paths. For the latter purpose shell gravel is frequently purchased, containing varying quantities of broken shell mixed with the stones or pebbles. Gravel is obtainable from builders' merchants or direct from the pits, and is sold in several grades and qualities, such as fine river or coarse beach. The latter, being impregnated with sea salt, cannot be used with cement until it has been washed. Fine gravel is employed for the rough-cast applied as a surface finish on modern cottages. Its use as an aggregate for concrete is dealt with under that head.

In commencing the work of path-making, mark out the path by means of lines secured to pegs and remove turf and top soil to a depth of about 6 in., until a firm foundation is obtained. The trench has to be filled with brick rubbish and covered with a layer of coarse gravel. It has then to be watered and rolled, care being taken to preserve a camber or curved surface. This is covered with a deep layer of fine gravel and again rolled. A certain clay-like consistency ensures the path being properly compacted. This can be detected by the eye and by touch.

Gravel has valuable properties as a filtering medium. A natural water supply such as that from a brook, when diverted and passed through a series of excavations filled with, clean, coarse gravel, will emerge in a practically pure state. *See* Concrete; Garden; Path; Soil.

**GRAVES.** This is the name of wines grown on the gravelly soil of the Graves district of Gironde, France. Generally of a lively and brilliant colour, with more body than the wines of Médoc, it has bouquet and fineness. The white wines of Graves are an excellent table wine, and are drunk with oysters and fish. There are many varieties. Amongst the most famous are Haut-Brion, Pape Clement, Carbonnieux, Laguloup, Ferrand and du Bouscaut. *See* Wine.

**Graves' Disease.** *See* Exophthalmic Goitre.

**GRAVY.** With few exceptions, gravy is the juice of roasted or braised meat, slightly diluted and seasoned, sometimes coloured with browning, but not thickened. That intended for roast meat should be prepared in the following way: Pour off all the dripping from the meat tin, carefully keeping back the sediment and rich brown particles that can be seen under the fat, for it is to these that the gravy owes its flavour and colour. Add a gill or more of boiling stock or water, according to the size of the joint.

Put the tin over the fire and let the gravy boil, stirring and scraping off all the brown pieces from the tin into the gravy with an iron spoon. Skim off any grease, add the necessary seasoning, and strain a little round the meat, serving the rest in a heated sauce tureen. Any bones removed from the meat can be boiled to yield stock, but no other flavouring is used.

The gravy for mutton and lamb may require a drop or two of caramel if it is very light in colour.

Slightly thickened gravy is made as follows: Pour off all except about 1 tablespoonful of the dripping from the tin. Stir into this 2 teaspoonfuls flour, and brown it carefully over the fire, stirring it frequently. Mix in gradually  $\frac{1}{2}$  pint of stock, and stir the gravy over the fire again until it boils. Skim and season it, and strain a little round the joint, putting the remainder in a sauce tureen. This gravy must never be thicker than thin cream. *See Baking; Beef; Browning.*

**GRAYLING.** The grayling is at its best during late summer. For frying, the fish is first washed, scaled, and cleaned, and the fins and gills removed. Dry it thoroughly in a clean cloth, then sprinkle it with seasoning and a little flour, and fry it in a pan of smoking hot fat. When the fish is of a golden brown colour, drain and dish it, using parsley as a garnish, and handing round some melted butter sauce.

If it is to be baked, put the fish, sprinkled with seasoning, in a baking dish, place a few lumps of butter on top, and then cover the dish with a lid. Bake the fish for about  $\frac{1}{2}$  hour, basting it occasionally, and just before serving make some sauce by mixing the gravy in the dish with melted butter. *See Fish.*

**GREASE.** Properly speaking grease is soft, thick, animal fat, but the word is used for oily matter of any kind. The grease that comes from the flesh of those parts of animals that are used for human food, e.g. mutton, is turned into dripping, while many kinds of grease are used for lubricating purposes.

Grease is useful to the gardener. Bands of grease-proof paper coated with grease or some sticky substance are applied to the stems of fruit trees to entrap the winter moth. The female moth, which is unable to fly, crawls up the stems to deposit her eggs and is caught by the grease. The bands may be prepared at home or purchased from horticultural dealers. They are fixed on the trees in autumn.

Cart grease may be used, but special preparations made for the purpose are to be preferred. It is impossible to put the bands very high in the case of bush trees on short stems, but on standards they may be placed at any convenient height between 3 ft. and 5 ft.

*Grease banding round a fruit tree, with winter moths caught upon it.*

It is useless to band trees and leave stakes unprotected. The bands are left on until spring; the grease must be renewed occasionally in winter. *See Clarifying; Gravy; Lubrication; Oiling.*

**GREAT DANE.** This is a useful dog for those requiring a guard dog that is also reasonably active. It is less heavily built than a St. Bernard, mastiff, or

Newfoundland. A buyer should see that its legs are straight, back and front, cow-hocks being a common fault. A long back and weak loins are also to be avoided. The body should be deep and the thighs muscular. The height for dogs should be not less than 30 in. at the shoulders, and the minimum for bitches 2 in. less. The neck should be long and well arched, free from loose skin, and it should carry the head well up, not poked forward.

*Great Dane. Champion of this strong, fearless breed. (Photo: Thos. Fall)*

The recognized colours are brindles, fawns, harlequins, blues, blacks, the first three being the favourites. When in action the movement should be free and graceful. Usually a Great Dane is docile, but much depends upon his training. He should be kept under control from the first and not spoilt. *See Dog.*

**GREEN FLY.** The pest known as green fly affects many garden plants. In the greenhouse the pest is easily exterminated by closing all ventilation and fumigating with one of many preparations sold for the purpose.

In the open air, spraying or syringing is the best cure. The best mixture is made up of the extract from 6 oz. of quassia chips, 4 oz. of soft soap, well mixed and added to 5 gallons of water. Paraffin emulsion and dilute paraffin are also efficacious. Abol, Katakilla and many other concentrated insecticides provide convenient remedies. *See Insecticide; Rose; Spraying, etc.*

**GREENGAGE.** One of the most delicious varieties of plum; it is self-sterile and uncertain in cropping. It does best on a sunny wall and must be planted near other plum trees, preferably cooking varieties.

*Greengage. Fruits of this delicious variety of plum.*

In addition to their uses as dessert, greengages are stewed and cooked to form various kinds of sweets, and are also bottled and made into jam. Generally all directions given for the cooking of plums can be safely adopted.

**Greengage Cream.** A good cold sweet is provided in greengage cream, which is prepared by first rinsing a pretty mould in cold water, and decorating it with clear sweet jelly and fruit. In a basin mix  $2\frac{1}{2}$  gills,

sieved greengages, 3 oz. sugar, and the juice of  $\frac{1}{2}$  lemon. Dis-solve  $\frac{3}{4}$  oz. gelatine in  $\frac{1}{2}$  gill warm water, and strain it into the fruit, etc., adding lightly  $\frac{1}{2}$  pint whipped cream, and, if liked, a few drops of green vegetable colouring. Pour the mixture into the mould and leave it until cold, when it is ready to turn out.

**Greengage Jam.** Choose under-ripe cooking greengages for making this jam. Put 6 lb. of cleaned fruit in the preserving-pan with 1 pint of water, and boil them until the fruit breaks. Remove the stones, cracking some of them and extracting the kernels, and to each lb. of the pulped fruit add  $\frac{3}{4}$  lb. of crushed loaf sugar. Let the sugar dissolve, then boil the jam quickly, stirring all the time, until it jells when tested on a plate. Add the kernels about 3 min. before the cooking is finished. Pour the jam into warm, dry jars, and fasten down at once.

**GREENHEART.** The wood known as greenheart is extremely hard, heavy, and tough, and close and even in the grain. In colour it is of a dark greenish hue, varying to a very dark centre. Greenheart is remarkably elastic, and is one of the best woods for salmon and trout fishing rods. *See Wood.*

#### GREENHOUSES: MAKING AND STOCKING How the Gardener can Make the Most of his Outfit

After some general considerations of design and arrangement, followed by hints on management and lists of suitable plants, the reader is told how to construct a useful greenhouse. See Conservatory; Frame; Garden; Glass, etc.

The principal object for which a greenhouse is designed is for the housing of plants not hardy enough to withstand the rigour of winter conditions. Three good types are the warm house, in which a minimum temperature of 55° F. is maintained during winter; the unheated house entirely without artificial heat, and the greenhouse proper, which can maintain a minimum temperature of 45° by means of gas, oil, or hot water. A house of the latter type is considered in this article, giving scope not for the culture of ornamental plants alone, but also for the growing of such profitable crops as tomatoes, cucumbers, etc.

There is variety in the shape of greenhouses, and possibly the most convenient and generally useful type is that known as a span roof, having its roof sloping downward from both sides of the ridge board at an angle of about 45°. Other kinds are the lean-to, a popular and useful structure, and the three-quarter span, a compromise between the two. Each of these types is illustrated, while for the benefit of those prepared to erect a home-made house, constructional diagrams are given.

It should be noted that if a greenhouse is to remain a tenant's fixture it must rest upon the soil and not be fixed to anything built into the soil, neither must its woodwork or other parts be nailed or attached in any

way to the brickwork, otherwise it automatically becomes the property of the landlord when the tenancy expires.

*Greenhouse. Span-roof greenhouse with wood base, suitable for growing plants of all kinds. (Courtesy of Boulton & Paul, Ltd.)*

*Lean-to greenhouse with brick base suitable for cucumbers and tomatoes or for plants.*

The greenhouse ought to be in a sunny position. A roller blind is usually fitted to provide shade in hot weather, or "Summer Cloud" can be applied to the glass.

Artificial heating is best maintained by hot water, the simplest system being a boiler, plus a flow and return pipe. For small greenhouses a hot-water apparatus heated by an oil lamp is serviceable.

Ventilation should be thorough. A glass-formed structure such as a greenhouse readily admits the sun's heat, but does not readily permit it to escape; thus its quantity must be regulated by ventilation, preferably at the apex of the house. Fresh air is essential to the well-being of plants. When weather is favourable, air should be given freely, day and night, from late May until mid-September, but at other times it should be given only during morning, if conditions are fair, and withdrawn or reduced in the early afternoon at latest. Top ventilators must be opened first, followed by the lower ones, but they should be opened on the same side of the house. Draughts are to be avoided.

Staging, three feet high, usually consists of wooden shelving. It is an advantage to lay thin sheets of corrugated iron or slate on the bench, covering with well-washed sand or gravel.

One of the most useful accessories is a potting-shed easily accessible to the house. It will be handy for storing garden paraphernalia apart from its actual purpose of putting plants into pots, but must contain a well-lighted potting-bench. This may be 3 or 4 ft. long, built at a height suitable for comfortable work. Underneath it should be boarded off into four compartments, to contain leaf-soil, loam, peat, and sand.

Watering and syringing are both important. A safe general rule is to water sufficiently to reach every particle of root, and then wait until repetition is necessary. The best times for watering are morning and evening, pot plants that have become very dry being placed in a pail of water to soak until bubbles cease.

With a warm greenhouse the gardener has opportunity to raise seedlings for the garden proper; to forward crops of beans, peas salads, onions, etc.; to raise early vegetables; to winter tender plants; to grow cucumbers, melons, and tomatoes, and perhaps to cultivate a vine or peach tree with success.

Chrysanthemums and carnations are prime favourites in the greenhouse, perpetual-flowering varieties of the latter being invaluable. So also are begonias of the fibrous-rooted type, such as Gloire-de-Lorraine, and its varieties Turnford Hall and Mrs. Leopold de Rothschild; others with drooping growth for baskets, like Golden Shower and Alice Manning; together with the handsome-leaved Rex begonias. Among other plants for the greenhouse are coleus, with its very attractive foliage, fuchsias as pot-plants or climbers, hydrangea (hortensia), cherry-pie Lord Roberts, show and fancy pelargoniums for early summer and zonals for winter blooming, scarlet sage for display in autumn and early winter, primulas, cineraria (stellata).

Amongst shrubby plants there are roses. Indian azaleas, genistas, spireas, as well as those old favourites the heaths; whilst evergreens include the well known and easily grown foliage plants, Kentias, fan palms, and aspidistras. To these may be added maidenhair, and other ferns; greenhouse asparagus, sprengeri and plumosus; and the grevillea. Then there is the wide range of bulbs and corms. Lilies, winter-flowering cyclamen, gladioli, freesias, tulips, hyacinths, daffodils, narcissi, amaryllis, gloxinias, and the little-grown, but lovely, nerine.

Unfortunately, plants grown in greenhouses are particularly subject to insect pests, but an occasional fumigation will enable them to be kept in check. Or the plants may be sprayed with an insecticide.

*Greenhouse. Fig. 1. Lean-to greenhouse which can be made by following instructions given in the text.*

**Making a Greenhouse.** Fig. 1 illustrates a greenhouse 9 ft. long and 6 ft. 6 in. wide, having a door at one end and a ventilation skylight in the roof. It is constructed by making six distinct frames, which are assembled together by coach-screws or nuts and bolts, and it can be removed easily when desired. The weatherboarding shown on the lower portion is nailed on horizontally, and is preferable to matchboarding nailed on the frames vertically. When natural decay sets in, this generally begins at the bottom of the

greenhouse. If the boarding has been nailed on to the frames vertically, decay necessitates taking off and renewing practically the whole of the boarding; whereas, if weatherboards, with their joints running horizontally, have been used, the board nearest to the earth can be readily removed and a new one put in its place.

The foundation may be made of odd bricks, broken stones or slabs, granite drippings and concrete, and it should be the first step towards building the greenhouse. The two end frames are built up out of square-edged timber (that is, timber not rebated on one of its edges). The portions marked S throughout the drawings refer to strips or laths of wood, which are nailed on to the framing to form the rebates which hold the glass, and their width and thickness will be in correct agreement with the rebating of the sash bars.

*Fig. 2. Part of front before weatherboarding is fixed.*

*Fig. 3. Fixing spar on wall to support back edge of frame.*

*Fig. 4. Bottom corner of skylight frame showing throating to turn water.*

*Fig. 5. Curb as fixed in window opening.*

The front frame, of which a portion is shown in Fig. 2, is built up in the usual manner by mortise and tenon or half-lap joints. It is stayed by two diagonal braces to prevent it from racking. The top edge will have to be planed or sawn

on the bevel, so as to allow the roof frame to fit and bed upon it. At the back the roof frame is supported by a spar fixed to the wall, as shown in Fig. 3.

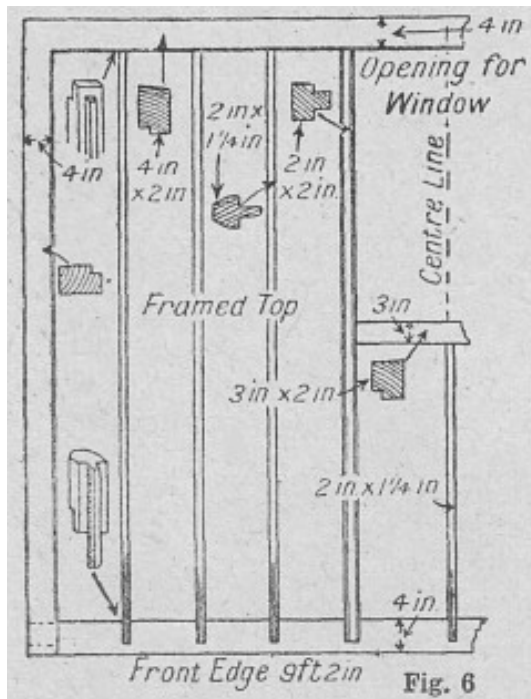

Fig. 6. Half of top frame showing joints and sections.

Fig. 7. End frame with door.

The roof frame (Fig. 6), of which a half-plan is shown, will probably be the most difficult for the home worker to make; but, after the experience gained in making the end frames, he will be more confident to tackle it. The joints and details are so clearly shown in the diagram that little in the way of a description is needed, except perhaps to say that a space is left for the ventilator window. Into this space a box or curb is made (Fig. 5), and fitted and nailed in, so that its top edge projects about 1 1/4 in. above the roof frame. This is to throw off the water and keep it out of the joint of

the window opening.

Fig. 8. End without door. The letter S indicates laths of wood nailed to framing to provide rebates for the glass.

The skylight frame is made to project about 1 in. over the curb, and it is throated with a small groove, as shown in Fig. 4, so as to turn the water. The skylight is hinged to the back edge of the curb with butt hinges, and the usual stay rod from the inside of the greenhouse is provided to raise and lower it. The whole of the timber framing should be given one coat of paint before the frames are assembled. This will prevent the new timber absorbing the oil out of the putty, which would otherwise peel off and drop out. Do not forget to make the end frames handed, that is, one frame for the left hand and one frame for the right hand (Figs. 7 and 8).

**GREENS.** This term is used for green vegetables generally, such as broccoli, cabbage, and spinach. Some people class cauliflowers as greens. *See* Cabbage; Cauliflower, etc.

**GREEN TEA.** Of the green teas hyson, young hyson, twankay, and gunpowder are the best known, and are chiefly used for blending. The characteristic colour of green teas is due to the particular processes to which they are subjected. These vary considerably from those employed for black teas. For green tea, the leaves of the tea plant are gathered and roasted off at once, before fermentation sets in, while the drying, too, is also specially hastened. From a digestive point of view, the use of green tea is undesirable, as it usually contains a larger percentage of tannin than black tea. *See* Tea.

**GREGORY'S POWDER.** The common name for compound rhubarb powder is Gregory's powder or mixture, of which the purgative dose is 10 to 60 grains. It is frequently prescribed for acute indigestion in children and is also useful in diarrhoea. Adults suffering from dyspepsia may benefit from small doses, as much as will lie on a sixpence, thrice daily before food.

**GRENADIN.** In cookery the term grenadin is applied to an oval or round cut from the fillet or cushion of veal. It is usually larded and braised, after which it is garnished and served with sauce. *See* Veal.

**GRÈS WARE.** This name usually stands for the old stoneware produced in W. Europe during the 16th-18th centuries. Because it was shipped mostly from Flemish ports it was called Grès de Flandres, although the bulk of it came from Cologne and other places in the Rhineland, and some of the best from Nuremberg, Siegburg, and other towns near.

*Grès Ware. Siegburg jug with raised designs of hunting scenes. (British Museum)*

It was essentially a fine salt-glaze stoneware, in greyish and other neutral tones, with designs in relief based on wood-cut illustrations in books, or the coats of arms of nobles and well-to-do burgesses. The surface resembled orange-skin, and the forms included cylindrical tankards, tall or squat, lidded and handled, sometimes with long oblique spouts.

Specimens of Rhenish origin are sometimes unearthed on old city sites in England, because they had a great vogue here until Fulham ware, and afterwards Staffordshire saltglaze, came in to displace them. There are modern potteries engaged in turning out, in the same local white clay, reproductions of favourite old designs. *See* Pottery; Stoneware.

**GREVILLEA.** The most popular kind is Grevillea robusta, an Australian shrub with decorative leaves, suitable for cultivation in pots, room and greenhouse. It is easily grown from seeds sown under glass in spring and good plants can be grown in 5 in. pots in a compost of loam, leaf soil and sand. The red flowered Grevillea rosmarinifolia, a bush 4 to 5 ft. high, is suitable for planting out of doors only in mild districts.

**GREYHOUND.** Through being regarded primarily as a sporting dog, with highly specialized functions, the greyhound is seldom kept as a companion, although there are many reasons to be urged in his favour. In outline he is exquisitely graceful, his movements being gentle.

The English greyhound is our representative of one of the oldest canine families. Many thousands are bred annually for the purpose of coursing and track racing. There are not many show kennels, but occasionally a greyhound is exhibited of such perfection that he can be fairly sure of winning the prize for the best of any breed in a show.

There are many colours, all of which are permissible. Although the bigger ones look the most imposing, they frequently lack the power to turn quickly when coursing. Experience commends dogs of medium size, and some of the most famous Waterloo Cup winners have been small. *See* Dog; Italian Greyhound.

*Greyhound. Two prize-winning specimens of the famous breed of sporting dog.*

**GREY MULLET.** Of inferior quality compared with the red mullet, grey mullet is, nevertheless, much liked by many, but needs to be very fresh when cooked. Most of the methods which are employed for cooking haddock may also be applied to grey mullet, but sauce should always accompany it. *See* Haddock; Red Mullet.

**GRID.** This system of national electricity supply, controlled by the Central Electricity Board, consists of a network of main transmission lines to distribute electricity at a standard frequency and take power to areas where it has hitherto not been available.

**GRID: In Wireless.** This is an electrode of fine wire mesh between the anode and filament (or cathode) of a thermionic valve. The ordinary three-electrode valve has only one grid, as distinct from a screen-grid valve, which has two, and a pentode with three.

The second grid in a screen-grid valve is usually called the screening grid, and this is connected directly to a positive terminal of the H.T. source of supply. In a pentode valve one of the additional grids is connected internally to the filament or cathode. As many as four grids are to be found in some of the modern multi-electrode valves, such as the Triode-Pentode and the Triode-Hexode.

**Grid Battery.** This is a small dry cell battery employed to maintain the grids of the amplifying valves (sometimes also the detector) at a negative potential in

respect to the filaments, or cathodes. The grid bias value depends upon the type of valve (e.g. its impedance) and the high tension voltage. The correct figure may be ascertained from the maker's instructions accompanying the valve.

Failure to apply the negative grid bias specified will result in excessive anode current consumption, distortion, and possibly loss of emission, i.e., valve failure. Although a grid bias battery is not called upon to supply actual current, it should be replaced about every nine months, or the valve may be damaged.

**Grid Leak.** This is a high resistance connected between the grid of a wireless receiving valve and a point in the circuit having a positive or a negative potential in respect to the filament or cathode.

A grid leak may be employed to assist in the process of rectification—e.g. a leaky grid detector—or to maintain the grid of a valve at a suitable negative potential, as in a resistance-capacity coupled low-frequency magnifier. No definite values can be given, although 2 megohms is commonly chosen for a leaky grid detector and 0.5-2 megohms for a resistance-capacity coupled magnifier.

A defective grid leak may produce crackling noises, distortion, and sometimes a choking effect on reception, which develops within a short period of switching on the set. *See* further the articles on Detector; Filament; Valve; etc.

**GRIFFON.** There are several different types of this wire-haired dog with its bearded and moustached countenance. There are longhaired and short-haired, red, grey, fawn black-and-tan; but the favourite is the long haired red, with pug nose and large eyes. The smaller dogs should not exceed 5½ lb. in weight but the larger race may run up to 9 lb. They should not be bought younger than about three months old, for from the age of five to eight weeks their rearing is attended with anxiety. At three months the critical time is well over. *See* Dog.

*Griffon. Long-haired and pug-nosed specimen. (Ralph Robinson, Redhill)*

**GRILL.** The term is used to describe both the appliance on which food is grilled and the cooked dish itself. Grilling is usually done under the griller of a gas-stove or by a grill or gridiron placed over or in front of the fire. For cooking over the fire, a single row of bars fastened at each end, with a long handle at one end, is used. For grilling in front of the fire, the iron has a double row of bars, enabling the food to be enclosed, while underneath is a shallow trough to catch the fat.

Electric grills on which breakfast, luncheon, or a

complete dinner can be prepared are useful table appointments. *See* Bacon; Chop; Cooker; Liver; Mixed Grill; Sausage; Steak.

**GRILLE:** In Building. A grating or structure of iron or other metal bars, known as a grille, is placed over an opening or aperture generally to prevent any forced entry. Such a grille is made of 5/8 in. diameter iron bars, to bolt over a basement window. Similar structures are often made for the openings in gullies or drains.

**GRILLING.** Besides being rapid in its operation, grilling is one of the most wholesome methods of cooking meat, which is exposed directly to the flame. If the process is to take place over or before the fire, the latter must be clear and free from smoke. A gas or electric grill should be made red hot before the meat is put underneath it. The bars of the griller must be greased to prevent the meat sticking. Grilled meat should not be overdone, otherwise it will harden and lose its flavour. It should be brushed over with melted fat before grilling. After cooking, rub it on both sides with butter and season it to taste. The most suitable meats for grilling are steaks, chops, cutlets from the centre of a leg of mutton, and small birds, while the best fish for the purpose are cutlets of salmon, mackerel, trout, and whiting. Fish for grilling should be wrapped in well-buttered thick glazed paper. When birds are grilled they should be cut in half and the inner side first exposed to the fire.

**GRILL SAUCE.** To make this, place a soup plate over a basin filled to the brim with boiling water. Put 1 oz. of butter in the plate and, when it is melted, stir into it first 2 teaspoonfuls of made mustard, then a dessert-spoonful of French vinegar, a teaspoonful of tarragon vinegar, and lastly a tablespoonful of cream. Season to taste with salt, pepper, and cayenne, and pour over the grilled meat. *See* Bones; Gravy; Sauce.

**GRINDING:** Of the Teeth. In children grinding of the teeth during sleep is most commonly due to indigestion, worms, or some irritating matter in the bowels. It also occurs in nervous diseases, such as St. Vitus's dance. The treatment is that of the condition.

**GRINDSTONE:** How to Use. A grindstone is an implement used for the sharpening of tools. It comprises a circular stone mounted on a spindle which is supported in a frame; it is adapted for driving by hand or by a treadle. It is an advantage if the frame is enclosed at the bottom to form a trough holding a supply of water to keep the stone wet and to prevent tools from overheating while being ground. The best type of grindstone is one with a cast-iron frame and fitted with a self-contained treadle, and is best fitted with a hood to prevent the water from splashing. Such a stone should be about 2 ft. in diameter and 3 or 4 in.

in width. Smaller grindstones can be screwed to the bench, but they have to be worked by hand, leaving only one hand free to hold the tool being ground.

*Grindstone. Fig. 1. Method of placing hands to control a chisel blade and obtain desired cutting angle. Fig. 2. Grinding back of a gouge. Fig. 3. Use of simple tool grinding rest. Fig. 4. Grinding a bill-hook, which is held obliquely across the stone.*

**Grinding Cutlery.** Grinding is the process by which knives and other cutting implements are sharpened on a grindstone. In grinding, the stone revolves towards the worker, the tool-rest being adjusted to the proper angle, and set as close to the stone as possible. This prevents the tool from catching and being dragged down. The stone should never be touched with the hands while it is revolving.

Fig. 1 shows how a chisel is ground. The method is as follows: Grasp the blade in the left hand, with the fingers uppermost, and grip the handle with the right. Incline the tool so that the angle of the bevel is about 20°. The rest should be set to this angle, and the chisel can then rest flat upon it. The tool is not held in one place, but moved about across the rest to avoid forming a groove in the stone. Grinding continues until the bevel on the tool is flat and true. Ordinary firmer chisels are ground on one side only, turning chisels and cold chisels on both sides.

Gouges are ground on the outside, and are held in a slanting position to the stone, as in Fig. 2. The gouge is twisted or turned so that the bevel is ground to a true curve.

Plane irons are treated in the same way as chisels, except that, being broader, they call for more care, especially to keep the edge square with the side of the iron. A spokeshave iron is held in both hands and the face of the iron is ground, very light pressure being needed. With axes and hatchets the head is held in the right hand, the shaft in the left; the head is rocked to

and fro on the face of the stone to produce the requisite curved edge.

A valuable aid to correct grinding is the device illustrated in Fig. 3 and known as a grinding rest, consisting of a roller and a tool clamp. The tool to be ground is placed in the clamp and fastened by the clamping screw, with such an amount projecting that when the tool and the wheel are both resting on the stone the angle so formed is that required for the tool. The greater the projection the flatter the angle, and vice versa.

**Gripes.** *See Colic.*

**GRIT.** Hard, sharp particles of stone, known as grit, are given in bulk to fowls in order to enable them to digest their food. A fowl at liberty instinctively forages for and finds an unlimited supply of suitable material, but in confined quarters the grit has to be provided. The best kind of stone for the purpose is flint, which must be broken to about the size of a pea for adult fowls, and somewhat smaller for chickens. *See Poultry.*

**GROG.** The drink known as grog is made by adding a little cold water to spirits, no sugar being put into the mixture. Sometimes, however, hot water is used, and this also is called grog. The spirit most generally used in making grog is rum, and as the drink is useful for maintaining the heat of the body, it is drunk by sailors and others whose duties compel them to face cold and inclement weather. *See Rum.*

**GROMWELL.** The English name of lithospermum, a beautiful rock-garden plant (q. v.), which is also known as borage-wort. The most useful species, prostratum, is a hardy evergreen trailer, with hairy stems and lance-shaped, hairy leaves, which covers itself with rich blue flowers in summer. It is a beautiful plant for the rockery, where it carpets spaces between large stones, and looks at its best when hanging over them in broad masses.

There is a variety called Heavenly Blue, which resembles the species closely, but is rather lighter in colour. These trailers like a soil of peat or leaf mould and a sunny position. They are lime-haters and are invaluable for hot, dry banks. Other desirable species are graminifolium, which has grassy evergreen leaves and clusters of blue, drooping flowers; canescens, a hoary herbaceous species with yellow flowers, height 9 in.; gastoni, also herbaceous, blue with white eye, an alpine growing about 9 in. high; purpureo-caeruleum, herbaceous, purplish blue, a trailer; and rosmarini-folium, evergreen, blue, 18 in.

The best of all for the rock garden is *L. petraeum*, a pretty little bush with greyish leaves, something like the lavender. It is about 9 in. in height, and bears purple flowers from May to July, the blossoms changing in colour to deep violet as they expand.

The gromwells are propagated by seed, cuttings, and

divisions. Seed is sown in a frame in spring. Cuttings are inserted in sand soil in a frame in summer. Division should be practised in spring. *See* Rock Garden.

**GROOM.** A groom is a manservant who has charge of horses. He should understand the care of horses and be a good rider, as he is often expected to exercise the horses. His duties include, in addition to looking after the horse or horses, the care of the stables and the cleaning of the harness. A male servant licence, which formerly cost 15s. a year, is not now required. He must be insured under the National Health and Unemployment scheme. *See* Harness; Horse; Insurance; Stable.

**GROUND BEETLE.** Although there are many kinds of beetles that live chiefly underground, the name is applied particularly to a group of 10 species of carabus. They are about 1 in. long, shiny black, in some cases with violet or golden reflections, and all wingless. The ground beetle is one of the gardener's best friends, and seeks and devours the fat caterpillars, such as that of the turnip-moth, which destroy vegetables at night. *See* Beetle.

*Ground Beetle.*  
*Useful garden insect*  
*which feeds on*  
*caterpillars.*

Ground Ivy. *See* Nepeta.

Ground Nut. *See* Monkey Nut.

**GROUND RENT.** A ground rent is the rent paid for the land on which a leasehold house or building stands. Its amount is fixed when the land is let to the builder, and cannot be altered during the period of the lease, usually 99 years. The owner of the house, not the tenant, is responsible for paying this rent to the ground landlord, and he should deduct income tax at the usual rates from it when he does so. *See* Income Tax; Leasehold; Rent.

**GROUND RICE.** This is a fine flour-like preparation made from rice. Like rice flour, it is much used in the making of cakes, hot or cold puddings, and for thickening soups.

**Ground Rice Cake.** To make these, sieve together 3 oz. ground rice, 2 oz. flour, and  $\frac{1}{2}$  teaspoonful baking powder. Cream together 2 oz. butter and 3 oz. castor sugar, then beat in 2 eggs separately. Stir in the dry ingredients, mix all thoroughly, put the ingredients into small greased queen-cake tins, and bake in a quick oven for about 10 minutes.

**Ground Rice Mould.** For this, mix  $1\frac{1}{2}$  oz. ground

rice to a thin smooth paste with a little milk. Put what is left of 1 pint milk in a pan on the fire, with 1 in. cinnamon. When the milk boils, add the ground rice together with 1 oz. sugar and boil gently for 15 min., stirring all the time. Rinse out some dariole moulds or small teacups with cold water. Take out the cinnamon and fill the moulds with half the rice. Colour the remainder a pale pink with a few drops of cochineal, and fill up the moulds. When set turn them out on to a glass dish and pour custard round. The mixture can also be set in one large mould.

**Ground Rice Pudding.** Baked ground rice pudding is made by rinsing out a saucepan with water, pouring in 1 pint of milk, and heating until it boils. Then stir in 2 oz. ground rice mixed to a thin smooth cream with a little cold milk. Continue the stirring until the mixture thickens, and then add 1 oz. butter, sugar to taste, and a little vanilla flavouring. Allow it to cool before adding 1 beaten egg. Thickly grease a pie-dish, pour in the mixture, and bake it gently until lightly browned. *See* Diet; Rice.

**GROUNDSEL.** The wild groundsel, called *Senecio vulgaris*, is a common weed which spreads very quickly by self-sown seeds. It should be destroyed by hoeing before it flowers. There are some valuable garden flowers in the genus *senecio*.

**GROUSE.** These birds, which are in season from Aug. 12 to Dec. 9, may be cooked in a variety of ways, but the most usual method is to roast them. They should hang for ten days to a fortnight before being plucked. All the methods of cooking described under the heading Game (q.v.) can be used for grouse.

**GROWING PAINS.** The ordinary process of growth causes no pain, and what in children are called growing pains are really manifestations of acute rheumatism and should be treated as such. If neglected, serious implication of the heart may result. *See* Rheumatism.

**GRUB: In the Garden.** Various garden pests are termed grubs when in the egg or chrysalis state during winter. They are usually just below the surface of the ground, or in the cracks and crevices of the bark of trees and shrubs. Methods of dealing with grubs are explained under the headings of the plants and shrubs which are liable to be infested by these garden pests. *See* Insecticide.

**GRUEL.** To make gruel, put into a basin 1 tablespoonful fine oatmeal and a pinch of salt. Pour over it 1 teacupful cold water and 1 teacupful milk. Stir thoroughly and let it stand for  $\frac{1}{2}$  hour. Stir again, strain, put the liquid into a saucepan, stir till boiling, and boil for 10 min. Serve hot in a soup-cup.

A little cream added last of all is an improvement,

and it may be sweetened with 1 teaspoonful of sugar. If wanted quickly, use 2 tablespoonfuls of oatmeal to the same quantity of milk and water. Stir and strain and make as above. The oatmeal that is left can be used for porridge. *See Invalid Cookery.*

**GRUYÈRE CHEESE.** This is a large flat cheese, distinguished from others by the presence of large holes, some of which are filled with moisture. It has a nutty flavour.

**GUAIACOL.** Prepared from creosote, guaiacol is frequently prescribed in consumption. It is given in the form of the carbonate of guaiacol. It has also been used successfully in the treatment of rheumatoid arthritis, but it must be taken for a considerable time.

Guaiacum resin is obtained from the wood of a West Indian tree, *Guaiacum officinale*, also called *Lignum vitae* (wood of life), on account of its high medicinal reputation in earlier days. The resin has a mild purgative effect. It was an ingredient of the electuary, known as the Chelsea Pensioner, formerly a favourite remedy for the pains of chronic rheumatism and gout.

**GUANO.** The valuable natural manure named guano is derived from sea-birds; the chief source of supply is the eastern coast of South America. It is rich in ammonia, phosphates, and alkaline salts. Most of the guano which reaches Great Britain is dealt with in proprietary form, and instructions are issued with it *See Manure.*

**GUARANTEE.** In English law a guarantee is a promise to be answerable for the debt, default or miscarriage of another. Examples are bank guarantees, in which one makes himself responsible for an overdraft or other advance made to another, and guarantees of debts of various kinds. A reference stating that a person is in a sound financial position is not a guarantee.

**GUARDIAN: His Duties.** A guardian is a person to whom belongs the care and custody of an infant (under 21). A father is the natural guardian of his child. He may appoint by his will a guardian to act after his death; but this guardian acts along with the mother.

The high court may always appoint a guardian for a child, though the rights of the father and mother are never interfered with, unless for the infant's benefit. If the father and mother separate, *prima facie* the father has a right to the custody of the children; but the court will consider the interests of the child as paramount and may order the mother to have the custody.

A guardian controls the ward's marriage, to the extent of being able to forbid a marriage without his consent. Anyone who takes a ward out of the guardian's control will be severely dealt with by the court. A guardian must not make a profit out of his guardianship; and may not deal with the ward's property except for the ward's benefit. A guardian must render an exact account when the ward attains the age

of twenty-one. *See Child.*

**GUAVA JELLY.** This can be bought in jars ready for use, or prepared at home from the ripe fruit. Guavas are cultivated under glass in Great Britain, but cannot be imported from the tropics in their ripe state. To make the jelly, peel and cut into quarters about a hundred ripe guavas, wash them thoroughly, then put them into a saucepan with sufficient water to cover, and boil for about 2 hours or until they are perfectly tender, and will break easily when touched. Strain off the juice through a sieve, pressing the fruit so as to obtain as much juice as possible, and if necessary letting it drip for a day or so. Pour the juice into a preserving pan and boil it well, skimming it frequently. Add gradually enough sugar to sweeten it, boil it for a few minutes, then add the juice of ten large limes or lemons. Boil until all the scum has risen and the jelly looks clear; then pour it into clean dry jars, and cover when cold.

Medlars are sometimes used to make imitation guava jelly.

**GUDGEON.** A small, well-flavoured freshwater fish that is in season from mid-summer until late autumn. The fish should first be cleaned thoroughly, and the gills removed. Use a soft cloth for drying, then dip the fish in the yolk of an egg beaten up with a little butter, roll it in breadcrumbs, and fry it in hot fat. Alternately it may be dipped in milk, coated with flour and fried for 4 or 5 min. in hot butter. Drain the fish on paper, and serve them garnished with fried parsley. Anchovy or shrimp sauce makes a good accompaniment. *See Anchovy; Fish; Shrimp.*

**GUDGEON PIN.** This is the name given to an axle which turns in a collar. An example is the gudgeon pin which connects the small end of the connecting rod in an internal combustion engine with the piston. *See Big-End; Motor Car; Motor Cycle.*

**GUELDER ROSE.** The popular name of *Viburnum*, a group of leaf-losing and evergreen shrubs of great garden value. The common wild guelder rose or wayfaring tree is *Viburnum lantana* which bears flat heads of white flowers in May, and showy fruits in autumn. For details of the best guelder roses for planting in the garden. *See Viburnum.*

*Guelder Rose. Flowers of one of the double varieties.*

**GUERNSEY LILY.** The popular name of *Nerine sarniensis*, a beautiful greenhouse bulb which bears rose-scarlet flowers in autumn. The bulbs are potted in August, and come quickly into bloom. The leaves develop in the autumn and winter months, so the soil must be kept moist during that period. The plants are grown in a sunny greenhouse in a temperature of about 45 degrees. When, in early summer the leaves turn yellow, watering must be reduced gradually and finally discontinued.

*Guernsey Lily, a greenhouse bulb which bears rose-scarlet flowers.*

**GUEST.** The greatest compliment which a guest can pay to a host and hostess is to enjoy himself or herself.

When invited to stay at a house a guest should intimate beforehand the hour at which he intends to arrive, and hold to that arrangement. Throughout his visit he should do his best to enter into the ordinary family life, thus making his entertainment an easy matter. Tidiness in his bedroom and punctuality at meals will add to his popularity with the household. After his departure he should write a letter of thanks to his late hostess.

Guests should arrive punctually when invited to luncheon or dinner. At an At Home or informal evening party the time may be any convenient hour within certain limits set out on the invitation, but at a bridge party or concert a guest should arrive rather before the time named. *See Etiquette.*

**GUILLOCHE.** The form of carving known as guilloche is frequently seen on English oak chests of the 16th and 17th centuries. It is an interlaced ornament, of which there are several variations. The most usual is formed by a row of circles placed so as just to overlap one another, with the wood cut to make the bands which form the rings go alternately under and over each other. In this way they are bound together in plaited formations of strapwork to simulate braiding. *See Jacobean Style; Tudor Style.*

*Guilloche. Interlaced form of wood carving seen on antique English oak chests.*

**GUINEA.** The English gold coin of the nominal value of 21s. is now obsolete. Guineas were last coined in 1813, and examples are valued by collectors. Pieces

of ½-guinea, 2 guineas, and 5 guineas were also coined. At the present day, although guineas are not used as coins, certain professional fees are reckoned therein. A spade guinea is one, coined in the time of George III, on which the shield on the reverse is pointed at the base, or spade shaped. *See Coins.*

**GUINEA FOWL.** As its flesh makes excellent eating and its eggs are rich and delicate, the guinea-fowl is a profitable bird to keep. The best plan of securing a stock is to get a sitting of eggs and hatch them out under ordinary hens. The period of incubation is 26 to 27 days. The young birds may be fed in the same way as ordinary chickens.

Guinea-fowls should never be mixed with other poultry, and are best kept in a semi-wild state where they can roost on trees in the open. Their egg is of a coffee-and-milk tint, pointed at one end, and the weight of the bird when fully grown is about 3½ lb.

The flesh of the guinea-fowl, though darker and drier than that of ordinary fowl, is extremely palatable. In taste it resembles pheasant, and is frequently served as a substitute for game when the latter is not obtainable. Almost any of the recipes given for chicken or pheasant may be applied with equal success to guinea-fowl. When the bird is to be roasted, proceed as for roast chicken, tying a liberal quantity of bacon over the breasts and basting frequently to counteract the dryness. It requires about ¾ hour's cooking. Celery sauce makes a good accompaniment. *See Chicken; Pheasant.*

*Guinea Fowl. Profitable bird for the poultry keeper, both its flesh and eggs being excellent for the table.*

**GUINEA PIG.** Guinea pigs can be kept comfortably in a more confined space than rabbits, and are generally run in pairs. The period of gestation is 9 to 10 weeks, and the number of young at a birth seldom exceeds five. Little guinea pigs are very precocious.

*Guinea Pig. Small animals which are popular pets with children. A great variety of colouring and marking is obtainable in the short-haired breed.*

The dietary of a guinea pig consists of any kind of

greenstuff, and in the way of solid food a mixture of  $\frac{2}{3}$  bran and  $\frac{1}{3}$  sharps. They are also partial to bread and milk. Water to drink should always be within reach. Good animals of a prize strain have a fair market value. *See Rabbit Hutch.*

**GUITAR: How to Play.** The guitar is one of those instruments which have a fretted fingerboard, and are played by plucking the strings with the fingers. Its parts are, firstly the body, the back and the sides of which are of maple, ash, or cherry wood, and the face or sound-board of deal. The sound-board is pierced with a large round pound-hole in the middle of the narrowest part, or waist, of the guitar.

*(See next page for diagram of guitar fingerboard and corresponding notes.)*

Secondly, there is the neck, the upper side or fingerboard of which is of some hardwood like ebony or beech: upon it are the frets, arranged so as to give a succession, of semitones. This terminates in the head, holding the six tuning pegs, which are now metal screws, three on each side.

The strings are carried from these pegs over the nut to the tail piece, which is fixed at the farther end of the sound-board. They are six in number, the first three being of gut, the others of silk spun over with fine wire, and they are tuned in fourths, except between the 2nd and 3rd, where there is the interval of a third, as shown in the diagram. These are the real sounds, but it is customary to write music for the guitar on the treble stave, an octave higher than the actual pitch. Tune the sixth or lowest string to agree with the corresponding note on the piano, or whatever instrument is to be used in conjunction with the guitar, and from that tune successively the other strings. Let the thumb and first finger of the left hand encircle the neck behind the first fret, the other fingers suitably curved being held over the strings. The body of the guitar is kept in position by firm pressure with the inner part of the right arm. The little finger of the right hand rests upon the sound-board, midway between the tail-piece and the sound-hole, the other fingers being used to pluck the strings, the lowest three by the thumb, and the 3rd, 2nd and 1st strings by the 1st, 2nd and 3rd fingers respectively.

Initial practice will consist in plucking only the open strings in varying order. When facility in thus finding the strings has been attained, it will be time to proceed to the stopped notes, to produce which the finger is pressed firmly upon the string just behind the proper fret. A table of fingering is given in every tutor for the instrument; it is sufficient to say here that to reach the higher frets it is necessary to shift the left hand up the neck.

When the first finger is in its normal position behind the lowest fret, the hand is said to be in the first position; when the hand is shifted so that the first finger is behind the second or third fret, it is in the second or third position respectively. It will be found best to shift after playing an open string.

After use, wipe the instrument with a soft duster, to remove any traces of moisture from the warm hand,

and put it away where it will be protected from dust.

**GUM.** Gum is a vegetable product from trees, which forms mucilage when dissolved in water. The chief gum is that obtained from the acacia tree, known as gum arabic. When dissolved in water in the proportion of gum 1 oz., water  $1\frac{1}{2}$  oz., a thick liquid is obtained which is employed as an adhesive. When the best quality gum arabic is used the resulting mucilage is taken internally as a soothing medicine for severe coughs and sore throats.

In making mucilage cold water is poured over the solid gum and allowed to remain for a few days, then, on stirring, the gum readily dissolves. If hot water is employed the mucilage soon becomes mouldy. To preserve mucilage intended as an adhesive it is necessary to add to it a small proportion of clove oil or formalin.

**GUMMING.** The formation of a semi-transparent exudation upon the bark of fruit trees is usually a sign that the trees have been over-pruned and over-manured. The gum may be scraped away and the affected parts washed with soft water. *See Fruit.*

**GUMS: Their Care.** The bone of the jaw forms sockets in which the teeth are placed, and the gum is closely adherent to the outsides of this bone. When healthy it is of a pale pink colour, and its margin is firmly applied to the necks of the teeth. When inflamed it becomes somewhat swollen and deeper in colour, and is liable to bleed on being rubbed with a toothbrush.

In ordinary cases trouble with the gums generally arises from neglect of the teeth. Regular daily brushing and rinsing the mouth with a teaspoonful of alum in  $\frac{1}{2}$  pint of water will soon restore the gums to normal health. In pyorrhoea the gums become chronically inflamed along the margin, the edge of the long sockets of the teeth become carious, and pus is formed.

**Gum Rash.** A pimply skin rash occurring in infants is known as gum rash, red gum, or tooth rash. It may consist of red pimples, or paler papules somewhat resembling flea-bites, or circular patches developing chiefly on the face, arms, and neck. The rash is usually due to some temporary upset of the digestion during teething-time. No treatment is required other than strictest attention to the cleanliness of the baby's bottles and to the state of the bowels. The child should not be allowed to scratch the pimples.

**Gumboil.** This is a painful swelling in the gum and generally occurs over the diseased root of a tooth, and is caused by the exudation of septic matter from the end of the root.

If there is a cavity in the tooth it may be temporarily filled with a piece of cotton wool dipped in strong carbolic acid and well squeezed out. The squeezing

*(Continued in page 1025)*

Guitar. Diagram of guitar fingerboard and the corresponding notes.

should be done with a tight wad of cotton wool to protect the fingers. If a gumboil has formed the matter should be let out. Fomentations or a hot bag to the face may give temporary relief, but should not be persisted in for long. A dentist should be consulted. *See* Pyorrhoea; Scurvy; Teeth.

**Gum Tree.** This is the popular name of the eucalyptus (q.v.).

**GUN: For the Sportsman.** The essential parts of a gun are the breech, into which the cartridge is inserted, the lock mechanism, to explode the charge, the barrel or tube which directs the shot, and the wooden stock, which rests against the shoulder when firing and is held by the hands. Unlike the rifle, with its spiral grooves, the barrel of the shot gun has a smooth bore, as scattering shot is generally employed.

*Gun. Fig. 1. Double-barrel shot gun.*

Sporting guns are made in two main types. These are the hammer guns, as in Fig. 1, which have exterior arms, known as hammers, which are cocked, or set in position for firing, by drawing back the hammer until a ratchet device holds it in position. It is released by pulling upon the trigger: a powerful spring then drives the hammer forward and causes it to strike against the firing pin. The latter is driven against the percussion cap formed in the centre of the cartridge, and thus explodes the charge. The other type is known as hammerless (Fig. 2), because they have no exterior hammers, these parts being enclosed in the frame of the gun. With this type there is less risk of accident.

The lock mechanism is contained in the frame, to one end of which the barrel is fitted, while the stock is bolted to the other. The locks of the hammerless gun are cocked by means of a piece of mechanism which operates when the breech is opened. The barrels are fitted to the frame by means of a bolt operated by a lever on the top of the frame. The size of the barrels varies according to the purpose for which the gun is required and to the individual taste of the purchaser. For all ordinary sporting purposes No. 12 bore will be found satisfactory; for ladies a No. 16 bore will answer well; while a No. 20 can also be used, and is very handy for short ranges.

With double-barrelled guns it is the general rule that one barrel, usually the left, should be choked, that is, tapered slightly towards the tip or muzzle. The first trigger on the gun is that of the right-hand barrel; after firing this at a moving target, the left-hand barrel can be fired at a longer range, the choking of this giving the

extra few yards required to make the shot effective.

*Fig. 2. Anson & Deeley double-barrel hammerless gun.*

To prevent accidents, various devices have been adopted. These generally consist of a trigger bolt fixed in a vertical position in the frame by pivoting it, and a slide attached to the upper part of the lever on the tang to the back of the top lever which opens the breech. As the slide is pushed, the lower end of the lever is brought close up against the triggers, thereby blocking them and preventing them moving when the safety catch is in the safe position. When the gun is to be fired, this slide must be pushed in the opposite direction so as to bring the lower end away from the triggers. Automatic devices are also employed to prevent accidental discharge.

*Fig. 3. Simple type of sporting gun. (Courtesy of The Midland Gun Co., Birmingham)*

Other types of sporting guns include a small rabbit, or saloon gun (Fig. 3), firing a B.B. cap consisting of a single-ball cartridge. These guns are often fitted with bolt action. The cartridge is inserted between the head of the bolt (when the latter is withdrawn) and the entrance to the breech, and is placed in its firing position by pushing the bolt home.

When not in use any cartridges left in the gun should be withdrawn to prevent accident. Provided it is properly cared for a gun will last a lifetime. It should be coated with a fine film of oil and stored in a dry place, the oil being wiped off when the gun is required. After use it should be taken to pieces, the fore-end taken off and the barrels removed from the stock and thoroughly cleaned, taking special care to get the bore quite clean and dry. If the barrels are exceptionally dirty, pour hot water down them from breech to tip, and thoroughly clean and dry them with a pull-through or other available means. Gun repairing should be entrusted to a gunsmith.

**Gun Licence.** A licence duty must be paid by any one who carries a gun. The licence, which costs 10s., is obtainable at any post office. Certain persons are exempt, e.g. anyone who has a game licence or certificate, and the owner or occupier of lands who

carries a gun for the purpose of scaring birds or killing vermin.

By the Firearms Act, 1937, no firearms (except a smooth-bore shot gun at least 20 in. long, or an air gun not declared to be dangerous) or ammunition may be possessed by anybody unless he holds a certificate granted by the chief officer of the police in the district where he resides. The certificate costs 5s. and the cost of renewal is 2s. 6d. It must be renewed every three years. It should be noted that the possession of a police certificate does not absolve the holder from procuring a gun or game licence. No one may sell a firearm to a person who does not produce a certificate for it. The vendor must take his customer's name and address and notify the police.

A licence to shoot or take game costs a sum varying from £3 to £1, according to the period for which it is required.

**GUN METAL.** This is an alloy consisting of about 90 per cent of copper and about 10 per cent of tin, with small quantities of iron, lead and zinc. Originally used for ordnance, gun metal is now employed for bearings and other mechanical parts. It is extensively used in ships, in the manufacture of valves and other fittings which are exposed to the action of the sea. The amateur will find it of service in the form of small castings and rods.

In model construction, gun metal forms the principal metal of which the small castings for the different parts are made. It is also utilized in hydraulic fittings such as pumps. Gun metal is deep yellow in colour and is machined, polished or lacquered as for brass.

**GUNNERA.** The two species *manicata* and *scabra* of this large-leaved, decorative foliage plant have enormous rhubarb-like leaves. The gunneras are nominally hardy, but it is desirable to cover the rootstocks with leaves or litter in winter. They like a deep, fertile soil, with plenty of moisture. The crowns can be divided in spring if more plants are wanted.

**GURNET.** This fish needs first to be cleaned thoroughly, and after the fins and gills have been removed it is placed in a pan containing boiling salted water, and is cooked gently until done. An average-sized gurnet, which is sufficient for 3 persons, requires about ½ hour's cooking. It may be served with anchovy, caper, parsley, or any other suitable sauce. If liked, the fish may be stuffed with veal forcemeat before being boiled.

Baked gurnet is prepared by filling a cleaned fish with veal forcemeat, sewing it up, and then trussing it with the tail in its mouth. Put it into a baking-dish with one or two thin slices of bacon laid over it, and bake it for ½ hour or more, according to size, in a hot oven. When cooked, it can be served with a sauce prepared as follows: Put 1 tablespoonful chopped onion into a stewpan with the same quantity of vinegar, cook these over the fire for a few minutes, then add ½ pint melted butter, 2 tablespoonfuls of ketchup, and the same

quantity of water. Cook the sauce until it is reduced and slightly thickened, then season it with a little pepper and add the fillets of an anchovy cut into strips. *See Fish.*

**GUSSET: How to Insert.** In dressmaking the piece of material termed a gusset is inserted at the junction of two seams of a garment to give more spring or freedom of movement at this point. It may also be inserted at the end of an opening in a seam, to prevent any strain from splitting the seam open further.

There are two types of gussets which can be inserted at the end of an opening terminating a seam, such as at the base of the sides and sleeves of men's and boys' shirts, the most generally employed being the square gusset illustrated in Figs. 1 and 2. To make such a gusset, cut a piece of material from 2½ to 3 in. square, turn down all the edges to the wrong side about ¼ in., then fold the gusset in halves, trianglewise, and crease the fold well. Open the gusset, set one point to the end of the opening in the seam, and neatly oversew the two sides of one half to the sides of the opening, which should first have been neatly hemmed, as in Fig. 1. Fold the gusset over at the crease-line, and hem the remaining two sides down to enclose all raw edges, as in Fig 2.

*Gusset. Methods of inserting a piece of material to give strength. Figs. 1 and 2. Square gusset. Figs. 3 and 4. Triangular gusset.*

The second type, known as a triangular gusset, is shown in Figs. 3 and 4. For this, cut a piece of material about 2½ in. square, fold it trianglewise, and cut through the fold to obtain two triangular pieces. Take one of these sections, and turn all edges down to the wrong side about ¼ in., turning in the cut edge first, then cut away the extending side points of this edge, and turn in these edges.

Fold the remaining point of the gusset up to reach the fold of the straight edge just mentioned, and crease the fold well. Open out the gusset, set the point to the end of the seam opening, and oversew the sides to the two edges of the opening as far as the crease; then fold

the straight end of the gusset over at this crease, and hem all edges down, as in Fig. 4.

The gusset that is let into the junction of two seams to give more spring and strength is arranged in a different way. Such gussets as these are often inserted into bathing suits and children's rompers of the combination garment type, at the base of the centre front and back, where these meet the top of the short seams that run down the inside of the leg parts. A portion of the leg seams is left open here for this purpose, as Fig. 5 shows.

**Fig. 5.** Portion of leg seam left open for insertion of gusset.

To arrange this class of gusset, cut a piece of material about 3 in. square or more, according to taste; then fold it in halves, triangle fashion, and crease it along the fold. Open it out, place one point to the base of the centre-front of the garment, and run the two sides of one half to the front edges of the open leg seams, as far as the crease, which should reach the end of the leg seams.

Fold the other half of the gusset up, so that the remaining point reaches the base of the centre-back of garment, and run the two sides of this half to the back edges of the leg seam openings. Now take a square piece of material similar to the first, turn in all the edges, and hem them down over those of the first gusset, on the wrong side, to enclose them neatly.

**GUT.** Gut is a cord made from the fibres of the silkworm. One of its chief uses is in the manufacture of fishing tackle, generally in the form of casting lines and points, and also in short lengths attached to a hook. It is available in several thicknesses, fine, medium, and stout. Gut is very strong and of a bluish white colour, and stands prolonged immersion in water. The best method of attaching it to another line is by forming an eye at the end of the gut and whipping it with fine silk, and then varnishing it with shellac varnish. It is also useful in the stringing of beads.

**GUTTA PERCHA.** The solidified juice of various trees grown in Asia, this substance has many of the properties of rubber. The two are, however, slightly different in certain ways. For instance, gutta percha is less elastic than rubber, while it cannot be vulcanized. It becomes plastic at the temperature of boiling water. *See Rubber.*

## GUTTERS AND GUTTERING

### Matters of Economic Importance to Owner and Tenant.

This contribution belongs to a group dealing with the erection and maintenance of buildings. See therefore in addition to Bungalow; Cottage, House, such entries as Drains; Eaves; Flashing; Roof; Water Supply

The purpose of the gutter is to collect rainwater and conduct it to a drain or other outlet. In domestic archi-

tecture the word is applied generally to a cast-iron channel fitted round the eaves or edge of the roof and connected by down pipes to the drainage system. Land or surface gutters are found occasionally in domestic work, more especially in the country. With roof gutters the essential requirement is that the cross-sectional area should be large enough to deal with the water from the roof. A gutter about 4 in. wide is found satisfactory for small property, or where the roof area is small.

The gutter must be rigidly and firmly attached to the roof, and have a regular and steady fall to the down pipe. The ordinary span roof only requires eaves gutters, but where a part of the roof is joined to another roof at right angles to it the joint between the two roof coverings is known as a valley, and the gutter formed in it is termed a valley gutter. Such gutters are to be found round the roofs of many dormer windows, and should receive attention both during construction and, in the case of an older house, from the point of view of repairs. Many of the older houses, both in towns and in the country, are built with curb or M roofs, surrounded on all sides by a parapet.

Gutters formed of sheet-lead or zinc may have perished in the course of time and become porous. The most appropriate methods of repair will be apparent by studying their construction. Whatever may be the type, the water should flow down the gutter to one or more outlets, which should discharge into an open, cup-shaped fitting known as a hopper, or rain-water head. This forms a funnel to the down pipe, which conducts the water from the roof to the ground level, where it should discharge from a shoe into the trapped gully connected with the drainage (Fig. 1).

**Gutter.** Fig. 1. Down pipe swan-neck, and stop-end of an eaves gutter system.

Essential features of the down pipe and fittings include the following (*see Fig. 2*): The down pipe should be truly vertical, attached to the wall by screws or rose-headed nails, passed through the holes in the ears or lugs cast for that purpose on an iron pipe. Lead pipe is secured by straps similarly attached to the wall. The pipe should not be fixed close to the brickwork, but project 2 in. to enable the back of the pipe to be painted or attended to at any time, for which purpose packing pieces are placed between the wall and the lugs on the pipe.

Gutter. Fig. 2. Essential components of a gutter system.

The standard cast-iron rain-water pipes are made in various sizes, from 2 in. in diameter upwards. One end is enlarged to form a socket, and the other is plain. The usual length is 6 ft., although shorter or longer lengths are sometimes available. The pipe should be set with the socket upwards, the upper length having the rain-water head fitted into the socket on the pipe. The bottom length of the pipe fits into the socket on the shoe. The proper size of pipe to use will be determined, as already explained, by the area of the roof, but a 3 in. or 4 in. down pipe is generally fitted to an ordinary eight-roomed house, and is used in conjunction with a 4 in. gutter. The 2 in. pipes are only suitable for small buildings.

The fixing of eaves gutters should be carried out with care and thoroughness, for the reason that the gutters are naturally inaccessible, and once fitted ought not to call for further attention. Rigidity of attachment is essential to regularity of fall. The gutter itself is usually of cast-iron, half-round, O.G., or rectangular in cross section. The former is cheap, the latter more expensive and, incidentally, more handsome, especially if used in conjunction with square rain-water heads and pipes. The O.G. is used most commonly, as it can be screwed directly on to the fascia board, or to the feet of the rafters, whereas the half-round and other sections have to be supported by the gutter brackets. These methods of application are illustrated in Figs. 3 and 4.

Fig. 3. Fixing a gutter bracket to the fascia board.

Fig. 4. Fixing gutter bracket to feet of rafters.

Fig. 5. Valley gutter, showing tiles cut back.

The construction of a valley gutter is shown in Fig. 5, also parts of the roof covering and the disposition of the eaves guttering. It should be made of stout sheet lead, as this has a very long life, and once properly fitted seldom causes trouble. A tiled roof may have the gutter formed by the use of the special valley tiles, which are worked in by the tilers as they cover in the roof. The parapet gutter should be laid with sheet lead or asphalt; the former is the usual material, and was used almost exclusively when this type of guttering was chiefly in vogue. The method of constructing such a gutter is shown in the diagram below (Fig. 6).

Gutter. Fig. 6. How the gutter is arranged in a parapet roof.

Wooden erections such as portable workshops or poultry houses, may have the kind of zinc and galvanized iron gutters sometimes known as shooting. They are supported by brackets or screwed to the feet of the rafters.

**Repairing Gutters.** A common cause of trouble is an obstruction in the gutter itself, such as a bird's nest or the accumulation of leaves. The outlet pipe of the rainwater head is choked up, and the remedy is to clear it out, either by means of an iron rod with a hook at the end, or by the removal of the obstruction from the top, and through the gutter itself. In so doing, where the gutter has a separate outlet pipe discharging into an open head, a piece of sack should be placed in the head to prevent dust and dirt falling into the down pipe, as this is very difficult to remove.

When the gutters have been cleared out, a jug of water should be poured on the roof at the highest point of the gutter. If the gutter is in correct line and has a proper and continuous fall, all the water will run away. If it is found that the gutter sags at one of the joints,

and a pocket of water remains, this indicates that the fastenings or the brackets are deficient in strength, and must be remedied. This is done preferably by fitting a new bracket, or, if that is not feasible, by inserting a packing piece between the bracket and gutter, thereby restoring the proper level.

In the case of the down pipe, it may be possible to clear it by using a heavy iron weight, sharpened at one end. Attach this to a cord, and pull it up and down in the pipe. If it fails, the pipe will have to be taken down, the choked section removed, and the obstruction got rid of by driving it through with a heavy bar, or by clearing it with a screw at the end of a drain-rod.

**GUY ROPE.** The use of a guy rope is to support some upright structure, which may be a tennis-net pole, a flagstaff, the mast of a wireless aerial, or a tent in the garden. As the safety of the structure largely depends upon the guy ropes, it is important to use a rope of the proper size, which may be of hemp or jute, or a steel wire or stranded steel cable.

Light mast. Height in feet	Tarred hemp rope. Circumference in inch	Equivalent size in plough steel wire. Circumference in inch.	Approximate breaking strain in tons
20	1½	½	¾
30	2¼	¾	1¼
40	3	7/8	2¼
50	3¾	1	4

The number of ropes varies; for example, a single rope of about 1 in. circumference at each corner post will suffice for a bathing tent, but a flagstaff requires more elaborate support. It may have one system of ropes from the ground almost to the top of the mast, another separate system from the ground to a point about  $\frac{2}{3}$  the height of the mast, and a third system still nearer the ground. These are to give a distributed support for the mast, so that it will not bend in the middle. The accompanying table will serve as some indication of the use of guy ropes. In the examples given there are four ropes to each mast.

Fig. 1

Guy ropes are set up, or tensioned, in various ways. A simple method is by the use of a tent-peg driven into the ground, and a wooden runner (Fig. 1).

*Guy Rope. Fig. 1. Tent peg and runner for setting up the rope.*

For permanent work, as in the erection of a flagstaff, the anchorage can be made to a concrete block

embedded in the ground. An anchor bolt should be fixed in the block, and should point in the direction of the line of the rope. The rope can be attached to the anchorage by a turn buckle or wire strainer, one end shackled to the eye in the bolt and the other having a cringle or eyelet, the rope spliced round it, as in Fig. 2. The tension is obtained by tightening the turn buckle with a spanner, the rope having previously been stretched and tightened by a small purchase tackle between the rope and the eyebolt. *See Aerial.*

Fig. 2. Diagram showing anchorage and attachment of rope.

Fig. 2

**GYMNASIUM: In the Home.** A simple gymnasium, with apparatus for all necessary exercises, can easily be fitted up in the house if a spare room is available. A suitable size is a room 20 or 24 ft. long and 14 ft. wide, but a smaller one can be utilized. There should be nothing in it to give rise to dust. A good light is desirable, and one at least of the end walls should be without a window so that the boys and girls can face this when jumping, and avoid accident due to a dazzling light.

The apparatus for such a gymnasium should include a portable and adjustable double beam to span the room; this should be counter-balanced in order that it can go to the ceiling and so be out of the way when it is not wanted. Two or four climbing ropes, a small vaulting horse and a pair of jumping stands are other necessary articles, as are three or four sections of wall bars and one or two mats. For men and boys a punch drum that can be fixed against the wall is useful, and the gymnasium should also contain a pulley-weight machine, boxing-gloves, Indian clubs, dumb bells and foils for fencing. As regards dress, the following is suggested as suitable for men and boys when practising in the gymnasium. A tight-fitting jersey or vest, with short arms, a pair of white flannel trousers, and a pair of canvas shoes with india-rubber soles and no heels comprise the necessary garments. A jersey of this kind will allow the arms to move freely, while for a like reason care should be taken that the trousers are not too tight at the seat. They can be fastened with a belt if the buckle and strap on them are not adequate. A sweater should also be provided, and should be put on as soon as the exercises are over, or during a pause.

Those responsible for the gymnasium should take special care that all the apparatus is properly fixed and fastened and therefore safe before being used. This is

especially necessary in the case of horizontal bars and other articles that can be raised or lowered. *See* Dumb Bells; Exercise; Indian Club; Parallel Bars; Vaulting Horse, etc.

**GYMNASTICS:** For Health. Remedial exercises may be usefully employed in a large variety of ailments either for their beneficial action on the general nutrition of the body or for a disability affecting some particular organ or part. Some involve the use of apparatus, a high or low plinth bicycles, bars, etc., but a large number do not call for anything of the sort. These exercises, as a rule, should be supervised by a doctor. General exercises are useful in cases of poor development, convalescence from acute diseases, obesity, indigestion, etc, and should be done in the open air, when possible.

Breathing exercises are given for the cure of early and slight adenoids, for the development of the chest, to complete the cure after pleurisy and empyema by expanding the lung and stretching adhesions, and in various other conditions. *See* Beauty Culture; Breathing; Drill; Dumb Bells; Exercise.

**GYMNOGRAMME.** This is sometimes known as the golden fern, because of the golden powder on the undersides of the fronds of some sorts. A favourite is gymnogramme chrysophylla. They must be grown in a warm, moist greenhouse and need shade from sunshine. *See* Fern.

**GYPSOPHILA** or Gauze Flower. Of these hardy perennial and annual herbaceous plants the most popular species is paniculata, a beautiful spreading perennial growing about 4 ft. high. In summer it becomes a gauzy, lace-like mass of small white flowers which are in great demand for mixing with cut flowers. Although it thrives in most soils, *G. paniculata* prefers a light, dry, chalky soil and an open ordinary site. It can be raised from seed, but the seedlings grow slowly. Once planted it should remain undisturbed. The finest

variety is one named *Bristol Fairy*. *Gypsophila repens* is a charming trailing perennial for the rock garden. *Elegans* is a dainty hardy annual which blooms in summer from seeds sown out of doors in April.

*Gypsophila. Delicate blooms of Gypsophila elegans, a graceful annual very useful for cutting.*

**HABENARIA.** A family of native hardy flowering orchids, the habenarias are found in meadows in Great Britain and Ireland. The best

known, the butterfly orchid, has greenish-white flowers in June and is fragrant at night. There are other hardy species, which are suitable for the rockery, where they thrive in sandy peat. *See* Orchid.

**HABERLEA RHODOPENSIS.** An alpine plant from the Grecian mountains, this bears small, lilac-coloured, gloxinia-like flowers which spring from a rosette of leaves in June. It thrives best in a shady crevice in a compost of peat and sand. It may be raised from seeds in spring.

**HABIT CLOTH.** Plain, self-coloured woollens in medium or light weight, suitable for riding habits, coats and tailor-made costumes, sell under the name of habit cloth. Some have the surface of wool velours, some are face cloths of a more glossy finish, and others spongy. Made customarily from fine, short wools, they have a softness of touch, with sufficient firmness and suppleness to hang well. *See* Riding.

**HACKING KNIFE.** This tool is used to remove old putty from window frames and plaster from ceilings, for the scraping of paint, and similar work in connexion with the re-decoration of the home. It consists of a steel blade with a piece of leather or wood riveted on either side of it to form a handle. It is pointed at one end, thick at the back and tapering to a sharp edge.

In removing putty, the point of the hacking knife is inserted into it, held in a horizontal position, and forced downward by tapping the back of the blade with a light hammer. When cleaning the plaster round a cornice or in any corners, the knife can be used as a scraper. If the end of the blade be broken, the knife can be restored to usefulness by regrinding it to a pointed shape. *See* Glass.

**HACK SAW: How to Use.** A hack saw is used for cutting metal, and consists of a blade carried in a frame. The blade is made of harder metal than the ordinary saw for cutting wood, and is either of dead hard or glass hard steel. The latter is extremely brittle. The frame of a hack saw is provided with pegs to engage the holes in the ends of the blade, and has a wing-nut so arranged that the blade can be strained quite tight by its use. Frames are made which are adjustable to take any standard length of saw-blade, but a fixed frame to take 12 in. blades will meet most ordinary requirements.

The blades vary in length, width, thickness, and fineness of teeth. The pitch of the teeth varies from 14 per in. to 24 per in. or finer. The coarser saws are used for most purposes, but the finer are essential for cutting tubing and thin sheet metal.

The blade is placed in the frame with the teeth facing outward, and inclined forward so as to cut on the push stroke. The holes in the ends of the blade being placed

over the pegs in the frame; the wing-nut is tightened so as to strain the saw quite hard. While tensioning the saw, care is needed to prevent the blade slipping off the pegs, and to see that the blade is not slightly twisted owing to the action of the tensioning screw.

*Hack Saw. Fig. 1. Pistol grip hack saw frame in use. Fig. 2. Bench hack saw machine in use, the vice ensuring accurate cutting.*

In use a hack-saw frame is held by its handle in the right hand and by the front bar in the left, and then pushed across the work with a light downward pressure. On the pull or recovery stroke the downward pressure is entirely removed. As the cut deepens, care is needed to ensure that the stroke is made along the direction of the cut, otherwise the saw will snap. Another cause of broken blades is allowing the frame to cant over to right or left during the stroke; the frame should be kept vertical. The full length of stroke should always be used, otherwise the teeth in the middle will get worn before the others.

A drop of oil on the teeth is sometimes a help when cutting mild steel, but the majority of mechanics use a saw dry on all materials. *See Saw.*

**HADDOCK:** How to Cook. Haddocks include the fresh, smoked and dried varieties, and also the specially cured finnan haddocks prepared near Aberdeen. Those caught in Dublin Bay and off the coast of Devonshire and Cornwall are said to be of the finest quality. Fresh haddocks, which may be served in various ways, should be cooked as soon as possible after purchase.

To boil them, place the fillets in a fish-kettle or frying-pan containing just enough salted boiling water to cover them, and simmer for about 10 min. or until the flesh is tender. A little vinegar may be added to the water. If steaming is preferred, cut the fillets into convenient-sized pieces, and place them on a greased plate on top of a saucepan of boiling water. Cover them with a piece of greased paper, and then with another plate, and steam them until the flesh is of a creamy appearance. This should take  $\frac{1}{4}$  hour. The water in the pan must be kept boiling rapidly. Oyster sauce can accompany boiled or steamed haddock, and parsley may be used as a garnish.

To grill haddock, fillet the fish, cut each fillet into two pieces, wash them, coat them with melted butter and dip them into 1 oz. of flour seasoned to taste. Then place them on a greased gridiron and cook them for about 10 min. turning them once only.

Baked haddock makes another good dish. To prepare it, wash, clean and scale the fish, and fill the inside with veal stuffing, sewing up the opening with fine string. Then either truss it in the shape of the letter S or put its tail in its mouth, brush it all over with beaten egg and

cover it with breadcrumbs. Put it in a baking-tin with a good lump of dripping. Bake it from 30 to 40 min., basting it occasionally with the dripping. Serve it with melted butter or anchovy sauce.

To fry a haddock, wash and dry the fish, and with a sharp knife cut the flesh down the centre of the back, carefully separating it from the bone. Cut the fillet across into convenient-sized pieces, brush each over with beaten egg and cover with crumbs. Fry them a golden brown in hot fat; drain them well, and serve them garnished with fried parsley. Alternatively the fish may be dipped in batter, fried, and then served with a good brown sauce.

Smoked haddock may be cooked and served in a casserole. Wash, dry, and trim the fish and cut it into quarters. Melt 1 oz. margarine in the casserole, add  $\frac{1}{4}$  pint milk and the same quantity of water, and lay in the fish. Cover the pan and let its contents simmer for about 10 min. or till the fish is cooked through, when it should be taken out. Then mix  $\frac{1}{2}$  oz. flour with another gill of milk and pour it into the bottom of the casserole, stirring all the time. Let the whole boil up and thicken, add seasoning to taste, and then serve. The sauce should be of the same thickness as cream.

**Haddock Ball.** A dried haddock may be used to make balls or rissoles. Boil the fish in a fish-kettle or frying-pan until it is tender. Drain it, and separate flesh from bones. Well pound the flesh before adding 1 or 2 tablespoonfuls of grated Parmesan cheese, a little chopped parsley, and seasoning. Bind the whole with one or two well-beaten eggs and 2 teaspoonfuls of Worcester or other sauce. Form it into balls and fry these in smoking hot butter. They may be served on small rounds of fried bread.

**Haddock Fritters.** These are made by beating up the boned remains of a cooked dried haddock with an egg, coating neat pieces with batter and dropping the mixture in spoonfuls into very hot fat.

**Haddock Scallop.** Melt 1 oz. butter in a small pan over the fire and add to it  $1\frac{1}{2}$ -2 gills milk and 3 well-beaten eggs. Stir these over the fire until they begin to thicken, taking care that they do not boil; then draw the pan away from the fire and add about 6 oz. cooked smoked haddock, broken into flakes, 2 teaspoonfuls anchovy essence, 2 oz. breadcrumbs, a dessertspoonful tomato sauce, the juice of half a lemon, and some seasoning. Heat up the whole thoroughly and turn it into scallop shells, the insides of which have been buttered and sprinkled with browned breadcrumbs. Cook the scallops in a quick oven until they are of a golden brown colour; then serve them immediately, garnished with small sprigs of parsley. This mixture can be spread on squares of buttered toast if preferred.

**HAEMOPTYSIS.** Coughing up or spitting of

blood which comes from the air passages or lungs is termed haemoptysis. It is one of the symptoms of consumption and may also occur in pneumonia, plastic bronchitis, and other diseases. When bleeding occurs the patient should lie down and keep quite still until seen by the doctor. *See* Bleeding; Consumption.

**Haemorrhage.** *See* Bleeding.

**Haemorrhoids.** *See* Piles.

**HAEMOSTATIC.** Certain substances used to stop bleeding are known as haemostatics or styptics. Cold, astringent salts of copper, tannic acid, ergot, and the perchloride of iron are all haemostatics, as they encourage clotting or cause the vessels to contract, and thus stop bleeding. *See* Bleeding.

**HAGGIS: How to Prepare.** This Scottish national dish is made chiefly from sheep's fry, chopped and mixed with other ingredients. To prepare it, procure the stomach of a sheep and wash the bags in several waters, rubbing them well with salt. Then scald them in boiling water, scrape them carefully with a knife, and soak them in a strong brine for 12 hours, trimming off any sinewy parts or pieces of gristle.

Wash the lights liver, and heart, and hang them up to dry for 12 hours; then put them in a saucepan with plenty of water and boil them gently. Take the small bag with the windpipe attached, wash it free from the brine put it into another saucepan, with the pipe hanging outside the pan and plenty of water, and boil it slowly for about two hours.

Rub about a third of the liver through a wire sieve, and chop rather coarsely the small bag and 6 oz. mutton suet. Mix these with the liver, adding 1 heaped breakfastcupful of Scotch oatmeal, season the mixture with salt and pepper, and moisten with about 1 breakfastcupful of the liquor in which the lights etc., were boiled. Let the whole stand for  $\frac{1}{2}$  hour then stuff it into the large bag and sew it up securely, using strong thread. Put the haggis into a large saucepan of boiling water, and place a plate underneath to prevent it from sticking to the pan. Boil it quickly for  $1\frac{1}{2}$  hours, pricking the bag occasionally with a skewer to prevent it from bursting, and add more boiling water as the water in the pan diminishes. Serve the haggis on a hot dish as soon as it is taken out of the pan.

## HAIR: ITS BEAUTY AND HYGIENE

### How to Stimulate the Growth and Preserve the Natural Gloss

For other information about the hair see the articles on Baldness; Beauty Culture; Electrolysis. The reader may also consult the entries on various cosmetics and washes for the hair, e.g. Brilliantine; Henna; Shampoo.

To keep it in good condition proper care is required for the hair from earliest childhood. Five minutes' massage night and morning is excellent. It causes the

blood to circulate more freely and brings the necessary nourishment to the hair follicles. It also loosens any dandruff, which is one of the worst enemies of the hair, and properly distributes the oily secretions. The last benefit is a particularly important matter in the case of fair hair, as any artificial oil at the roots has a darkening effect, and nature provides the necessary gloss. Massage with the cushions of the finger-tips, beginning by placing the fingers under the hair by the ears and with gentle pressure going over the whole scalp until it glows with the friction. Rub in such a manner that the scalp is moved and kneaded. This daily hair drill is more important even than brushing. Another method of stimulating the circulation is to take small strands of the hair and give them short, quick pulls, going over the whole head strand by strand. It is interesting to remember that whatever improves the circulation of the scalp will improve the complexion, as the muscles and tissues of the whole head are closely related.

The scalp should be kept scrupulously clean. This prevents blocking up of the hair follicles with dirt or dried sebum. Every hair has associated with it a sebaceous gland. These glands secrete a greasy substance known as sebum, which is nature's lubricant for the hair. If the follicles are blocked the escape of the sebum is prevented, and thus the hair is not only deprived of natural gloss, but the damming up of the secretion in the gland may cause pressure on the delicate hair root and permanently damage it.

The head should therefore be washed regularly, and the hair dried properly afterwards. An infant's scalp requires washing daily and drying with great care. A child should have its head washed once a week, a man usually requires a shampoo as often, and a woman about every ten days. Very dry and brittle hair should not be washed quite so frequently as normal or greasy hair.

**Method of Shampooing.** To shampoo the head the scalp and hair should be thoroughly wetted, and then a good lather rubbed briskly on to the scalp with the tips of the fingers. Cake soap should not be applied, as it is almost impossible to rinse it completely out. Pure castile soap may be shaved and dissolved by pouring hot water over it. This is a suitable shampoo for young children, and for fair or white hair. Tar soap lather is recommended for dark hair. A good herbal shampoo is satisfactory, and obviates the danger of leaving any soap in the hair after rinsing. The importance of complete rinsing cannot be too much stressed, and the final rinse should be with cold water. If the scalp is tender an egg shampoo is beneficial. A little borax may be dissolved in the rinsing water. For fair hair the juice of a lemon may be added to the water for the penultimate rinsing, and a little washing blue to the final one for white hair. When peroxide is employed to lighten the colour of hair, frequent rinsings in vinegar and water are advisable, as the vinegar counteracts the

weakening effect of the peroxide.

After thoroughly rinsing the hair should be dried with warmed towels. Artificial methods of drying hair, though difficult to avoid when time is a consideration, are not to be recommended, as they tend to make the hair brittle. A little brilliantine brushed through the hair after it is dry will improve its appearance and replace the natural oil temporarily removed by the shampoo.

The hair should be combed daily with a comb of good quality having rather thickly cut teeth. A comb should not be used to scrape the scalp, and no comb should be allowed to touch a baby's head, as it may damage the delicate skin.

**Brushes and Brushing.** The softest brush only should be used for a baby; stronger bristles will not injure the scalp once infancy is past, provided the brush is of good quality. Stiff-bristled brushes are good for strong crops of hair, but whalebone and wire brushes are seldom advisable. The hairbrush with bristles embedded in a rubber foundation is a comfortable and healthful type of brush to use for the average head of hair. Such a brush should be frequently cleaned with the smaller brush usually sold with it for this purpose. The latter can be dipped in warm soapsuds, shaken free of drips, and used to brush vigorously across the hairbrush. Rinse by applying the cleansing brush dipped in cold water, and dry as quickly as possible in the sun, or in a warm place, but not too near a fire. An ordinary wooden-backed brush can be washed by dabbing it up and down in hot water containing a little household ammonia. When clean rinse the brush in cold water, or the bristles will soften. As brushes are capable of conveying skin infection, they should be kept perfectly clean, and each child or person should have his own brush. It is unwise to use other people's brushes. A disinfectant, such as a few drops of Lysol, should be used in the rinsing water for the brush, should the scalp be troubled with dandruff.

The following method of stiffening the bristles is said to be successful. Dissolve 2 oz. alum in  $\frac{1}{2}$  pint of warm water, and then dip in the brush. Leave for a few moments and rinse in plain water. The operation of dipping in the alum may be repeated several times, should the bristles seem to require it.

For older children and adults, unless the hair is very brittle, a good brushing for five minutes at least once a day is beneficial. The scalp should feel slightly warm after this. The brush removes particles of scurf, stimulates the scalp, and so increases the blood supply to the hair roots and distributes the natural oil along the whole hair shaft. Brushing enhances the glossy appearance of the head.

**Treatments for Bad Conditions.** Should hair of any shade have been allowed to get out of condition through illness or too much exposure to sun and sea winds, and the scalp be troubled with scurf, a special treatment may be given. The head should be well massaged once a week at night with olive oil which has been heated in a small saucepan. A towel should be

placed over the pillow to protect it from the greasy head and the hair shampooed in the morning. Tar soap lather is recommended, a double application being often necessary to get rid of the oil. Rinse afterwards in water to which a little borax has been added. This treatment can be assisted, until the hair is in good condition, by massaging into the roots twice a week an ointment composed of 4 oz. vaseline, 80 grains salicylic acid, and 60 grains boracic acid; alternating with this some lotion such as one made from 6 oz. bay rum, 3 drachms tincture cantharides, and 1 oz. spirit of rosemary, which should be used as a cleansing stimulant. An oil shampoo is not advisable for dyed hair, as it removes the colour.

The natural colour should return to faded hair after a two-months' course of such treatment, and it is unwise to brighten it artificially beyond the occasional use of a camomile shampoo for fair hair and ordinary henna shampoos for light brown or red hair. Brightening lotions which contain peroxide dry the natural oil out of the hair and thus contribute to premature greyness.

Any lotion or tonic treatment should be started just after the hair has been shampooed, and may be applied by means of a tiny sponge or cotton-wool swab on the end of an orange-stick, after the scalp has been thoroughly stimulated by massage. Tonics should be left off when the condition of the hair improves. Premature greyness of an hereditary nature seldom yields to treatment, but when due to dandruff, or some similar cause, may be corrected by the following pomade: Hydrochloride of pilocarpine, 2 grains; tincture of jaborandi,  $\frac{1}{2}$  oz.; lanolin, 1  $\frac{1}{4}$  oz.; coconut oil, 1  $\frac{1}{4}$  oz.

The value of most hair restorers depends to a great extent on the massage which is given prior to or during their application. The best contain ingredients which increase the flow of the blood to the scalp and thus stimulate growth. The commonest ingredients are some preparations of sulphur, ammonia, bay rum, pilocarpine, cantharides, capsicum, spirits of rosemary and quinine. A good tonic restorer is composed of liquor of ammonia (strong),  $\frac{1}{2}$  oz.; chloroform,  $\frac{1}{2}$  oz.; oil of sesame,  $\frac{1}{2}$  oz.; oil of lemon,  $\frac{1}{2}$  oz.; spirits of rosemary, 2 oz.

Restorers which contain sulphur are useful in cases of loss of hair due to dandruff. They act by destroying the cause and at the same time stimulating the skin. In general terms it may be said that the use of hair restorers is futile in cases of baldness where the hair papillae (the papilla is the active part of the hair) have been destroyed, whereas if the hair papillae still exist the stimulation of a good hair restorer may quicken the local circulation and the papillae may recover some of their old activity.

Despite every care a child's hair may become infested with parasites at school. To get rid of the nits the hair should be thoroughly moistened with equal parts of vinegar and water and carefully gone over

with a fine toothed comb. Care must be taken to see that all nits and scurf removed are burned in the paper in which they are collected.

The simplest preparation for killing lice is paraffin oil. This should be rubbed into the head at night, a rag soaked in the oil placed over the head and covered with a rubber cap. The treatment should be repeated the following morning and evening, and on the morning after the head should be thoroughly washed with soap and water. Paraffin is very inflammable and naked lights must not be brought near it. If there is any soreness of the scalp an equal mixture of olive oil and paraffin should be applied at night for the next ten days.

Alternative applications are the B.P. ointment of stavesacre, which is obtainable from any chemist, or the following: white precipitate ointment, 60 grains; zinc ointment to make 1 oz.

Brushes, combs and caps must be disinfected by being soaked in Lysol solution—1 teaspoonful to a pint of warm water—and then rinsed thoroughly in soapy water.

**Hair Dyes.** Hair dyeing and tinting is best performed by experts, and henna dyes are usually the most satisfactory and also the safest to use. Some of the preparations sold for dyeing hair contain powerful irritants which may cause skin trouble involving not only the scalp but the face and neck. Unfortunately these dyes include some of the most satisfactory brown colourings. At a reliable hairdresser's an expert will experiment with a small portion of hair before applying such a dye over the whole scalp, in order to see if the customer is immune from possible bad results. Henna dyes for various shades of hair are sold with full instructions for use.

The henna paste is left on the hair for the time required for the particular tint, and then washed off with water. If using any form of hair dye at home it is advisable to wear rubber gloves and protect the skin of face and neck by smearing them with vaseline before applying the dye. The troubles with dyed hair are that it is difficult to keep the scalp in good condition owing to the effect of oil and tonics on the colour, that the white hair growing at the roots shows fairly soon and requires frequent touching up, that it presents a hard and lustreless appearance and that it can rarely be successfully permanently waved.

Hair can be bleached to blonde shades if this is carefully done. The bleaching should be effected gradually or the hair will suffer. Some women go over the scalp after a shampoo with peroxide (10 volume solution), applying it with a small toothbrush specially kept for the purpose.

**Superfluous Hair.** Peroxide is particularly useful for bleaching dark superfluous hairs on the face or arms, and rendering them less noticeable. It can be used in a treatment with resorcin soap, a cake of which is dipped in hot water and rubbed on the skin. Water will remove the stain of this soap, but it should be left on at night. After washing the face in the morning

apply peroxide of hydrogen and ammonia in the proportion of 10 drops of peroxide to 1 of ammonia. The solution must be freshly mixed each time and applied with a pad of cotton wool. It may smart a little at first, but the skin will grow used to the treatment, which should be persevered with. After some time the skin may be able to stand a stronger solution in the proportion of 5 drops of peroxide to 3 of ammonia. Apply cold cream afterwards if the face feels sore. This treatment should eventually not only bleach but kill the hair roots. For strong, persistent growths of superfluous hair on the face either electrolysis or diathermy is often employed. It is essential to have such treatments performed by a good operator (See p. 709).

**Waving the Hair.** Home waving with curling irons is always a difficult matter and apt to be unbecoming. The simplest method is to part the hair and wind it round rather thick irons. This gives big natural looking waves, but is only suitable for longer hair. Hair with the slightest disposition to a natural wave should be encouraged by being set in combs after a shampoo. Straight hair when beautifully kept to give it a smooth sheen is becoming to women with well-shaped heads.

Permanent waving solves many hairdressing problems. At the same time it is not a means of lessening proper care of the hair. The scalp should be in good condition before the hair is permanently waved, and the process should be considered as a decorative step towards a charmingly finished head rather than as an end in itself. Cheap permanent waving should not be risked. The best operators—and the operator is of more importance in this connexion than the system employed—are to be found at the best hair-dressing establishments, or in such departments at well-known stores.

Where disappointment follows after permanent waving it is usually due to lack of experience on the part of the operator or to lack of subsequent care of the hair. If the scalp is dry the permanent wave will make it dryer. The hygiene of the hair, as described in the first part of this article, must be daily practised and foolish prejudices about disarranging the set of the waves by massage and brushing must be discarded if the result is to be worth the expense not only of the initial operation, but also of the settings, necessary at least once a fortnight, to keep the waves from developing into a mere frizz.

This setting can be done at home with a setting lotion and by careful adjustment of special combs or metal clips used after a shampoo. A net should be worn over the head while the hair is setting. Some women wear a shingle net over combs at night to keep their permanent waves set, but the practice is not really good for the hair, which benefits by being left quite loose.

In dressing long hair the smallest number of hairpins, compatible with making the knot securely close to the head, should be used. Slides for children's hair should be of non-inflammable material.

**HAIRCLOTH.** Mohair, alpaca, camel-hair and other cloths made from hair as fine as or finer than wool are only technically haircloths. What are usually known by this name are such coarse fabrics as horsehair or crinoline cloths, used by tailors to stiffen the shoulders of jackets, or the hair interlining for making soft lapels. Haircloth is employed for interlinings because of its resiliency; when bent, it tends naturally to return to its position, thus keeping the garment in shape.

Crinoline cloth lent its name to the style of dress in which the skirt was distended by the stiffness of the horsehair. Tail hairs of horses woven one at a time across a set of cotton or linen threads make both crinoline cloth and the horsehair seating to be seen on furniture. As chair-seating material, haircloth is immensely durable. Crinoline made from real horsehair for hat shapes has been largely replaced by a form of artificial silk.

To make flexible canvas hair interlinings, Chinese human hair, as well as goat and other strong hair, is used; the fabric resembles a brown flax canvas, but is more springy. The hair carpet sold for stairs and passages is made in the Brussels style from cowhair. Cowhair often forms the pile of cheap plushettes for portières, mantelpiece drapery, and the covering of toy animals, such as Teddy bears.

Haircloths are made for strainers for kitchen use, and for belts for driving machinery. In buying haircloth for interlining coats the resiliency may be tested by folding and creasing the sample, and noting how it recovers its flatness.

**HAIRPIN WORK.** This work is so named because of the fact that it is done on a two-pronged fork which resembles a large steel hairpin. It is made in several sizes, and there is also an adjustable fork, the width between the prongs being regulated by a screw. On this implement insertions from 1 in. to about 4 in. wide can be worked in thick silk, cotton, or raffia.

*Hairpin Work. Fig. 1. Showing how the first pattern is worked on the prong. Fig. 2. Medallion of coloured raffia, a suitable trimming for a summer hat.*

Fig. 1 shows the first pattern in hairpin work, and it is on a prong measuring  $1\frac{1}{4}$  in. wide. A steel crochet hook is also required of a size according to the thickness of the working thread. Make a loose crochet chain on the hook and draw it out until it is about as long as half the width between the prongs of the pin. Draw out the crochet hook, slip this loop on the left-hand prong, and see that the length of working thread is in front of the fork. Hold the pin with the thumb and middle finger of the left hand and the rounded part in the palm. Pass the thread round the right prong from

the front, and put the hook upward, from the front, through the loop on the left prong. Catch the thread and draw it through the loop, thread over the hook and draw it through the loop which is on the hook, making a double crochet.

Pass the thread from behind round the left prong, and turn the latter to the right, so that the thread now surrounds the right prong. As the pin is turned, let the crochet hook pass between the prongs so that it will be in position to work from the front again. \* Draw the thread through the loop on the hook, then put the hook upwards from below through the loop on the left prong, draw the thread through and work a double crochet as before. Repeat from \* until the pin is full, then take the loops off the prongs, and if more are wanted replace two or three of the loops at the top and continue working as before.

When the work is taken off the prongs the little loops twist into a figure 8. To make an insertion, join the silk to the first loop by working a double crochet into it, inserting the hook from right to left all through to preserve the twist or figure 8. After the double crochet make one chain stitch, and continue all along, alternately working one chain and one double crochet in the loop. Work the opposite loops in the same way to complete the insertion. A lace can be made by working a shell edging along one side.

Fig. 2 shows the hat trimming worked with raffia, and a No. 00 steel crochet hook, on the small prong  $1\frac{1}{4}$  in. wide. Raffia can be bought in many colours, as well as natural colour. Before working the raffia it is best to soak it in cold water for about 10 min. to make it more pliable, after which wipe the water off. Proceed as in Fig. 1 until there are 18 loops on each prong, slip off the pin and cut the raffia, then tie this cut end to the end at the beginning of the work to form a ring. Run a piece of raffia through one round of loops and draw up so that it forms a flat piece; tie and secure the raffia. A piece of silk could be used for the latter purpose, as it is inside the loops and the ends need not show. When a sufficient number of these rings have been made in various colours they can be arranged round the crown of a shady garden hat made of coarse straw. See Crochet, Raffia.

**HAIRSPRING.** This name is given to a small spring used in conjunction with the balance-wheel staff of a timepiece. Its function is to control the regular motion of the balance wheel. It is a very delicate spring and should never be interfered with. See Clock; Watch.

**HAKE:** How to Cook. Many consider hake to be superior to haddock and plaice, both in flavour, digestibility, and nutritive qualities. To bake it, cut four slices from a medium-sized hake, wash and dry them, and lay them in a greased fireproof baking-dish. Dredge them with flour and sprinkle over them a good seasoning of salt and pepper, a teaspoonful each of finely chopped parsley and onion, and 1 oz. butter cut into small pieces. Bake the fish gently for  $\frac{1}{2}$  an hour,

basting it occasionally; then place it on a hot dish, strain the liquor over it, and it is ready for the table.

Hake au gratin is prepared in the same way except that the parsley and onion are omitted and a tablespoonful each of browned crumbs and grated cheese used instead. Hake may also be cooked according to any of the recipes given for cod. *See* Cod; Fish.

**HALATION: Of Negatives.** Halation is a fogging of negatives caused by scattering or reflection of light in the film. Thus if a window through which sunlight or a strong light passes is included in a photograph, not only will the window part of the picture be considerably over-exposed, but all round it a fog of light, without any detail whatever, will appear in the print.

Similarly, halation will appear when trees against a bright sky are photographed. The trouble is largely overcome by coating the back of a glass plate with a preparation which absorbs the light passing through the film and prevents its reflection on the underside of the film. This is known as backing the plate. It has been found that unbacked plates coated with a matt emulsion hardly suffer from halation at all.

Films do not suffer from halation to the same extent as plates, but care should be taken not to over-expose if strong high-lights are in the picture. Where moderate halation occurs with over-exposed high-lights, the defect can be overcome to a certain extent by local reduction of the negative. The fogged over-exposed portion is treated with a weak reducing solution applied with a piece of cotton wool on a match-stick. *See* Reducer.

**HALF TIMBER.** This term is used to describe those buildings, chiefly houses, in which the framework is of timber, the intermediate panels being filled with brick, plaster stucco, or other material of that kind. In some of these houses the masonry or brickwork rises through two storeys, and the half-timber work is confined to the gables. Many old examples were covered with plaster or stucco, but in some cases this has been subsequently removed.

This style, which prevailed in England in the 16th century, when native timber was plentiful, has been much imitated in the 20th century. Modern half-timber houses, however, differ essentially from the old ones, for in them the timbers are merely on the surface, being only thin pieces of wood nailed to a brick backing and lacking the solid look that real half-timber work can produce. *See* Architecture; Cottage.

**HALIBUT.** Baked halibut is prepared in the same way as hake (q.v.), except that it is covered with thin slices of bacon or ham.

To stew halibut, wash and dry 3 to 4 lb. of the fish, put it into a stewpan, and barely cover it with milk. Add an onion with 3 or 4 cloves stuck in it, a bay leaf, and a little salt and pepper, and bring all gently to boiling point. Mix together 1 oz. flour and 1 oz. butter; add this to the halibut and simmer the whole gently until the bones can easily be separated from the flesh.

Serve it on a hot dish and pour over it some of the liquor, to which has been added a teaspoonful of lemon juice and seasoning. The remainder should be sent to table in a sauce boat. This provides a specially good way of cooking the head and shoulders of halibut.

## HALLS: DECORATION AND FURNISHING Suggestions for Treatment in Various Styles

This article concludes with a section on the construction of a hall stand. *See* also the entries on Carpet; Chair; Chest; Chimney Piece; Cupboard; Door; Electric Light Fittings; Flowers; Frieze; Furniture; Grandfather Clock; Landing; Panelling; Settle; Staircase; Table

It sometimes seems as though the hall had been neglected in a scheme of house decoration; yet, apart from the fact that every corner of the home should be well and suitably planned, the hall is also important because visitors take their first impressions of the house from the entrance. Therefore it is necessary to give the hall as hospitable and friendly an air as possible.

This is especially difficult with the small narrow hall, which is still too often merely completed with an umbrella and coat stand, a hard wooden chair and a hall table of un-pleasing shape. For the larger type of hall it is easier to evolve a good decorative scheme, whether on classical lines or with comfortable lounge furniture; but here, too, details of colour, flooring and lighting fittings are sometimes not carried out to a harmonious conclusion.

In furnishing much depends on whether the staircase opens directly out of the hall or from an inner hall, which may or may not be entirely cut off. A beautiful staircase opening out of the hall directly makes all the difference; it is an architectural feature which can only be modified or disguised at considerable cost if it is not well designed and executed when building the house.

In some modern houses there is a square entrance hall, of which the fourth wall is left incomplete, leaving an open archway to the back hall from which the staircase ascends. If the hall is to be used as a lounge and living room, it is convenient to have an inner glazed door, so that there is light and a view on to the garden, as the main door can then be left open. This is desirable, because it is rarely possible to secure more than one window in the hall. The glass panels and wrought ironwork of this type of door look particularly well in a dignified hall with black and white tiling and one or two pieces of beautiful furniture.

In some houses the hall is converted into a lounge by removing the partition which separates it from the front room. Here also an inner door is advisable, more for the purpose of keeping out draughts than for giving extra light. In the absence of such a door, draughts may be avoided to some extent by the use of a leather screen.

**Suitable Furnishing.** If there is a fine pavement, such as a black and white square, this is always effective. A composition paving which simulates stone, an oak plank or a good parquet flooring, an inlaid linoleum to resemble the last, or rubber-tiled and marble floorings are all suitable. Persian, other Oriental, or modern rugs which introduce brilliant colouring in geometrical designs, give an air of comfort. For the long narrow corridor often met with in a flat, a strip of wide stair carpet in a good design is usually a better choice than intermittent rugs when the boards have to be stained. Plain carpet looks attractive but shows every footmark. Hall door mats should fit neatly.

Where there is either an outer hall or a back hall the question of the position of the hall stand is solved. These pieces of furniture are not decorative, and coats, especially when they are wet, are not benefited by being hung up on them. The cupboard, either built-in or movable, is a welcome alternative and serves also for an umbrella stand, when fitted with a rack for this purpose fixed to the inside of the door. In the small flat wet coats and umbrellas are often accommodated, while drying, in the bathroom, a row of pegs being provided on the door for the former and the latter being left open till dry. In larger old houses and in most modern ones there is usually a cloak room off the hall where coats and mackintoshes can be properly hung up.

In old country houses the open fireplace is usually an important feature of the hall. In the modern house, if there is no central heating, the most practical fireplace is the anthracite stove. Radiators can be cleverly hidden behind wrought iron or wooden grilles under the window or at a turn of the stairs.

A favourite style of furniture for the lounge type of hall is the Jacobean, or, if it can be obtained, Normandy oak. Old oak chests for keeping requisites for outdoor games, a big oak cupboard for hanging mackintoshes and coats, a gate-leg table for tea, an oak bureau, high-backed chairs, some easy chairs and a settee covered in velvet or in a printed linen of Jacobean design, a table for visiting cards, in post and out post, and in the country, should there be no electric lighting, another table by the staircase for bedroom candles and lamps—these are the usual pieces of furniture required for such a hall. As there are often many exits and entrances, a tall draught screen placed where wanted is a useful addition.

For floral decoration much depends on the type of hall and the taste of the owner. Formal orange trees in big tubs are picturesque in a hall with paved floor. In a country house such plants as hydrangeas, azaleas or geraniums in tubs or large pots, palms or small flowering trees or Japanese trees can also be used with good effect. In many country houses a feature is made of this floral decoration of the hall, and it is transformed into a winter garden during the gloomy months. In the summer an arrangement of flowers on the hearth gives a very inviting air.

The colour scheme must be carefully thought out, as the decoration of the hall is the keynote to the whole house. Where this is treated on modern lines, the furniture and decoration of the hall will, of course, fall

in with it. Where there are panelled walls and an old wooden staircase the choice of furniture and flooring for the hall will not quarrel with the period. The latter type of hall needs few wall ornaments. Pictures should be scarce and oil paintings look best when let into a panel over the fireplace. Panels of tapestry also give good notes of colour.

The question of lighting is important. The choice of hall fittings is varied and many firms specialize in good designs suitable for various styles and periods.

*Hall. Fig. 1. Panelled and tiled hall, with Jacobean oak furnishing and heavy beams.*

**Our Illustrations.** A particularly charming old wrought iron lamp head fitted for electric light completes the newel at the base of the polished and uncarpeted stairs in the first illustration. This hall is furnished in a delightful style. Its dark panelling, leaded casement and heavy beams demand plain furniture. The Jacobean table and stools accord perfectly with them, while the early 18th century grandfather clock is equally happy and the red tiled floor adds a rich note of colour. This is further enhanced by the azaleas and a few pieces of old brass.

*Fig. 2. Small oak furnished hall with panelled and carved oak staircase and doors. (Humphrey Joel)*

Another inviting but smaller panelled hall is shown in Fig. 2. Here the interest is centred on the carved oak of the double doors into the sitting room and of the staircase. A Persian rug on the oak boarded floor makes a connecting colour link between the Oriental design of the silk casement curtain and the pottery on the shelf formed by the

architrave of the door. An old settle is visible on the left and there is an attractive gong. This hall is warmed by a radiator and lit by a hanging oil lamp.

Although imitations are seldom deceptive, quite a good effect can be obtained by using lincrusta moulded wall covering, which simulates oak panelling. Made in rolls and fixed like wallpaper, some of the designs are exact copies of old English panelling. In flats or houses rented for periods of a few years, most people would hesitate to pay the large sum necessary to panel a hall and staircase in real oak. These lincrusta wall coverings are useful in such cases especially when sur-mounted by an anaglypta frieze with plaster-like relief, as shown in Fig. 3. The dark oak coloured cornice is a change. Both frieze and ceiling are distempered an old ivory shade. The carved pedestal with its Chinese jar, the oak chair and the Oriental carpet are all well chosen to furnish this small but rather highly decorated town hall, which requires no heavy pieces.

*Fig. 3. Lincrusta panelling to imitate carved oak surmounted by a frieze, suitable for a modern flat. (Courtesy of Arthur Sanderson & Sons, Ltd.)*

A very different type of entrance is shown in Fig. 4. Here the black and white marbled tiling and pillared archways call for dignified and restrained furnishing. The white painted staircase with its mahogany handrail has a suggestion of Georgian style. Colour accents are

supplied by the pieces of old china and the flowers on the table.

*Fig. 4. Large hall, simply furnished, with low pillared archways and windows set near the ceiling.*

A difficult hall to decorate successfully is the long narrow corridor type found in many flats. Fig. 5 shows a hall of this kind panelled in simple Georgian style in accord with the furnishing of the sitting rooms opening off it. The polished chest just breaks the straight look of the passage, the round mirror also helping to do this on the other side. Wherever an appearance of space is

needed light self-coloured walls should be chosen. A modern treatment for such a hall might be pale grey papered walls and a silver ceiling. Colour would be introduced by the curtains and carpet. For either flat or small town house the treatment shown in Fig. 6 is suitable. The landscape wallpaper motif is bought separately and applied with the framing of raised moulding. In a tiny hall, one such motif is sufficient, but in the case of a house the landscape might be repeated on suitable spaces on the landing walls. The paper used with the motifs has a marble tiled effect in grey-green colouring which is in pleasing harmony with the sky, foliage and water of the landscape.

*Hall. Fig. 5. A narrow hall treated in such a way as to give an effect of spaciousness.*

Hall Stand in Oak. The hall stand shown in Figs. 7 and 8 is made from a set of prepared materials put up by a well-known firm of dealers in handicrafts requisites. Joints are already cut, and the difficult

portion of the work has been done.

*Fig. 6. Wallpaper treatment with applied landscape motif on a varnished and marbled paper. (Arthur Sanderson & Sons, Ltd.)*

The diagram shows the method of assembling the component parts. The back is taken in hand first, the joints being glued up and the whole cramped and put aside for the glue to set. It will be seen that dowels are largely used, this method presenting little difficulty to the worker. The mirror and plywood panel fit into the grooves in the uprights (Figs. 8 and 9), a bead being mitred round the front to finish. The mirror is secured at the back as shown (Fig. 9), and is covered in by a plywood backboard.

The front of the stand is glued up, less the shaped brackets, and put aside to set hard. It is connected to the back by glueing up and fixing the top and bottom rails. The board which receives the two drip pans is supported by slips glued to the side rails. The shaped brackets are added afterwards. The methods of fixing the capping and securing the plywood panel are shown in Fig. 9.

*Hall. Fig. 7. Hall stand, the making of which is described in the text.*

*Fig. 8. Details for the construction of this useful piece of furniture.*

*Fig. 9. Diagram showing method of fixing mirror, panel, and capping of the hall stand illustrated above.*

**Hall Mark.** See Silver.

**HALLOWE'EN.** Hallowe'en, or All Hallowe'en, is kept on Oct. 31, the eve of All Saints' Day, and from the customs of pagan times some games have come down to us.

Chestnuts are used for purposes of divination. They are roasted on the bars of the grate by different people in turn. If a girl is in charge she names three chestnuts after men of her acquaintance, and the one that pops first bears the name of the man she will marry. The

men name their chestnuts after girls with the same purpose. If two nuts are put on the bars side by side, one named after the girl and the other after the man, and they both burn together, the two will be married.

Another familiar game is bob apple. A tub is filled with water and a number of apples floated in it. The players have to catch the apples with their teeth as best they can, which usually means ducking their heads well into the water. In another form of the game, apples are suspended by a string from the ceiling, or some high bar near the ceiling, and each player in turn stands in front of an apple and, with hands clasped behind the back, endeavours to catch it with his or her teeth.

**HALMA.** This game is played on a square board divided into 256 squares, 16 each way. Wooden pieces are employed, something like the pawns in chess, but smaller. It is usually played by two players, who have each 19 pieces, one group being black and the other white. The pieces are grouped when play opens in opposite corners of the board, enclosures being marked off for them on the board.

The object of the game is to get one's 19 pieces into the opponent's enclosure before he can do the same. The players move alternately, one piece at a time, into an adjoining square, except when a piece can be moved over another piece into a vacant square beyond. In one move a piece can be passed over as many pieces as possible, and the pieces can be moved over friendly as well as hostile ones. If four persons play, each has 13 pieces, coloured white, black, red, and green, and they can play either each for his own hand or two against two.

**HALVED JOINT.** The general appearance of a lapped halved joint is illustrated on the next page. As an example, suppose it is desired to make a joint at the corner of a simple frame work, and that the material is 3 in. wide and 2 in. thick. First plane up the material on all sides, and square off the ends. Then at a distance of 3 in. from the end square a line around three sides of the material, set the marking gauge exactly at half the thickness of the wood, and mark a line on the edges of the pieces of wood, on both sides, and the end where the joint is to be made.

*Halved Joint. Method of joining two pieces of wood, securing the carefully fitted parts with glue or screws.*

Place the wood horizontally in a vice, or rest it against the bench hook, and saw across the wood exactly on the line marked across it, and to a depth of half the thickness of the material. Put the material in

an upright position in the vice, and then saw along the line cut by the marking gauge, sawing to the edge of the line. This will remove a square piece of wood, 1 in. thick, from the main portion, and if both are carefully sawn, the result should be a neat and accurate joint when the two pieces are put together.

The joint surfaces should be trued up with a sharp chisel, and the two pieces accurately fitted. The joint is completed by glueing, screwing, or nailing the parts together. The same principle can be adopted for oblique-angled joints, or for running joints, as when joining the ends of two pieces together in a straight line.

**HAM: Curing and Cooking.** When selecting a leg of ham choose one that has a short shank and a moderate amount of fat, and test its freshness by inserting the knife under the bone. The ham is good if the knife comes out clean and smells fresh, and bad if daubed and of a rank, disagreeable odour.

Hams may be cured at home by rubbing them well with common salt, leaving them to stand for three days, and then draining off the brine. Mix 1 lb of brown sugar, the same quantity of common salt, and 2 oz. of saltpetre, rub the hams well with this mixture, and put them in a vessel large enough to hold them. Leave them for another three days; then pour a quart of vinegar over them. Turn them over in the brine once every day for a month, then drain them well and hang them up to dry. When sufficiently dry put them in muslin bags to protect them from flies and dust. After draining them from the brine, an alternative method is to smoke them over a wood fire, hanging them directly above it.

To boil a ham, first soak it for about 12 hours, or longer if it seems very dry, wash it thoroughly and trim away all rusty parts. Put it in a pan with enough cold water to cover it, and bring it gradually to the boil, removing all scum as it rises. Then let it simmer gently until tender. A ham weighing about 10 lb. will require 4 hours' gentle cooking. When done, take it out of the pot, strip off the skin, and sprinkle over it some browned crumbs or raspings. If the ham is to be served cold let it remain in the water until quite cold, as this renders it more mellow.

*Ham. Boiled ham sprinkled with breadcrumbs and garnished with parsley and a paper frill round the bone.*

A ham may also be baked. To do this, first soak it in cold water for 12 hours, then wipe it dry and trim off all rusty parts. Make a crust of flour and water, thick enough to keep in all the juices, cover the ham entirely with this, put it into a baking tin in a moderately hot oven, and bake it for about 4 hours. Then remove the crust, and skin. Cover the top with raspings, and pin a

paper frill round the knuckle.

A favourite breakfast dish, fried ham and eggs, is prepared by cutting the required number of slices and frying them. Cook the ham on both sides and then keep it warm while the eggs are being prepared. Break these, one at a time, into a cup and then cook them in the fat which remains in the pan, adding a little more if necessary. Baste the eggs with the hot fat to set the tops. When set take up with an egg slice and lay them on the ham. Ham prepared in this way may also be served with baked or grilled tomatoes. Grilled ham may be cooked in a Dutch oven before the fire or beneath a gas grill.

Potted ham is made by mincing together  $\frac{1}{2}$  lb cold lean ham and 3 oz. cold roast veal, and then pounding them in a mortar with  $\frac{1}{4}$  lb. butter, added by degrees. When all are well beaten, sprinkle over them a mixture comprising  $\frac{1}{2}$  teaspoonful freshly pounded mace, a little less than quarter of a grated nutmeg and a good pinch of cayenne. Mix all together, and then press the meat into pots, pouring clarified butter over the top. If kept in a cool, dry place this meat will remain good for over a fortnight.

To glaze a ham, take off the rind, trim it and, after placing it in the oven for a few minutes, dry it with a cloth. Dip a paste brush into some melted glaze and brush it over the ham, giving two or three coats.

**Ham Pie.** To make this pie, boil 3 oz. of macaroni, allow it to get cold, and cut it into inch lengths. Mince  $\frac{1}{2}$  lb. ham, and put a layer of this at the bottom of a pie-dish. Season with pepper and sprinkle over it some minced parsley; then add a layer of macaroni, some chopped onion, and some small pieces of butter. Continue these layers until the dish is almost filled, and then add a little white sauce, a layer of fine breadcrumbs, and some more pieces of butter. Bake the pie in a moderate oven until it is lightly browned.

**Ham Soufflé.** A large cold ham soufflé or several small ones can be made as follows: Chop  $\frac{1}{2}$  lb. lean cooked ham, and pound it in a mortar with  $\frac{1}{2}$  pint brown sauce, afterwards rubbing them through a sieve. Whisk  $1\frac{1}{2}$  gills of melted aspic jelly until it begins to set; then stir it into the ham mixture, seasoning it with salt, pepper, ground nutmeg and mace. Whip  $\frac{1}{4}$  pint cream until it will just hang on the whisk; then stir it in, whisking it for about 5 min.

Have ready some small soufflé cases, tie a band of foolscap paper round each, reaching about 1 in. higher than the top of the case. Put in the mixture, arrange in the centre a star or other design cut from truffle or chilli, and pour over a little melted aspic. Leave the soufflés until they are set; then draw off the bands of paper. *See Bacon; Carving; Chicken; Glaze; etc.*

**Hamamelis.** *See Witch Hazel.*

**HAMBURG FOWL.** One of the most graceful and attractive of fowls, the Hamburg is a fine layer where a good strain is secured. It does better on a wide range than in confinement. The best known colours are the blacks, gold, and silver spangled, and gold and silver pencilled. *See Fowl; Poultry.*

**HAMMER.** The commonest type for metal-worker's use is that known as the engineer's ball-peine hammer, Fig. 1. These are made in all weights, from  $\frac{1}{4}$  lb. to 4 lb. or more, the weight being that of the head, or metal part, of the hammer, which is of cast steel, with an ash or hickory handle. For use in ordinary woodwork, a Warrington hammer or an Exeter pattern hammer is convenient. The former is similar to the engineer's cross peine hammer, but longer in the head. In the Exeter pattern (Fig. 2), the cross peine is set to the back of the head, and not central as in the former case.

*Hammer. Fig. 1. Engineer's ball-peine hammer. Fig. 2. Exeter pattern. Fig. 3. Pin hammer in use.*

The Kent pattern claw hammer is useful in the house, the claw being handy for the withdrawal of nails. Riveting hammers are made with a small cross section and a long head with a cross peine. The ball-peine pin hammers (Fig. 3) are almost as suitable for riveting,

and extremely handy for driving all classes of fine tacks, panel pins, and for such purposes as fixing the bead round a window frame. The upholsterer's hammer (Fig. 4) is notable for its great length of head, and is made in two forms, one with a claw and the other, known as a cabriole, with a narrow cross peine.

*Fig. 4. Upholsterer's hammer. Fig. 5. Mason's club hammer. Fig. 6. Repoussé or chasing hammer.*

The hide-faced hammers comprise a wood handle, and a cast or wrought iron socket with inserted pieces of raw hide. They are used

for sheet metal work, or on parts where hammer marks or bruises would be objectionable. A somewhat similar hammer is made of brass. Jeweller's or watch hammers are small and very light in weight; their use is necessary in this class of work.

Sledge hammers are outside the scope of amateur work, except perhaps the 3 lb. hand sledge or smith's hammer, which is often useful for small forging jobs worked cold in the vice. A somewhat similar hammer is the mason's club hammer (Fig. 5). The lath hammer has a flat face for driving the nails, and a broad axe-like face for cutting the lath. Chasers or repoussé hammers (Fig. 6) have a face large in diameter and a ball or other shape peine.

**Fitting a Handle.** When fitting a hammer head to a handle the end of the handle is shaped to fit tightly through the eye of the hammer. A slot is cut in the end of the handle, and a thin metal or hardwood wedge driven into it. Very often the hammer head and the end of the handle are first dipped into water, as this causes the wood to swell and makes the handle fit tight. Generally speaking, the lighter the hammer, the longer and finer the handle, a more effective blow being struck when the handle is resilient. Claw hammers and some others are provided with forged ears or side plates, which are fitted to the side of the handle.

After heavy wear a hammer may require re-grinding to restore the smooth and true surface of the face, which is essential to accurate work. If the head gets slack on the handle it should be refitted, otherwise it is liable to fly off. No hammer should be used except

when its face is clean and dry. Oil or glue on the face will cause the hammer to slip, and painful bruises may result. *See* Amateur Carpentry; Claw Hammer; Nail; Repoussé; Tool.

**HAMMER TOE.** In this condition the toe is bent upward at the first joint and downward at the second. The second toe is most commonly affected. It may be due to wearing short and narrow boots, and is often associated with hallux valgus, or displacement of the great toe towards the middle line. Claw foot is usually accompanied by some degree of hammer toe. Corns form on the parts pressed on, with resulting pain and discomfort. In the early stages the condition may be rectified by wearing well-fitting boots and perhaps a splint; but generally an operation is necessary. *See* Boots; Clawfoot; Foot.

**HAMMOCK.** In the domestic sense, the hammock is a swinging seat fixed up in the garden, and may serve on occasion for a bed. There are numerous types, varying from the simple article made of cord or canvas and slung between two trees, to elaborate devices fitted with specially constructed stands, spring mattress and cushion beds, wind shields and awnings. Simple hammocks vary in prices from 10s. to 50s. A padded couch hammock with an adjustable canopy, and upholstered in gaily striped canvas, is considerably more expensive, especially a model with a patent adjustable tea tray.

A simple form of hammock may be made by taking a piece of stout canvas and turning a very strong hem at each end, inserting through each a 1 in. diameter hardwood rod. Strong ropes are fitted to the extremities of the rods, an eyelet or thimble being worked into the bight of the rope. The hammock is suspended by chains or ropes hooked into or passed through these eyes. Another style of hammock is made from separate strips of webbing, such as is used in upholstery work; a good plan is to make the stretchers first and to fix them on to the back of a chair, so that they are at the desired distance apart. A sufficient quantity of webbing having been obtained and cut off to the proper length, the outer pieces are applied to the stretchers, putting a double thickness of webbing at each side and securely sewing them together.

*Hammock. Fig. 1. Hammock of netting hung between two trees.*

Other long pieces of webbing are then spaced about 1

in. apart, folded round the stretchers and sewn together at the joints. Those in the centre should hang down a few inches below the line of the side pieces. The cross pieces should be placed underneath the long-way pieces and sewn to each of them. They may be spaced about 2 in. apart. The hammock is suspended by ropes.

Fig. 1 shows a netting hammock suspended between two apple trees. Any good-quality twine or string may be used, picture cord or stout cotton cord. The hammock can be made like a net with shuttle and cord, and another method is to tie the cords together, using a reef knot. To make a hammock about 12 ft. long, which is the usual length, will require a set of cords each measuring 18 ft. long; these are arranged in pairs, and 24 pairs are required. Work is commenced in the centre by looping the pairs of string round a stick such as a broom handle, supporting this at each end on the backs of chairs so that the stick is at a convenient height; the loose ends are hung up out of the way while the first half of the knotting is in progress, as in Fig. 2.

*Fig. 2. Tying the first row of knots in netting a hammock. Fig. 3. Close view of first stage in tying a knot.*

All the knots have to be made at the same distance apart, and to do this it is necessary to make a mesh stick or post. The latter has a foot-piece that enables it to be kept upright with the foot while the hands are free to effect the knotting. Fig. 2 shows the first stage. The mesh stick is simply a post of wood about 30 in. high, 3½ in. wide and about 1 in. thick. The upper end is shaped to an oval form, and half of it cut back to a depth of ½ in. to serve as a guide for the first row of knots; the other knots are tied around the thicker part. The shape of the top will be clear from Figs. 3 and 4.

*Fig. 4. Second stage, showing how reef knots are made.*

Commence at the left-hand side of the centre post, and place the mesh stick against it, with the outer pair of strings separated by the mesh stick. The outside cord A is taken in the left hand and placed behind the smaller notch on the mesh stick. The cord B to the right is taken in the right hand, passed over A and held by the left hand. A is passed over and under B, then under and over B, and the result is a reef knot that will not slip. Figs. 3 and 4 show how all the cords are tied with this knot.

After tying the first pair of cords the mesh stick is removed and the next pair tied, and so on until all the 24 pairs have been tied once. The mesh stick is then used at its full width for all the remaining knots on the first half of the hammock, but instead of starting by tying the outer pair together, only the inner one of the outer pair of cords is used, as the outer cord has to remain straight. The inner cord of the outer pair is tied to the outer cord of the next pair; and so on, as in Fig. 5, continuing to the other side of the hammock, thus leaving a single cord on the outside.

Fig. 5. Second row of knots in process of tying.

The knots that make up the third row are then tied in the same order as the first, and this procedure is continued until the netted portion is about 4 ft. long. The centre bar is then removed by sliding the cords off it, and the loops smoothed out; the stick is then placed through the original second row of knots and the other half of the hammock is tied as before, starting the first row of the knots with the full width of the mesh stick. When all the cords are knotted in this way the ends are brought together and worked around the end rings, and the hammock is ready for use, but can be embellished with a pendant fringe, if desired, attached to the sides of the hammock. The hammock is suspended by chains or ropes, as shown in Fig. 6, or can, as before stated, be slung between two trees. *See* Garden Furniture; Knot; Netting.

Fig. 6. Simple stand for use with the hammock.

## HAMPER

. A hamper is a large basket usually made of wicker or cane and fitted with a lid. It is used by laundries for conveying clothes, and also by many persons for carrying food to race meetings, picnics, and the like. *See* Basket; Picnic.

**HAMSTER.** This fur, obtained from the rodent of the same name, is cheap and of hard-wearing quality. Short and shading from yellow to grey, with curiously shaped black markings down the back, it is used chiefly in the form of linings for winter coats. *See* Fur.

**HAND.** The utility of the hand mainly depends on two factors: namely, the power to oppose the thumb to the other fingers so that we can grasp implements, and the large amount of brain surface devoted to its surface.

A wound of the upper part of the palm may divide one or both arches and lead to very free bleeding. It may be arrested by putting a firm pad of moderate size over the wound and making the hand into a fist over this; then applying a firm bandage and supporting the hand, well elevated, on a lesser arm sling. If some difficulty is experienced in checking the bleeding, the brachial artery should be compressed, an improvised tourniquet being applied if necessary.

**Care of the Hands.** Well-shaped, supple hands with long, smoothly jointed fingers, nicely kept nails, and skin which retains its softness and delicacy of tint in all weathers are a rare but important point of beauty culture. Although structural shape cannot be altered, much can be done to improve appearance and render defects less noticeable, but it is the constant everyday attention which counts; spasmodic treatment is of little use.

Unightly hands are a drawback, causing a feeling of discomfort which renders their possessors self-conscious. Those who suffer from red, swollen hands in cold weather should pay particular heed to general hygiene, as well as to local care. Regular massage and electrical treatment are beneficial in many cases. Vigorous scrubbing with a soft nailbrush when washing stimulates the circulation, and it is a good habit, after the use of hot water, to run the cold tap over the hands before thoroughly drying.

A pure toilet soap—that is, one which does not contain free alkali and is made of the best quality of fats—should be used to cleanse the hands. A night treatment is started by washing and kneading them well in the soapy lather, drying on a soft towel, care being taken to press down the cuticle of each nail in turn, massaging a hand balm into the skin and leaving a liberal allowance of the emollient on the backs of the hands, to be protected during the night by a pair of loose wash-leather gloves from which the tips of the fingers have been cut.

An excellent balm for this purpose, adapted from an old French prescription, is made by mixing 2 oz. hydrous lanolin with  $\frac{1}{2}$  oz. olive oil and  $\frac{1}{2}$  oz. almond

oil in a warmed mortar or in a basin placed over hot water; beat in 2 drams zinc oxide and 1 dram boracic acid until quite smooth, and then, while continuing to beat the cream, slowly add  $\frac{1}{2}$  oz. orange-flower water with which 2 drams of glycerin have been mixed.

This balm has a smoothing and whitening effect on the skin, and should be applied at least three times a week. A little glycerin jelly may be massaged into the hands on other nights, or a bleaching lotion made of 4 oz. rose water and  $\frac{1}{2}$  oz. each of hydrogen peroxide and strained lemon juice may be used when it is desirable to reduce redness or tan from exposure or freckles. Warmed buttermilk is a good and soothing bleach.

For chapped hands, the use of glycerin and rose water is a simple but efficacious remedy. Great care should be taken, especially in cold weather, thoroughly to dry hands which are liable to roughness. A little fine oatmeal rubbed over the skin after drying absorbs any moisture.

*Hand. The principal stages in manicure. Fig. 1. Clean the nails with cotton wool soaked in peroxide. Fig. 2. Press back the cuticles after washing. Fig. 3. Paint on the nail varnish in firm downward strokes. Fig. 4. Use a hand cream at night.*

Loose gloves should be worn when doing rough work, and after laundry or washing-up glycerin jelly should always be applied. Stains are best removed by pumice-stone, which is also helpful for rubbing down hard skin on the finger-tips or palms of the hands. Lemon juice is of constant use. Half a cut lemon should always be kept on the wash-hand stand or by the sink. Rubbed over the hands and washed off with cold water, lemon juice tightens up wrinkled skin and removes dirt from nails when each finger-tip is thrust into the pulp in turn, and then the nail is carefully cleaned by means of an orange stick, its point wrapped in a shred of cotton wool.

Before starting any work which may soil the nails it is a good plan to dig them into white powder—cornflour will do—leaving it under the nails until the work is finished and then removing the powder with an orange stick, when the nails will be perfectly clean.

Perspiring hands are a great nuisance and a source of expense in the matter of gloves. Washing with formalin soap at night is often recommended, and a good hand astringent applied regularly in the daytime. The following powder may be dusted over the palms after washing, or before putting on gloves: Powdered starch, 2 oz.; powdered talc, 1 oz.; powdered alum, 15 grains.

If hands are kept in good condition, ten minutes devoted to them will further improve their appearance when desired.

The nails should be filed and then nicely shaped with an emery board. They should not be filed down at the sides (a common fault) as this removes the support from the tip, causing it to break. They should be cleaned with a piece of cotton wool soaked in peroxide (Fig. 1) round the end of an orange stick. The hands should then be washed and dried carefully with a soft towel and the cuticle pressed back with the fingers (Fig. 2). Nail varnish can be obtained in liquid or cream form, in varying colours. It should be applied evenly in firm, downward strokes to the end of the nail (Fig. 3) and wiped off the end with cotton wool, or not, according to taste. A greaseless hand lotion or cream can then be worked into the hands from finger tips to wrists. A greasy cuticle cream, and hand cream, can be applied at night (Fig. 4) and cotton gloves worn if desired. Many are the hand preparations nowadays marketed; but women know how essential, too, are graceful movements of the hands, lest the trouble of manicure be wasted by clumsiness. *See Bandage.*

**Hand.** This measure of length, which is used for measuring horses, is one of 4 in. *See Horse.*

**HANDBAG.** Small bags that can be carried in the hand are of two main types, those carried by women for purses, travelling or shopping, and those carried by men. The former are made in a great variety of styles and materials, and some are beautifully ornamented and fitted.

Handbags as carried by men have been largely supplanted by attaché or despatch cases, but bags are still seen. These are mainly of leather, and are provided with a lock and key. When purchasing one care should be taken that the fastenings are sound and the bag well lined and finished. The leather is cleaned as are other leather articles. *See Attaché Case; Bag; Leather.*

**HAND BELL.** Hand bells are still used to some extent in the home, although they have been largely supplanted by electric bells and gongs. The better ones usually are made of brass, either genuinely antique or reproductions of old designs. *See Bell; Gong.*

**HANDKERCHIEF.** Fine handkerchiefs are of pure linen with hand-embroidered initials. Coloured varieties may be of linen, but are more usually of some thinner fabric, such as cotton cambric or a silk that

may be boiled without losing the original colour. Women's fancy handkerchiefs are made of crêpe-de-chine, silk, ninon, floral chiffon, or are lace-trimmed. Men's handkerchiefs are 16 in. to 18 in. square, and may be of silk, linen, or various cotton fabrics, white or coloured. Contrasting borders are frequent.

All handkerchiefs except the purely decorative varieties should wash readily and without losing colour. White handkerchiefs should be boiled or, if that is not possible, soaked in water and lemon juice for several hours to keep them white. Coloured ones need washing in moderately warm water. All kinds should be ironed damp. The hems, which are of doubled material and hold the damp longer, should be ironed first, otherwise the moisture from them will penetrate into the already ironed centre portion and spoil its appearance. When ironed flat they should be folded, and each fold ironed down.

Machine-made handkerchiefs for everyday use can be bought so cheaply that few people make their own. Real silk and linen handkerchiefs, however, are worth the trouble. The following method involves the use of a very easy drawn-thread work, and is consequently only suited to materials with a thread that draws readily.

For a woman's handkerchief take a 12 in. square of linen, drawing threads to make sure the edges are straight. An inch from each edge draw a thread straight across, then draw the thread immediately inside this one just far enough to get an end long enough to tie. Take a strand of filoselle silk or stranded cotton at least 24 in. long, double it, and tie the end of drawn thread to the looped silk.

This done, draw the thread out gently and gradually from the opposite end. As the thread is pulled out from one end it draws the doubled coloured silk tied to it into its own place at the other, leaving a line of perfectly woven colours stretched across the handkerchief. Two or three coloured threads  $\frac{1}{2}$  in. apart along each edge make a charming decoration to the handkerchief, which is then hemmed down very neatly to the outermost line of colour, and may be embroidered in one corner if desired. Men's linen or silk handkerchiefs should be made in the same way, choosing suitable colours, and may have an embroidered monogram in one corner.

Various methods of trimming coloured handkerchiefs are employed. Sometimes the whole handkerchief is coloured, with the merest line of white at the edge in the shape of a rolled hem; while in other cases the order is reversed, the handkerchief being white, bound with a colour. Widely striped borders are used as well as veining edges in a pale colour, with small initials or monograms to match. Cross-stitch is introduced in others for ornamental corner designs.

The fragrance of fresh violets may be imparted to handkerchiefs without the use of scent. Tie a few pieces of orris root in a muslin bag and put the latter into the water in which the handkerchiefs are boiled. When dry they will be found to be delicately perfumed. *See Hemstitch; Initial; Laundry.*

**HANDKERCHIEF SACHET.** The most

serviceable sachets are those made of fine white lawn, muslin, or linen embroidered or trimmed with drawn-thread work, as they can be washed repeatedly.

More elaborate sachets are made of fancy and plain silk, crêpe-de-chine, satin, velvet and ribbon. These are usually padded and ornamented with embroidery. Silk cord and ribbons are utilized to form fastenings.

A simple sachet can be made by folding in half a padded length of satin 18 in. by  $10\frac{1}{2}$  in. The outside can be made of embroidered satin, of taffeta, or of a tinsel brocade, and the lining of some pale self-colour. Gold or silver cord is sewn round the edge, and is also used to make fastening loops. *See Drawn Thread Work; Embroidery.*

**Handle.** *See Door.*

**HAND SAW.** There are many types of hand saw, the straight-backed pattern illustrated being suitable for most work. These are made in various lengths, from 20 in. to 30 in., with teeth of different shape. Saws with ratchet-shaped teeth are preferable to those of the pyramidal shape, and the 26 in. size is handy for general use.

*Hand Saw: three types. Top, London pattern; centre, skew back; bottom, farmer's saw.*

*Left, method of holding; note position of thumb and forefinger.*

Hand saws in general are intended for two classes of work. The cross-cut saw is for cutting across the grain; the rip saw is better adapted for cutting or ripping timber in the direction of the grain, the teeth being larger. The handle is held with the first finger of the right hand extended along the right-hand side of the handle and the right thumb along the left-hand side of the handle, as in the illustration. For ordinary

household work, the crosscut saw will answer most requirements.

Another type, known as the farmer's saw, is made with teeth of a different shape, a number of notches being cut at regular intervals along the edge of the blade, thus enabling the saw to cut wet timber. This type is indispensable where rough logs have to be sawn up, as for firewood. *See Cross Cut Saw; Saw.*

**HAND SCREW: Its Uses.** Hand screws are a useful form of cramp, used by wood and metal workers. They consist essentially of two blocks, which are drawn together by the rotation of two long screws fitted with hand grips. Those favoured by wood-workers are usually made of hardwood throughout. An improved pattern is made in pressed steel, and adapted for grasping work that is tapering or of irregular shape. Hand screws intended to be used for metal work are generally smaller in size. These tools are employed on work such as holding one part to another to act as a drilling jig or guide piece while preparing a duplicate.

The woodworkers' hand screws are invaluable to the home worker. They can be employed to hold together the corners of a light framed building in course of erection. They serve as a clamp when glueing up joints, and another use is clamping a piece of work down to the work bench. They should always be kept in a dry place, otherwise the wood screws are liable to swell and work stiffly; this can be remedied by coating the thread with black-lead. Unless they turn freely, much of the strength of the grip will be lost, and there is a risk that the screw will be twisted asunder.

*Hand Screw: method of action. A key to the lettering will be found in the text.*

The diagram clearly illustrates the action of the appliance. A and B are the two blocks whose movement is controlled by the two screws C and D, A' and B' being the jaws or gripping faces. The screw C passes freely through a plain hole in A, but screws through B; D also screws through B, but the end of D works freely in a blind hole in A; both screws are right handed.

In order to bring the jaws A' and B' closer together while keeping their faces parallel, C is screwed up while D is unscrewed by an equal amount. When the jaws have thus been brought near enough together the clamp

is put in place and C is screwed up and D unscrewed at the same time, so that the jaws are home on the work. If the jaws are biting tighter at the throat than at the tips, C must be unscrewed a little and D screwed up by a larger amount; if, on the other hand, the jaws are slack on the job at the throat and tight at the tips, D must be unscrewed a good deal and C screwed up a little. This method of adjustment also enables the tool to be used to hold jobs whose opposite faces are not parallel.

When the clamp has been adjusted to press evenly on the work, it is tightened by first screwing up C quite tight and then screwing up D as far as it will go; this order is adopted because D has a bigger leverage on the job than C. To release the clamp, first unscrew D till it is quite free, and then unscrew C.

**HANDSPIKE.** This is a long bar of wood about 3 in. in diameter, tapering at one end, the other shaped in the form of a shoe and clothed with iron. Its general appearance is illustrated, and the implement has many uses in the handling of heavy articles. The shoe should be inserted underneath the sack or other object, and it can be raised slightly by depressing the handspike.

*Handspike. Long bar of wood, capped with metal at the tip, used for lifting stones and other heavy articles.*

For domestic purposes a useful implement can be made from ordinary deal about 4 in. wide and 3 in. thick, shaped on the lines illustrated. The iron shoe should be fitted if possible, as it adds greatly to the effective strength of the implement, and can be bent from a piece of wrought iron 1 3/4 in. wide, 1/4 in. thick, and 18 in. in length. It may be secured by screws, or preferably by riveting with long rivets. *See Lever.*

**HAND VICE.** A small vice that can be held in the hand is a very adaptable tool that can be turned to many uses in the home. It is useful for a great many small filing operations, as it can be turned about in any direction. The ordinary black pattern is shown in the illustration. Another type with wooden handle and a parallel action to the jaws is useful for fine work, such as model making or clock repairing. In choosing a hand

vice note that the jaws close up evenly, that they are free from shake, and that when closed they are quite true and level on the upper side, the faces in close contact. *See Amateur Carpentry; Vice, etc.*

*Hand Vice. Manner of holding and method of use for small work.*

**HANGING: Of Meat.** The length of time required for hanging meat depends mainly on the weather. English beef and mutton, if kept in a well-ventilated larder and the weather is cold, may hang for 2 or even 3 weeks in carcass. In summer, on the other hand, meat should not hang more than a week.

Mutton keeps better than beef, and all meat keeps longer in the carcass than in joints; but it should always be hung up in the larder and never laid on a dish on the shelf. Always remove the kernels if meat is to be hung, also the marrow, as both have a tendency to become tainted and infect the meat. The flesh of young animals cannot be hung so long as that of older beasts. Foreign meat should not be hung, as it will waste; it is supposed to come from the butcher ready thawed and in condition for cooking. When the weather is frosty, however, all meat is better for hanging some hours in a warm place after being exposed to the frosty atmosphere during carriage. Pork and veal should not be hung longer than is necessary before cooking, as they taint very quickly.

The time varies for hanging poultry. In warm weather fowls can be hung only for a day, and that must be in a cool, well-ventilated place. In winter hang them for about 4-6 days. Turkeys in very cold weather may hang as long as a fortnight, but the time must be regulated by the weather. Geese should hang some days, pigeons for a few days only. In cold weather venison may be hung for 14 days, but it must be examined occasionally. An old hare can be hung for 10 days, but a young one not more than a week, and neither should be paunched before 4 days have elapsed. Game may hang any time from 10 days to 3 weeks if the weather is cold, but neither venison nor other game is now eaten very high. Birds keep better if the feathers are left on and they are undrawn. It should be remembered that poultry is hung by the feet, game by the neck. *See Food; Game.*

**Hanging Cupboard.** *See Cupboard; Corner Cupboard.*

**HANK.** A hank is two or more skeins of wool, thread or silk tied together. Silk, both real and artificial, as used for knitting, is often sold in hanks. *See Knitting; Silk; Wool.*

**HAPPY FAMILY.** For this card game, which is best played by four persons, a specially prepared pack is necessary. A pack consists of 44 cards, each containing a fantastic figure representing a member of one of the eleven families. Each family has four members, Mr., Mrs., Master, and Miss, and each is pictured with the implement of the family trade, e.g. a bone for the butcher. The names given to the families vary, but the most popular are as follows: Block the barber, Bones the butcher, Bun the baker, Bung the brewer, Chips the carpenter, Dip the dyer, Dose the doctor, Grits the grocer, Potts the painter, Soot the sweep, and Tape the tailor.

The game consists in each player in turn asking any one of the others for a card he himself has not got, but

he can only ask for a member of a family which is represented in his own hand. The player to the left of the dealer begins. If he asks for a card which the person asked possesses, it is handed over and he asks again, continuing until he asks for a card which the player asked does not possess. The latter thereupon answers "not at home," and it becomes his turn to ask. Each player aims at getting the four members of one family into his hand, and each family counts one trick. The player who secures the most tricks wins.

The game may be continued as follows: The players in turn ask for whole families instead of for single cards, under the same conditions as before, and continue until all have passed into the possession of one player.

**HARDBAKE.** Hardbake is a simple form of toffee, its chief constituents being sugar and butter. Almonds or other nuts may be used to give it a flavour. *See Almond Toffee; Toffee.*

### HARDENING AND TEMPERING.

Tough though it is, tool steel in its soft or annealed condition is not hard enough to resist hard wear. Tools must therefore be hardened, after being made, by heating them to the correct hardening temperature and plunging them into a quenching bath. Tool steel so hardened has the defect of extreme brittleness; this can be overcome by tempering, raising it gradually to the appropriate temperature and then plunging it in cold water. The process of case hardening is quite different, and is dealt with in a separate article.

The art of hardening and tempering tool steel consists in getting the correct hardening temperature for the particular steel, choosing the right liquid for the quenching bath, having in view the use for which the tool is intended, and getting the distribution of tempering temperature in the tool so arranged that the different parts of the finished article are all of suitable hardness and toughness for their particular work.

Tool steels vary considerably in composition, and each has its own special colour of red heat for hardening. Each steel that is used for making tools loses its magnetic qualities entirely at and above a certain temperature, which is identical with the ideal hardening temperature in every case. This fact enables the hardening operation to be carried out with certainty by the use of an ordinary pocket compass; but attention must be paid to avoiding complications from the presence of such iron articles as stoves, fenders, fire irons, etc., near the compass. In particular, iron or steel tongs or pincers must not be used for handling the red-hot tool.

The procedure recommended for hardening a tool is to hold it by tying a piece of stout copper wire round the middle, and place the pocket compass on the floor a yard or so away from any iron, but within convenient reach of the fire and the quenching bath, remembering that if the bath is of tin or enamel it must not be too close to the compass. Any fire will do for the work if it

is hot enough; a hot coal fire or a paraffin blow lamp is satisfactory, or even a gas ring if the tool is not too big. Then the tool is to be made red hot in the fire and tested from time to time by withdrawing it by the copper wire, and holding it close to, but at one side of, one end of the compass needle.

If the needle responds by a movement, the steel is not yet hot enough, and must go back in the fire; but when the steel is so hot that the needle disregards its presence, the tool is to be plunged at once into the quenching bath and moved rapidly about in it till it is cold enough to handle, when it may be withdrawn and wiped dry. When transferring the tool from fire to compass and from compass to bath, the movements must be smartly carried out to avoid any unnecessary cooling of the red-hot metal.

In heating it is essential that the tool should be of a uniform temperature all over. Evenness of heating is readily secured by turning the tool about so that any part that is noticed to be at a darker red than the rest comes in a hotter place in the fire and so catches up to the general average temperature.

In quenching, a rapid agitation in the bath is necessary to secure even and rapid cooling. The bath is simply any kind of vessel containing enough of the quenching liquid to ensure that it does not get much heated when the red-hot steel is plunged in it.

Various liquids are in use. Cold, fresh water, soft, not hard, is satisfactory in most cases. If, however, it is found that a tool quenched in water cracks, oil should be tried, and any lubricating or other heavy oil will be found to overcome the difficulty.

**Tempering.** After hardening, the tool has to be tempered. This is done by raising it slowly to a temperature which depends on the use to which the tool is to be put, and then quenching in cold water. Steel has the property that when it is clean and heated slowly in air a thin film of oxide forms on the clean surface, and the colour of the film changes progressively as the temperature rises. First a pale straw colour appears and gradually deepens to brown, then the brown gives place to a purple, which presently clarifies into a clear violet; next the violet turns dark blue, and finally the blue fades out.

After hardening, therefore, the tool is first rubbed bright with emery cloth, taking care not to touch it with the hand, as the slightest trace of grease prevents the proper formation of the temper colours; then, if it is required to be at the same temperature throughout, it is laid on an iron plate, which is placed over a flame. The succession of colours is watched, and the tool is quenched at once when the desired colour is reached. If by accident the colour changes have advanced too far before quenching, the tool must be hardened and correctly tempered all over again; but if the colours have not gone far enough, it may be repolished and retempered without hardening.

Most tools require to be of a certain hardness on the point or working end, but to be softer in the shank and at the handle end. This result is obtained by taking the tool by the middle in a pair of pliers and holding the

butt end in a flame such as a blow lamp or gas ring; the series of colours then passes along the tool, which is quenched when the desired colour reaches the point. If it is desired to keep the hard region near the point as much as possible, the butt end must be put well into a hot flame, when the successive colours follow each other so closely that the bulk of the tool is soft.

To obtain the reverse effect, i.e. a tool which is of progressive hardness over a considerable length of the point end, the tool is caused to warm up more slowly by occasionally withdrawing the butt end from the flame; the colours then follow down the tool at longer intervals so that the hardness extends for some distance from the point. Slow tempering is preferable to fast tempering, as it is easier to carry out accurately, and tools so tempered are more satisfactory in use.

When tempering, a very pale straw colour is used for reamers; light straw for twist drills and tools for turning metals; dark straw for woodworking tools in general and for taps and dies for screwing metal; brown for hatchets and chipping chisels; and dark purple for springs. *See Case Hardening.*

**HARDENING-OFF.** This is the process of treating plants grown under glass to render them fit for planting out of doors; it is carried out by gradually inuring them to cooler conditions. They are transferred from greenhouse to frame; the frame is at first kept closed, and after a week the ventilation is increased gradually until finally the top of the frame is removed.

**HARD STOPPING.** Usually a mixture of resin and beeswax, hard stopping is employed to fill up small holes and defective places in woodwork, being first warmed and then worked into the cavity with a warm knife. A superior variety is known as beaumontage (q.v.). Various proprietary mixtures can be purchased ready for use from the oil and colour shops.

**HARDWARE.** This is the name given to all kinds of household and other articles that are made of the baser metals, especially iron and copper. Among them are the ordinary cooking and kitchen utensils, fire irons and tools of all kinds. *See Baking; Copper; Hammer; Kettle; Lawn Mower; Nail; Poker; Tool Chest, etc.*

**Hard Water.** *See Water Softener.*

**HARDWOOD.** The various woods are divided into two classes, hard and soft. Of the former there is a great variety, but the softwoods are few in number and belong to coniferous trees. Those in common use are pine, spruce, fir, and pitch pine, the first three coming under the general head of deal.

Chief among the hardwoods are oak, mahogany, walnut, elm, ash, birch, beech, greenheart, teak. They are mostly heavy woods compared with ordinary deal, and more power is required to cut them with chisel or plane. The grain is often more curly than that of the

soft varieties, and the cabinet maker has to finish with a scraper, because a plane tears up the grain in some kinds.

Hardwood of some particular kind may be selected because it is better adapted for the purpose required, or its appearance may be the main consideration. Colour or the figure of the grain may make it desirable, though, as far as utility is concerned, it may be no better than cheaper woods. This is the case mainly in furniture. Hardwood costs more than soft, and some varieties of it cost far more than others. It is usually sold according to size, at so much per foot; in a few cases, where the wood is heavy and scarce, it is sold by weight. *See* Beech; Elm; Oak; Walnut; Wood, etc.

**HARE.** Caught in the leveret stage, hares, though by nature timid, are easily tamed, and will appeal to those who like a pet out of the common. They require a large roomy hutch, and may be fed principally on greenstuff, such as lettuce and cabbage tops, and bread. The hare does not breed in confinement.

**How to Cook.** It may be roasted, jugged, braised, or cooked in other ways. After cleaning, wash the hare quickly in lukewarm water and dry it with a cloth.

**Braised Hare.** To braise a hare, skin and clean it, and line the inside with slices of fat bacon. Chop the heart, liver, and kidneys, adding to them 1½ oz. chopped calf's liver, the same quantity chopped fat bacon, 3 oz. breadcrumbs, a small chopped onion, and 2 teaspoonfuls each of chopped herbs and parsley. Season these to taste and bind them with 2 beaten eggs. Put the stuffing inside the hare, sew the latter up, and cover the back with a piece of raw fat bacon. Wrap the whole in buttered paper.

Cover the bottom of a long braising pan or fish-kettle with some bacon trimmings, 2 onions, 2 sticks of celery, a carrot, and a turnip, and lay the hare on these, adding a bunch of herbs, a pint of good stock, seasoning, and, if liked, 2 glasses of sherry. Cover the pan closely and braise its contents over a low fire for 3 hours, basting the hare occasionally with stock and renewing the latter whenever necessary. When almost cooked through, take out the hare, remove the paper from the back, and strain off the stock, at the same time skimming off any fat. Pour a pint of good brown sauce into the pan, put back the strained stock and the hare, and finish cooking. Serve the hare with the sauce poured over it, garnish with thin rolls of fried bacon, and hand round some red currant jelly.

**Jugged Hare.** A hare that is to be jugged should be cleaned, cut into joints, and the blood reserved. Wash the head, heart, and liver in cold salted water, and put them into a saucepan with the blood and bones. Add 4 pints of cold water and a teaspoonful of salt, and bring the stock to the boil. Remove the scum, add a few mixed herbs tied in a piece of muslin, a little powdered mace, and pepper to taste. Scrape and wash a carrot, and add it to the stock with an onion, peeled and stuck with 3 or 4 cloves. Simmer the whole for 3 or 4 hours, keeping it

well skimmed.

Dredge the joints of hare with flour and try them to a light brown colour; then place them in a large brown jar or casserole. Mix 6 oz. flour to a smooth paste with water, and add it to the stock previously strained into another saucepan. Stir these well, boil them for a few minutes, and, if necessary, add a little browning. Strain the gravy over the hare, just covering it, and reserve about 1 pint in which to cook the forcemeat balls (q.v.). Put the casserole in a moderately hot oven, bring its contents to the boil, and then simmer it for about 2 hours.

The forcemeat balls should first be rolled in flour, then fried, and afterwards put into a saucepan with the remainder of the hot gravy and simmered for about ½ hour before the hare is ready to be served. Just before sending the latter to table add a wineglassful of port wine.

**Roast Hare.** For roasting, a young hare is best, preferably under a year old. First press some forcemeat inside, and sew it up with a trussing needle and fine string. Truss as for roast rabbit, tie a few pieces of fat bacon over the top, and cover with greased paper. Cook the hare in a moderately hot oven, basting it frequently with milk and dripping. When it has almost finished cooking take off the bacon and greased paper, dredge the back with flour, and continue roasting. Untruss the hare when done, and serve it with the gravy thickened with flour and flavoured with port wine and red currant jelly. Red currant jelly may also be served separately, and bacon rolls used as a garnish.

**Hare Forcemeat.** This is made by part boiling the liver, heart, and kidneys of a hare, and then adding an equal quantity of grated breadcrumbs, twice as much fat bacon, chopped finely, and a piece of butter about the size of a walnut. Mix these well, season them with salt, pepper, nutmeg, a tablespoonful each of chopped thyme and parsley, and a little grated lemon rind, and bind the whole with a well-beaten egg.

**Hare Pie.** To make this pie, soak a hare in warm water for 15 min., then wipe it dry, cut it into joints, and season it with salt and pepper. Fry these until they are golden brown on both sides, reserving the head and any other inferior parts for the making of jugged hare, etc. Line the edge of a pie-dish with short-crust pastry, and arrange in it the joints of hare, the minced liver, a sliced onion, a teaspoonful each of chopped parsley and thyme, and seasoning to taste. Lay on these four rashers of bacon and pour over all ½ pint of gravy to which ½ glass of claret or port wine has been added. Cover with some more short crust, and bake the pie in a moderately hot oven until the crust is brown. Then reduce the heat and continue cooking. In all, the pie requires about 1 ½ hours. It is sufficient for about six persons.

**Hare Soup.** Half a roast hare may be used in the preparation of soup. Cut the meat into small joints and slice 3 or 4 onions, 2 carrots, and a little celery, putting these into a pan with a bunch of mixed herbs, a bay leaf, 2 or 3 rashers of fat bacon,  $\frac{1}{2}$  gallon of stock, and seasoning to taste. Boil the soup for 3 hours before adding a tablespoonful of red currant jelly, and then put it through a fine sieve. Re-boil it, adding more stock if necessary, and pour in a tablespoonful of Worcester sauce or sauce and ketchup mixed. Add also a few forcemeat balls and a glass of claret or port wine. Serve with fried croutons. *See Game; Pastry.*

**Hare Fur.** This fur, though not hard wearing, has soft, long fine hair and forms a favourite trimming for evening wraps. Generally it is dyed to imitate the more costly kinds of fur. The pure white variety is imported from Russia and Siberia. Hare fur may be cleaned according to the directions given in the article on furs. *See Fur.*

**HAREBELL.** The common name of *Campanula rotundifolia*, a perennial herb of the order Campanulaceae. It is a charming wild plant with blue, bell-shaped flowers. It grows 10-12 inches high and is suitable for planting in the rockery.

**HARELIP.** Children are sometimes born with this deformity, which consists of one or two splits or fissures in the upper lip. In about half the cases there is a cleft palate, a fissure in the roof of the mouth. Generally a child with harelip has a broad, flat nose.

A child should never be allowed to grow up with this disfiguring affection. The surgeon will advise an operation, and the best time to perform it should be left to his decision. In the case of strong, healthy children the operation is usually performed at the age of six or eight weeks, but if the infant is delicate it may be deferred a little longer. After six months, teething interferes with the success of the operation.

**HARE'S EAR.** The popular name of *bupleurum*. The chief kind of garden value is *Bupleurum fruticosum*, a shrub from Spain, 3-5 feet high, which bears umbels of yellow flowers in late summer. It should be grown against a wall except in mild districts. Propagation is by cuttings in a frame in August.

**HARE'S FOOT FERN.** The best known hare's-foot fern is *Davallia canariensis*, whose long creeping roots or rhizomes grip the sides of the pot or pan in which the fern is grown, and resemble or suggest the foot of a hare. *D. bullata* is sometimes called the squirrel's foot fern. These ferns should be grown in pots or pans containing a mixture of peat, sand, and sphagnum moss, in a warm greenhouse. A Japanese variety of the hare's foot fern consists of roots, or rhizomes, of *D. Mariesi*, fashioned into the shape of monkeys, birds, crosses, coconuts, and other designs. The plants arrive in Great Britain in the wintertime, when they are brown and dormant; in early spring, if

they are hung up in a warm greenhouse and liberally watered with tepid water, they are speedily covered with masses of delicate, vivid green fronds. *See Fernery.*

*Hare's Foot Fern. Indoor foliage plant with creeping brown roots.*

**HARE'S TAIL GRASS.** This is the common name for *lagurus*, a hardy annual flowering grass, growing about a foot high. It grows in ordinary soil in a sunny border, and is useful for mixing with cut flowers. Seed may be sown outdoors in March or April.

*Hare's Tail Grass. Ornamental grass bearing soft furry heads.*

**HARICOT BEAN: In Cookery.** Certain sorts of French and kidney beans which have white pods and seeds are known as haricot beans. They need no special culture, but, instead of being consumed when fresh, are usually dried and stored for future use, as they are highly nutritious, and are much used in cookery, either as a vegetable or for soups and curries. They require to be soaked for about 24 hours before being cooked.

To prepare haricot beans as a vegetable, after being soaked they are put into a pan of cold salted water, brought rapidly to the boil with the lid on the pan, and then allowed to simmer slowly until they are tender. Strain them and return them to the saucepan to dry, placing the latter at the side of the fire. Add a small lump of butter or margarine and seasoning to taste; shake the whole over the fire for a minute or two, and then serve the beans in a hot vegetable dish, with a little finely chopped parsley sprinkled over them.

Haricot beans make an excellent addition to stews and other made dishes, for they serve both to thicken and to flavour. They also make an appetizing dish when curried and form the basis of vegetarian cutlets or rissoles.

**Bacon and Haricots.** Stewed with bacon, haricot beans make an excellent dish. Soak and boil a pint of beans as already directed, and, while they are draining, cut  $\frac{1}{2}$  lb. of bacon into dice. Over the latter pour some boiling water, let them stand for 2 or 3 min., and then drain them also. Put the bacon into a pan and shake it over the fire until it is slightly browned; then add to it  $\frac{1}{2}$  pint of good brown gravy, previously thickened with a little flour, and a large, finely minced onion. Add seasoning to taste, and let the stew simmer for about 20 min. before putting in the beans. Continue simmering for another 20 min. or so, and then serve the stew hot. *See Butter Beans; Parsley Sauce; Tomato Sauce.*

**HARICOT MUTTON.** This dish is generally prepared with a neck of mutton which has the breast attached, but the scrag is not used. If the dish is designed for an entrée, only the cutlets are to be used.

To prepare the haricot, cut about 3 lb. neck of mutton into neat pieces, removing all superfluous fat. Fry the meat till it is a nice brown colour, using a little good dripping to start it. A brisk heat will be required. Remove the meat and lay it in a stewpan, then pour off most of the fat and sprinkle over the hot pan about 2 tablespoonfuls of flour. Stir this over the fire until the flour is well coloured and cooked, but do not let it burn. Moisten the whole by degrees with a quart of well-flavoured stock or water and keep stirring until the liquor boils. Pour the gravy thus prepared over the meat and set the stewpan on the fire, then add  $\frac{1}{2}$  lb. carrots and turnips, previously washed, peeled and cut into dice or neat shapes, also 2 moderate-sized onions and a bouquet garni. Season well and let the whole simmer for about two hours.

Before dishing, skim off the fat, remove the bouquet, and place meat and vegetables neatly. If the liquor is too thin, dish the meat and boil the gravy quickly to reduce it. Haricot beans, soaked and blanched, are sometimes added to this stew. Haricot mutton cooked in a hay box is prepared in the same way except that simmering continues for 10 min. only, instead of 2 hours. The whole is then boiled quickly for 2 min., with the lid on the pan, placed in the hay box and left there for  $2\frac{1}{2}$  hours. *See Hay Box; Mutton.*

**HARMONICS:** In Wireless. These are frequencies which are multiples of another frequency, called the fundamental. Thus frequencies of two, three and four times the fundamental frequency are known as the second, third and fourth harmonics respectively. *See Frequency.*

**HARNESS:** Its Care. A set of single harness, i.e. harness for one horse, comprises a bridle with blinkers; a collar, with hames and traces attached; a saddle, with turret rings, back strap; crupper and breeching. The breeching is unnecessary, excepting in hilly districts, though it always forms part of a set of harness, together with the reins. Its use is to prevent the hind-quarters coming in contact with the vehicle. It is better to have a breeching strap attached to the back part of the shafts,

as this gives the animal more freedom of movement, and annoys it less. Moreover it only comes into operation when it is needed.

*Harness. Parts comprising a set of single harness: A, collar; B, saddle band; C, hames; D, back strap; E, crupper; F, traces; G, reins; H, nose band of bridle; J, brow band of bridle; K, bridle band on poll; L, turrets; M, snaffle; N, blinkers; O, check piece of bit.*

The bridle is composed of a throat-strap, a brow band, cheek straps, and a bit, either single or double ringed, called a snaffle, or bit and chain. All the bridle straps have keepers, so that they can be adjusted to fit properly. The proper adjustment of the bit and the curb requires to be carefully attended to. Many horses have had their mouths and manners permanently ruined through faulty biting; the so-called hard mouth may be produced in this manner. The curb chain ought to be so fixed as to allow it to lie loosely in the curb groove beneath the lower jaw.

The collar necessarily forms an important part of the harness, and unless it fits properly, its movement is very liable to bruise and chafe the skin, resulting in the production of the collar gall, just as a badly fitting saddle produces saddle gall. Leather-lined collars are preferable to those lined with cloth; the carhorse's collar, lined with felt, is often used, but cannot be recommended. When a horse comes in from work the hames should be removed from the collar, and the latter allowed to remain in position for half an hour until the skin beneath the collar has had time to cool. Neglect of this precaution favours sore shoulders, owing to the sudden cooling of the skin. The same remarks apply equally to the saddle.

The driving saddle is, preferably, lined with leather, and it ought to combine lightness with strength. In addition to the turrets for the reins to pass through, the stout shaft band forms part of it, and so does the belly band. In fitting on the saddle the belly band must not be adjusted too tightly, whilst the shaft band is adjusted so as to allow the points of the shafts to lie in a straight line just below the level of the points of the shoulders, and not tilted. In the latter case the power of draught is greatly diminished and the appearance of the equipage unsightly. Sometimes a breastband is used in place of a collar, especially for trotting purposes. For

a pair of horses double sets are sold.

Neither harness nor saddlery should be kept in the stable, as the odour from the latter rots the leather. To clean harness, remove the mud by sponging, and as soon as the harness is dry rub it over with either black or brown harness paste, and then polish. Damp leather will not polish, therefore the harness must be thoroughly dry. Soft soap should not be employed as a substitute for paste, as it rots the leather. Take particular care to have the lining of the collar and saddle clean and dry. Unfasten all buckles and keepers to facilitate cleansing of both. Every horse-keeper should insist that leathers and bright parts are kept polished and burnished with regularity, and repaired immediately if damaged. *See Horse.*

**HARP: How to Play.** The harp has 47 strings. All but the 11 longest are of gut, each C being generally coloured red, and each F blue; the others are of steel wire wound over. The compass is from

and every note stands in the major scale of C flat.

The harp is now as it always has been, an essentially diatonic instrument, and the difficulty of making it available for use in keys other than that in which it stood was partially overcome by the invention of the single action, in which by means of seven pedals it became feasible to raise the pitch of the strings by a semitone. Erard's invention of the double action, however, made a tone as well as a semitone possible, so that notes of any pitch became available.

The mechanism by which these modifications of pitch are effected is contained in different parts of the instrument. That part which stands upon the floor is the pedestal, or pedal box, which holds the pedals. Rising from this, but in divergent directions, are the vertical pillar in front, and the inclined soundbox at the back. These are united at the top by the curved neck.

Each of the pedals acts upon all strings having the same alphabetical name; consequently there are seven of them, B, C, and D to the player's left, and E, F, G, and A to his right, the order being away from him. In the frame of the pedal box are two notches for each pedal. When a pedal is fixed in its first notch, the pitch is raised by a semitone; when in the second, by a whole tone. A spring enables the pedal to return to its static position.

It will readily be seen that as each string can thus supply the flat, natural, and sharp pitches of its alphabetical name, the key of seven flats was the obvious one to be selected. The mechanism by which the strings are shortened is placed within a portion of the neck called the comb, the connexion between it and the pedals consisting of metal rods concealed within the pillar. The tuning pegs are fixed in the neck, and it is

very important to bear in mind that as the harp requires constant tuning, the performer needs always to have a tuning hammer handy for use when occasion arises. The thorough understanding of the pedals is of primary importance as the harp can not only be set thereby in any key, but also so as to make it possible to play certain chords scale-wise or even glissando. Within the limits of space available, the possibilities cannot be fully set out here. One or two simple examples must suffice.

Remembering that the fundamental key is C flat, it is evident that in order to play in the key of C it is merely necessary to depress all the pedals to their first notches. To get the key of D flat or C sharp, it would be possible to fix them in their second notches, but it would be preferable to fix only the F and C pedals in their first notches. Accidentals and modulations, if not too abrupt, can also be effected by means of the pedals.

The tone of the harp is full and rich throughout the greater part of the middle compass, but the extremely high notes, owing to the shortness of the strings, are dry and brittle in character. The flat keys have a more resonant tone than the sharp keys, the reason being that in them the strings are more open.

Changes of tone colour can be got in different ways. By damping the string with either the hand or the fingers as soon as it has been plucked, a somewhat dry-sounding pizzicato, like that of the violin, is produced. By plucking the string near the sound-board with the finger-nail, a metallic tone is the result, similar to the guitar. Harmonics are another beautiful effect. They are confined to three octaves from:—

or even less, as outside those limits they are very ineffective. The only harmonic used is that produced by lightly stopping the string at

half its length, with the result that the note sounds an octave higher. An harmonic is indicated thus:—

but its sounds may be set down thus:—

A harpist plays seated, and rests the hollow sound-box against his right shoulder, the instrument being tilted back to allow of this. The little fingers are not used in playing, but, owing to the closeness of the strings, a greater range of notes lies under the hand than with the pianoforte. Instead of an octave, a tenth may be regarded as the normal stretch. The pedals

required to be set are indicated by their names being given in brackets. For example, to set the harp in D flat the indication would be

(F# C#). Two staves, as in pianoforte music, are required for the notation, the F and G clefs being used. Almost invariably chords are slightly spread; when that effect is not desired, the French word *sec* (dry) is used. The playing in succession of two constituent notes of a chord is so characteristic of the harp, that it gives rise to the term *arpeggio* (in the harp style) in music. Repeated notes are possible in rapid tempo on different strings, according to the setting of the pedals, whereby enharmonic unisons, called *homo-phones*, are secured on adjacent strings. The *glissando* is another effect used. It is performed by drawing a finger rapidly over the strings, and it is applicable, according to the use of the pedals, not only to scales, but to chords.

*Harp. Left, diagram of strings showing altered positions when playing, left, flat; centre, natural; right, sharp. Above, relative positions of the pedals when the strings are keyed as left. (Courtesy of S. & P. Erard)*

The old single action harp in E flat was at one time extremely popular as an instrument for ladies, but the double action harp, which speedily rendered its predecessor obsolete, was never

such a favourite with dilettanti. So far as fingering was concerned, however, it was certainly not more difficult. It is rare now to meet with it in the drawing room, though it is still an indispensable member of the orchestra. To those who can afford its purchase as well as the time necessary to overcome its difficulties, the harp offers undeniable attractions, if only by way of change from the piano and the violin.

**HARPSICHORD.** The harpsichord was never standardised. Some had two keyboards, and stops whereby differences of quality were obtainable. The harpsichord differs radically from the piano in almost

every way. The strings are plucked by quills attached to the jacks which rise from below the wires when the keys are depressed, and the action also is entirely different, so that the performer must employ a distinct kind of touch, firm but light.

*Harpsichord.*

*English 17th. century instrument in walnut case. It has cut and engraved brass hinges, two key-boards giving a range of five octaves, and four draw stops. It originally stood in the*

*chapel of Ightham Moat, Kent. (By permission of the Director, Victoria & Albert Museum, South Kensington)*

The instrument has but a very limited dynamic variety of tone, this deficiency being partially compensated for by the second keyboard and stops spoken of above, the effect of which on any individual instrument must be discovered through experiment. It has no sustained tone whatever, a circumstance which gave rise to the numerous graces and ornaments which are such a feature of 17th century music.

Many old specimens exist in public collections and in private hands; they are more or less delicate in constitution and require to be handled carefully by an expert. Modern harpsichords of more robust character are still manufactured for those who indulge in the cult of old world music played on the kind of instrument for which it was originally composed.

**HARRIS TWEED.** This cloth is defined by the Harris Tweed Association as tweed hand spun, hand woven, dyed and finished by hand in the islands of Lewis, Harris, Barra, and their several purtenances, and all known as the Outer Hebrides.

In working the wool before spinning it the crofters apply an oil, the effects of which are too penetrating to be entirely removed by any subsequent process; the oil retains the characteristic odour of peat smoke. The tweed is woven mostly with a diagonal twill, which gives it a bulky appearance. Similar cloth, known as kelt, has long been made in the Hebrides from wool dyed with vegetable colours obtained from plants and blended into heather moorland tints.

Harris tweeds are made in rather soft-handling wool not very fine spun or hard twisted and from single-ply yarn. They are about 28 in. wide, and 7 yd. are needed for a man's suit. Being hand-made and finished, they vary from piece to piece of what is nominally the same pattern, and some are heavier and more densely compacted than others. A favourite pattern is the cassimere twill.

The pattern most to be recommended for wear is the herring-bone, or chevron formed by short zig-zag

opposed twills.

Harris tweed is especially suitable for shooting, fishing, and golf suits. It makes good overcoats and capes, because it sheds water better than tweeds of some other kinds.

**HARSLET.** An alternative name for pig's fry, the word harslet is also used to describe a country dish prepared from the whole fry or a mixture of fry and pork. To make the latter, wash the liver and blanch the sweetbreads and pound  $\frac{3}{4}$  lb. pork to make it tender. Season all highly and flavour with a small chopped onion and 6 sage leaves, chopped if fresh, and rubbed through a sieve if dried. The liver and sweetbreads may be cut into slices or minced finely or left whole.

Mix these ingredients together with 3 oz. finely chopped suet, place them in a cleansed bladder and sew up the end securely. The harslet may be either boiled or roasted, but if roasted it should be well basted and served with a rich brown sauce. The cooking must be gentle and will take from an hour to an hour and a half. When the whole of the fry is used, omit the pork, and use 4 oz. suet. *See Fry.*

**HART'S TONGUE FERN.** There are many pleasing forms of this hardy fern, *Scolopendrium vulgare*, which will thrive in ordinary soil and prefers a damp shady position. If grown in pots they are useful for the cold greenhouse and window. Among the best named varieties are *crispum*, *cristatum*, and *laceratum*. *See Fernery.*

*Hart's Tongue Fern. Hardy fern with undivided fronds, grown as a pot plant for house decoration.*

**HARVEST BUG.** The minute reddish-coloured beetle known as the harvest bug is often present in immense numbers in fields and gardens, especially in chalky districts. It mostly attacks the legs, children being the greatest sufferers. Red pimples or wheals like those of nettlerash appear on the skin, and there is intense itching. As a preventive, eucalyptus ointment rubbed on the legs and feet sometimes is successful. When the insects succeed in attaching themselves, the rubbing in of a weak sulphur ointment will destroy them. On the following morning after applying the sulphur ointment a hot bath with plenty of soap should

be taken. The itching and irritation may be relieved by smearing with carbolic acid ointment.

*Harvest Bug. Minute beetle, the bites of which produce an itching rash. It is here highly magnified.*

**HASH: How to Prepare.** Beef hash is prepared by melting 1 oz. good dripping in a stewpan, stirring in  $\frac{1}{2}$  oz. flour and frying it till brown. Add  $\frac{1}{2}$  pint gravy or stock, and stir it over the fire until it boils; then put in a tablespoonful of Worcester sauce, a teaspoonful of made mustard, and, if liked,  $\frac{1}{2}$  wine-glassful port wine. Season well with salt and pepper. Cut  $\frac{1}{2}$  lb. cooked beef into neat slices, put them in the sauce and heat the hash very gently, without letting it approach boiling point. Serve in a hot dish, garnished with sippets of toast and small heaps of red currant or rowan jelly.

To make mutton hash, cut 1 lb. cold mutton into neat slices, putting the bones and trimmings in a saucepan with  $\frac{3}{4}$  pint water to make stock. Let them cook steadily over a moderate fire, and in the meantime wash and prepare 2 or more carrots and potatoes, scooping them into neat balls with a round vegetable cutter. Boil these until tender in salted water, then peel and slice an onion and a carrot, and fry them in a saucepan containing 2 oz. butter. Sprinkle in 1 oz. flour, fry that also, and then add  $\frac{1}{2}$  teaspoonful vinegar, stirring all over the fire for 2 or 3 min. Strain in the stock and continue stirring until it boils. Season the whole carefully, adding a tablespoonful of ketchup; then pour it over the mutton previously placed in a casserole. Put in also the potato and carrot balls, place the casserole in the oven and let the meat heat through very gently. Serve in the casserole. Cold veal or pork may be hashed in much the same way with the addition of a bunch of herbs instead of the ketchup or sauce.

A rabbit makes a good hash when enriched with red-currant jelly and port wine. Cut the flesh from the bones, and season to taste. Put the bones into a saucepan with a pint of water or stock, a slice of ham, a bunch of herbs, an onion, and a little seasoning, and let them simmer for about 1 hour before straining.

Melt a lump of butter about half the size of an egg in a saucepan over the fire, add a heaped tablespoonful of flour, and mix the two smoothly. Pour in the stock, stir the whole until it boils, and then put in the pieces of rabbit and cook it very slowly for 10—20 min. Small forcemeat balls added shortly before it has finished cooking make a good garnish. The port wine and jelly, a wineglassful and a tablespoonful each respectively, can be added before serving. *See Casserole; Stew.*

**HASP: How to Fit.** The hasp is a hinged fitting passed over a staple and secured by means of a padlock or other fastening. The usual pattern, as fitted to doors of outbuildings, comprises a sheet of metal plate, to which is hinged the clasp, bent to shape from stout iron wire. Stronger patterns are made like a butt hinge from stout wrought iron plate. Those of ornamental shape are more appropriate for the door of a garage or for any prominent position.

For security the hasp and staple should always be fastened from the inside of the door by passing a bolt through from the front, and securing it by a nut at the back of the door. A metal plate or washer is interposed between the nut and the surface of the door. To avoid rusting, the joint should be well oiled when fitted, and lubricated from time to time. *See Door.*

**HASSOCK.** From a remnant of carpet or felt a hassock or round or oblong footstool can be made at home and stuffed with shavings, the bottom being covered with coarse canvas. A small, semicircular tab of the felt or carpet, lined inconspicuously with a strong material, should be attached to either side to allow of the stool being easily handled. In certain districts of the north of England a hassock is known by the name of buffet.

**HASTY PUDDING.** To prepare the cheaper variety, boil a pint of milk, salted to taste, in a pan over the fire. Immediately it boils sprinkle in gradually enough flour to make a stiff batter, stirring and beating all the time. Let it boil for a few minutes so that the flour may cook; then put it into a dish with a few lumps of butter, a little grated nutmeg, and, if liked, some sugar. Golden syrup, jam, or any other kind of preserve may accompany this pudding. If a richer pudding is desired, two or three eggs should be added after the flour and milk have been mixed. The batter must be allowed to cool a little first, and must not be brought to the boil again, otherwise the eggs will be certain to curdle.

**HAT: Choosing and Wearing.** Fashions in women's hats change from season to season, but the well-dressed woman adapts the fashion to suit her own features. If she is tall, with a thin face, she avoids narrow hats with high crowns as these accentuate both height and thinness. She chooses instead the styles that give width, such as the low-crowned "cartwheel" hat, the flat, peaked beret, or any similar style that is in vogue. Also she studies her reflection in a full-length mirror, for only by seeing the combined effect of hat and gown can she avoid an unbalanced or top-heavy look. By using her own candid judgement, she helps designers to bring individuality into hats.

**Straws and Felts.** Straw hats are mainly manufactured at Luton in Bedfordshire. The kind of plait used depends on fashion, and much millinery straw is imported either ready dyed or natural. Crinoline or tagel plaits are classed as straws, though

the former is usually made of artificial silk and the latter of hemp. Pedal straw is largely manufactured in Italy. From Italy also are imported large quantities of straw hoods. A hood is the material of a hat, either straw or felt, formed into an unstiffened, roughly shaped piece, ready for making into the required style. This piece may be woven as in Panama fabric and its imitations, or made of straw plait machined into shape, of felt, or of velours.

Felt hats are made from the fur of rabbits, hares or beavers in the better qualities. Cheap grades are of wool, sometimes finished with a fur veneer. Fur felts are lighter and more pliable than wool felts; also, they retain their gloss owing to the bright hairs of the fur fabric. Although there are brushed wool felts they cannot be said to imitate velours successfully. Real velours is an expensive material, composed chiefly of hare's fur with sometimes a slight mixture of rabbit's fur. Many velours hats are imported, both finished and in the form of hoods, from Czecho-Slovakia, Austria, Germany and Italy.

**Hats for Men.** The hats chiefly worn by men and boys are stiff and soft felts, straws for summer and silks for evening wear.

The silk hat has a cylindrical crown made from several layers of muslin stiffened with shellac, covered with a silk plush, and sewn so neatly that the seam is invisible. From time to time hat manufacturers make slight alterations in the height and shape of the crown, or size and curl of the brim, so that a wearer should ascertain if his silk hat is of the style in vogue.

The most popular hats are the soft felts and velours, although the stiff black felt or bowler enjoys a very big sale. The cheapest varieties are those made from wool; they lack the finish and wearing capabilities of the fur hats, and are harsher to the touch. Quiet tones of grey, brown and fawn are generally fashionable in soft felts, which can be bought with wide or narrow brims, flat set or curled, bound or unbound.

Velour hats originally were made only from hare's fur. For a cheaper hat rabbit's fur is used extensively, but it is distinctly inferior, and anyone can detect the difference between velours made respectively from hare's and rabbit's fur by the feel. It is not possible to obtain the pile of the real velour made from hare's fur if inferior material is used. The velours is made on the same principle as the soft felt, the pile being obtained by repeated brushings during the stage of manufacture known as planking. Straw boaters are made with a saw or cable edge to the brim, and usually finished with a broad black ribbon.

Practically all hats have a sweat band of leather or other suitable material sewn into the crown, and this is the only part of the hat actually coming in contact with the head. This band should allow perfect adjustment to the head and at the same time permit ventilation.

When buying a stiff felt or silk hat obtain it from an establishment where care is taken in fitting. With a soft felt or velours fitting is a much simpler matter, but it is

well to remember that all felt hats stretch slightly in wear. Hats of all kinds should be frequently brushed, and if possible kept in hat-boxes when not in wear. As a matter of economy it pays to buy a good quality hat, be it velours or soft felt, as it will stand the renovating process, whereas a low quality hat scarcely pays for the trouble. Most hatters undertake the pressing of silk hats and the renovation and re-blocking of others, whether of felt or straw.

The sizes of hats are calculated by their circumference, measured just inside the crown divided by 3-1/7. A ready way of reckoning is to add the length to the breadth, and divide by two. Thus, a hat measuring 8 in. by 6 in. is size 7. The sizes run in eighths, and the usual range of sizes for men is 6½ to 7¼, the middle sizes predominating.

**Hats for Children.** Children's hats usually conform to their school regulations. Caps of light-weight flannel or tweed in winter and straw hats or basin-shaped felts with pliable brims in summer are worn by boys, while for girls, berets may be of knitted or crocheted wool, and hats of felt, straw or velvet. Trimmings should always be simple.

**Hat Bands.** On men's hats black bands are most usually worn. In the case of grey and other light-coloured velours or felts a band of the same colour is sometimes worn, but here, too, many persons prefer black. Black bands are also often seen on Panama hats and on straw ones. Many men, however, like to have on a straw hat a band of club or association colours.

With school children, of both sexes, hat bands striped with the school colours and completed by a badge in front are worn. Hat bands can be bought separately from most hatters.

**Hat Box.** Hat boxes are of two kinds: the large square or oval boxes of stout cardboard in which hats are sent home from hatters and milliners, and the strong fibre or leather ones with handles in which they are carried in travelling.

A travelling hat box, if of fibre, has the merit of lightness over a leather one; but it should be finished with leather corners for greater durability. For women more popular are the round hat bags made of American cloth, with soft lids, and straps which make them easily carried on the arm.

**Hat Brush.** Silk, felt, cloth, or real velours hats all require the regular use of a brush. A good hat brush, like the clothes brush, is everlasting, being similar in make and quality, but the shape is narrow, and curved to meet the requirement of rounded brims.

To brush silk hats, a soft mixture of bristle and horsehair will not disturb the even surface of the silk, which should then be finished with a plush pad. For all other hats, including ladies' hats, a pure bristle brush is the best, soft substitutes being less durable, and coarse adulteration like fibre may depreciate the quality of the hat. Both single and double brushes are made, the former having well-finished backs of polished satin-

wood, walnut, mahogany, etc. *See* Brush; Clothes Brush; Headlining.

**HATCH.** In one sense a hatch refers to a small gate or door, and especially to the lower part of a divided door. Hatches are put in houses, inserted in the dividing wall between the kitchen and the dining room, in order to facilitate the service of meals. *See* Dining Room; Service Hatch.

**HATCHET: Varieties and Use.** The hatchet is a small, short-handled axe, adapted to be used with one hand. Several varieties are obtainable, each comprising a steel head or blade and a wooden handle or helve. For household use the Canadian or hunter's hatchet is handy for splitting firewood; the carpenter's or Kent hatchet, slightly different in shape, is used for heavier timber. The shingling hatchet, with its broad cutting edge and short steel poll or hammer head, is useful for cutting timber for rustic work, one part of the head being employed for cutting, and the other for driving nails. Apart from the preparation of firewood, the hatchet is important in the garden for shaping the ends of stakes and light fencing posts.

In use the tool is grasped firmly in the right hand and the wood to be cut is supported in the left, with the end resting upon the ground, but in any case so positioned that the cutting edge of the blade will not be damaged. The method of use is shown in the illustration.

*Hatchet. Showing how the tool is held when in use.*

The edge should be kept sharp and free from notches. This may be accomplished by grinding the blade on a grindstone and whetting with a whetstone, using this with a circular rubbing motion. The cutting edge is variously formed according to its purpose. Ordinary varieties are ground uniformly on each side of the face, and the cutting edge becomes central, but on the Kent squaring hatchet the grinding is restricted to one face, bringing the cutting edge to one side of the head, and is thus like the chisel. By this means work can be cut more square than would otherwise be practicable. *See* Adze; Chopper.

**HATTER'S PLUSH.** Specially made for hat coverings, hatter's plush is a light silk fabric with a laid, glossy pile which can be smoothed down by brushing in one direction. The support of a firm foundation is required to show off the principal feature of the material, which is made principally in black;

brown and other colours are obtainable for millinery. Hats made of this plush need frequent brushing.

**Haunch.** The haunch of an animal is the fleshy part of the hip and buttock. *See Beef; Mutton; Venison.*

**HAVANA RABBIT.** The Havana rabbit excels as a flesh producer, weighing, when fully grown, from 5½ to 7 lb., and its meat is of first-class quality. It is also bred largely for its fur, which is of a deep rich chocolate colour with a purple sheen. It is very hardy and does well either indoors or in outside hutches. *See Fur; Rabbit.*

*Havana Rabbit. Prize specimen of a rabbit largely bred for its beautiful fine brown fur.*

**HAWK:** For Plastering. The plasterer's hawk is a species of board with a handle projecting vertically downwards from the centre. It is held in the left hand, to support the plaster or mortar when carrying it from the mortar board. The diagrams show its parts, and give the necessary dimensions and details of construction. Although deal is generally used for this tool, a close-grained wood such as birch or beech is preferable, as neither is so liable to warp. Moreover, hardwood will stand rough usage much better than softwood such as deal.

*Hawk. Figs. 1-3. Measurements and details for making board, wedge piece and handle.*

The board piece, Fig. 1, may be made from 9 in. by 1 in wood, and should be planed up on both surfaces, and on all the edges. A tapered groove, with a V-shaped undercut, is cut across the centre of the underside of the

board, this being done with a tenon saw, by cutting the sides or shoulders and then chiselling out the surplus material. Into this groove is fitted a piece of 1 in. hardwood, planed and bevelled, so that it fits firm in the groove. This can be fitted by the aid of a plane, and to ensure proper contact the sides of the groove may be rubbed with blacklead or chalk, the wedge piece inserted, and on its removal the high parts will be indicated by the black-lead.

A perfect fit having been obtained a 7/8 in. diameter hole is drilled into the centre of the wedge piece, Fig. 2, the hole slightly tapered, and a wooden handle, Fig. 3, prepared to the shape shown in the illustration. It is tapered at the end, slotted to take a hardwood wedge, and the whole glued and wedged into the hole in the tapered piece, any surplus that projects upon its surface being removed with a chisel or plane.

*Hawk. The correct way to hold and to use a plasterer's hawk.*

The use of the hawk will be apparent from the illustration. The board should always be kept clean and free from hard lumps of plaster or mortar. These are scraped off with a trowel every time the supply of material is replenished and at the end of the job the wedge piece is knocked out of its place and the board washed clean, the wedge replaced, and the hawk stood aside until it is again required. *See Plaster; Trowel.*

**HAWKER.** English law does not distinguish very clearly between a hawker and a pedlar, although one Act of Parliament defines a hawker as a man who goes about with a vehicle in which to carry the wares he has to sell, and a pedlar as one who goes on foot. In practice, however, there is no difference between the two.

A hawker, therefore, may be defined as one who trades by going from house to house, having with him, either on his person or in a vehicle, the goods he wishes to sell. He may be, too, one who seeks to secure orders for the sale of goods to be delivered immediately, or who offers for sale his skill in any handicraft; for instance, repairing chairs or grinding scissors.

Under an Act of 1871 a hawker or pedlar must take out a licence before he can carry on his trade. These licences can be obtained from the police authorities at a charge of 5s. each. The licence only lasts for a year, and must be renewed at the end of that time. An applicant for a pedlar's licence must be at least 17 years old, and must have resided for at least a month in the district where he makes his application. He must be of good character, and must show that he really intends to trade as a pedlar. If a hawker makes use of a cart

or truck the words "licensed hawker" must be visibly and legibly inscribed upon it.

A hawker's licence is issued by the Inland Revenue Commissioners and expires on March 31 in each year. A certificate of good character must be obtained signed by a clergyman or minister and two householders, or by a justice or superintendent of police. If a hawker acts contrary to the provisions of the law concerning hawking he may be punished by a fine or by the withdrawal of his licence. The latter takes effect if he is convicted of begging.

Dealers in certain commodities can sell their wares from door to door without a licence, and so in the eyes of the law are neither hawkers nor pedlars. Such wares include fish, fruit, vegetables, and other victuals. The word "victuals" includes all foods. Coal can also be sold without a licence, while commercial travellers, canvassers, and others who seek orders for clothing, books, etc., are also free. Hawkers, therefore, are chiefly confined to men who sell notepaper, matches, buttons, bootlaces, needles, cotton, cheap jewelry, and other articles of that kind. Gipsies form a large proportion of the hawker class, offering for sale baskets and other articles of wicker, as well as lace curtains and various household requisites. Many hawkers, especially in the poorer neighbourhoods, do useful service by catering for legitimate wants, conferring a benefit on the busy housewife by bringing to her door the articles she needs. Others, however, are little more than beggars in disguise. They will offer some worthless article for sale, and when the goods are declined will beg for old clothes or a copper.

Housewives should firmly decline to buy from hawkers goods they do not need, and on no account should allow themselves to be intimidated. If a hawker refuses to go away when told his wares are not wanted the police should be informed.

**HAWK MOTH.** This is the name of a group of twilight-flying moths, so called because their method of flight is similar to that of the hawk. They cannot be regarded as pests of serious importance in the garden, although one of their number, the death's head hawk moth, is sometimes the cause of damage on the potato plot. This member is not often seen, but may be identified by its large size, black and yellow hind wings, blackish brown marked fore wings, and the curious semblance of a skull upon its thorax. Its caterpillars appear from midsummer to autumn, measure about 5 in. in length, and have fat yellow bodies with violet stripes. No special remedy is necessary beyond destroying the larvae and pupae if they are found when lifting crops.

**HAWKWEED.** A hardy perennial of the daisy order, the hawkweed (*hieracium*) is not particular as to soil, but prefers a sunny position on banks or rockeries. The best is *aurantiacum*, 12 in. high, with orange-coloured flowers, easily grown from seeds.

**HAWTHORN.** A group of hardy ornamental trees of which the commonest is *Crataegus oxyacantha*

(hawthorn, whitethorn or "may"). There are many varieties of this species, some with double, others with single flowers which are beautiful in May. The variety *praecox* is the Glastonbury thorn. The whitethorn or quick forms an excellent hedge. Some of the hawthorns introduced from other countries are splendid garden trees, valued for their flowers in May and their ornamental fruits in Autumn. Two of the best are the scarlet haw, *coccinea*, and the cockspur thorn (*crus-galli*). The firethorn (*Crataegus pyra-cantha*) is described under its correct name, *Pyracantha*.

*Hawthorn, Flowering spray of this fragrant wild tree which, under the name of whitethorn or quick, is used for hedge planting.*

**HAY.** Apart from its use as food for cattle, hay is of value for other purposes, both in the house and the garden. In the poultry yard it is common as a nest lining for sitting hens, although its tendency to turn fusty perhaps reduces its value when compared with short, broken straw. Whichever may be used, either for nesting or as litter in house or run, it must not be allowed to get damp or dirty, and the poultry-keeper should scatter hay or straw loosely, so that grain may sink into it, and thus compel the birds to scratch about for food. Hay, especially clover hay, may also be used as a substitute for fresh green food, being steamed for some hours until it swells to something resembling its original state.

The keeper of small livestock should, without trespass, endeavour to secure free hay from lane and hedgerow, gathering clover, grass, and herbage, and exposing them to sun and wind until dry and sweet for use in winter. Cutting is best done when the majority of the grasses are in flower, and should always be completed before seeds begin to ripen, otherwise the stems become tough and dry.

Hay also has its use in the garden, being handy as a mulching medium; stuffed into a small flower-pot as a trap for earwigs, especially those attacking dahlias; or as a substitute for manure in making mild hotbeds for plants such as vegetable marrows. In the latter case it must be very firmly trodden and damped before use. In the home, pillows stuffed with hay are esteemed as a soporific for insomnia, while hay boxes are used for cooking purposes.

**HAY BOX: To Use and Make.** In using the hay box, if it is intended to cook two dishes at the same

time, the pans must be put in and taken out together, or two separate cushions made so that one pan can be removed without causing loss of heat to the other. Soups, stews, porridge, puddings, etc., may all be cooked by the hay box method. Suet puddings are best cooked in a basin with a screw-down lid, and put into the hay box in a pan of boiling water. For stews prepared in a hay box the meat must be perfectly fresh.

All food must be actually boiling when put into the box, and most will require to be partly cooked in addition. The pan must not be uncovered until it is to be removed, and its contents must be reheated before serving. The main advantage of a hay box is that it effects a great saving in fuel and gas, and needs no attention during the cooking process.

A rough and ready hay box can be prepared at a cost of a shilling, or less. Procure a wood box, say a sugar case, and line it with seven or eight thicknesses of newspaper to keep out all draughts. A useful size, which will allow of two divisions, is about 22 in. by 15 in., and 15 in. or 16 in. deep. A box for only one stew-pan will do at about 14 in. cube. The size depends on the cooking vessel used. At the bottom of the box there should be an allowance of 6 in. for hay, and a minimum of 3 in. of hay at each side. Above the pan it is necessary to allow 4 in. for a cushion filled with hay.

About sixpennyworth of hay will fill the larger-sized box. This should be packed as tightly as possible. Cushions to place above the stewing-pan can be made of linen. These are tightly stuffed with hay, and should be of a size to fit the divisions closely. Any ordinary saucepan can be used, but as beginners find the handles in the way, it is better to commence with either aluminium pans with a small handle on either side (aluminium holds the heat well), or enamel cans with a handle over the top. An ordinary brown stewing-jar will serve equally well. These jars can be bought for a few pence, are cleanly and can be placed over a low gas flame.

The stew-pan, with the food, is brought to the boil over a gas-ring (or a fire) and is then placed in the box. It rests on the hay; hay is all around it, and the hay cushion is put above, being held down either with a weight or with the lid of the box. The water remains practically at boiling point for many hours, and in this way food may be cooked without requiring the usual constant attention. In many cases it may be cooked over-night.

**HAY FEVER.** This is an acute inflammation of the mucous membrane of the nose, eyes, and air passages. It usually appears in Great Britain between May and August and affects about twice as many men as women.

The cause of hay fever is the pollen of certain grasses and other plants, the pollen containing a poisonous principle. The pollen of rye is particularly rich in this poison. But pollen or any other irritant is capable of producing the affection only in certain susceptible subjects. In some people dandruff from horses or other animals, in others some particular food, and in others still the inhalation of a larger variety of substances, is the exciting cause.

The symptoms are much like those of a severe cold. There is violent sneezing, and a copious watery discharge from the nose and eyes. Itching of the palate and the back of the mouth becomes troublesome, and there is not infrequently a hard, dry cough, and perhaps asthmatic paroxysms with wheezy breathing. The sense of smell may be lost, taste impaired, and hearing more or less affected. The patient suffers from depression and low spirits. There is usually loss of appetite, a feeling of lassitude, and often sleeplessness.

When practicable, a person who suffers much from seasonal hay fever should go to live at the seaside or some mountain resort during the summer. As the specific irritant varies in each case, an effort must be made to find out which is responsible. The patient's own observations may be very helpful in such an investigation. Where it is not possible to ascertain the cause, inoculation with pollen extracts or vaccines may be successful in preventing or mitigating the severity of the attacks.

The general health must be kept up. Locally a simple spray may be used, such as weak boric acid solution, 3 gr. to the oz. of water; a solution of 2 gr. bicarbonate of soda and 2 gr. common salt in 1 oz. of water; a 1 per cent solution of protargol. Very often some defect within the nose favours the occurrence of hay fever. Sufferers should therefore be examined by a surgeon. *See Asthma.*

**HAZARD: A Card Game.** This is a game for four players, two being partners against the other two. The pack consists of 25 cards, all the cards below the nine in an ordinary pack being thrown out, and the joker added for the 25th card. Players cut for partners, the two lowest playing against the two highest, aces counting high in cutting. The player cutting the lowest card deals.

The joker is the best trump, then the jack of the trump suit, then the jack of the same colour, and then the ace, king, queen, ten, and nine. The cards of suits not of the same colour as trumps rank ace, king, queen, jack, ten and nine.

Six cards are dealt each player three at a time. The last card is placed by the dealer on the table face downward, and must not be looked at till the game is over. Eldest hand has first bid, and he names or hazards the number of the tricks he thinks he can make, without, however, naming any suit as trumps. Each player in turn either passes or bids higher, the highest bidder naming trumps and leading the first trick. Each trick counts one point, and for each trick he fails to make on his bid the player is set back a point. Ten points constitute game.

In the double-pack game, two, three, four or six players may take part. The pack consists of a double pack of ordinary cards from which all cards below the nine have been removed. The joker is not used in the double-pack game. If duplicate cards are played on a trick the first one played takes the trick. With two or

three persons playing, each plays for himself, with four, two against two, and with six, three against three. Four cards at a time are dealt. The lowest bid allowed is six tricks. If a bidder thinks he can win all tricks he may name the trumps and discard two of his own cards, asking his partner for his two best cards. The bidder then plays a lone hand.

If the game is four-handed his side scores 24 if he succeeds, and is set back 12 points if he fails. In a six-handed game his side scores 26 for the win or is set back 8 points. Normally each trick counts 1 point, and 62 points constitute a game.

**HAZEL.** The hazel is a native British tree that grows plentifully in the home counties. The timber, which is a reddish white in colour, soft and highly elastic, is not sufficiently durable for good cabinet making, but it is employed for crates, barrels, and fencing stakes. Charcoal is also made from it, and the water diviner uses a hazel twig.

**Hazel Nut.** The hazel nut is the fruit of the hardy shrub *Corylus avellana*, which flourishes in ordinary soil. The golden-leaved variety, *aurea*, is ornamental. The purple-leaved variety of another hazel, *Corylus maxima*, is also showy. Propagation is by setting the nuts in autumn out of doors or by layering in summer.

*Hazel Nut. Fruit and leaves of a decorative tree which can be trained to form a garden hedge.*

**HE.** This name is sometimes given to the popular children's game known also as touch, tag, or tick. *See Touch.*

**HEADACHE: Its Treatment.** An occasional headache is due generally to some purely temporary cause such as overwork or stomach disorder, but if it is persistent medical advice should be sought, as more serious troubles may be involved. In children especially a headache requires attention. Women always suffer more than men and very often do harm to themselves by the excessive use of drugs which produce temporary relief.

Eye strain, decayed teeth, adenoids, ear trouble and disease in the nose are all possible sources to be considered. Headaches due to eye strain are common in children. The eyes should be examined by a reputable oculist, and suitable glasses provided. The commonest causes of the condition in women are constipation, neurasthenia, and anaemia. In men, overwork, work done at high pressure, and particularly when distracted by noise or poisoned by bad air, excessive smoking and drinking, with its usual consequence, catarrhal

dispepsia, are very common causes. Heavy indigestible meals, drinking strong tea or coffee, wearing too close-fitting hats, sleeping in ill-ventilated bedrooms, sleeping too long, using heavy impervious bedclothes, any kind of mental strain, may, any of them, give rise to troublesome headaches.

Where disorders of the stomach are at the root of the trouble the pain is felt towards the front of the skull and equally on both sides. The pain of the anaemic headache is most severe on the top or at the back of the head. The congestive form, in which the brain is overloaded with blood, is accompanied usually by throbbing in the head and a flushed face. Alcohol and strong tea or coffee should be avoided. Aperients such as 5 grains of blue pill may be taken twice a week at bed-time, and the diet should be light and digestible. To relieve an attack, put the patient's feet and legs in a hot mustard bath, bathe the forehead with ice-cold water or put an ice-bag to the head. The safest remedy for a nervous headache is to rest in a darkened room.

*Certain drugs are much used, to the great injury of the patients. The doctor should be asked to prescribe, as harm may result from frequent resort to headache powders.*

**HEADER: In Brickwork.** The word header is used to describe a brick that is set horizontally with its greatest length at right angles to the face of the wall. The proper arrangement of bricks, and the relative placing of headers across the wall and bricks laid in the same direction as that of the wall and called stretchers, is known as bond, or bonding. A header course is a row of bricks set at right angles to the face of the wall. *See Bond; Bricklaying.*

**HEAD-LINING.** Material shaped to fit the inside of a hat is called the head-lining. Such things are usually of silk and are quite simple to make, but a correct fit is important as they wear or tear quickly if too tight, besides being uncomfortable on the head.

*Head-lining. Fig. 1. Measurements for the crown lining.*

*Fig. 2 shows a simple method of attaching the lining to the hat.*

A strip of material, cut on the cross or straight as desired, measuring  $23\frac{1}{2}$  in. or 24 in. long and about  $6\frac{1}{2}$  in. wide, must be cut, and an oval-shaped piece, as shown in Fig. 1, is necessary to line the top of the crown. Place the oval piece into the crown, catching it through with long stitches to the outer part (Fig 2). Pin the straight piece round the inner edge of the brim so

that it fits exactly. Leave  $\frac{1}{2}$  in. for turning at the ends, which must be joined up. Run a slot,  $\frac{1}{4}$  in. wide, along the outer edge, leaving eyelet openings on each side of the join so that a China ribbon may be threaded through; this enables the lining to be drawn up to fit the head. Should the hat be of a soft material the head-lining may very easily be sewn in as shown in Fig. 2, leaving a good  $\frac{1}{2}$  in. margin in case the material should fray; but if the hat is straw, the needle should be pushed right through to the outer side, making very tiny stitches on the outside and long ones, inside which will not show when the lining is turned over them.

**HEALTH: Its Essentials.** Speaking broadly, health consists in all the organs and parts of the body performing their functions quite comfortably and with such vigour as to allow of our doing the day's work, including reasonable strain, without undue fatigue.

In addition to the sudden and great danger from infectious diseases and physical injuries, health may be undermined by personal habits which are hygienically wrong. Amongst the many things essential to bodily and mental welfare, there are three which are too frequently inadequate, viz. fresh air, exercise, and sleep.

Lack of exercise is usually associated with a lack of fresh air, and the results may be rickets in young children, anaemia, constipation, a sluggish digestion, and an inelasticity of mind and spirits, partly due to the bodily state and again reacting upon it. Late hours, especially when too many of them are filled with feverish excitement, are also undermining factors, and as life becomes more strenuous a sufficiency of sleep becomes all the more necessary.

Much ill health is due to want of knowledge and judgement in the use of food. It is now recognized that vitamins play an essential part in nutrition and that the foods containing these, such as fresh milk, butter, meat fat, eggs and fresh vegetables, cannot be neglected with impunity. Almost as important for our nutrition is the possession of sufficient teeth and proper habits of eating and drinking. The abuse of alcohol, tea, tobacco, and other drugs are dangers to be avoided.

It has been noted that most people who live an unusually long span of years have been characterized by cheerfulness of disposition. *See Breathing Exercises; Diet; Drill; Exercise; Insurance; Ventilation; etc.*

**HEARING.** When anyone finds his sense of hearing becoming in the least defective, he should at once consult a doctor. There are some affections of the ear which can be cured when treated at an early stage, but which, if neglected, may result in complete loss of hearing. The ear is one of the most delicate and complicated of our organs, and when affected in any way it is imprudent to practise self-treatment. *See Deafness; Ear.*

**HEART: Structure and Disease.** The main organ of the circulatory system is the heart, which is divided into four chambers, the two upper ones being termed auricles and the two lower ones ventricles. The two great veins, through which passes all the blood

returning from the body, open into the right auricle. From this chamber the blood flows into the right ventricle and passes along the pulmonary artery into the lungs. Having been recharged with oxygen in the lungs, the blood is carried into the left auricle, then to the left ventricle and, passing into the aorta, is then distributed to the body. The heart being a group of four pumps, each of which is emptied in the same way as is a rubber bulb when it is squeezed, valves exist at the openings to maintain the flow in one direction. The sounds audible when the heart beats are made chiefly by the closing of these valves. The average number of beats per minute in an adult is 72.

**Diseases of the Heart.** The great majority are valvular diseases, and these are of two main kinds, stenosis, or narrowing of the valve, which obstructs the blood flow, and incompetence through leaking of a valve. In the treatment of valvular disease the main objects are to lessen the work of the heart by removing resistance and avoiding strain as far as possible, to strengthen the heart itself and to relieve distressing symptoms when they appear in the later stages. Valvular diseases may, for this purpose, be divided into two main classes, those in which compensation is maintained and those in which it is failing or has failed. In the former the patient will suffer no great discomfort unless he overworks his heart.

A boy or girl suffering from valvular disease cannot safely join in violent games such as football. The clothing should be warm, the diet nutritious, and everything indigestible should be strictly avoided. At school study should not be carried to the point of mental exhaustion, and excitement must be avoided. With adults similar precautions should be taken. Slight ailments such as colds, bronchitis, etc. must be taken more seriously than in people with healthy hearts. It is of great importance that the mouth be kept clean, carious teeth being removed, and pyorrhoea dealt with energetically; the same applies to sepsis anywhere.

Functional or nervous disorders are very common, and are frequently referred to as D.A.H., or disordered action of the heart. They are not due to organic disease, but to some outside influence acting usually through the nerves. Thus excessive use of tobacco, tea, or other drugs, as well as hysteria, neurasthenia and dyspepsia, may give rise to irregular heart action. The condition may follow acute disorders such as influenza, rheumatism, trench fever, malaria, etc. A septic mouth or sepsis elsewhere in the body may also cause the symptoms, or these may be due to anaemia. The treatment of D.A.H. will vary to a large extent with the cause.

Angina pectoris is a disease due to morbid changes of the heart muscle, and is generally characterized by agonizing paroxysms under the breast-bone, accompanied by a feeling of suffocation. No person who has suffered from angina should ever be without the small glass phials of amyl nitrite (two to five

minims each), which any chemist can supply. At the first sign of an attack he should break one of these phials in his handkerchief and inhale the fumes. The doctor should be summoned at once, and meanwhile a hot-water bottle may be placed over the heart and sips of hot water and brandy should be given. After an attack the greatest care must be taken to avoid physical and mental strain.

Like any other muscle, the heart may be weak without being actually diseased. It then gives rise to distressing symptoms and often causes needless alarm. Tobacco smoking, drinking strong tea, and other habits may cause weakness of the heart, which is always curable by removing the cause. After an attack of influenza or any of the infectious fevers the heart may be weak for some time, but this passes away as the patient grows well and strong. It sometimes occurs that the heart becomes weak in middle-aged people, solely because they eat and drink too much and do not take sufficient exercise.

**HEART:** In Cookery. The heart of a bullock, calf or sheep makes a savoury dish if properly flavoured and roasted. Two or three sheep's hearts are generally required. Wash them in several waters, warm for preference, removing any clots of blood remaining in the cavities. Cut off the lobes, remove any cartilage or gristle and separate the cavities inside the heart. Then stuff it with a well-flavoured forcemeat, skewer or stitch up the opening, and tie greased paper over it.

Roast or bake the heart in a tin with plenty of dripping, and baste it well, but do not let it cook too quickly or the flesh will be hard. As soon as the stuffing is set remove the paper so that the surface of the heart may brown evenly, and turn it over in the tin from time to time. Serve it with brown gravy, to which should be added the sediment left in the tin after the fat has been poured off. Remove skewers or thread.

A bullock's heart takes from 2½ to 3 hours to roast, a sheep's heart about 1 hour, and a calf's heart 1½ to 2 hours. *See* Forcemeat.

**HEARTBURN.** A burning sensation in the gullet and stomach behind the lower end of the breast bone is known as heartburn, but it is in no way connected with the heart. It results usually from the presence of excessive quantities of acid in the stomach. When some of this is forced up the gullet it causes a scalding sensation in the throat.

Relief can usually be obtained by using one of the following remedies, but none of these remove the cause, to which appropriate treatment should be directed. Perhaps the best remedy is a powder of menthol, 1/6 gr., carbonate of magnesia, 10 gr., and bicarbonate of soda, 12 gr., taken in ½ tumbler of hot water. Another useful remedy is a powder composed of 10 gr. subnitrate of bismuth and 10 gr. of the compound tragacanth powder, three times a day. One or two sodamint tablets ½ hour after meals often give relief. *See* Gastritis; Indigestion.

**HEARTH:** Its Construction. Literally the hearth

is the fireproof flooring immediately in front of the fireplace, of which it is a part, and various forms of decorative treatment are applied to it. On the ground floor level, if the floor is solid, the hearth may be built up with concrete, covered with tiles, stones, or brickwork, but is mostly constructed of one material.

In most small houses the ground floor is built up of timbers, and to protect this woodwork a little wall of bricks is built around the fireplace opening, filled with rubble, and concreted to a level surface. This terminates about 1 in. below the floor, so that when faced with tiles the hearth will be level with the floor.

*Hearth. Construction of a hearth on an upper floor, showing how the trimmers are arranged to furnish the necessary support.*

In a cheap construction, the hearth may be floated off with granolithic concrete and worked to a smooth, trowelled surface.

On an upper floor the floor joists are trimmed to form a framework about 2 ft. away from the fireplace opening and extending to the sides of the chimney breasts, or to the width of the mantelpiece. A fillet of wood is nailed round on the inside of this framework, near to the bottom of the joists, and the aperture temporarily closed by rough boarding supported on props to the ground floor. The box-like structure thus formed is filled with concrete strengthened by reinforcing bars of iron about ¾ in. in diameter, disposed according to the structure of the building. The concrete is then allowed to set thoroughly hard, and finally the wooden props are removed. The surface of the concrete is left about 1 in. below floor level, floated over with granolithic concrete, and trowelled to a smooth surface, tiled or otherwise finished.

When it becomes worn or cracked a concrete hearth may be repaired by chipping off the surface and floating off with new concrete composed of one part of Portland cement and one part of fine granite chips.

To clean a hearth, remove the cinders with a shovel and brush up the ashes that remain with a hearth brush. If it is tiled, wash it with warm, soapy water; then rinse and dry it, and finally polish with a soft cloth or chamois leather. Stone hearths should be washed with warm, soapy water and then rubbed with

hearthstone. *See* Chimney Piece; Concrete; Fireplace; Floor; Grate, etc.

**Hearth Brush.** Brushes of this kind are employed to sweep up the ashes from the hearth and to remove the soot and dust from the back of the grate. They have handles which are usually made of brass or of oxidized metal to match the fire irons.

A neat type of hearth brush is fitted with a cylindrical brass case which slides up and down the handle according to the position in which the brush is held. When the latter is hung up, the case slips to the bottom of the handle and so acts as a covering for the brush. Hearth brushes are sometimes included in sets of fire irons which hang on small stands and are conveniently placed beside the fire. *See* Fire Irons; Grate.

**Hearth Cloth.** Employed to protect that portion of a carpet surrounding the fireplace when the latter is being cleaned, a hearth cloth can be made of any coarse material such as sacking, felt, etc. While the cleaning is being done, the fire irons, sticks, and cleaning materials may be placed on the cloth. Care must be taken in laying the latter that the clean side is always placed underneath.

**Hearth Stone.** This is a preparation sold in block form for cleaning stone hearths, steps etc. It is made by mixing equal parts of whiting and plaster of Paris with enough water to turn them into a stiff dough-like mixture. The latter is then placed in moulds to set.

**Hearth Rug.** *See* Rug.

**HEARTSEASE.** This lovely old-fashioned flower may be treated as an annual, biennial, or perennial. It may be raised from seed sown in July in light, leafy soil, in pots or pans, and placed in a cool spot. It may also be increased by cuttings or by layers. *See* Pansy.

**HEATH.** The botanical name of heath or heather is *Erica*, a genus which contains many beautiful hardy flowering and greenhouse plants. By planting a collection of hardy heaths it is possible to ensure flowers almost all the year round. They prefer peaty or leafy soil but will flourish in lime-free ground to which mould has been added freely: they do not thrive in limestone soil. Planting is best done in early autumn. Cuttings placed in pots of sandy peat in a frame in August provide the best means of propagation. The only pruning needed is to cut off faded flowers, but the tips of young plants should be pinched off to make them branch out.

These are the best hardy heaths for general cultivation—*carnea*, reddish, spring; *darleyensis* (*mediterranea hybrida*), rose red, November-May; *mawean*, red, August-September; *cinerea*, the common hillside heather, purplish, September; *vagans*, the Cornish heath, pinkish, August-September. *Arborea* and *lusitanica*, the so-called tree heaths, grow 5 feet or more high, bear white flowers in spring and need a

sheltered place.

**Heath.**

*Greenhouse variety bearing spikes of white flowers in great profusion.*

For cultivation in the greenhouse the following are some of the most attractive heaths: *caffra*, white; *Cavendishiana*, yellow; *gracilis*, reddish; *hyemalis*, red and white; and *melan-thera*, white.

They must be potted in well-drained sandy peat and grown in a temperature of about 50 degrees. After flowering the shoots should be cut back lightly. Heaths in pots must be watered very carefully; the object should be to keep the soil uniformly moist. If it becomes sodden or is allowed to get dry the plants will fail. In summer they should be placed out of doors or in a cold frame.

**HEATHER.** This name is usually given to *Erica cinerea*, which covers large tracts of country in various parts of the British Isles and is very beautiful when in bloom in September.

*Heather. Flower sprigs of the summer moorland plant.*

## HEATHER

**MIXTURE.** Cloths, usually tweed, in colours closely resembling the heather of the moors, and known as heather mixtures, are employed in the making of sports and other outdoor costumes and hats. Stocking wools in heather mixture are made by blending in differing proportions wools which have been dyed brown, red, green, and purple. *See* Tweed.

**HEATING:** Some General Directions. In this work the various methods of heating a house are described in such primary articles as Central Heating, Electricity, Gas, and Oil. Reference should be made also to Anthracite, Coal, Coke, Fireplace, Grate and Stove.

An open fire radiates heat from the incandescent coals, coke or logs used as fuel. The heat travels out in rays from the glowing surface, heating only the solid bodies upon which the rays impinge, and passing through the intervening atmosphere. Such heat is analogous to that given off by the sun. Modern well designed gas fires furnish most of their heat by radiation, and in electric fires the same end is aimed at, the fireclay back plate being shaped so as to reflect into the room the heat emitted by the glowing element.

Here it may be pointed out that the term "radiator," used loosely for tubular warming appliances heated by steam or hot water, is not a good one, as these function mainly by convection, not radiation. It is true that the casing radiates heat, but owing to its shape only a comparatively small portion of its surface area can effectively send out heat waves into the apartment. A steam or water-heated appliance, or an air warmer, of the electric type illustrated on page 703, heats the air in contact with its walls or casing. This heated air expands and rises, giving place to colder air, which in turn becomes warmed, so setting up a circulation of heated air in the apartment. This is warming by convection.

Another type of convection heater is the cylindrical slow combustion stove. The fireclay lined iron walls become heated and thus warm the surrounding air. Disadvantages of convection heating are that the air in an apartment may become stuffy, and the air currents set up tend to cause draughts. There are difficulties also in suitably ventilating the room without unduly cooling it.

Radiated heat, on the contrary, passes through the air in rays (i.e. straight lines), and after impinging on walls, furniture and other solid bodies, is partly absorbed and partly reflected. It does not warm the intervening air to any great extent, although air in contact with the walls, etc., which have absorbed radiant heat, gradually becomes heated by convection.

An apartment warmed mainly by radiation is generally more comfortable than one in which a convection system is employed. The contrast can be realized by comparing the enervating heat of a Turkish bath, provided entirely by convection, with the bracing warmth of sunshine (radiant heat) on a day when there is a slight but cool breeze blowing.

If it is desired to heat uniformly throughout, particularly if a constant hot-water supply is to be maintained, the merits of central heating should be considered. The economy of labour and fuel effected by this method is considerable, and the atmosphere of the house is kept at a uniform temperature throughout. On the other hand, central heating exhibits a total lack of those cheerful qualities associated with the open coal or log fire. The chief objection to open fires is that they cause a certain amount of extra housework as well as smoke and dirt; but these factors have been reduced practically to a minimum by the modern forms of slow combustion grates.

Those who, while insisting on the cheerful effect and other qualities of the open fire, dislike the extra labour and absence of scrupulous cleanliness associated with coal and other solid fuels, should investigate the

claims of the gas fire and the electric fire. If neither of these is available, there remains the oil stove; it is seldom realized what strides have been made in the design of heating apparatus for consuming oil.

**HEAT STROKE.** Exposure to excessive heat may cause heat stroke, a condition having some resemblance to an apoplectic seizure. When following exposure to the rays of the sun the condition is described as sunstroke, or insolation, but exposure to the sun is not the only way in which heat stroke may be caused, it may occur in stokers and others similarly placed. Its occurrence is favoured by alcoholic habits, inability to sweat freely, and by too heavy clothing.

The patient may suddenly fall unconscious, or there may be preliminary symptoms, such as headache, giddiness, vomiting, and sickness. Usually the face is flushed, the pulse bounding, and if the temperature is taken it will be found to be very high, perhaps 107° to 110° F.

The immediate treatment for heat stroke is to take the patient into the shade, or the coolest place available, strip the clothing from the trunk and souse the trunk and head with cold water. As soon as possible he should be taken home or to a hospital, where an effort will be made to lower the temperature by rubbing him over with ice or giving an iced pack or bath, and possibly an iced enema. *See* Fever.

**HEDGE.** Certain leaf-losing and evergreen shrubs are suitable for planting as hedges. Among the former are privet, whitethorn or quick, beech, hornbeam and myrobalan plum.

Beech makes a first rate boundary hedge, for the dead leaves remain on the branches most of the winter. Planting may be done at any time from November to March, though early autumn planting is to be preferred. A useful hedge results from planting a double row, the plants in one row alternating with those in the other and being set at 12-15 inches apart. Thorough soil preparation is essential to ensure satisfactory growth. In the spring following planting the shrubs ought to be cut back to within 8 or 10 in. of the base to make them branch out. In future years it is wise to keep the top narrower than the base. Clipping is usually done in spring and early autumn. Privet requires to be cut frequently to keep the hedge neat.

Holly and yew are the best evergreen hedge shrubs, but they grow rather slowly. Plants not more than 2-3 ft. high become established most quickly and surely. May and September are the best times to plant evergreen hedges. Clipping should be done in April and August. The plants may be set 15 in. apart in a single row, or if necessary in a double row. A comparatively new hedge shrub that is strongly to be recommended is an evergreen honeysuckle named *Lonicera nitida*: it bears clipping well, and can be kept low or allowed to reach a height of 6 ft. *Cupressus lawsoniana*, *Cupressus macrocarpa*, common

laurel, Portugal laurel, and thuya (*arbor vitae*), are other evergreen hedge shrubs, and box may be planted though it grows slowly. *Cupressus macrocarpa* makes quick progress and soon forms a tall hedge.

*Hedge. Cut yew hedge, a feature of great beauty in the formal type of garden. Above, evergreen hedges which make an effective background to flower borders.*

*Escallonia macrantha*, tamarisk and hardy fuchsia, make splendid hedges in mild districts, especially those near the sea. *Berberis Darwinii*, and *Berberis stenophylla*, two flowering evergreen shrubs, make attractive informal hedges, so do the Penzance briars and other vigorous roses. The best dwarf hedge is provided by lavender.

**The Legal Aspect.** The ownership of a hedge is frequently a matter of dispute, but in strict law where a hedge separates two fields it belongs to the owner of the field on whose side there is no ditch. Where there is no ditch on either side, the ownership of the hedge is established by evidence of acts of ownership, e.g. where one owner's family has tended it throughout a long period.

A hedge which has a ditch on both sides is the property of the owners on each side, who are equally responsible for its upkeep. A person must not cut a hedge or any portion of it that does not belong to him.

Hedges in town and suburban gardens should be kept well pruned. Failure to do so may lead to a passer-by being injured by straggling branches and to consequent liability for damages. Where a garden

adjoins pasture land care must be taken that the trees or shrubs forming the hedge are not of a noxious nature. Yew trees, for example, should never be planted under these circumstances, as cattle may eat the leaves, with injurious and perhaps fatal consequences, and the owner of the hedge may be held liable.

A tenant is not permitted to grow a hedge that will damage the landlord's property, as for example, too near a window-sill, blocking out light from a window, or allowing its roots to develop so as to cause settlement, and so on. Overhanging leaves and branches of a hedge in a neighbour's property may be lopped by the person whose land they overhang, though it is usual first to request the owner to cut them. On the other hand, fruit growing on branches overhanging a neighbouring garden is the property of the owner of the hedge. *See* Box; Concrete; Fence; Garden; Holly; Privet; Yew.

**HEDGEHOG.** There is no pet that is less trouble to keep than a hedgehog. Housewives who are troubled with black beetles or cockroaches in the kitchen will find in the hedgehog a valuable ally, for he will effect a speedy clearance. Young hedgehogs can be bought at bird and animal shops.

**HEDGEHOG CACTUS.** Most kinds of echinocactus require cultivation in warm and dry greenhouses, but one species, *Simpsoni*, can be grown in a sunny position out of doors in gravelly or sandy soil if protected from rain in winter. Propagation is by cuttings or offsets taken with a sharp knife and placed in a sunny spot until cuts heal and root growth begins. At this stage they may be potted in a mixture of fibrous loam, finely broken lime-rubble, and sand.

**HEDGEHOG CAKE.** A hedgehog cake is so called because of its shape and the number of browned and halved almonds used to decorate it. The ingredients and method of making are the same as those described for almond cake, but a more rounded appearance is given. When cooked, the cake is coated with almond paste, brushed over with a little yolk of egg, and placed in a hot oven till of a golden brown colour. The almonds are then stuck into the paste to suggest hedgehog spines.

**HEDGING TOOL.** This is a tool adapted for cutting hedges, and especially for hedges of considerable size and not easily trimmed with an ordinary hedging knife or bagging hook. The tool comprises a long handle, or shaft, 3 ft. or more in length, and has a steel blade fixed to the end, shaped in much the same form as a billhook. *See* Billhook.

**HEEL BALL.** A composition of tallow, or beeswax, and carnauba wax, coloured with drop black, is employed under the name of heel ball in the repair of boots and shoes, for colouring and polishing purposes.

It is also used for taking impressions of coins, brasses, and other incised decorations. This is done by placing a piece of white paper over the object, and rubbing upon the surface with a lump of heel ball, with the result that the high parts of the design are reproduced in black, and the incised lines appear on the paper in the form of white spaces. *See* Boot Repairing.

**HEIRLOOM.** This word is used for articles, e.g. plate, furniture and pictures, which go with a settled estate. Since 1925, these may be settled in the same way as land so as to make it difficult, if not impossible, to dispose of them apart from the land to which they are attached. More generally the term is employed in order to denote articles of value which have been for some time in possession of the same family.

**HELENium.** Hardy perennials which are of great value in the flower border in summer and autumn. They flourish in ordinary soil, are easily propagated by division in spring and autumn and bear large daisy-like flowers. The best kinds are *Crimson Beauty*, 2 ft., July, crimson-brown; *pumilum magnificum*, 2½ ft., July, golden yellow; *Riverton Gem*, 4 ft., Aug.-Sept., reddish; and *Moerheim Beauty*, 3 ft. crimson.

*Helenium. The daisy-like flowers make effective indoor decoration.*

**HELIANTHEMUM.** The name belongs to a pretty family of dwarf flowering plants, popularly known as the sun roses. The flowers of different varieties are white, yellow, pink and crimson in colour, and the plants average about 12 in. in height. Sun roses are useful for the rock garden; they thrive best in light soil. They

are raised from seed in spring. The common kind is *helianthemum vulgare*, of which there are numerous varieties, some with single, others with double flowers, in many showy colours.

**Helianthus.** This is the botanical name of the sunflower (q.v.).

**Helical Gear.** *See* Gear.

*Heliopsis.* Flower head and leaves of a single form of the *scabra* variety.

**HELIOPSIS.** Of the small genus of hardy herbaceous plants known as *heliopsis* and sometimes as orange sun-flowers, which they much resemble, only *laevis* and its varieties *pitcheriana* and *scabra* are much grown. These are showy plants with rough, toothed leaves and large yellow flowers in summer; height 4 to 5 ft. The method

of propagation is either by seed or by division of the root-stock in autumn or spring.

**Heliotrope.** *See* Cherry Pie.

**HELLEBORE.** This group of hardy plants contains the Christmas rose (*Helleborus niger*) and the Lenten rose (*Helleborus orientalis*), which are valuable winter and spring flowers. They flourish in partially shady places in deeply dug and manured soil which does not dry out in summer. The best time to plant or transplant is in July. Small pieces become established quicker than large ones.

There are some beautiful varieties both of the Christmas and the Lenten rose. The finest Christmas rose is one named *altifolius* (*maximus*), which bears large white flowers. Of the Lenten roses some of the most beautiful are *Isolde*, pale rose; *Faerie Queen*, blush marked with crimson; *Snowdrift*, white; and *Robert Froebel*, crimson. Propagation is most easily effected by division of the clumps in summer.

**HEM: How to Make.** A hem is made by folding over an edge of material on to the wrong side to any required depth, its extreme edges turned in and prevented from fraying by being sewn down to the outer part. The line of sewing should hardly show through on to the right side, if the stitches are small and evenly made. Hems which are made to neaten the raw edges in lingerie, or in sewing very fine silk, should be as tiny and flat as possible, while hems to answer the same purpose in heavier materials are usually made ¼ in. wide so that they can be pressed down flat.

The depth of a hem varies according to the demands made upon it, and the material. A very deep hem several inches wide is often used to give weight, helping to make the part of the garment upon which it is placed hang evenly and well. If the material is too heavy to be turned up to any depth, or if not enough material has been allowed to make a deep hem, 1 in. or more may be turned up and a facing or false hem made with some lighter-weight material of the same shade, to give the appearance of a deep hem.

The edges of a hem made in very thick material should not be turned in, but one edge of a Paris binding should be sewn well over the part which is likely to fray, the outer edge of the binding being firmly hemmed down to the outer part of the garment. The hem will then press quite flat with no unnecessary thickness. In turning up the hem of an unlined coat the edges are usually bound by a crossway strip of material or binding before hemming to the outer part. The hem of a lined garment is kept in place by the lining, and is not sewn down to the outer part at all. Hems made in cloth which is not likely to fray are sometimes turned up and herring-bone stitched flat.

To hem the material, which is done from right to left, hold the hem over the forefinger of the left hand and under the middle finger, holding it down with the left

thumb, and keeping the inner fold towards you; then, pointing the needle outwards, pick up a few threads of the material just below the inner fold and push the needle up through the edge of the fold itself. Draw the needle through, and repeat. All the stitches should be made uniform in size, slant and space. If the material is not too thin, the needle can be passed through the upper surface of the fabric, so that practically nothing is seen from the right side.

**HEMLOCK: The Drug.** Both the fruit and the leaves of the hemlock, or conium, are used in medicine, but the drug and its preparations are not officially recognized by the medical authorities. The drug is rarely prescribed to be taken internally, as its action is uncertain. Conium ointment has been found of much use as a cure for itching and fissures about the anus.

The chief symptoms in hemlock poisoning are heaviness in the legs, staggering gait, and finally complete loss of power over the muscles. The eyes become fixed, the pupils dilate, the breathing becomes more and more difficult, until finally death ensues from asphyxia. After an overdose of hemlock an emetic should be given at once, and then strong warm tea freely. The patient should be kept warm with hot-water bottles and blankets. If the heart flags, or breathing becomes very laboured, stimulants should be given and artificial respiration should be carried out. *See* Emetic.

**HEMP AGRIMONY.** This is a hardy perennial suitable more particularly for a large garden, owing to its coarse growth. There is one species, however, which may be recommended for smaller gardens, namely, *Eupatorium ageratoides*. This makes a fairly compact bush about 3 ft in height bearing pure white flowers and requiring a sunny position in ordinary soil. Propagation is by division of roots in spring or autumn, or by seeds sown outdoors during April.

*Hemp Agrimony (Eupatorium) which bears large heads of white flowers in late summer.*

**HEMSTITCH.** This is used chiefly on house-linen, when it actually holds down the hem, but it is employed also on dresses and lingerie.

On a tea-cloth a hem is turned, usually about 2 in. wide, tacked down, and several threads drawn just under the edge of the hem; the number of threads to be drawn depends on the texture of the linen or other material in use for the cloth. The stitch then proceeds as in drawn thread (q.v.)

**HENBANE.** This is the popular name for *hyoscyamus*. It grows wild, especially on and around heaps of old rubbish, but in some places it is cultivated

because of its use medicinally. Every part of the plant is poisonous, particularly the root, which is often mistaken for chicory or parsnip. The leaves are oval, lobed or toothed, the upper ones clasping the stem. The flowers are large, shaped like a funnel, and in colour a dull yellow veined with purple. The fruit is a many-sided capsule with a distinct lid. The whole plant has a somewhat unpleasant smell.

The leaves and flowering tops of the plant are used for making its various medicinal preparations, the leaves being of most value in their second year, or in the autumn of their first. Its actions resemble those of belladonna and stramonium, and it is frequently used as a sedative in bladder affections, and combined in pills with purgative drugs to prevent severe griping.

**HENNA: For the Hair.** Henna is a small shrub, the leaves of which, when dried and powdered, are used to make a reddish-brown dye. In small quantities it makes an admirable shampoo, for brunettes, giving brightness to the hair after washing.

In using the hair dye about 7 oz. of powder are required for one application. This quantity is divided into two portions. The first part is mixed with a pint of boiling water, allowed to stand for a short time, but whilst still hot applied to the hair by means of a brush. The second portion is made into a moderately thick paste with water and applied to the hair, being kept in place for about half an hour by wrapping a towel round the hair. The hair is then rinsed in tepid water. Re-colouring is necessary in about a month. *See* Hair.

**HEPATICA.** Belonging to the anemone family, hepatica is a spring-flowering primrose-like plant which loves the shade.

There are single and double varieties of white, blue, and red colouring. Hepaticas need rather light leafy soil in a partially shaded place and should be left undisturbed for years as they dislike being moved. In time they may become overcrowded and bloom sparsely: then lifting and replanting as soon as the leaves have died down is recommended.

**HEPPLEWHITE: The Style.** This style in English furniture is named after George Hepplewhite, a cabinet maker and designer who worked in London until his death in 1786. The general lines of his furniture, like those of Sheraton, show the Adam influence, and the pieces are in good taste, with the ornament dignified and restrained.

Hepplewhite used carving to ornament his chair backs where Sheraton generally relied for decoration upon marquetry or painting. His wheat-ear shield-back chairs, those with the Prince of Wales's feathers, and others with carved festoons of drapery, or a vase forming the centre, to which the husks or drapery were attached, are now highly valued by collectors. Like Sheraton, he favoured square, tapering legs, but these were ornamented by flutings or grooves, into

which he often introduced carved husks. The friezes of his sideboards and the console or pier tables of the time he ornamented with carved paterae of rosettes, which sometimes were alternated with vases and scrolls; occasionally the masks of lions, rams or goats were introduced. Some of his mirror frames were designed for gilding, and these are generally similar to those of the Adam style.

*Hepplewhite. Chairs in walnut, with silk upholstered seats, and backs showing designs characteristic of this maker's style. ( By permission of the Director, Victoria and Albert Museum, S. Kensington)*

One of his specialities was enamelled or painted furniture, and for this he used beech or birch, which was first covered by an enamel lacquer, generally black, white or ivory colour, and then decorated with painted flowers, or occasionally with cameo-like medallions. Some of the titles of his furniture now strike us as peculiar, e.g. cabriole chair, which in his case meant a stuffed back and did not refer to the curved form of leg; bar-backed sofa, which was a settee for three or four people, formed like chairs joined together side by side, with an arm at either end; tea chests; knife urns and some other terms which have since gone out of general use.

The knife urns are distinctive and attractive accessories, sometimes in the form of Etruscan vases, often made of richly figured Spanish mahogany. They stood upon the pedestals which, together with a side table, formed in combination the sideboard of the period. Some of Hepplewhite's oval trays are inlaid with marquetry, generally having a centre ornament surrounded by festoons of husks. Like Chippendale and Sheraton, whose books of designs furnished the patterns for contemporary makers, Hepplewhite has got the credit for a great deal of furniture which actually was made by his contemporaries. *See* Antique Furniture; Armchair; Knife Box; Mahogany; Settee; Sheraton; Sideboard.

**HERACLEUM.** Also known as the giant parsnip, *Heracleum giganteum* is only suitable for the wild garden or shrubbery, by reason of its exceedingly robust growth. It bears very large lobed leaves and umbels of creamy-white flowers; under suitable conditions it will reach a height of 10 ft.

*Heracleum* can be grown in any ordinary soil, and is best planted in autumn. Propagation is by seed sown in spring, or by division of roots in October or March. The plant is sometimes called the cartwheel flower because of its huge heads of bloom. Pron. He-rak-le-um.

**HERB:** In Cookery. Herbs are employed in cookery for flavouring many dishes. The best flavouring is afforded by freshly gathered powdered herbs, but there are one or two special mixtures of preserved herbs on sale. The ordinary sweet herbs sold by grocers contain about two parts parsley, the remainder being made up with thyme, and occasionally marjoram.

The herbs most frequently employed include sage, thyme, marjoram, mint, parsley, hyssop, chervil and coriander, the cultivation and uses of which will be found described under their separate headings.

Among all the herbs marjoram may be said to excel in flavour. Marjoram is an excellent addition to soup, meat and fish, and can be used in stuffing.

Herbs to be dried must be gathered on a dry day. Remove all discoloured leaves and put the remainder in a cooling oven, leaving them until they are crisp enough to be pounded. Any great degree of heat must be avoided, for this will destroy the aromatic properties of the herbs. When the leaves are thoroughly dried shake them in a large sieve or basket and then pound them into fragments. Put these into wide-mouthed and well-stoppered bottles, in which they may be stored for 12 months or more. In purchasing dried herbs select those stored in bottle in preference to those made up in packets.

**Herb Vinegar.** Fresh herbs only should be used in making this vinegar. Collect the young leaves of as many different varieties of herbs as possible, wash and dry them, and then put them into glass jars or wide-necked bottles, filling them three-parts full. Fill the jars with vinegar, seal them down, and then store them in a cool, dry place. In three weeks the vinegar may be strained and bottled. *See* Bouquet Garni; Herb Garden.

**HERBACEOUS BORDER.** The herbaceous border consists of herbaceous perennial plants, that is to say, plants the foliage of which dies down in the autumn, but which comes up again season after season. The plants may be left permanently where first established, but many benefit by being dug up and transplanted every 3 or 4 years.

Plants which increase too rapidly may be separated in the spring. When once established the herbaceous border needs only superficial attention, provided it has been well prepared in the first instance. The border should be dug out to a depth of 2 ft. and enriched with manure.

The best periods for planting perennials are spring

and autumn, the more robust plants during October and November, and the choicer kinds in March and April.

By planting a careful selection of kinds and varieties it is possible to ensure a brilliant display of bloom throughout the summer and autumn months. It is usual to place the plants in groups of three, five or seven, according to the size of the border, rather than to set them singly. Charming colour schemes can be arranged by grouping the plants according to the colours of the flowers. The most effective arrangement is to start at each end of the border with white and pale blue, and follow with pale yellow, rose, mauve, and purple; working up to crimson and scarlet in the middle of the border.

*Herbaceous Borders which provide a display of bloom in summer and autumn.*

Some of the chief hardy herbaceous perennials are the following: Lupin, delphinium, Shasta daisy, phlox, paeony, pyrethrum, oriental poppy, sea holly (eryngium), globe thistle (echinops), heuchera, Michaelmas daisy, golden rod (solidago), Japanese anemone, purple sage (*Salvia virgata*), day lily (*hemerocallis*), and summer starwort (*erigeron*). To fill spaces between the permanent plants, annuals are sown and gladioli, lilies, and montbretias are planted in spring and dahlias are put out early in June. *See* Border; Flower Garden.

**HERB GARDEN.** The cultivation of herbs on account of their medicinal properties and as a flavouring in cookery is one of the oldest forms of gardening, and herb gardens are still to be found in many parts of Great Britain. Herbs most usually found in gardens include mint, thyme, marjoram, hyssop, peppermint, borage, dill, fennel, angelica, sorrel, tarragon, chervil and coriander. Although strictly not an inhabitant of the herb garden, lavender is often to be found therein. The best position for the herb garden is between the flower and kitchen gardens.

The majority of herbs are propagated by slips taken in the autumn, or, in the first place, by seed sown in the early spring. They may be arranged in drills or patches, and the plants should remain undisturbed, except for thinning.

**HERMITAGE:** A French Wine. There are three varieties of hermitage, which is a high-class French wine of the Côtes du Rhône, and is either red, white, or straw colour. The red wine, when it is of the first quality is not bottled until it has been four or five years

in cask. It has a bouquet recalling the raspberry, and has a remarkably clean, fresh, full vinous flavour, great firmness and softness, and a rich deep purple hue.

White hermitage, which is made of white grapes only, has been described as the finest white wine France produces. Its colour should be a pale yellow. Its bouquet is like that of no other known wine, rich and spirituous in flavour and perfectly dry. The straw colour hermitage is rare and expensive. It is noted for its freedom from all acidity, its smoothness, and marrowy richness of flavour.

**Hernia.** *See* Rupture.

**HERON'S BILL.** A plant somewhat similar to the hardy geranium, and sometimes called stork's bill: its botanical name is *erodium*. It flourishes in light, sandy soil in the rock garden. Some of the best sorts are *guttatum*, white, 6 in.; *Reichardii*, pink and white, 2 in.; and *macradenum*, white and violet, 6 in.

*Heron's Bill.*  
*Geranium-like*  
*flowers of a plant*  
*useful in the rock*  
*garden.*

**HERPES:** A

**Skin Disease.** Simple herpes, fever blister, or cold sore is an acute inflammation of the skin, accompanied by the development of small blisters. Beyond lightly covering over the spot or sore with cold cream or a little zinc ointment, no treatment is required, the eruptions tending to heal themselves spontaneously. *See* Shingles.

**HERRING:** How to Cook. The usual way of cooking herrings is to fry them. After it is cleaned the fish can either be slit open or can be cooked as it is. Heat a little dripping in a frying-pan, and fry the herring in it, turning it when one side is done.

To broil the fish, gut and clean them, but dry them well. Score the fish across each side, season them, and dredge a little flour over them; then cook them on a well-greased gridiron. Before dishing, brush the fish over with butter, which should be ready melted in a small pan. Sprinkle them with lemon juice and a little cayenne pepper, and garnish with fried parsley.

Another method is baking. Remove the heads and tails, gut the fish and clean them. Grease a pie-dish with good dripping and lay the fish in it. Add one or two chopped shallots and a little chopped parsley, thyme and marjoram; a bay-leaf may also be laid in the dish. Season well, and put more dripping on the fish. Cover the dish with greased paper, and bake it in a moderate oven for 15 to 20 min. Each fish should be laid separate, not one on top of the other. Serve with mustard sauce.

To sous herrings, clean and bone them, roll them up with a small piece of onion in each, and pack in an enamel or fireproof dish. Cover with vinegar and water, adding 2 or 3 cloves, 3 bay-leaves, some black peppercorns, and salt. Bake in a hot oven 20 to 30 min. Serve cold. These are known as "Mops" in some parts of the country.

When cured, herrings are known as bloaters and kippers. Bloaters are salted whole, then strung on thin piles and smoked with wood smoke until dry, and the curing process is completed. Yarmouth bloaters have always been considered the best. Kippers are herrings salted and smoked, but before curing they are split open and gutted. They can be cooked by the same methods as bloaters.

**Roe of the Herring.** The roe of the herring, either fresh or salted, can be served in a variety of ways, and makes a savoury or a breakfast dish. This is one method of cooking soft roes: Fry lightly in butter 3 or 4 roes from fresh herrings, lay them in a greased pie-dish with two tablespoonfuls of chopped mushrooms, 1 tablespoonful of chopped parsley, and 2 shallots, also chopped. Bone and fillet 3 anchovies, add these with a good squeeze of lemon juice, and season well. Pour over the roes the butter used in frying, and cover with brown sauce. Put a greased paper over the dish and bake for 5 min.

The roes may also be served plain. Blanch them, cut them in convenient pieces, cook them a few minutes in butter, and serve on croûtes of toast. A better flavour is given if, before serving, a little lemon juice is sprinkled over the roes and they are seasoned with salt and cayenne. The roes may be left whole.

Hard roe may be boiled, pounded, and made into potted meat if mixed with butter, flavoured with mace and well seasoned. *See* Bloater; Cod's Roe; Fish; Kipper.

**HERRING-BONE STITCH.** This stitch is chiefly used for seams on flannel and similar materials that are too thick to be turned under, the raw edge being herring-boned on the wrong side. It takes the position of the ordinary hemming stitch. It is sometimes called Figure 8 work, and reference to the illustration will show the similarity.

*Herring-bone Stitch, used for catching down the raw edge of a seam in a thick material.*

With a little care and a good eye for measurement, it is not necessary to space out the actual places for the

stitches, but, for the beginner's guide, dots can be placed along an imaginary top and bottom line, which will decide the depth of the stitch. For an ordinary hem this is  $\frac{1}{2}$  in., and each stitch is  $\frac{1}{4}$  in. apart on the same line. Dots can be marked with a lead pencil at equal distances apart, or on loosely woven materials a thread can be drawn at the top and bottom of the space to be covered, and an even number of threads taken up and missed on the material. The work proceeds from left to right, and the stitch is taken up on top and bottom lines alternately, as shown in the illustration.

**HESSIAN: A Canvas.** Common canvas, or jute hessian, employed for packing bales and making a foundation for oilcloth and linoleum, is sometimes known as burlap. The material has sundry household uses, such as making coarse aprons, ovencloths and underlays for mattresses to preserve the ticking from contact with the wire springs of the bed. Hessian can be used for wall decorations; for example, in making panels or friezes. The natural colour is buff, but it can be dyed a deeper shade, black, dull green, or blue quite successfully. Pictures look well against a background of burlap or hessian, and advantage is often taken of this at exhibitions.

The material is cheap and obtainable in different widths and qualities. It is often stencilled; or embroidered in simple designs and used for short curtains, garden cushions, blotters and work bags. It is effective, when dyed black and embroidered in bright coloured wools, for a writing table set and in buff for cushions. *See* Woolwork.

**HETERODYNE.** When alternating currents of two different frequencies flow together in a circuit they combine to form a new frequency (called the "beat" frequency) which is equal to the difference between the original frequencies.

The superimposing of two sets of alternating currents or oscillations of different frequencies is known as "heterodyning," and the method may be used in wireless for the reception of continuous wave (C.W.) transmissions (heterodyne reception) and also for the measurement of wave-length.

The formation of a "beat" frequency in the manner described above constitutes the principle upon which the superheterodyne receiver is based.

**Heterodyne Interference.** This is the interference caused by the carrier-wave of a broadcasting station beating with that of another station working on a slightly different wavelength or frequency, thus producing an audible beat note in the receiver. This can be remedied by spacing stations farther apart in wave-length. Another source of interference (rare nowadays) is oscillation from another set.

**HEUCHERA.** Alum root is the popular name of this invaluable hardy border plant, which produces

long, graceful sprays of bloom in rose, crimson, blush and other colours in May and June. These add to the charm of the garden in early summer and are most useful for cutting. The plants, which form low, leafy tufts, may be planted in spring or autumn; it is wise to leave them undisturbed. They thrive in ordinary well-drained soil in a sunny place. Propagation is by division of the plants in autumn, or by seeds. There are now many beautiful varieties with long flowering stems. Some of the best of these are Edge Hall, rose-pink; Rose Cavalier, rose-cerise; tiarelloides, blush; and Pluie de Feu, red; sanguinea, coral-red, which is an old sort, is also a beautiful and useful variety.

**HIBISCUS** (Mallow). This is the name of a group of shrubs and herbaceous perennials some of which are hardy, while others are suitable for the greenhouse. The Syrian mallow (*Hibiscus syriacus*) is the best of the hardy kinds; it is a shrub 5 ft. or more high which bears mallow-like flowers of various colours in August. There are double and single varieties. For cultivation in the warm greenhouse, coccineus, red, manihot, yellow, and rosasinensis, red, are to be recommended. They may be grown in large pots or planted in a border of a soil of loam and peat.

*Hibiscus. Flowers of the Syrian mallow (Hibiscus syriacus).*

**HICCOUGH:** How to Check. The commonest exciting cause of hiccough is indigestion. Children who bolt their food are especially subject to it. Drinking very hot or very cold liquids may cause it. It occurs in hysteria, gastritis, appendicitis, alcoholism, sleepy sickness, etc.

There are many ways of bringing an ordinary attack to a close, among which are the following: Give a teaspoonful of raw whisky, a teaspoonful of lemon-juice in which a pinch of salt is dissolved, or a teaspoonful of sal volatile with very little water. Put a pinch of salt on the back of the tongue. A tablespoonful of peppermint water or of cinnamon water, or a few drops of spirit of sal volatile with very little water. Put a pinch of salt on the back of the tongue. A tablespoonful of peppermint water or of cinnamon water, or a few drops of spirit of a close, among which are the following: Give a teaspoonful of raw whisky, a teaspoonful of lemon-juice in which a pinch of salt is dissolved, or a tea-spoonful of sal volatile with very little water. Put a pinch of salt on the back of the tongue. A tablespoonful of peppermint water or of cinnamon water, or a few drops of spirit of chloroform in  $\frac{1}{2}$  tablespoonful of water, are also good remedies.

In the case of children with overloaded stomach an

emetic, such as  $\frac{1}{2}$  teaspoonful of mustard in a tumbler of warm water, may be very useful. When the hiccough is severe and prolonged, a doctor should always be consulted.

**HICKORY.** This wood resembles English ash, and is used for much the same purposes. It is slightly superior to ash in hardness and toughness, and also heavier, but it is not very durable in moist, warm, and exposed conditions, as it is liable to be attacked by insects and worms. Hickory is close-grained and nearly white in colour. In boards it shrinks and warps. Its flexibility adapts it for bending and for purposes where it will be subjected to shock and vibration. Hickory is used for hammer, axe and agricultural implement handles, for the hoops of casks, in vehicle building, for the spokes of wheels and backs of chairs, for oars. etc. *See Wood.*

**High Chair.** *See Baby Chair.*

**HIGH FREQUENCY (H.F.).** This is a term applied to alternating currents or oscillations having a frequency above approximately 10,000 cycles per second, as distinct from alternating currents of low or audible frequency. High frequencies (radio frequencies) are employed for broadcast transmission purposes, etc. When the frequency is very high it is often termed an electric oscillation.

**HIGHLAND FLING.** In the Highland Fling the dancer, while hopping on one foot, makes a series of rapid movements with the other, and finishes with a complete turn. The arms may be held akimbo, but it is usual to raise one arm above the head, and this is invariably done in turning.

The dancer begins by pointing the right foot to the side while hopping on the left. The next motion is to bring the right foot behind the left leg, then in front of it just below the knee, and again behind it. These movements are repeated with the left foot while hopping on the right, then again with the right, and again with the left, finishing with a complete turn to the right. The whole series of steps is repeated, beginning with the left, and finishes with a turn to the left.

In the second step the dancer hops on the left foot and points with the right, brings the right up behind the left leg, points with the right again, then brings the right up in front of the left, just under the knee. This is repeated three times, with alternate feet, finishing with a turn to the right, and the whole is again performed beginning with the left, with a turn to the left.

The third step resembles the first. 1, 2, 3, 4, fling movement 3 times with the right foot, finishing complete turn to the right. Repeat over again, beginning left. In the fourth, while hopping on the left foot, the right is pointed as before, brought up behind the left leg, pointed in front, and kicked out in front,

then the dancer rocks from leg to leg, beginning on the right. The step is repeated three times, on left, right and left feet alternately, each of the four steps taking eight beats instead of four.

The other steps are similar, but the heel and toe movement is introduced as a variety, the dancer touching the ground first with the toe, and then with the heel, instead of bringing the foot up before and behind the leg. There are variations also in the times and number of turns. Each step takes 8 bars, or 32 beats of music. In the first, second, third, and sixth steps the turn is on the fourth and eighth bars, while in the fifth step it is on the second, fourth, sixth and eighth bars.

In the seventh step the first four beats are the same as the second, then the right foot is slipped behind the left leg, brought to the ground, and as the weight is transferred to the right leg the left foot is passed in front of right shin. This back step is repeated with the left leg, then the right, then the left, and the whole is then repeated from the beginning, with left, right, left. Like the fourth step, this step is done four times only, and with no turning.

In the eighth and last step after the first four beats as in the first step, left toe and heel are pointed in front, and the same movements are made with the right foot and repeated with left and right, turning round to the right with the left foot working round the right leg. The movements are then repeated, toe and heel once only this time, finally turning round to the left twice on the left leg.

**HIGH TENSION VOLTAGE.** This is the voltage which is applied to the anode (plate) of a wireless receiving valve, and may be derived from a battery of dry cells or accumulators, or (in all modern sets) from the mains. The high tension voltage necessary depends upon the type of valve and its position in the set. Suitable values are given on the leaflet supplied by valve makers.

High tension batteries of either the dry cell or accumulator type comprise a number of cells connected together in series. Tappings are provided to enable the required voltages to be obtained. H.T. dry batteries employed with receivers utilizing three or more valves should be of the large capacity type. Batteries of the ordinary type, having smaller cells, require more frequent replacement.

H.T. accumulator batteries are equally suitable for small or large sets, but must be re-charged at regular intervals. Sulphation will rapidly occur if the cells are allowed to remain in a discharged condition. Never short-circuit the battery. H.T. batteries are now mainly confined to battery-operated portable sets. *See* Accumulator; Battery.

**Himalayan Poppy.** *See* Meconopsis.

**HIMALAYAN PRIMROSE.** This is the popular name of *Primula denticulata*, a beautiful hardy plant which bears lavender-mauve blooms in spring. It is suitable for the rock garden or flower border, and

should be planted in loamy soil in partial shade.

*Himalayan Primrose. Rosette of leaves and lavender-mauve flower heads of a beautiful rock plant.*

## HINDQUARTER.

The hindquarter of meat consists of the leg and loin either of beef, veal, mutton, or lamb. That of beef is always divided into joints. Of these the shin is used for boiling and stewing; the topside and silverside for roasting, boiling, or pie meat; the aitchbone for roasting; the rump for roasting or steaks; and the sirloin for roasting. Part of the thin flank also belongs to the hindquarter of beef, and this piece is suitable for braising.

The hindquarter of veal, like beef, is cut into joints. The top portion of the leg is divided into the fillet and cushion, which is the part used for roasting and cutlets, and the lower half is the knuckle, suitable for boiling or stewing. The loin is usually roasted, but sometimes is braised in a casserole.

The hindquarter of mutton is either cooked whole, when it is called the haunch, or it is divided into the leg and the loin. The leg can be boiled or roasted, the loin roasted, braised, or divided into chops. The hindquarter of lamb is frequently cooked whole, and is called hindquarter, not haunch; it can be cut into leg and loin, and treated as for mutton. *See* Aitchbone; Beef; Joint; Mutton, Veal.

**HINGE.** A hinge is a movable joint, whereon a door turns, in relation to a frame or other fixed portion. Types vary from a tiny metal fitting to one weighing several lb. The form in common use is the butt hinge, made in brass cast iron, or steel. The kinds here illustrated include back-flap hinges (Fig. 1) made of steel or wrought iron with welded butts, and useful for an object that is long in proportion to its breadth. Counter-flap hinges have two separate centres about which they turn, so that the hinge is flush with the surface when the flap is down, and lies flat upon the counter after it has been swung aside.

Skew butts, or rising hinges (Fig 3), are those in which one element of the hinge is adapted to rise and fall upon the hinge-pin, by cutting the faces of the butts at an angle instead of having them square. As the door rotates the hinge lifts, and the door with it. This enables the door to clear the carpet, and where the floor is not quite level it may obviate the necessity of cutting a part off the bottom of the door. Where it is

desired to remove the hinged member from the fixed portion or frame, the lifting butt is of service; one part of the hinge may be lifted, from the other.

*Hinge: various types. Fig. 1. Back-flap. Fig. 2. Parliament or shutter hinge. Fig. 3. Skew or rising butt.*

*Fig. 4. Trestle-joint hinge.*

Parliament or shutter hinges, shaped as in Fig. 2, are made so that when the shutters are open they fall flat against the surface of the wall. Trestle-joint hinges (Fig. 4) are in malleable iron, for step-ladders or trestles. Cranked chest hinges of wrought iron are specially for the lids on chests or boxes. T hinges (Fig. 5) are for hanging doors, as are the cross-garnet, similar in pattern. The tumbler T hinge, or cellar-flap hinge (Fig. 6), is for hanging the flap of trapdoor; the trap can rest upon supporting battens and relieve the hinges of their weight. Large doors, as in stables and garages, are made with a gate hinge or hook and ride. Collinge's patent spherical gate hinge is fitted with a ball-shaped pin, and the hinge or ride has a cup which forms a bearing for the ball, furnishes a receptacle for oil, and is fitted with a leather washer, which renders it watertight. Ball and cup are specially hardened, and this type is very useful for heavy doors or gates.

*Hinge. Fig. 5. T hinge being fitted to the door jamb.*

*Fig. 6. Cellar flap hinge with wood cut away to show construction.*

Table-flap bracket hinges are handy for supporting flaps or hinged brackets; they act as a supporting bracket, and can be folded back with the flap. Draught-screen hinges (Fig. 7) are used for folding draught screens and similar purposes; by their aid the hinged member can turn in two directions. Brass centre hinges (Fig. 8) are used for struts and similar supports.

*Left Fig. 7.*

*Screen hinge, at the top, fitted in place; at the bottom, in the first stage of fitting Hinge. Fig. 8. Brass centre hinge, separately and with one half fixed.*

**Fitting Hinges.** When fitting hinges the pins must be true and in line. The flap should sit fair and square in the recess cut for it in the framework. This recess must be so shaped as to preserve the alinement of the hinge pin, otherwise the hinges will quickly bind and break away, even if the door can be induced to turn upon them. When hanging a door or a casement window, it should be placed in the frame and wedged up off the ground, the positions of the hinges being marked on door and on frame, and from them the outlines of the hinges are marked upon both, squaring them off. A recess has then to be cut in the frame and in the door for the flanges of the hinges, which may be fixed temporarily in place. The door is then tried, and if all is correct the remaining screws are driven home. It is important when screwing the hinges in their place that the door be wedged up, otherwise its weight will cause the hinges to sink, and the door will jam at the bottom. It is also important to see that the door is plumb and upright, or, in the case of refitting the door, that it fits closely against the door stopping.

To remove old hinges when the screws are rusted in is often troublesome. The difficulty may be met by tapping the hinge itself, especially round the parts where the screw-heads are countersunk. This will often free the head of the screw and allow it to be withdrawn. Paint should be chipped away, or burned off with a painter's blow lamp, which will loosen the screws. When all else fails, the pins may be punched out and the flanges of the hinges chipped out with a cold chisel and hammer. Another plan is to drill out the heads of the screws and then cut them away with a countersink. See Casement; Cross Garnet Hinge; Door.

**HIP DISEASE.** Generally hip disease means

chronic tuberculous disease of the hip joint. This is not uncommon in children. In the early stage the affected leg is apparently longer than the sound one, the muscles show wasting, and the buttock becomes flattened. The joint grows stiff and the child limps, the pain increasing and the leg becoming apparently shorter than the sound one.

As soon as the disease is discovered the child must be put to bed (on a hard mattress) and kept there for at least three months, or preferably for a longer period. Complete rest of the joint may thus be secured and extension carried out by means of special apparatus. When the pain disappears and the disease shows improvement, the child, fixed in a Thomas' splint, may be allowed to walk about on crutches. The splint should be worn continuously until six months after all signs of active disease have passed away. As in all other forms of tuberculosis, the child's general health must be carefully attended to. *See Tuberculosis.*

**HIPPEASTRUM.** This bulb plant, which is commonly known as amaryllis, is invaluable in the greenhouse, where it blooms in late spring and early summer. The large lily-like blooms are very handsome, and the modern varieties are of brilliant colouring; they vary from white through rose to crimson. The best time to make a start is in winter or early spring. The dormant bulbs are then potted singly in 5-inch or 6-inch pots in a rich soil compost consisting of loam two-thirds and leaf-mould and decayed manure one-third, together with a scattering of sand. A temperature of 50—55 degrees is suitable. Watering must be carried out very carefully until the bulbs start into growth, so that the soil does not become sodden.

When the flowers are over, and the leaves begin to turn yellow, watering must be discontinued gradually, and, finally, when all the leaves have fallen, the soil is kept quite dry. The pots of bulbs are placed on their sides in a greenhouse or frame, where they will be safe from frost. When in winter or early spring the bulbs start to grow again, some of the old soil should be removed and replaced with fresh compost. It may be necessary to repot some of the largest bulbs, but annual repotting is not necessary.

*Hippeastrum.*  
*Brilliantly coloured*  
*flowers of hip-*  
*peastrum or*  
*amaryllis, a favourite*  
*greenhouse plant.*

**HIPPED ROOF.** In building this is the name given to a roof in which the adjacent sides are inclined and form salient angles. It is a more difficult construction than the ordinary lean-to or span roof, and is used in gable construction or where a more

ornamental roof is required than the normal span roof. *See Roof.*

**HIRE PURCHASE SYSTEM.** The hire purchase system has to-day taken the place of the old tally trade and has increased enormously of recent years. It is now very frequently adopted not only for the purchase of luxury articles, such as motor cars, gramophones, furniture, and wireless sets, but also for the supply of business machinery and plant. Probably 50 per cent of motor cars sales, 50 per cent of furniture sales and 10 per cent of jewelry sales are made under hire purchase agreements.

The system enables the purchaser to obtain the use of goods on payment of a small deposit, the rest of the price being paid in instalments out of his future earnings. If properly used it is undoubtedly of great value, but the temptation to acquire some article at once for a small payment is apt to lead the hirer to incur liabilities in the way of future instalments beyond what he can easily pay. A period of illness, bad trade, or loss of employment may then follow and the hirer will be unable to keep up the payments; the goods will be seized and the payments forfeited.

**The Agreement.** A hire purchase agreement is in form an agreement by which the owner agrees to let goods on hire for a period to the hirer, who agrees to pay a rent. If the hirer punctually pays the rent and keeps all the terms of the agreement, he is ultimately given the right to purchase the goods by payment of a further nominal amount (e.g. one shilling). The new Hire Purchase Act of 1938 makes very considerable changes in the law in favour of the hirer. In all agreements to which the new Act applies the hirer must be given a notice which sets out in simple terms what his rights are. In particular he will be entitled to end the agreement at any time by returning the goods, paying all instalments in arrear and any further sum needed to make his total payments equal to half the hire-purchase price. Once the hirer has paid one third of that price the owner cannot take back the goods without first applying to the Court. Before the agreement, the hirer must be informed in writing of the cash price of the goods, unless it is marked in a catalogue or price-ticket which he has seen.

Until the final payment has been made, the goods remain the property of the owner and the hirer cannot sell or pledge them in any way. If he attempts to do so he automatically terminates the agreement and the persons to whom he hands the goods acquire no right to them. Persons should exercise great care in purchasing second-hand cars, gramophones or furniture, for if the goods have been held on hire purchase, they will lose both the goods and their money. Goods held under a hire purchase agreement may be taken by a landlord on distress for rent.

Some protection has been given in litigation. In the past, hirers have frequently found themselves sued in the county court of the owners of the goods, perhaps

many miles away, and in consequence have been unable to defend the action. Now, when one third of the payments have been made, the action must be brought in the County court of the hirer.

Hives. *See* Nettlerash.

**HOARSENESS.** Commonly due to laryngitis (q.v.), hoarseness is readily produced in some people by exposure to damp, cold air, by fogs, loud talking, or living in damp houses. Those subject to it should keep the feet warm, and should be careful to breathe only through the nose. Inhaling steam gives relief. A hot bran poultice or a cold compress may be applied to the neck at night, precautions being taken next day against catching cold. Gargles are sometimes of use, but less so than inhalations and sprays (q.v.).

**HOB.** In the house the hob is a part of the fireplace; in the workshop it is a tool used for shaping gears, chasers for screw threads, and other mechanical purposes.

Some of the older houses are fitted with register stoves made of cast iron with hobs at the side. They are picturesque, but uneconomical compared with the modern barless fire. An example is the Sussex grate, having two hobs with a fire basket between them.

In many cottages the hob grate or fire is a central feature, being either constructed of bricks or tiles, or cast in concrete and coloured. An existing fireplace with an iron register stove can be removed, and a modern hob fire constructed of brickwork, and fitted with a dog grate or barless fire, can be fitted. A typical example is illustrated in Fig. 5, p. 775. The hob provides space whereon to rest the kettle or saucepan. *See* Fireplace; Grate.

**HOCK: The Wine.** The generic name for a number of Rhine wines, mainly white, is hock. It is derived from Hochheim, a town in Germany in the Prussian province of Hesse-Nassau, Johannisberger has the reputation of being the finest flavoured wine in the world. Other well-known hocks are the Steinberger, Rauenthaler, Geisenheimer, Rudesheimer, Marcobrunner, Niersteiner, Hocheimer, and Liebfraumilch. There are also various makes of sparkling hocks. A few red hocks of the Aar district have some reputation, and are recommended for insomnia. French hock is procurable from Alsace-Lorraine.

**Hock Cup.** There are several recipes for hock cup. It is particularly good for garden or tennis parties, and should be served in a large glass jug. The following is an excellent recipe: Put a large lump of ice in a big jug, and add 1 liqueur glass of curaçao, 2 liqueur glasses of brandy, 1 bottle of hock, and 1 bottle of soda-water or Perrier. Stir well and add borage and a few slices of cucumber.

A simple form of hock cup is made from a bottle of hock, one of soda-water, 2 tablespoonfuls of castor sugar, and 2 slices of pineapple. Put these into a glass jug and place it on ice for an hour or more. Just before

serving put some small pieces of ice in it. *See* Cup; Dinner; Glass; Ice; Wine.

**HOCK:** In Cookery. The term hock is usually applied to the fore end of a side of bacon, and represents the shoulder. It weighs about 10 lb. The gammon hock, which is the next cut, is of higher value. The hock is suitable only for boiling. *See* Bacon; Gammon.

**HOCKEY STICK.** The choice of a hockey stick is not a difficult matter, since its size and other properties are defined and limited by the rules of the game. The few details which can differ, such as a let-in rubber grip for the hands, etc., are a matter of personal choice, and must be considered when buying the stick, together with the most suitable weight, and various other details. The wood should be straight-grained, that is, running straight down from the handle. Such a stick may cost more than one of poorer quality, but it is far more certain to stand the strain of hard and persistent usage.

Like a cricket bat, a hockey stick improves with keeping; and, if possible, it should not be used until it has had a chance of getting mellow, and has become well saturated with linseed oil, which should be rubbed in with a soft rag every few weeks, or oftener. During the summer months, when the hockey stick is out of action, it should be wrapped in an oily rag and kept stored where it cannot get too hot. It should periodically be unwrapped, and, if the wood shows signs of becoming too dry, a little oil should be rubbed in.

**HOE:** In the Garden. The gardening implement known as a hoe is used for breaking and loosening the surface soil of growing crops in order to admit air and warmth to the roots, and also for eradicating weeds. Hoes are divided into two sorts, draw and thrust.

*Hoe. Fig. 1. Dutch hoe.*

*Fig. 2.*

*Cultivator hoe, with spanner for adjusting. Fig. 3. Draw hoe.*

The draw hoe is pulled towards the operator, and in travelling the sharp edge of the blade not only breaks up the soil, but cuts through any weeds it encounters. The blade is solid. The Dutch or push hoe has a flat blade, attached to the handle by two metal arms which together make the shape of a horseshoe. The edge of the blade goes into the earth with a cutting motion, and removes the weeds, leaving them lying on the surface.

Hoes are made in all sizes, from 3 in. to 10 in. across, and the handles are 4 ft. or 5 ft. in length. *See Gardening; Weeds.*

**HOGMANAY.** The night preceding New Year's Day is known in Scotland as Hogmanay. It was formerly the occasion of widespread festivities in the north of England, as well as across the border, and it is still customary to give parties on this night, the guests remaining to welcome in the New Year with song and dance. On the stroke of midnight the dancing is interrupted, and all join hands and sing a verse of Auld Lang Syne.

The custom of exchanging gifts has been superseded largely by the Christmas observances, but it is still a feature of many gatherings. Another old custom which is widely practised is for children to go at night from door to door singing and receiving presents of money and fruit, after the fashion of the carol singers in England. They are known as guisers, and usually wear masks or blacken their faces, wear borrowed clothes and otherwise disguise themselves.

**HOLD ALL.** In form this is a straight length of waterproof canvas, lined with some strong material and bound with leather. The lining has various pockets in it, designed to take sponge, etc., slippers, and all the small things which have to be packed at the last moment. When this has been done, umbrellas, walking-sticks, etc., are placed in the middle and the hold-all is rolled round them, so that they are held compactly with their ends protruding. A strap with a handle is then adjusted to secure the whole, and the parcel is complete. *See Luggage.*

## HOLIDAYS AND HOLIDAY MAKING

### Touring Abroad and Seaside and Country Vacations

For further interesting information on this subject see *Boarding House; Furnished House; Lodgings; Packing; Tent, etc.*

Apart from the question of expense, several considerations enter into the choice of a holiday resort. Persons with young children will usually select one that does not involve a long railway journey, while they will want to go where the sands are good and safe. Personal tastes largely determine the choice. An increasing number of persons play golf on holiday, so they will look for a place with good golf links.

Of those who go into the country for a holiday, many simply seek change and quiet, and as long as these are secured the exact spot chosen matters little. Others will select an area which is pre-eminently a holiday ground, such including N. Wales, the Lake District and Dartmoor. These attract the lovers of wild and beautiful scenery, which in two of the cases mentioned is attained by the combination of lake and hill. Much of Scotland forms a popular holiday resort of this nature. The Trossachs, the islands of the west coast, the glens of Perthshire and the border country afford some of the finest holidays that the active body and brain can

desire. In addition to these special areas, there are all round the coast, as in England, watering-places varying in size and attraction. Ireland is less popular than Scotland, and there the tourist is less amply catered for, but the scenery in the west, both in Kerry and Galway, as well as in Donegal and elsewhere in the north, is not inferior to that of Scotland.

**Holidays Abroad.** A continental holiday is becoming increasingly attractive. Switzerland, mainly but not solely loved by the mountaineer, has long been visited by thousands. Others go to see the architectural and other glories of the cities of France, Italy and the Netherlands. The beauties of the Rhine and Tirol attract others, while an excellent holiday can be spent in the Ardennes, or in Brittany. Apart from these holidays, which are rather in the nature of tours, people can take their families to French and Belgian resorts, where are all the advantages of the ordinary seaside holiday, and gain in addition some insight into the speech and customs of a foreign land. Such visits cost little or no more than holidays at home.

As regards accommodation, holidays may be divided into tours, where one journeys from place to place, and those passed all in one spot. In the former case some persons go from one town or village to another, trusting to find board and lodging when they arrive. Many of these are motorists, for whom the hotels cater, but others are walkers who may desire humbler and cheaper quarters for the night. The addresses of such quarters can usually be obtained from the police and the post office, while many will turn to a village inn.

### Motoring and Foreign Tours

Motoring tours are arranged by companies for an inclusive fee. These holidays involve constant movement and staying at a different hotel every night during the period of the trip, but enable persons to see a great deal of the country at a minimum of trouble to themselves and in a very short space of time. One drawback is that as seats must usually be booked some time in advance, the holiday may be taken in unfavourable weather.

The advantages of personally conducted tours arranged by various tourist agencies for an inclusive fee are more obvious when they are taken in foreign lands than when they are taken at home. In both cases the tourist is saved trouble, but in a foreign country this is much greater. He may be ignorant of the language, or at least imperfectly acquainted with it; he probably knows little or nothing of the charges made by the hotels and pensions, or of their suitability or the reverse; while the business of getting from place to place presents other difficulties. Moreover, he need only carry with him a comparatively small amount of foreign money.

Under the direction of qualified conductors tourists can go in parties to the lakes and cities of Italy, the cities of the Loire, the Rhineland, Belgium, Holland, Provence, Brittany, and many other districts further

afield. The fees for these tours are paid in advance, a small sum being required when the tour is booked and the balance just before leaving home. The fee does not include the cost of travel to London, or wherever the trip starts from. The intending tourist should acquaint himself with the conditions, and will be justified in assuming that the fee only provides for those items that are specifically stated as covered by it. For instance, on some tours teas are not provided.

**Holiday Accommodation.** For persons who take their holidays at the seaside or in the country there is a choice of accommodation, but this depends largely on the money available. Many persons go to hotels, where the charges are usually so much a week, and for those who can afford it there are many advantages in this kind of accommodation. The names of hotels can be obtained from a railway guide, or the advertisements in the newspapers. It is well to write beforehand and inquire the charges and also to book the rooms required.

Many persons go to boarding-houses where they are accommodated at a fixed price per week. These are usually less expensive than hotels. Hydros, turned from their original purpose, cater especially for visitors who wish for social life. In these cases, as with hotels, charges should be ascertained beforehand and the rooms should be booked, especially if in the season.

The majority of visitors to the seaside, however, go into furnished rooms or apartments. Here the usual method is for the visitors to pay for rooms and attendance, but to provide their own food. They pay according to situation, size and other matters, usually so much a week. The local paper and also papers circulating in large towns generally contain the addresses of persons who let apartments, and the railway companies issue lists in their guide books. Most watering places also issue guides, obtainable from the town clerk.

Persons taking apartments should see that the terms of the contract are clearly stated in writing so that they may know what to expect from the landlady. Farmhouses are specially attractive to some persons who like a country holiday, and some of them take in visitors, much as boarding-houses do; but their number is not large. Such addresses can be obtained from the guides issued by the various railway companies.

Another method is to take a furnished house. This has some advantages, especially for a large family, but it entails much work upon the mistress of the house and her assistants, who have not only to do the catering, as in apartments, but also the cooking and other household duties as at home. On the other hand the family can do as they like, being free from the restraints of an hotel or boarding-house. Furnished houses are usually taken through an agent at so much for the week or month. Here particular care should be taken about the contract. The person taking the house should know exactly what is provided and what is not, while the understanding as to breakages and the like should be clearly set out. Furnished cottages and bungalows can be taken on similar lines. They can be obtained through

the advertisement columns of a newspaper or from a local house agent.

**Safeguarding the Home.** Before going away for the summer holiday the householder has to arrange for the security of the house during his absence; the longer he is away the more necessary it will be either to shut the house up or put in a caretaker. Caretakers are usually married couples of the working class, but of late years many ex-service men have undertaken this kind of work. They receive a fixed sum per week and very often gas and coal in addition.

Sometimes two families living in different parts of the country exchange houses, to their mutual advantage, particularly if one house is at the seaside and the other in some inland town. Such arrangements are not confined to friends, but are carried out through the medium of advertisements, which bring people living in widely separated areas, into communication. The result is a holiday for both parties on more economical terms than is possible under ordinary conditions.

If the house is to be shut up during the absence of the family, the chairs can be assembled with other articles in the centre or in a corner of the various rooms, and covered over with dust sheets. Carpets and linoleum are seldom touched even when the holiday is a long one, and mats also may be left to protect the carpets, although sometimes these are beaten and put away, sheets of paper being laid over the carpets.

Curtains need not be taken down, as a rule, nor are blinds always drawn; but in rooms that get much sun the blinds are better drawn, if only to save the carpets. This, however, has the disadvantage of indicating to those who may be on the watch to rob an empty house that it is in that condition.

It is when clearing up prior to a holiday that the housewife realizes the value of cupboards. Into them will go the vases and ornaments that need not be left out to collect the dust; they also take in the glass and china, together with a miscellaneous collection of other goods. Cooking utensils should never be left dirty, but be thoroughly cleaned and dried so that they are ready for use when the family comes back. The bright parts of the kitchen range and the gas cooker, as well as the grates and fenders in the other rooms, may be rubbed with vaseline to prevent rusting.

Where poultry are kept it is usual for a neighbour to undertake the task of feeding in return for the eggs. Another plan, which many prefer to make, is a business arrangement with some trustworthy person living in the neighbourhood who for a weekly sum will take charge of the birds, and dispose of the eggs at the market price. When all these things have been attended to, turn off the gas and water, and see that doors and windows are securely fastened. The post-office should have been apprised already of the new address, which is also communicated to the police when the keys are entrusted to their keeping; and they should be infor-

med of the time during which the house will remain without an occupant. Any specially valuable plate or jewelry is sent generally to a bank for safe custody, but if in a safe at home, this fact should also be made known to the police.

**HOLLAND.** Made chiefly for use as window blinds, hollands are medium-weight linens or cottons, plain woven, stiffened and glazed in finishing to fill up the texture of the cloth, the better to exclude light and prevent the lodgment of dust. Unglazed, plain brown linen sold for children's dress, overalls, etc., is known as holland. Holland may be washed according to the directions given for white cotton goods, and if of a yellow-brown colour, a little tea should be added to the final rinsing water. Holland should be starched and ironed in the same way as prints.

**HOLLANDAISE PUDDING.** To make this, a custard, flavoured with ratafia, is poured over 4 small sponge-cakes and 15-20 ratafia biscuits broken into small pieces. After this 3 oz. of mixed preserved fruits cut up finely and 1½-2 oz. of sweet almonds, blanched and shredded, are stirred in and the pudding poured into a mould.

**HOLLANDAISE SAUCE.** To prepare this 3 tablespoonfuls white vinegar, 2 oz. butter, 2 yolks of eggs, and salt and pepper are required. Boil the vinegar to reduce to one tablespoonful, then add two tablespoonfuls water and pour over the egg yolks. Melt half the butter in a small basin and add the egg mixture. Put the basin in a pan containing boiling water and stir until thick. Add remainder of the butter away from the fire and stir until smooth. If too thick add a little hot water.

**HOLLY.** This, the finest native evergreen, is invaluable for hedge planting, and the ornamental varieties are admirable lawn trees. It grows slowly and is long-lived, therefore it pays to dig the ground deeply and to manure it before planting. Plant holly at the correct season, otherwise it may fail, especially if the plants are large. May and September are the proper times for this work. If the weather is dry the soil must be kept thoroughly moist by watering, and it is beneficial to spray the leaves with water in the evenings of hot days.

*Holly. Berry-bearing twig of the common British holly tree.*

As the male and female flowers of holly are on separate trees it is necessary to plant trees of both sexes to ensure a crop of berries. The correct time to clip holly, whether grown as a hedge or as a specimen tree, is in April or early May and in August. In order to preserve the symmetry of isolated holly trees, long straggling shoots should be cut out in summer. Propagation is by cuttings inserted

in sandy soil in a frame in August or by seeds sown out of doors in autumn. There are many fine varieties of the common holly (*Ilex aquifolium*). These are some of the best: Golden Queen, aurea marginata, Silver Queen and Handsworth Silver (all of which have coloured leaves), camelliaefolia. and altaclarensis.

**HOLLY FERN.** This is the popular name of a British fern (*Aspidium lonchitis*). It makes an excellent pot plant for a room window or may be grown out of doors in shade.

*Holly Fern grown as a pot plant for indoor decoration.*

**HOLLYHOCK.** This stately old plant, of which the botanical name is *Althaea rosea*, is a general favourite and invaluable for planting towards the back of the herbaceous border, where its tall spikes of bloom are conspicuous in summer. It needs rich, deeply dug soil to be seen at its best. Planting may be done in autumn or in spring, preferably at the latter season, on heavy soil.

*Hollyhock. Tall flowering spikes of different coloured single varieties.*

Although the hollyhock is a perennial it is usually most satisfactory when treated as a biennial and grown from seeds sown each year out of doors in June: the seedlings are planted finally in October or if necessary are potted and kept in a frame during the winter. Both single and double varieties may be raised from seeds. If it is wished to perpetuate any specially fine variety, cuttings of basal shoots may be inserted in pots of sandy soil in a frame in August. If hollyhock seeds are sown in a heated glasshouse in January and the seedlings are planted out in May they will be in full bloom in August. The fig-leaved hollyhock (*Althaea ficifolia*), with ornamental leaves and yellow flowers, is not commonly seen.

**Home Safe.** See Safe.

**HOMESPUN.** Homespun yarns are normally thicker and more lumpy than factory spun, and this irregularity is imparted to any cloths made from them. Hence homespun has become a name chiefly for woollens of a rough character.

Wool and flax are the two materials most capable of

being homespun, but whether cloth is any better, apart from its rarity, in being homespun is to be doubted.

Dissatisfaction has been expressed with the durability of cloths admittedly homespun, and too much should not be expected of them. The fact that they have been made by hand does not necessarily qualify them for good service. The quality of the raw wool, the fineness of the thread, and the tightness of its twisting decide the question of durability. Homespuns rightly command a higher price than machine-made articles, and are valued for their individuality more than for any other feature.

**HOMINY.** The coarse kind of flour known as hominy is prepared from the inner portion of the maize: it is not considered so nourishing as preparations made from the whole grain. It is used principally for the making of porridge.

Some recipes advocate cooking nearly all day after soaking it overnight in boiling water. But if well soaked and boiled slowly it should not take longer than an hour to cook. Add salt before boiling, and more water if necessary. After the grain is cooked drain away surplus water and add a lump of butter, salt or sugar, and cream—some people prefer salt and pepper to sugar. Hominy cooked thus will make a good pudding for children, and it can be served with jam, honey or treacle. *See* Flour.

**HONE: Its Uses.** The word hone is often applied to an oilstone, which to a large extent it resembles, except that a hone is a finer-grained stone, and adapted to the sharpening of the keenest tools. It is made from a block of compact stone having a smooth surface, or very fine grain such as novaculite. Other varieties are made from a soft, smooth, yellow slate known as German hone. The carborundum is made from the finest hand-washed abrasive powders, and produces a very keen edge. For general instrument sharpening the carborundum is good; for razor work the yellow, or Belgian rock, hones are preferred.

**HONESTY.** This is the popular name of a hardy biennial plant (*Lunaria biennis*) with purplish flowers in spring which are followed by the silvery seed pods so much valued for vase decoration in the home. Honesty will flourish, in poor soil and in sunny or shady places: it is grown from seeds sown out of doors in May each

year. Once it has been grown in a garden there are usually numerous self-sown seedlings to be found. The white variety, *alba*, is very attractive.

*Honesty. The flat, white seed pods of this old-fashioned plant, much used for indoor winter decoration.*

**HONEY.** The honey produced

by the bee consists chiefly of levulose and dextrose, the former being the fluid portion. Its flavour depends to some extent upon the flowers visited by the bee when a particular section of the comb was being filled.

The finest liquid extracted honey is bright and clear, of a light amber colour, and delicate in flavour and aroma. Extracted honey, when granulated, should be of fine, even grain, creamy white in colour, and of good flavour. There are many grades of medium and dark-coloured honeys which fail to reach this standard, but which are excellent in flavour and aroma; and in some localities these will sell more readily than the lighter samples. Colour does not affect the eating qualities. For instance, heather honey commands the highest price of all. It is in a class by itself, dark amber in colour, gelatinous in consistency and redolent of the moors both in aroma and flavour.

**Honey Cakes.** The ingredients required are 4 oz. honey, 8 oz. flour, 1 teaspoonful ground cinnamon,  $\frac{1}{4}$  teaspoonful carbonate of soda, 4 oz. sugar, 4 oz. butter, 1 egg, a little milk.

Sieve the flour with the ground cinnamon and carbonate of soda. Cream the butter and sugar. Separate the egg yolk from white, and beat the yolk into the creamed fat and sugar. Then add the honey gradually. Stir in the flour with a little milk as required to make a fairly stiff mixture and mix all together lightly. Whisk the egg white to a stiff froth and fold into the mixture. Half fill some small baking tins with the mixture, dredge the top of each with castor sugar, and bake in a hot oven. They will take 15 to 20 minutes.

**Honey Pudding.** Four eggs,  $\frac{3}{4}$  pint milk, a tablespoonful honey, and some slices of bread are required to make honey pudding. Cut the bread into cubes, put these into a buttered mould, and pour over them a custard made with the milk, eggs, and honey. Allow it to soak for 15 mm., and then steam the pudding gently for 1 hour. When set, turn it out of the mould and dust it with castor sugar.

**Medical Uses.** Apart from its use as a food, honey is employed medicinally. It serves as a demulcent and a laxative, but large doses should be avoided, as they may cause flatulence and griping. It is frequently used as a vehicle for administration of drugs, as an addition to gargles and an external application to ulcers. Because of its soothing properties, it is excellent for relieving affections of the throat, and, mixed with lemon juice, forms a cure for coughs. One recipe for this preparations is as follows: Pour the juice of a lemon over two teaspoonfuls of honey and mix well. A teaspoonful of brandy in addition is useful as a corrective, and assists in cutting the phlegm. Honey is also employed to make soap, and in cookery. *See* Bee; Beehive.

**HONEY SOAP.** This is made by cutting 2 lb. of

common yellow or white soap into thin shavings, and putting them in a pan over the fire with just enough water to keep them from burning. When they have melted, add  $\frac{3}{4}$  lb. of honey, and stir the mixture till it boils. A few drops of any perfume may then be added, and the soap poured into a deep dish to cool. *See Soap.*

**HONEYSUCKLE.** There are both climbing and non-climbing honeysuckles, but the former are the chief favourites. The climbing honeysuckles are first rate summer flowering plants for covering arches and trellises. If planted against a hot sunny wall they often become disfigured by the attacks of greenfly. The plants should be pruned when the flowers are over by cutting out some of the oldest shoots: if this work is neglected overcrowding and sparse blossoming will result. Propagation is by cuttings inserted out of doors, or in sandy soil in a frame in autumn. Plants set in autumn or spring in deeply dug and manured soil grow quickly.

*Honeysuckle. Beautiful flower spray of a fragrant climbing plant.*

The common woodbine or honeysuckle (*Lonicera periclymenum*), with reddish-yellow, fragrant flowers, and its varieties *belgica* and *serotina*, which bear reddish blooms, are valuable climbers; so, too, is *Lonicera caprifolium*, cream white and scented. Two evergreen varieties of the Japanese honeysuckle (*Lonicera japonica*), named *flexuosa* and *halliana*, which have pale yellow flowers, are other good climbing plants: the variety *aureo-reticulata* is grown for its pretty green and yellow leaves. The scarlet honeysuckle (*Lonicera sempervirens*) is less hardy than the others named, and except in mild districts is better suited to greenhouse cultivation. *Lonicera fragrantissima*, with white sweet scented flowers, and *Standishii*, with cream-coloured blooms, are two of the best shrub honeysuckles: they bloom in early spring and should be planted in a sunny place.

**HOOK:** In Dressmaking. The hooks used in dressmaking are usually sold on cards, together with an equal number of eyes to match. They can be had in black or white and in various sizes. Hooks and eyes are frequently replaced by patent fasteners, which are neater.

**HOP.** The common hop (*Humulus Lupulus*), which is perennial, and the Japanese hop (*Humulus japonicus*), an annual, are vigorous, quick-growing climbing plants for covering arches and arbours. Both thrive in ordinary well tilled soil. The perennial hop, which may be planted in autumn or in spring, is decorative when laden with its fruit clusters late in the summer. The stems are cut down in winter. The variegated leaved variety of the Japanese hop is more ornamental than the green-leaved one and is usually

grown in preference to the latter. Seeds of the Japanese hop are sown in the greenhouse in March, the seedlings being planted out of doors in May.

*Hop. Spray of the common hop, showing leaves and scaly green fruit.*

**HOPSACK.** Hopsack cloths are almost invariably wool and of a single colour, though they may be striped or checked presenting a neat draught-board or chequer appearance. In a perfectly plain cloth the threads go under and over each other one by one; in a hopsack squares of four, six, or eight threads go alternately over and under. Hopsack woven in small squares is stronger and firmer than when the chequers are large. The cloth feels rather fuller than if the same materials had been plain woven.

**HOP SCOTCH:** The Game. The children's game of hop scotch can be played on any flat stretch of ground, provided the surface can be marked with chalk or a similar substance. The only implement required is a flat stone, an oyster shell, or something of the kind, called the clipper. It can be played by two or four players. The space is marked out into squares or oblongs, the number, arrangement, and size of which varies to a considerable extent. Seven oblongs make a simple game. They are numbered 1 to 6, the top one being known as the pudding. More compartments and a more complicated arrangement may be used. The ground plan is called the scotch.

Standing a little way from the first compartment, the players decide who shall play first by throwing the clipper to the pudding. The one who lands it nearest a circle in the centre of the pudding plays first. Each player in turn takes the clipper and throws it from the point marked A into the first compartment. He then hops to it, and while hopping kicks it with the foot which he has on the ground back towards A. This done, he pitches it into the second compartment and, again hopping kicks it again towards A. This process is repeated until all six compartments have been reached and the clipper kicked back each time compartment by compartment to A, provided the player has not lost his turn for one of the reasons given later.

When compartment 6, or whatever is the highest number in the game, has been reached, the player pitches the clipper into the pudding compartment. Then, hopping to it, he sends it with one kick straight down to A. A turn may be lost in various ways. The clipper when pitched must not lie across a line. It must not be pitched into the wrong compartment. The player when hopping must not put down the raised foot until he has kicked the clipper out of the compartment. His foot when hopping must not touch one of the lines. The clipper must not lie across a line when it is kicked.

The player must kick the clipper in proper order through all the compartments. If any one of these rules is broken, the player who is placed next in turn takes up the game.

**HOREHOUND.** The dried leaves and flowering tops of *Marrubium vulgare*, or hore-hound, contain a volatile oil which is utilized in bronchial affections mainly as a constituent of lozenges and cough syrups and also a bitter principle which has tonic properties. *See* Bronchitis; Cough.

**HORN:** In Decoration. Handles for sticks, umbrellas, knives, and other cutlery articles are sometimes made of carved horn. It is also occasionally used for beads and pendants and frequently for spectacle frames in place of tortoiseshell.

A cement for horn consists of shellac dissolved in methylated spirit to form a mixture of the consistency of thick cream. The horn should be warmed, thinly coated with the cement, and the parts bound together and left until the cement has set hard. *See* Spectacles.

**HORNET:** Its Sting. A member of the wasp family, the hornet is not common as a depredator of gardens, but sometimes it strips the skin from dahlia shoots to use as material for nest-building. Interference with them is best avoided, as the bites are very painful. When bitten, if the sting is still in the skin it should be extracted, and if solution of ammonia or bicarbonate of soda is at hand it should be applied, the latter as a paste. Pain may be relieved by fomenting with a hot solution of bicarbonate of soda. *See* Bite.

*Hornet. Garden pest, the bites of which are very painful.*

**HORNET MOTH.** This insect is usually seen about the beginning of June, and its larvae, whitish-yellow with blackish-brown heads, during autumn and winter feed on the stems and roots of poplar trees. Suggested remedies are spraying in February with a caustic soda wash made of 2½ lb. of caustic soda and 10 gal. of water. Uncovered portions of the body should be smeared with vaseline and gloves worn, during use, to avoid burns from the solution. During autumn spray the infested trees and dig in deeply around them a mixture of one part naphthaline to two parts of fine ashes. *See* Insecticide; Spraying.

*Hornet Moth. Insect pest which attacks the stems of poplar trees.*

## HORS D'OEUVRES.

Savoury small dishes are served under the name of hors d'oeuvres at luncheon and dinner before the soup, with the object of giving a zest to the appetite. These dishes are prepared from various fancy sausages, smoked fish or fish preserved in oil, choice salad herbs, olives, gherkins, foie gras, caviare, oysters, and hard-boiled eggs, which serve as cases, the yolk of the egg being stuffed and the white forming the case.

*Hors d'Oeuvres. Typical dish of hors d'oeuvres, six favourite varieties being served in separate compartments.*

The sausages are skinned and cut in very thin slices, and the fish, if in oil, must be dressed; that is, the oil should be strained off, the fish wiped, and fresh oil poured over, with a little white wine or flavoured vinegar and a seasoning of salt and cayenne. Anchovies are soaked in cold water to remove the salt, and they should be boned. Sardines also should be boned. Smoked fish is served in slices or small portions, according to the character of the fish. Russian and mayonnaise salads are always popular. Beetroot or potato for salads should be diced. Cucumber is sliced and dressed with oil, vinegar, and seasoning. The yolk of hard-boiled eggs is pounded with anchovy butter and chopped gherkin to make fillings for the halved whites.

Scalloped rounds of fried bread make dainty hors d'oeuvres with either a teaspoonful of caviare decorated with savoury butter or a fillet of anchovy wrapped round a ball of egg yolk which has first been moistened with tomato sauce placed on them. Celery may be dressed with mayonnaise sauce. Tomatoes may be dipped in boiling water, skinned, sliced, dressed with equal quantities of oil and vinegar, and sprinkled with finely chopped parsley and onion. Salads for hors d'oeuvres can be made out of any left-over vegetables, such as cauliflower, beans, carrots, peas and potatoes, and dressed with salad cream or with mayonnaise.

**How to Serve.** Long glass or china dishes are obtainable for hors d'oeuvres with separate compartments for from 4 to 10 varieties. The one illustrated contains a good selection for a small party, comprising potato salad, sliced beetroot marinated in vinegar and oil and sprinkled with minced parsley and onion, prawns (excellent tinned prawns are obtainable), truffled liver sausage thinly sliced, stuffed

olives and sardines. An equally good choice would be Russian salad, egg mayonnaise, fillets of smoked herring, Spanish olives, tomato salad, smoked salmon on buttered canapés. Grape fruit and melon are also served as hors d'oeuvres.

Butter should be attractively made into small pats, balls or curls, placed in a glass dish on the table. Rolls, crisp bread, and toast should be also offered with this first course at luncheon or dinner. Special sets of knives and forks are obtainable, or fish cutlery can be used. *See* Cocktail; Dinner; Luncheon.

## HORSES FOR DRIVING AND RIDING

### Hints on Buying a Horse and Its Maintenance

Our work contains articles on Bit; Groom; Harness; Stable and other subjects associated with the horse, and also entries on the several vehicles drawn by horses, e.g. Landau; Victoria. *See* also Curry Comb.

The horses that are chiefly in demand to-day are saddle hacks and ponies used for riding. A horse of this kind should stand still when being mounted, possess a snaffle mouth and be easy to ride. For general utility, the best horse is the hackney, but this is more suitable for the harness than for riding. A good hackney can be of any colour, but bay and chestnut are the most favoured.

**Buying a Horse.** Perhaps the best method of purchasing a horse is to write to one or two studs and state requirements, or to insert an announcement in one or other of the stock breeders' journals, stating the wants in the advertisement as to age, sex, colour, pedigree, and whether perfectly broken to harness and free from any form of vice or objectionable habits, either in the stable or in traffic. The best age to buy is five or six years, and the best colour is dark bay, but this is a matter of individual choice.

Do not let colour prevent purchase if the animal is sound and suitable in all other respects. Previous to purchase have the animal examined by an experienced veterinary surgeon; the fee ranges from one to two guineas for each horse examined. The intending purchaser should satisfy himself first of all as to the suitability of the horse in all other respects. Many buyers purchase at the horse repositories either in London or in the provinces, and some high-priced horses are bought and sold through these channels.

The animals can be examined prior to sale, but the opportunities for examination and trial are not always very satisfactory. Anyone visiting a repository should read the catalogue carefully, as many of these announcements are liable to deceive the unwary buyer. Many animals carry a specific warranty, such as sound in wind and eyes. In some instances these two features are about the only qualifications that the animal does possess.

If a horse purchased does not comply with the catalogue description, the buyer should proceed to have it examined and certified by a veterinary surgeon. The horse, together with the veterinary surgeon's

certificate, should be immediately returned to the auctioneer, accompanied by a letter from the buyer stating the reason for its return. The horse repositories have regulations providing for the return of an animal that does not conform to description; therefore if the buyer complies with stipulation he should have no trouble whatever concerning the return of his money, together with any reasonable expenses incurred.

The foregoing remarks apply to all classes of horses, both light and heavy, ponies, cobs, hunters, etc., purchased at repositories. Horses bought at farms, markets, repositories, etc., without any warranty are purchased under the legal rule of caveat emptor (let the buyer beware), and cannot be returned unless the transaction has been a fraudulent one. If buying from a private person the buyer should endeavour to obtain the animal on a week or ten days' trial, this being a reasonable request when the parties are known to each other. When a warranty is given, it is better for the buyer to have it in writing, though a verbal warranty and the presence of a witness is quite good in law. The price paid for a horse, no matter how high, has nothing whatever to do with its soundness or otherwise.

**Necessity of Shoeing.** All horses require to be shod regularly, say, every three weeks, but some carry their shoes several weeks longer than others, whilst the same animal may wear out two sets of fore shoes to one set of hind ones, or the converse. The feet should never be allowed to become long, as this predisposes to stumbling. Shoes must be removed every three weeks to prevent this.

During frosty weather frost cogs should be fitted to the shoes, but the farrier will usually see to this matter if instructed at the proper time. The shoeing of heavy draught horses in winter, especially if there is ice on the roads, necessitates roughing or sharpening the toe and heel caulks. Shoeing with pads and leathers should be avoided, if possible, as they are liable to damage the feet.

**Care of the Horse.** Regular exercise, good grooming, and a liberal allowance of food and water, with a comfortable bed of straw and well ventilated, properly drained stables, are necessary for the health of all horses. When in the stable a horse requires feeding three times a day, and a liberal amount of hay between meals.

Oats, either whole or bruised, should be the staple food, but these can be mixed with dry bran, chaff, beans, peas, lentils, etc. Ponies thrive well on 6 lb. of oats per day if these are mixed with chaff, and ½ lb. of some other cereal such as maize. The amount of oats per day ranges from 6 to 15 lb., the latter for heavy draught horses. The condition of the animal and the work it has to perform must be taken into consideration. If turned out to graze, it is an advantage to give 2 or 3 lb. of oats daily, and a little linseed cake, say, 1 lb., as grass flesh is much too soft for working purposes.

Horses with long coats require clipping several times a year. The whole of the body and limbs may be clipped, or the hair corresponding to the saddle and that on the limbs may be left untouched. In the winter a heavy woollen rug or two should be put on whilst the animal is in the stable, after it has been clipped, with or without bandages on the lower part of the limbs. Never put rugs on a horse directly it comes in from work, but allow its body to cool first. Again, do not give a feed whilst the animal is overheated, for the same reason. A couple of quarts of cold water will help to cool the body, and this never does any harm.

*Horse. Prize-winning hack, with names of the various parts.*

The general-purpose horse is generally kept steadily at work, and is therefore stabled and not run at grass. But an animal that is well and carefully fed and driven will stand an immense amount of work without suffering. It must be fed according to the work it is doing. Enforced rest and rich feeding will produce swollen legs and other troubles. It must be remembered that the stomach of a horse is small, and that it works best with its stomach about two-thirds full. It is not well to leave a horse for more than five hours without a feed. In any case, it must never be worked hard on top of a full feed, as that treatment invariably results in broken wind. A horse should be watered before it is fed, but it is a great mistake to allow it to drink freely of cold water when it is sweating. After severe exertion warm gruel should be given.

After a horse is taken in from grass the ration of oats should be small at first. Oats and beans are the strongest diet, and a horse of 15 to 16 hands which is in steady work will require 12 lb. of oats daily besides hay. But no rule can be laid down, for horses vary considerably in the matter of appetite. When a reduction of diet is necessary bran mash should be given instead of oats.

Next to feeding, good grooming is most important, and it takes a man an hour daily. The implements required are dandy brush, water brush, curry comb, mane comb, and hoof pick. Many grooms use the curry comb on the horse's body, but this is a mistake, as the curry comb is for cleaning the dandy brush. When a horse comes in hot it must be rubbed down first with a wisp of twisted straw, afterwards, if necessary, with a cloth. No attempt must be made to use the brush until

the animal is quite cool. The feet of a horse are usually its weakest point. If a horse's feet are neglected, or if it is allowed to stand on wet bedding, cracked heels and the ailment called grease will supervene. The feet should be cleaned with the hoof pick three times a day. In the harness-room a bottle of antiseptic should be kept for cuts or galls.

Good bedding is essential, and wheat straw is the best material. If moss litter is preferred, 1 cwt. should be put down to begin with, and it must be renewed at the rate of about 6 lb. per day. If sawdust be used, the depth over the stable floor must be 4 in. Bracken makes good bedding, but the stiff stalks should be removed.

**HORSE CHESTNUT.** The common horse chestnut (*Aesculus hippocastanum*) is a native of Greece, though it has been largely planted in Great Britain. Chestnut Sunday is the day on which the famous chestnut trees forming an avenue in Bushey Park, Hampton Court, are in full bloom. This leaf-losing tree attains a large size and grows quickly. Propagation is by seeds sown out of doors in autumn: named varieties are increased by budding in summer or by grafting in March. The red-flowered horse chestnut (*carnea*) is to be recommended for planting on a lawn. Other chestnuts are *flava*, yellow-flowered (the American sweet buckeye), and *parviflora*, which grows only 10-12 feet high and bears white flowers in August.

**HORSE FLY: Its Bite.** In cases of this kind bleeding should be encouraged, and then a solution of ammonia, bicarbonate of soda, washing soda (weak) or permanganate of soda (strong) applied. After, a dressing of moistened boracic lint covered with gutta-percha tissue or oiled silk may be used. *See Bite.*

**HORSEHAIR: In Upholstery.** This is the best stuffing material for furniture and mattresses. It is procured from the tails and manes of horses, that from wild horses being the most highly prized. Very little is obtained from England, the greater proportion used in the upholstery trade in Great Britain being imported from the Continent, China, the Argentine, Australia, etc. It is the shorter hair that is used, and of this there are several qualities, judged according to springiness, length, and curl. The curl, or spiral form imparted by the manufacturer, emphasizes the buoyancy which makes horsehair so valuable in upholstery. Adulteration with other hair often takes place.

Besides its resiliency, horsehair is light in weight, and when made up with skill it enables furniture to preserve its shape and comfort for many years. Even after half a century's use, when renovation may be essential, the horsehair stuffing can be reteazed or carded, and replaced almost as a new material. The cost makes it an expensive medium, but the buyer will be repaid by the comfort and durability of the furniture in which it is used, and by a good return of

capital so spent in case of re-sale.

Articles upholstered entirely with hair are necessarily more expensive than when made up with a mixture of hair and other materials. In the latter case, the first stuffing of the piece of furniture is either of fibre or wood-wool, or a mixture of hair with these or with flock, the second stuffing, or that which comes immediately under the outer coverings, being alone of pure hair. It should be borne in mind that although quite serviceable, articles stuffed in this way cannot be expected to equal in ease or durability those made up with horsehair alone. *See* Mattress; Upholstery.

**HORSERADISH.** The way to grow good horseradish, which is so much liked as a flavouring, is to plant a few roots each year in January or February in deeply dug soil; they should be set at 10-12 inches apart, the tops 6 inches below the surface. The only treatment required during the summer is to keep down weeds by hoeing between the rows. In autumn and winter the roots may be lifted as they are wanted, or all can be taken up and stored in sand, ashes or soil. For replanting, choose some of the straight pieces of root. The horseradish bed is often left undisturbed for years, with the result that it becomes a very difficult matter to get rid of the roots.

**Uses in Cookery.** In cookery, the horseradish, with its strong, mustard-like taste, is used mainly as an accompaniment to roast beef. When required it should be washed and scrubbed, left to soak for an hour in cold water, and then scraped into shavings with a sharp knife. It may be served separately in a glass dish or used to garnish the meat. Horseradish may be stored in powder form in tightly corked bottles. The sticks should be sliced and dried in a cool oven before being pounded.

To make horseradish butter, clean and scrape a stick of horseradish, and pound it in a mortar with a lump of butter about twice the size of an egg,  $\frac{1}{2}$  teaspoonful of chilli vinegar, a few drops of lemon juice, and cayenne. Pass the mixture through a fine sieve before spreading it on a dish to set. Serve with grilled steak.

**Horseradish Pickle.** A pickle may be prepared by scraping off the outer skin from some horseradish roots, cutting the latter into short lengths, and then putting them into jars containing just enough vinegar to cover them. Keep the jars air-tight and in a cool, dry place.

**Horseradish Sauce.** To a grated stick of horseradish add  $\frac{1}{2}$  teaspoonful of made mustard, a teaspoonful of castor sugar, a tablespoonful of vinegar, and a pinch of salt. Slightly whip  $\frac{1}{4}$  pint of cream mix it in and keep in a cold place until required.

**HOSE PIPE.** The term hose pipe is applied to rubber, canvas, and other tubing adapted for watering purposes. Varieties include the ordinary rubber pipe, made from india-rubber, and a similar type made with

an internal lining of canvas. A stronger pattern has an external armouring of coiled wire, that acts as a protection. Suction hose is so constructed as to be non-collapsible. Hose pipe for fire extinguishing purposes is made of canvas or leather.

The ordinary garden hose is made in three sizes,  $\frac{1}{2}$  in.,  $\frac{5}{8}$  in. and  $\frac{3}{4}$  in. in diameter. The usual stock length is 60 ft., with a branch and jet, and an attachment to connect to the house water-tap. Fittings include branches, or nozzles, with and without a tap, unions and connexions for joining two or more lengths of hose, and a reel for safe storage. When not in use, the hose should be drained and coiled up, and hung in a cool, dry place.

To repair a hose, if the leak is small, procure a piece of tire duck, such as is used for a cycle cover. See that the hose is perfectly dry, and clean the place where the patch is desired by rubbing with fine sandpaper. Then apply a thin coating of rubber solution, such as is used for cycle tubes, on the hose and also on the patch. Allow both to dry thoroughly, then apply another coat to both, and leave it until slightly dry, but sticky, and press the patch on. It is advisable to have the patch wrapping completely round the hose. If the leak is extensive, it is best to cut out the bad part and rejoin the two ends with a ferrule, binding it firmly with copper wire.

*Hose Pipe. Various types of union joints and fittings.*

**HOT BATH.** The effect of a very hot bath resembles that of a cold one—it is stimulating if it lasts only for a few minutes, but if prolonged further it has a debilitating effect. The morning tub is not sufficient to keep the skin clean, and a very warm or hot bath with a thorough soaping, once a week at least, is necessary for this purpose. A hot bath is a ready means of raising the body temperature and restoring energy in cases of shock.

The effects of a hot bath may be enhanced by adding mustard, 1 oz. to the gallon. This is made into a paste with cold water and squeezed through muslin into the bath. A child in a convulsion, or collapse, for example, after profuse diarrhoea, should be kept in the bath for 15 or 20 min., and then taken out and dried quickly. A hot bath taken at bedtime often proves a cure for

insomnia. *See* Bath.

**HOTBED:** In Gardening. A hotbed is made by heaping up fresh manure which provides "bottom heat" and so helps the development of plants grown in the soil placed on it. The usual procedure is to make up a bed of manure about 2 feet deep and of such a size that it projects 1.2 inches all round beyond the garden frame placed on it. Sifted soil to a depth of 8 or 10 inches is put inside the frame. Numerous vegetables and flowering plants can be raised in spring by sowing seeds in the sifted soil.

To make the hotbed, fresh stable manure is necessary: this material must be turned several times to allow some of the rank steam to escape before it is heaped up to form the bed; the manure must be trodden down fairly firmly. Seeds should not be sown until a few days after the soil has been put on the manure and during that period the frame must be ventilated slightly. In a few weeks the temperature will decline, but it can be maintained by adding fresh manure outside the frame. Hotbeds are also made with manure and dry leaves, the latter being used in the proportion of one third of the bulk. *See* Frame.

*Hotbeds of various types. 1. Base plan showing hotbed extension and frame. 2. Economical manure compost: a, grass or leaves; b, horse manure. 3. Common hotbed. 4. How to bank with fresh manure. 5. With covering of soil (a) for plunging or outside forcing. 6. Brick frame with interior hotbed. (By special arrangement with Amateur Gardening).*

**HOT CROSS BUN.** This is a special bun eaten on Good Friday. It is a spiced bun, made as described in the article Bun, and on it a cross is marked with a knife or made in candied peel before cooking.

**HOTHOUSE.** This is a glasshouse in which a minimum winter temperature of 60 degrees is maintained to allow of the cultivation of tropical plants, or for forcing plants into early bloom. *See* Greenhouse.

**HOT PACK.** The medical treatment known as a hot pack consists in stripping the patient and rolling him in a blanket wrung out of water at a temperature

of about 110°. Two or three other blankets are wrapped outside this, and the patient is kept in the pack for 20 to 30 min. He is then quickly dried with soft, warmed towels, and put in flannel night clothing. A warm drink may be given while the patient is in the pack. The mattress should be protected by a waterproof sheet, over which a blanket has been laid.

The hot pack is often prescribed as a means of inducing free perspiration in conditions such as Bright's disease and other kidney complaints. *See* Cold Pack; Nursing.

**HOT PLATE.** A short-legged iron cooking table or stove with one or more burners is known as a hot plate, but the term is also used loosely to describe the top portion of a stove where cooking is done. Plates used for covering food to keep it warm at meal-times are also sometimes known as hot plates.

An electric hot plate is a useful table appointment in flats and other small houses where cooking accommodation is limited. It can be used in any room by fitting the plug into the nearest lamp socket and switching on the current. This stove will fry bacon and eggs, toast bread or crumpets, boil the kettle, heat an iron or shaving water, and also cook vegetables. On a double-burner hot plate, two vessels can be used at once. *See* Cooker.

**HOT POT.** The following is a winter recipe: Soak ½ lb. haricot beans overnight and half cook them. Butter beans, lentils, or dried peas might be used. Cut up 1½ lb. middle neck of mutton into neat cutlets, cutting off some of the fat, if there is too much of it. Then cut into slices 1½ lb. potatoes, 2 moderate sized carrots and one turnip, and chop ½ lb. Spanish onions.

Put all these ingredients, in layers, in a casserole, or fireproof baking-dish, with a layer of potato on top, and cover with stock or water. Cover the dish and bake the hot pot in a good hot oven for about 3 hours, adding seasoning ½ hour before serving, and re-moving the cover of the dish so that the potatoes may brown. This should be served very hot in the dish in which it was cooked.

For a summer hot pot: Cut 2 lb. neck of lamb into chops, put it in a casserole with enough water to cover it, bring it to the boil, and bake for about 1 hour. Then add a little salt, ½ lb. new potatoes, ½ lb. young carrots, ½ lb. young turnips, ½ lb. spring onions, some sprigs of cauliflower, and ½ lb. green peas. Do not cut the vegetables unless they are large. Bake the stew gently until everything is tender, then add more seasoning if necessary and serve with the meat in the centre, the vegetables round it, in the casserole. *See* Casserole; Mutton; Stew.

**HOT WATER BOTTLE.** Hot water bottles are

made in a variety of shapes and sizes and in several different materials. Of these the two most commonly in use are rubber and stoneware, while occasionally they are found in copper, aluminium, or tin.

Stone bottles should be heated before they are filled. This may be done either in the oven, providing that it is not too hot, or with hot water. In very cold weather only the latter method is suitable, and the water should not be too hot or the bottle will crack. Boiling water should be used for the final filling, and should be poured in until it runs over the top. This will ensure the exclusion of air and cause the heat to be retained as long as possible. If the bottle is only partly filled, the resulting steam may cause it to burst. The stopper must be screwed in securely so as to prevent any leakage of water, and the bottle should be rubbed over before it is placed in the bed.

Rubber bottles may be slightly warmed before filling, but only with warm water. Boiling water should not be used, but as they do not retain the heat as long as stone bottles, it is essential that the water should be as hot as possible. A solution of the difficulty is to pour the water from the kettle into an enamel jug with a sharp spout, and thence into the bottle. This will allow some of the steam to escape without materially lowering the temperature of the water. The rubber bottle should not be filled too full, as it is liable to burst. If it is filled to about two-thirds of its capacity and the empty part is then pressed over before the stopper is put in, so that the water runs up to the neck, pushing the air out in front of it, the stopper may be inserted and the bottle will keep hot for a long time. While filling, the bottle should be rested on a table to prevent the weight pulling on the neck.

Hot bottles for invalids, whether of rubber or stone, should never be put into the bed without a cover of flannel or other woollen material. An uncovered bottle is liable to burn, and the flesh of old or sick people is peculiarly sensitive to dry heat. Covers may be made from blanket cloth or cotton plush and embroidered with a monogram, and may take the form of a bag into which the bottle is slipped when filled.

India-rubber bottles are the least likely, tin the most likely, to cause burns. In the case of the paralysed or very weak, or patients recovering from a general anaesthetic, the greatest care must be taken to prevent this accident. Very often several thicknesses of flannel should surround the bottle. It is not desirable that people who suffer from cold feet and are liable to chilblains should use a hot water bottle, but if used it should be placed in the bed at some distance from the feet.

When not in use the bottle should be emptied of water, air allowed to penetrate, and should be kept in a cool, dry place.

When the sides of a rubber hot water bottle become stuck together, no attempt should be made to force them apart. A simple remedy is to pour in some hot water to which a few drops of ammonia have been added, and, after leaving it to soak for two or three minutes, work the sides gradually apart with a wooden skewer or pencil. Before putting rubber bottles away

for the summer, blow some air into them with a small pair of bellows.

Electric hot bags are sometimes preferred to hot water bottles, because they are more quickly heated, can be left warm for any length of time, and will not burst. *See Nursing.*

**HOT WATER DISH.** Food which requires to be kept hot after cooking should be placed on a hot water dish. This utensil is provided with a reservoir beneath the dish itself into which hot water may be poured. If used to hold a large joint for a family, the dish may be taken to the table so as to keep the meat hot while it is carved. Such dishes are made in, silver or all electroplate, but the one illustrated is more practical for cleaning.

## HOT WATER SUPPLY IN THE HOME

### Comparative Advantages of the Various Up-to-date Systems

The article on Central Heating may be consulted in this connexion, since some heating systems are arranged to furnish domestic hot water. Reference should also be made to Anthracite; Boiler; Geyser; Grate; Oven; Range; Water Supply

A good supply of hot water is one of the essential domestic services. A common method is to draw hot water from a boiler associated with a fire in the kitchen range (*see Boiler*), or from one of the many types of combination ranges. The heated water is conducted from the boiler to a reservoir or container at a sufficient height to supply the highest point at which it is desired to draw off the hot water, this being taken to the various points by means of ordinary piping.

*Hot Water Supply. Fig. 1. "Super Chattanooga" combination grate, which warms the kitchen, cooks and provides ovens for plate warming and hobs for pots and pans, in addition to supplying hot water for baths, etc. It can be installed without trouble by linking up to existing pipes and making minor brickwork alterations, although if the storage tank is enlarged larger flow pipes may be necessary. (Courtesy, Mitchell, Russell & Co., Ltd.)*

A combination boiler designed primarily for a central heating system, will also furnish hot water for domestic uses, a very convenient arrangement for a small house. Fig. 1 shows a useful type of combination cooking range and boiler for hot water supply. Another system employs a separate and independent hot water boiler heated by a solid fuel fire, which is kept alight day and night when a constant supply of water is desired. For really ample supplies of hot water at a low cost the coke or anthracite fired independent boiler is without equal. During the cold months it will help to warm the room in which it is installed.

In warmer weather the merits of a gas or electric system are more apparent, avoiding as they do the need for stoking, and the unpleasant warming of the kitchen. There is no reason, however, why the householder should not instal a dual system, using a gas boiler or an electric immersion heater for summer service, when the coke fired boiler or the cooking range is shut down.

**Gas-heated Systems.** Gas provides a medium for heating water by two main methods. In one of these the gas burner is kept constantly alight and heats a small boiler known as a circulator. In another type, shown at Fig. 2A on this page, the heater is combined with a storage tank and forms one complete unit. Heat losses are prevented by lagging the cylinder with insulating material, so that a relatively small consumption of gas at the burner suffices to maintain the water at the desired temperature, once the contents of the cylinder have been heated up.

*Hot Water Supply. Fig. 2. Gas circulator unit for use with coke boiler system. Fig. 2a. 2-gallon storage single-point gas-water heater, thermostatically controlled.*

*Fig. 3. Electric storage heater fitted in a bathroom (Courtesy of Electric Development Association).*

For a small house the thermal storage heater, as this type is named, might have a capacity of 12 gallons, the size being governed by the probable maximum demand at one time. By means of a device known as a thermostat the gas flame is raised or lowered by the temperature of the water. The maximum consumption of gas is 10 cu. ft.

per hour, and when all the water in the cylinder has been heated up the thermostat automatically cuts down the consumption to about one-fifth of the maximum. The temperature of the water is raised to about 140 deg. F. For a warm bath about half water from the cylinder and half cold water would be needed; for a hot bath the cylinder would be called on to yield two-thirds of the total.

The other system of water heating by gas is represented by the instantaneous type, commonly known as geysers, from which a steady flow of nearly boiling water is obtained within a few minutes of lighting the burners. These are dealt with in detail in a separate article. They are available both for local use, i.e. over a single basin or a bath, and for multi-point service. In the latter arrangement hot water may be drawn from a number of taps in different parts of the house, the opening of any water tap automatically setting the geyser in operation. A small pilot burner remains alight under the geyser and this ignites the larger heating burners as the automatic gas valve is caused to open by turning on the distant water tap. The instantaneous heater is suitable for multi-point service. A small water heater fitted over a sink is also handy. This automatically yields three gradations of hot water when the tap is turned, using gas only when hot water is running.

**Electric Water Heaters.** Water is heated electrically by means of a heating "element" enclosed in a tube. The element is fixed in the tank so as to be immersed in the water, and that all the heat generated is utilized.

Self-contained electric water heaters are made in various sizes suitable for all house-hold requirements, from the small 1½ or 2 gallon water heater, useful for supplying a wash-hand basin or sink (see Kitchen), to an installation of 30 or 40 gallons capacity capable of providing all the hot water required in the largest house. Fig. 3 shows an electric storage heater fixed in a bathroom.

In small houses where there is no undue length of hot water piping, it is possible to convert the present hot water tank into an electric water heater by fitting an electric thermostat and heater into it (Figs. 4 and 5) and by surrounding it with suitable packing of cork or other non-conducting material, so that the heat is not wasted when no water is being used. If the capacity of the hot water tank is at least 20 gallons, and the conversion work is carried out by experienced engineers, satisfactory results should be obtained.

*Fig. 4. Electric immersion heater for fitting into an existing hot water tank. (Courtesy of Belling & Co.)*

The installation of an electric heater is a simple and inexpensive matter. Only a small amount of plumbing

is necessary, and the heater itself can be fitted at the most convenient point in the pipe line. In some cases the old heating system may be retained so that during the winter months when the fire or coke boiler must be lit the water heating is done by this method, the electric heater being automatically switched on when the fire dies down. This is a very economical method.

**Oil-fired Boilers.** When neither gas nor electricity is available, and it is not convenient to use solid fuel, it is possible to utilize an oil-heated geyser. Most of these employ a paraffin oil burner of the vaporising type. Oil fired independent boilers are extensively used abroad for domestic heating and hot water supply, and it is now possible to obtain automatic equipment of this kind suitable for the medium sized house. Heavy fuel oil is fed as a fine spray into the firebox of the boiler, where it is ignited and burns with an intensely hot flame. The pressure pump is electrically driven, and is controlled by a thermostat which, when the water reaches the desired temperature, switches off the pump motor and shuts off the fuel. Conversely, when the temperature falls the pump is set working again and the oil spray is ignited by an electric spark. The apparatus is entirely automatic and is silent in action.

**Choice of System.** The relative merits of the various systems must be determined by individual circumstances, but points for consideration are, that when the solid fuel system of the cooking stove is used, the fire must be adequate to meet all demands, irrespective of the temperature of the kitchen or the cooking requirements. The system works well when used in conjunction with a modern portable range, if only intermittent supplies of hot water are needed for baths, etc., and will furnish at other times plenty of water for washing up and similar purposes. The range may be adapted to burn coke, or anthracite coal, or otherwise arranged to remain alight over very lengthy periods.

There are several reasons why the older type of kitchener seldom functions satisfactorily or economically as a source of hot water supply. The boiler at the back of the fire absorbs a great amount of heat whether hot water is being used or not, and it has been estimated that this wasted heat may be as much as one third of that given out by the fire. The reader is referred further to the article on Range.

In choosing a water heater it should be borne in mind that, although gas and electric systems when properly installed cost little if any more to run than a coke fired boiler, it is important that heat losses by radiation from tank and pipes should be prevented. Unless the pipes, etc., are lagged with insulating material the cost for gas or electricity may be very largely increased. The hot water storage tank should be enclosed within a casing, and the insulating material packed in the space between tank and casing. Where the tank is situated in and heats an airing cupboard, the top of the tank may be left exposed, as this portion will give off enough heat for airing purposes. The space between tank and walls of airing cupboard may be filled with the insulating

material, and no casing is necessary.

**Tank or Cylinder.** Fig 6 shows the arrangement of a hot water system as fitted to a solid fuel cooking stove of the ordinary portable type with a side boiler. This is known as the tank system, because a storage tank is situated above the highest level of the taps. In the cylinder system, the storage tank is below the level (Fig. 7).

Most hot water systems comprise a flow and return pipe, and to ensure that the hot water should rise always up the same pipe, the flow pipe is situated at the top of the boiler and the return pipe at the bottom. When a tap is turned on some of the hot water ascends from the boiler and some descends from the cistern, to flow out of the tap.

It is not difficult or expensive to convert a system utilizing the kitchen range to one employing gas or independent heating. It is merely necessary to disconnect the flow and return pipes from the cylinder to the boiler of the kitchen range, and connect them to those on the new heater. The boiler should be removed from the range and the space filled in with firebrick. This arrangement will be found to overcome most of the difficulties associated with the failure of the ordinary system as installed, otherwise immediate attention should be given to the flow and return pipes of the boiler and the hot storage tank. If the circulating pipes are choked up they will have to be cleared by one of the solutions sold for the purpose, or in bad cases the whole of the pipes must be taken down and cleaned out with a scraper.

**Combined Heating and Hot Water Supply.** As mentioned earlier, it is often possible to combine these services. There are several points to notice, however. If water were drawn direct from the central heating system (after circulating through distribution pipes and radiators) it would probably be found to be discoloured by the corrosion of the latter. In a system primarily designed for hot water supply, it may be possible to attach a couple of small radiators, and so warm rooms from the hot water boiler. The arrangement will only function properly in districts where the water is hard and does not corrode the interior of pipes, radiators, etc.

A central heating system intended to furnish domestic hot water also should have a boiler designed to that end. The water for radiators is drawn from an inner cylinder enclosed within the storage cylinder and connected to the boiler. The domestic hot water does not mix with that used to heat the radiators, but comes from the outer cylinder, being warmed by heat transmitted through the walls of the inner cylinder (see Fig. 8). A is the hot water flow, and B the boiler flow. C is the cold water feed and D the boiler return. E is plugged.

**HOUR GLASS.** An hour glass, or sand glass, as it is sometimes called, is an old form of timepiece, being planned to measure time. The early ones were made to measure an hour, hence the name, but afterwards others came into use for shorter periods of time. One consists of two glass bulbs fitted to each other at the narrow ends and having a tiny passage between them. Glasses used for eggs contain sufficient sand to pass from one bulb into the other in the time which is required to boil an egg. Hour glasses are sought by collectors, and good specimens are valuable. Some of the most coveted examples formerly stood in churches, being used to mark the length of the sermon. The glass bulbs were usually enclosed in a frame of wood, in some cases curiously and beautifully carved. Glasses of the same kind, known as log glasses, were used on board ship for measuring time. *See Egg Boiler.*

*(Hour Glass in silver gilt stand, c. 1590 (British Museum)).*

## THE HOUSE: ITS PLANNING AND CONSTRUCTION

### With Important Legal Points Clearly Explained

Other important aspects of home-making are considered under Architecture; Bungalow; Cottage; Flat. Several hundred articles also deal with the building, repairing and furnishing of the home. These include Brick; Carpet; Colour; Decoration; Dining Room; Drains; Lease; Paperhanging; Roof.

A broad classification divides existing houses into three types, detached, semi-detached and terrace house. The first of these is only possible for most people where land is comparatively cheap. The semi-detached and terrace houses are the ones most frequently seen in towns, whether in the poorer or the richer quarters. The structure of terrace houses, even in the best neighbourhoods, shows at a glance that there land is costly. They usually have a basement and a comparatively narrow frontage.

The semi-detached house is a compromise between the two. The fact that one side is exposed enables the house to have a certain amount of land, even if it is only sufficient for a passage at the side, while there is an economy in building two houses together. The arrangement is convenient, too, where it is desired to build a garage beside the house.

A growing artistic sense leads more people to desire houses that are attractive to the eye, both externally and internally. To a large extent homes to-day are planned to save labour. Gone are the basements and some of the long flights of stairs; gone, too, are many forms of floor and window coverings and other furnishings that demanded constant attention, or, if left alone, were harbourers of dust. Light and air are

allowed to penetrate to the fullest extent rooms designed to take advantage of them.

**Period Styles.** The builders of old days adopted ways that were always direct and real, arising out of local conditions and suited to these. Thus, when timber was plentiful there arose that manner of building which is called half-timber, i.e. having a stout oaken framework, with a filling of plaster, brick, or other material. This is essentially constructional work; modern imitations of the style fall far short of the original, the apparent timbers being merely on the surface, thin pieces of wood nailed to a brick backing, and having none of that solid look that real half-timber alone can produce.

In a later age, when brickwork came into general use, particularly in the eastern and southern counties of England, there was a new expression of building, exemplified in the Tudor style, and much later in the Georgian. Tudor houses were largely the product of craftsmen working in traditional ways of building; they were not houses built to any precise drawings, but rather the outcome of individual fancy and free craftsmanship. That is a point to bear in mind when a Tudor house is attempted to-day.

The old work has all kinds of variations in it; for instance, the brick walling is not meticulously exact, either in its surface or in its jointing, and the bricks themselves are full of variation and colour, and have a texture quality. These variations are often copied to-day with successful and artistic results. Window and door openings in the front of the house may vary in shape and size quite appreciably, while maintaining a general balance. To-day these are set out on the drawing-board, and while it is pure affectation to imitate some of the vagaries which sprang from the original craftsman's fancy, it is equally true that anything like mechanical precision in the work will inevitably produce a hard, unsympathetic-looking house. The quality of craftsmanship in house building cannot be too strongly commended.

In the Georgian style of building that was common in England throughout the 18th century it is seen that though design had then become very much more a matter for the architect than for the craftsman to determine, the houses of the period still exhibited a marked sense of craftsmanship. Within the last half century there has been general appreciation of the qualities which constitute the charm of our old houses. Anyone proposing to build a house to-day should have at least some little perception of these qualities, and so long as the essentials of good house design are kept in view and sound work is demanded in every case, there is the basis for satisfactory results.

**Choice of Site.** Soil and aspect are two important factors. The former is discussed at some length in the opening paragraphs of the article Architecture, which should be read in conjunction with the present one.

As regards aspect, an endeavour should always be

made in the placing of the house and in the planning of it to get as much sunlight as possible into the rooms. A room that gets no sun is not necessarily unhealthy, but it is distinctly less healthy and less pleasant than one that has been planned to get abundance of sunlight.

A living-room which is used for the best part of the day should have a sunny aspect, preferably facing south and west, while in a kitchen a north-easterly aspect is suitable. Bedrooms should be placed so that they not only secure sunlight, but also cross ventilation. In this connexion it may be noted that where ventilation through openings in outside walls is not possible, good results can be obtained by the provision of fanlights, which enable cross currents to pass from the outside air into the landing, staircase, and hall.

The combining of the kitchen and the scullery, provided that the room thus made is of a good size, making it into a proper domestic workshop, is a modern expedient that has great merit when a maid's sitting room is provided. Above all things space should not be saved on the kitchen quarters in a house, however necessary this may sometimes be in a flat. A kitchenette for family cooking is inadequate. The inclusion of a service hatch, with handy store cupboards adjacent, saves a great deal of walking to and fro in the serving and clearing away of meals. Consideration may also be given to the inclusion of built-in fitments. This applies both to rooms upstairs and down. In the dining room such features as a built-in sideboard and cupboards may be included; while upstairs commodious built-in wardrobes are excellent features.

Very desirable in the equipment of the bedrooms are fitments with hot and cold water services. These also can be built-in, preferably in an enclosed recess having a small outside window. Fitments of this kind involve a good deal of expense, as plumbing is always a big item, and they mean long runs of piping. There can, however, be no question of their convenience and merits.

**Dealing with the Architect.** Some hazy notions exist as to what an architect actually does and what his fees are. Anyone desirous of getting precise and full information about this matter should apply to the Secretary of the Royal Institute of British Architects, 66, Portland Place, London, W.I, for a copy of the institute's professional scale of charges, the price of which is 3d.; but it may be of service here to set down briefly the chief items.

An architect's fees are 6 per cent, on the total cost of building on jobs of £2,000 and over, and on a sliding scale varying from 10 per cent, to 6 per cent, when from £100 to £2,000 is spent. This sum includes working out the scheme, making an estimate of the cost, preparing detailed drawings and specification, arranging matters with the builder, issuing certificates, and generally supervising the erection of the house, assuming this is within a reasonable distance. If the job is far away, extras must be incurred for travelling, out-of-pocket expenses, and time occupied.

The benefits of calling in an architect are that the best possible advantage is taken of a site and that many

labour-saving ideas may be introduced into the building that are practical and inexpensive in themselves and the ultimate means of saving cost of living and ensuring comfort.

The remarks on page 62 regarding builders' tenders and the arrangement of contracts may usefully be referred to. Assuming the job to be proceeding normally, the builder would ask for payment on account from time to time, and the architect, having satisfied himself that the work had been carried out to his drawings, would approve these payments to be made in due course by the client. The drawings, specifications, and other documents relating to the house remain the architect's property, but it is a customary arrangement for the client to have copies of the drawings for his own private use on payment of an agreed fee.

**Brick or Stone.** The question of the materials to be used for the construction of a house is influenced by local conditions. The golden rule is that what is native to the soil is right; that is to say, a stone house is right in a stone country, as, for example, in the Cotswolds or in the Yorkshire dales, just as brick and tiles, or weatherboarding and thatch are of the soil and right for many districts. A well-designed house that would quickly look at home in old-world surroundings where thatched roofs are to be found is shown in our first illustration. There are two or three points about a brick house that should be noted. If it is proposed that the brickwork shall be exposed on the face, then it is imperative to use a good brick, one with not too smooth a surface, and with a play of colour in it. Attention should be given to the jointing. In some kinds of houses, more especially those which follow the freer style of the Tudor, walling with thick mortar joints looks best, the mortar being wiped off flush with the trowel; but in a house of Georgian character a finer joint is more suited to the design, and if struck in cement it gives a thoroughly watertight result.

**Exterior Details.** The details of house design are so numerous and diverse that no attempt to deal with even a tithe of them can be made here. A few points, however, may be noted. Take, for example, the front entry. It is most desirable that this should have some sort of protection either in the form of a hood or of a porch. Neither of these structures need be cumbersome.

There are old houses up and down the country dating from 100 years and more ago which have quite slender hoods, lead-covered, and supported on delicate brackets, and the fact that they are still sound to-day after so many years of exposure is proof that a cumbersome hood is not needed.

The colour used for painting outside woodwork and plaster is another point worthy of remark. Drab and dirty colours should be eschewed. For a house in the country nothing looks better than deep cream for

plaster work, and the colours chosen for the front door, gate, window frames, etc., should be in pleasant contrast to the surrounding landscape. Vivid shades are more suitable for town terrace houses, where the surroundings are dull. Thus, if a stucco house is painted cream the door and window frames may be painted light green, red, orange or blue without risk of providing a violent or unpleasant contrast, provided that it is in some harmony with the houses on either side.

Painting is a considerable item in upkeep, and it may be considered desirable to eliminate it as much as possible; as, for instance, in a house which has brick-framed windows filled with leaded lights in steel frames that are built-in; oak doors that can be safely left to look after themselves; and eaves formed of tiles in projecting courses set in cement. Such a house involves practically nothing in the way of paint cost for maintenance.

**Interior Design.** As with the exterior, so with the interior: there should be good design and sound workmanship. Above all, it is essential not to attempt make-believe, not to introduce features which, however appropriate in a baronial hall, are ill-suited to a little place perhaps not 10 ft. square. Take, for example, the matter of fireplaces. These are frequently incongruous. In the majority of cases a simple mantel enclosing a hearth fire is all that is needed, with perhaps a panelled picture or a mirror on the chimney-breast above. In a room of average size this will be a far more satisfactory arrangement than the introduction of a pretentious chimney piece.

*Dining room, showing the brick-arched fireplace and the panelling effect produced by broad oak-stained splats, which also serve in place of a frieze banding, running in an unbroken line round the room.*

In this matter we suffer from the exploitation of what is called the Jacobean style. It should be realized that many things perpetrated in that name are not Jacobean at all, and even if they were they would have no proper relation to our own day. The Jacobean style, if we may so call it, was evolved in the first half of the 17th century, and was a mingling of the then new Italian manner with the lingering Gothic tradition. In the

original work it is interesting, as any genuine old work is, but to copy all its quaintness, and to do so in a mechanical way according to standardized factory models, is often merely to produce travesties. Something simpler and more direct, as indicated above, is what we should seek to attain.

As a finish to the house walls, distemper is excellent, especially for a house that has been newly built, for every house must have its time to dry out, and this may take the best part of a year. For this reason it is always preferable to distemper a new house, even though the walls may ultimately be papered.

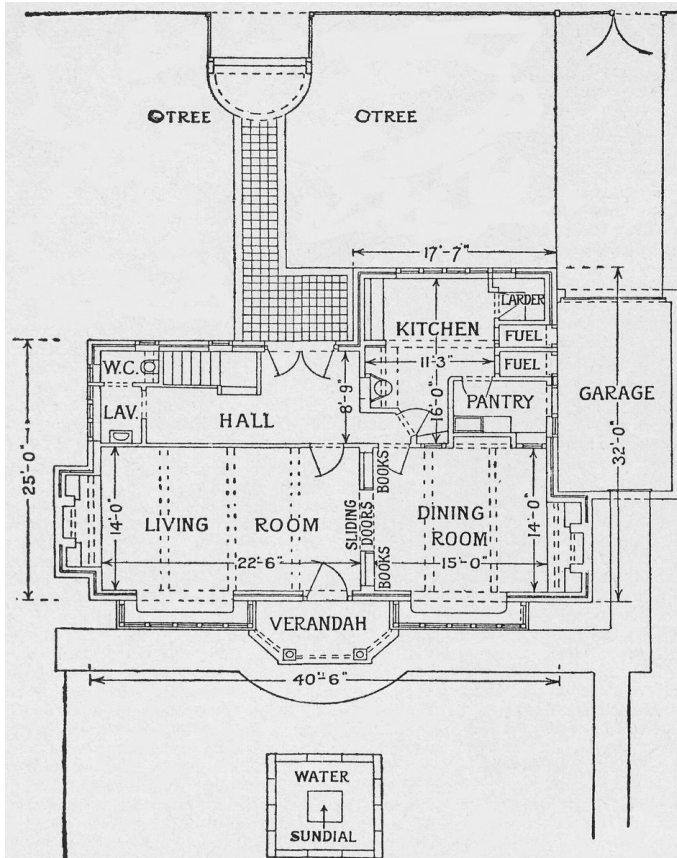

*House. Dining room and living-room of the house described in the previous pages, showing how sliding partitions run into the bookshelves and thus avoid the disadvantages of clumsy folding doors.*

Floors offer a wide range of choice, from deal boarding to parquet, and from jointless composition floors to tiles and rubber floorings. For the service quarters and passages there is linoleum, which should be inlaid and not surface printed, to withstand long wear. The following point, however, should be noted about linoleum: if ground-floor rooms are tight-covered with it, there is a risk of dry rot being set up. The risk is small, however, when the floor is well ventilated underneath.

**The Plan.** The house shown in the plans and the accompanying photographs is an example of the excellent results that can be obtained by intelligent and close co-operation between owner and architect. It has some interesting and ingenious features, a number of which were worked out by the architect at the owner's suggestion. It occupies to full advantage a comparatively small site in a seaside town. As the plans show, it is of an oblong shape, a form which has many advantages in a house of moderate size. This shape involves a somewhat large frontage, but the present relative cost of land and building, especially in the smaller country towns, makes larger frontages more economical than formerly. In a house of this type an extra outlay upon land of £25 would, by reason of the

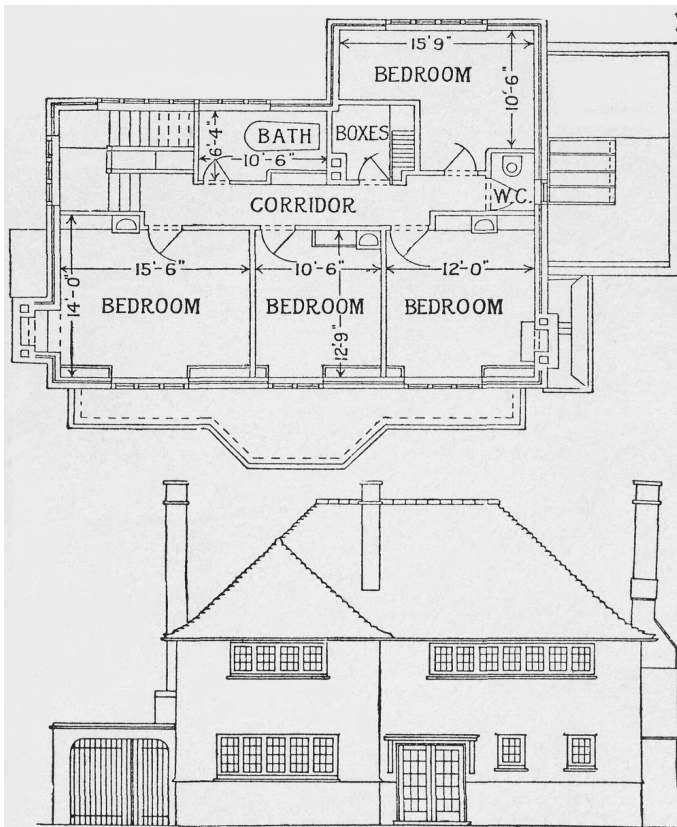

*(Continued in page 1094)*

House. Left. Ground-floor plan and indication of garden of the modern house illustrated below.

House. South elevation of a well-planned modern house. It is of oblong shape and the exterior is of brick, the upper half being finished in roughcast. Casement windows form square bays on the ground floor continuous with the roof of the brick-floored loggia porch. The upper windows have deep-cut sun louvres which keep the rooms cool notwithstanding their southern aspect. (Designed by H.M. Potter. L.R.I.B.A.)

Left. Top, first-floor plan; note the large cupboards and basin fittings in bedrooms. Bottom, north elevation, showing front entrance and kitchen premises, leaving the southern aspect for the living-rooms.

Above. Charmingly designed house at Byfleet, showing the modern use of thatch in conjunction with weatherboarding and plastered brick walls. The upper storey projects over the lower one. (Designed by G. Blair Imrie and T.G. Angell.)

more attractive planning thus permitted, add quite £100 to its ultimate value.

The basis of the design is the continuous dining room and large lounge living-room, separated by sliding doors which run into bookshelves. The two rooms can thus be thrown into one without the disadvantages and awkward appearance of folding doors, while the dining room portion is easily and completely separated from the living-room in winter, or at any other times when desired. On either side of a built-in sideboard in the dining room are service hatches, one opening directly into the kitchen, and the other into the scullery, so that the dishes are in one movement placed ready for washing up immediately the meal is finished. The fireplaces in both rooms are set in brick arches with raised brick hearths. Both rooms are well lighted with five leaded casement lights, built out to make roomy and comfortable window seats, the proportions being carefully designed. The space between the two bays is utilized for a brick-floored loggia porch, supported on two concrete columns with a flat lead roof continuous with the roofs of the two bays.

An excellent panelling effect is obtained by the use of broad splats treated to give the effect of dark oak. It will be noticed that the splat which is carried round both rooms in the place of a frieze runs exactly along the tops of the square window bays and of the fireplace, so that a continuous and unbroken line is given. This idea of panelling with broad splats and continuous frieze lines is carried out throughout the house, the obvious difficulties in hall and staircase being ingeniously overcome.

A warm colour effect is obtained throughout the interior by the use of sunny-coloured distemper for panels, and a lighter shade for ceilings and friezes. The staircase is particularly well designed, having a very easy rise. There are 16 rises 7 in. wide with 11 in. treads in a total height of 9 ft. 3 in. from hall to upstairs landing; the treads are 3 ft. 2 in. wide. The main flight is kept down to 10 rises by disposing of the remaining steps as follows, two reaching the landing at the bottom, one on the half landing, and three in the thickness of the upper floor and beams.

**The Bedrooms.** Four bedrooms, including a maid's room, are provided, with a bathroom and boxroom. Each bedroom has two ample cupboards built-in on one wall, with space between, which is occupied by a hand basin with hot and cold water; a convenience which greatly reduces the amount of work to be done by the maid in the bedrooms. On the opposite wall two wardrobe cupboards are built-in to provide recesses for casement windows, which open inward for easy cleaning. All windows are casement with leaded lights. Those in the bedrooms have outside shutters with exceptionally deep louvres, giving wider spacing and effective shelter from rain and light. Two of the rooms have brick built arched fireplaces similar to those downstairs.

As will be seen from the plans, practically all the rooms, both ground floor and first floor, face south, only hall and kitchen downstairs, and bathroom and

one bedroom upstairs, being on the north side. The kitchen has no range, but in its place are supplied a large gas stove and an independent stove for hot water supply to bedrooms and bathroom. Both these are placed under a canopy communicating with the chimney, an arrangement which ensures the removal of all fumes from the kitchen. Spare heat from the back of the independent boiler may be allowed to pass into the hall through a low arched opening.

*House. View of hall and stairs in the house illustrated in the previous pages. The staircase, which is in oak, is cleverly designed to give an easy rise, and is a decorative feature. Like the rest of the house, the hall is beamed and the panelled effect of the walls is carried out here also.*

**Legal Considerations.** He who proposes building a house must first of all secure the land. He may either purchase or rent a piece of freehold or leasehold land. In either case the contract should be in writing signed by the seller or landlord.

It is usual on the sale of land to have a formal contract drawn up by solicitors, and the solicitor for the vendor inserts many provisions by which the purchaser, to save expense, is to waive his objections to various points in the title.

When anyone is about to purchase land, whether freehold or leasehold, and the solicitor for the vendor asks him to sign a contract containing a number of clauses about the title in advance, he should take it to a solicitor for investigation. After the title has been investigated the land must be conveyed by a deed under seal.

Building sites can also be secured on lease for a ground rent, particularly in the neighbourhood of London. Sometimes, in addition to the ground rent, a lump sum or premium for the land will have to be paid. In some cases the landlord rents the land to the lessee, who covenants that he will put up a house within a certain time. In other cases the lessor enters into an agreement that if the lessee will put up a house on the land named a lease shall be granted to him after the house is put up.

There is a great deal of difference between these methods if the lessee is unable to carry out his bargain, for if a person partly builds a house on land of which he has not yet got a lease, and then is unable to carry on, the owner of the land can take possession of the land again and confiscate whatever has been put upon it. If, however, the lessee has actually got a lease of the land, he will probably be able to get somebody else to finish the house on terms, or to transfer the land with the house partly built at a price sufficient to cover most of what he has spent upon it.

In nearly all cases the lease contains a clause that the lessee shall erect the house or houses of at least a certain value upon the site, such value to be prime cost of labour and materials. In very many cases also, the plans must be passed by and the work done to the satisfaction of the landlord's architect and surveyor. This means that it is to be done to the "reasonable" satisfaction.

The purchaser of a site should make sure what restrictions there are upon the use to which the land may be put. For instance, he may be prohibited from building a shop.

The next thing is to make a contract with a builder. The intending house-owner may get an estimate from the builder and submit it to an architect. He will do better still to employ an architect to make a plan of the house and obtain tenders from several builders. Builders always make specifications, i.e. detailed estimates of buildings, showing what they intend to put into them, and conclude with a statement of the prices to be charged. If something which is not in the specification is required, it will become an extra, for which the builder may charge a reasonable sum.

#### Payment of the Builder

When a tender is accepted, it should be subject to the builder entering into a written contract drawn up by a solicitor or by the architect. This ought always to contain a clause that the builder is not to be paid unless and until the architect certifies that the work has been properly done. An architect who has to certify in this fashion must give his certificate honestly. Most building contracts stipulate that the builder shall be paid by instalments; so much when he has cleared the site, so much when he has put in the foundations, so much when he has built the walls, and so on, the amount generally being calculated at, roughly, two-thirds the value of the work done.

A date for the completion of the work may be fixed and for every day beyond that time during which the building is not finished the builder may be required to pay a penalty. Other clauses ought to be that if the builder is unable to carry out the work to completion, the employer may take it over and employ another builder to finish it, and only pay the first builder for what he has actually done.

Care should be taken not to order extras, for this will get rid of any stipulation as to time of completion. It is best to have a clause that no extras shall be put in by the builder unless they are ordered in writing. If a substitute of one thing for another is suggested, and the

owner does not intend to pay extra for it, he should make it perfectly clear to the builder in writing that the substitution is to be effected without extra charge or delay in the work.

No house can be built except according to the requirements of the local authority with regard to the materials to be used, the drainage system and the like. All plans have to be passed by the local council, and once passed the building-owner must not deviate from them without the consent of the council. The drainage system must also be inspected before it is covered up.

When building, the owner should be very careful not to interfere with his neighbour's ancient lights, or he may find himself involved in legal proceedings.

When a person builds upon a plot of land which is his freehold, the land and the building are his for ever; but if he builds upon leasehold land, at the end of the lease the house and everything on the land revert to and become the property of the freeholder from whom he held his lease. Moreover, building leases usually contain stringent clauses that the lessee shall be responsible for the repair of the house and for painting and the like. These covenants are not very strictly enforced by the landlord for the first part of the lease, but as the lease draws near to its conclusion the holder of the lease will find himself frequently subjected to requisitions by the landlord to carry out considerable repairs.

**Buying a House.** Every contract for the purchase of a house, whether freehold, leasehold, or copyhold, must be evidenced in writing signed by the party to be charged. To this rule there is one exception, that is if a contract for the sale of a house has been partly performed in such a way that the parties cannot really be put back into the same state again.

In making a contract to buy a house, it is well to employ a solicitor, because such contracts very often contain clauses which have a bearing upon the title which is to be accepted by the purchaser. Particularly is this caution necessary when buying a house at an auction sale. There is always a set of conditions of sale, which are sometimes printed and circulated in the auction room. Anyone who purchases a lot has put in front of him what amounts to a contract to buy the house subject to the conditions, and it is well to have a solicitor to see these conditions.

Contracts for the purchase of a house invariably contain a stipulation that the completion of the purchase, i.e. the execution of the conveyance and the payment of the money, shall take place on a certain date. If, however, the vendor or the purchaser is not ready on the exact date the contract does not go off, but an allowance must be made always of interest to the vendor and sometimes of the rent and profits of the land to the purchaser.

When the contract has been made, the next thing to do is to investigate the title of the vendor, which is done exactly as in the case of a sale of land, and should always be done by a solicitor. The next thing is the con-

-veyance, which should also be prepared by a solicitor, and is always by deed.

The lease should be examined. If there are repairing covenants, it should be observed whether they are very onerous or fairly light. Notice should be taken of any restrictive covenants. Suppose that Brown contracted to sell Jones a leasehold house. Jones is not obliged to take it if, on looking at the title, he discovers that there are any restrictive covenants upon the use of the house or the land—e.g. forbidding it to be used as a hotel or boarding-house—unless Brown told him beforehand that there were such covenants.

### Obligations of the Leaseholder

The purchaser of a leasehold house is bound to covenant in the purchase deed to indemnify his vendor against all breaches of covenant. This means that he undertakes to pay the rent and carry out the covenants contained in the head lease, and that if he does not do so, and the lessor compels his (the purchaser's) vendor to make it good, the purchaser will in turn make it good to the vendor. The original lessee of a leasehold house for, say, 99 years is responsible to the landlord for the payment of the rent and the performance of the covenants during the whole 99 years of the lease, although he may have assigned (i.e. sold) the lease to somebody else, and it may have passed through some fifty hands.

But an assignee of a lease is only liable for such breaches of covenant as occur while he is the holder of the lease himself. For example, X grants a lease for 99 years to A in the year 1900. In 1910 A assigns it to B. In 1915 B assigns to C, and so on until in 1998 the then owner assigns to Z. The lease contains a covenant to keep the house in repair, and in 1998 X finds the house in disrepair. He can sue A and A's heirs and executors or he can sue each person who has held the lease in respect of the disrepair during his period.

Before buying a house, whether freehold or leasehold, it is well to have the drains examined by the sanitary inspector or to employ a surveyor to do it.

On the conveyance of a house, stamp duty must always be paid on the conveyance, varying according to the amount of the purchase money.

**Taking a House.** A tenancy may be either under a lease for a period of years fixed or a tenancy from year to year, or from quarter to quarter, month to month, or week to week. A contract to let a house must be in writing; but the letting as apart from the contract to let need not be in writing, unless it is for three years and upward. This means that if A goes to a landlord or a house agent, and he verbally agrees that he will let him a house on a yearly or monthly tenancy, and afterwards refuses to carry out the contract, A cannot sue unless he has some acknowledgment of the contract in writing signed. But if he lets A into the house, and an actual tenancy has begun, A is not obliged to have any writing to prove what the terms of that tenancy are.

At the same time, it is better to have the main terms written down. These main terms are: the rent, the nature of the tenancy, whether quarterly, monthly, or

weekly, and the notice required to terminate same.

In entering into the more formal agreements of tenancy by written agreement or by lease, the householder should always be careful to see that the document really contains all the terms, for otherwise the landlord will not be bound by them. This should be specially noted with regard to repairs, for it is one of the peculiarities of the English law of landlord and tenant that nobody is bound to do any repairs except by agreement.

### Grounds for Annuling a Lease

Another thing a tenant should always be careful about is to stipulate that if the house should be accidentally destroyed, or rendered uninhabitable, except by his (the tenant's) own fault, he, the tenant, shall not be bound to go on paying rent for it. In the absence of such a stipulation, a tenant is bound to go on paying rent for the house so long as his tenancy has not come to an end by lapse of time or due notice, even if not one brick should be left upon another.

In leases for more than three years, it is usual for the tenant to agree to do the repairs. The most reasonable kind of repairing covenant is a covenant to keep the house in good and tenantable repair and condition. This means that the house is to be kept in such a state that a reasonably minded tenant would accept it to live in. What is reasonable in this connexion depends upon the class of house, neighbourhood, and the sort of tenant who might be expected to want a house of that kind.

If a tenant agrees to keep a house in repair and does not do so, the landlord may make him pay whatever it would cost to put the house in repair according to the covenant. It is also usual for landlords to insist upon the insertion in their leases of a proviso for forfeiture and re-entry. This means that if the tenant breaks any of his covenants, the landlord can put an end to the lease and forfeit the remainder of the term which has to run. A landlord cannot enforce such a forfeiture without first giving the tenant notice of the breach of covenant complained of, and requesting him to remedy it, and to pay compensation for the breach if compensation is required.

To this rule there are some exceptions. For instance, if the landlord is entitled by the terms of the lease to forfeit the tenancy if the tenant does not pay his rent, he can forfeit the lease without notice. But in this case the tenant can always escape the forfeiture by paying his rent and the costs up to date.

So also, if a landlord has given a tenant notice to do certain repairs and he has not done so, and the landlord consequently brings an action to recover possession of the house, the tenant can at the last moment come to court, offer to do the repairs, and have the case stayed for a certain time to give him an opportunity to perform his obligation. Then, on paying the costs to which the landlord was put, he is relieved of the forfeiture.

**Subletting.** Unless there is an agreement to the contrary, a tenant may always assign his tenancy or sublet the premises or any part of them. But it is quite common for landlords to insist upon a clause in the lease that the tenants shall not assign or sublet without the landlord's consent.

Wherever such a clause appears the law always assumes that it is qualified by the words: which consent shall not be unreasonably withheld in the case of a respectable and responsible tenant. The tenant who encounters an unreasonable refusal can bring an action asking the court to declare that the landlord's refusal is unreasonable, and if the tenant proves his case the landlord will have to pay the costs. It is not reasonable for a landlord to refuse his consent to an assignment or subletting on the ground that he, the landlord, happens to want the premises for himself.

**HOUSE AGENT.** House agents are middlemen who bring together those who have houses to let and those who wish to rent them. Many of them are also auctioneers and valuers. A house agent charges a fee or commission for the work done. If he lets a house, he charges the owner a percentage on the first year's rental, 5 per cent being the usual charge. The tenant pays nothing.

The house agent lets furnished flats on about the same terms and collects rents for persons on commission, 5 to 7½ per cent on the amount collected. If he is an auctioneer and valuer he will sell and value goods, 5 per cent on the amount collected being usually charged. House agents also sell houses by auction or by private treaty. *See* Agreements; Furnished House.

**HOUSE DOG.** Some breeds of dogs are suitable only for the house. Among these may be mentioned most of the toy varieties and all which come under the heading of lap dog. Sporting breeds, however, often make excellent house dogs provided that they are given sufficient exercise and otherwise kept in good condition. The smaller terriers are universal favourites, English, Scottish or Aberdeen, and Irish. Their house manners are admirable, and they enjoy their privileges as family pets; but persons adopting them as such must be prepared to give the dog at least one good walk a day, and must not imagine that it is sufficient for him to be taken the round of the shops.

Most of the larger breeds have excellent qualities as house dogs, but their size is a drawback except in the larger houses. Great Danes, wolf-hounds, setters and St. Bernards, occupy considerable room in a small house, and even the Airedale is at a disadvantage in this respect, though as a family pet he is a great success. It is, however, not difficult to make a house pet of any breed. *See* Airedale; Dog, etc.

House Fly. *See* Fly.

**HOUSEHOLD BREAD.** This term is used to describe loaves that are moulded in two parts like cottage loaves. They differ from the latter, however, in

that both parts are the same size, or the top slightly larger than the bottom. They are packed closely together in the oven so that there is crust on top and bottom only. *See* Bread.

**HOUSEKEEPER: Her Qualifications.** There are various openings for the trained housekeeper who takes up this work as a means of earning a livelihood. A great advantage of this calling is that if a girl marries she reaps the full benefit of her training, and can always return to the work in case of adversity or widowhood. It is also often the best opening for the woman no longer young, and proficient in running a house.

This last type of woman, untrained but with years of practical experience behind her, will most easily find a post in a private family, either supervising a maid or maids, or in many cases undertaking the cooking herself.

For housekeeping work on a larger scale, such as that in a hotel, boarding-house, hospital, school, or other institution, training is almost always necessary to give the requisite knowledge of catering and cooking, the science of domestic economy, the management of staff, accounts, and the care of linen. Even if the housekeeper has no cooking to do as is probably the case in an institution, it is essential she should know the subject in order to be able to supervise the cook and check waste—a very important point in a large place. Cookery and domestic management generally may be learnt at many domestic science centres in all parts of the country, courses varying from 6 to 12 months. Salaries are now excellent in this kind of work.

The woman who intends to earn her living as a housekeeper, besides having the technical qualifications mentioned, must be willing to take responsibility, should be enough of a teacher to direct assistants clearly, and must have sufficient tact and personality to get on well with the variety of people who live under one roof in any institution. *See* Servant.

## HOUSEKEEPING: MODERN METHODS

### Advice on the Management of the Home

The reader may also consult the articles Accounts; Clothes; Cooker; Diet; Food; Furniture; Kitchen; Labour Saving; Larder; Laundry; Linen; Mending, Refrigerator; Servant; Spring Cleaning; Table Laying; Vacuum Cleaner.

The woman who has to save her pennies usually goes out marketing herself. The economy of buying over the counter and paying on the nail is undoubted, and she obtains the advantage of variety for the daily menu. All large stores have bargains in food just as they have in dress. An abundant supply of salmon, a large consignment of asparagus or of strawberries or oranges, sufficiently inexpensive to encourage jam and marmalade making, lobsters, ducklings, and other luxuries at the price of commonplace foods, are the

reward of those who look for them.

If there is room in the home for a store cupboard, it will prove an economy. Soap and candles, for instance, harden with keeping, and do not waste as new soap and candles will when put into use; rice and other commodities of this kind are cheaper if bought in bulk, and in all such and other cases, as there are several prices for different grades of the articles, personal shopping tells advantageously. It is well to have in reserve a few emergency commodities of which the kitchen may run short at a critical moment.

In these days of informal entertaining it is also most useful, whether living in town or country, to have an ample provision of bottled or tinned soups, fruits, and vegetables. Those who are fortunate enough to possess large kitchen gardens are sure of supplies, either fresh or home-bottled, for the extra vegetable or fruit course that will supplement the menu in the event of an unexpected guest; others should have no difficulty in doing this if they keep a certain number of tins of vegetables and fruits in the store cupboard. Such vegetables are easily and quickly prepared, and if reliable brands are purchased they make safe and varied additions to meals. Beetroot, tomatoes, asparagus, peas, beans, and corn are a most useful selection of tinned vegetables. Pineapple, grapefruit, cherries, loganberries, peaches, apricots and pears, either bottled or tinned, will furnish the chief ingredients for many kinds of sweets. Sardines and other tinned fish, tongue, sausages and potted meats may be stored at the housewife's discretion according to her likely requirements.

### Importance of Early Training

A point that the really capable housewife who likes to do everything herself often overlooks, and that the undomesticated mother minimises the importance of, is the value of early training for girls in good housekeeping. It does not matter what a girl is going to be or do in after life, she is handicapped unless she really knows how to keep house. This does not mean a return to domestic slavery, but the emancipation of taking a live interest in the things she ought to know. On no account should good housekeeping be presented as drudgery, but as a real and exciting achievement. Nearly all children, often boys as well as girls, delight in a cookery afternoon—arranged for them preferably when the cook is out—and not only to be allowed to make toffee and other sweets, but to concoct a whole menu or prepare the dishes for Sunday supper.

Pleasure in doing this is chiefly a matter of clever suggestion. Many girls have been turned against domestic accomplishments for life by being forced to do housework, needlework, or cookery as very dull lessons, instead of having all these things made to appear so interesting that they ask to be allowed to do them, as they will ask to do gardening or painting. Just as children are taught to put away their playthings, so they can be taught to clear up after cookery or any other domestic pursuit. Equally important is it to see that things are done in the right way from the beginning instead of allowing wrong or slipshod habits

to be acquired.

Well-balanced menus are the aim in good housekeeping. Diet is now a matter which is more scientifically considered, and the old haphazard method of choosing meals no longer satisfies the careful housewife, who wishes her family to live on a dietary capable of producing the best results of physical fitness. The most important department in housekeeping is the provision of proper food, which includes not only its purchasing and cooking, but also its serving in an appetizing way.

**Business-like Methods.** If there are books to pay, it is better to have them sent in weekly than monthly. All the slips sent by the butcher and fishmonger with their goods, stating the weights delivered, should be kept for reference after the goods have been weighed and the books checked.

Women who like to manage the family exchequer in a business-like manner prefer a certain sum of money to be placed quarterly or monthly to their own banking account, and it is generally understood that any surplus that accrues goes to pay for breakages, to renew the stock of household linen, and so forth. The sums for servants' wages and the dress allowance of wife and children, if paid to this account, simplify matters considerably. When it is neither possible nor desirable to follow this plan, so much a week may be paid to the housewife for marketing and current expenses. Every item should be entered in a book as paid for and the money made to balance daily or weekly.

In domestic management a time for everything and everything at its proper time is a good rule. Kitchen orders given at the same hour each day and regular supervision in cleaning processes create between mistress and maid the reciprocity that makes for harmony and efficiency in the home. Any labour-saving inventions that have been tested and approved will help the smooth running of the establishment. The mistress who takes pains when changing servants to engage those with a good personal character is the one who, in the long run, saves herself trouble. It is well to remember, however, that even the least experienced of maids may be trained, if willing, into a valuable help when the mistress is herself an adept at cooking and domestic economy in general.

House pride goes naturally with good housekeeping. The woman who possesses it in full measure takes a personal joy in cleaning and polishing, in making her glass sparkle and her silver shine. There is, again, a great feeling for beauty, and an orderly, well-arranged home is one of its best expressions.

It is good economy to replace glass and china as it is broken, thus preventing the necessity of buying a complete outfit in course of time, or of using pieces that do not match. The wise housewife to-day does not hoard. She has too great a sense of the value of space-saving to lumber up the home with useless articles.

A periodical attention to the linen cupboard and personal underwear of the household is another necessary duty, so that gaps in supplies can be filled as they occur. In this connexion a careful scrutiny should be kept of what goes to and what is returned from the laundry; and the plan of putting away all napery and lingerie at the bottom of its pile, instead of at the top, should be observed, so that each item may be used in its turn, thus preventing the premature outwearing of one or two.

The housewife who prides herself upon all-round efficiency makes a point of being a good hostess. This can be achieved without much expense owing to the simpler standard of entertaining. Short meals and light are the rule, costly wines are not looked for, but attractively laid tables, good cooking, well-made tea and coffee, appetizing little extra dishes, and the consideration of individual tastes are what constitute successful housekeeping from the angle of the visitor.

**HOUSELEEK.** The houseleeks, of which the botanical name is *sempervivum*, form rosettes of thick, fleshy evergreen leaves; these when well developed produce spikes of flowers, chiefly of reddish or yellowish colouring. After having flowered the rosette dies, but propagation is easily effected by detaching small pieces or offsets, which develop freely. Houseleeks will flourish in rock crevices, on house roofs, and in walls, and need little or no soil, though when planting a little soil should be pressed round them.

Some of the houseleeks have most ornamental leaves; the most distinct is the cobweb houseleek (*arachnoideum*), with a white cobweb-like covering to the leaves, which ought to be protected in winter by a covering of glass if the plant is grown out of doors; it makes an excellent pot plant for the cold greenhouse. Others are the red-leaved houseleek (*triste*), hen and chickens houseleek (*globiferum*), *calcareum*, with reddish brown leaves, and the common houseleek (*tectorum*). The Madeira houseleek (*tabulaeforme*) is sometimes used as a summer edging to flower beds: the plants must be lifted in autumn and stored under glass for the winter.

*Houseleek. Rosette-like leaves of the houseleek; it flourishes on a roof, in a wall or on rocks.*

**HOUSEMAID.** The most important part of a housemaid's duty is regular sweeping and dusting, as well as the periodical turning out of rooms. This includes the cleaning of the grates and the lighting of the fires. She is also responsible for calling the household, distributing hot water, early morning tea, etc., making the beds and doing up the bedrooms, and preparing the bedrooms at night.

In large houses where a first, second and perhaps

third housemaid are kept, they will divide these duties between them, as they will where there is a housemaid and an under-housemaid. In smaller ones the housemaid may be expected to lay the table and do some of the washing-up. In many households the two servants kept are the cook and the housemaid. In such cases they divide the household duties between them, the housemaid doing practically all outside the cooking and the care of the kitchen. In many situations she will be expected to do some of the mending, and may also have charge of the linen; but such duties should be stipulated for when she is engaged.

Housemaids, like other servants, should be insured under the national health scheme, and also against accidents that may happen to them in the course of their work. *See Insurance; Parlourmaid.*

**HOUSEMAID'S BOX.** This receptacle for brushes, rags, polishes, and other things necessary for cleaning up ashes, laying fires, polishing grates and similar work can be carried from room to room, and the lower part of the box is reserved for the ashes, which can thus be conveyed to the dustbin, or wherever else the refuse is put. The top of the box is fitted with a tray in which there are compartments for brushes and other utensils.

*Housemaid's Box. Fig. 1. Compact receptacle with tray for grate-cleaning requisites. Fig. 2. Side of box, with measurements.*

*Fig. 3. End in section, showing method of attaching handle.*

*Fig. 4. Sides joined by a rebate.*

Fig. 1 shows a box with a movable tray. The main box is made from  $\frac{3}{4}$  in. deal, and the tray from  $\frac{1}{2}$  in. deal, and involves no elaborate jointing. The four sides of the box should be first cut from a  $10\frac{1}{2}$  in. wide board to their full length, and as the slope of the box is the same in both directions, there need be

no waste at all in the cutting. Notice that as the short sides fit into a rebate, Fig 4, they will be

cut short the thickness of the lap left on the long sides. This rebate is now cut to a depth equal to the thickness of the stuff, and having trued up the ends the four sides may be glued together and nailed, the nails being driven askew to form a dovetail grip. When dry, plane down top and bottom edges square, and screw on the bottom. All sides are then cleaned up.

The handle is made from two pieces of 1 in. by  $\frac{1}{2}$  in. stuff, with a piece of  $\frac{3}{4}$  in. dowel as a grasp. This latter is cut away at the ends, as in Fig. 3, to fit into corresponding holes bored in the side pieces. It is glued in, a fairly thick nail being driven in the end to make it fit tightly, and is fastened to the box by means of screws (Figs. 2 and 3). The tray is made in a similar way, except that grooves are cut across the sides to take the divisions, the centre one of which forms a handle. They are glued in and nailed. Small slips should be screwed to the main box to support the tray. *See Box.*

**HOUSEMAID'S KNEE.** What is popularly known as housemaid's knee is a swelling of the bursa, a small sac or bag of fluid situated on the kneecap. The medical term is bursitis. It occurs in occupations which involve much kneeling. A kneeling pad or mat, with a cavity for the knee, relieves the pressure on the kneecap, and the condition may disappear after painting with strong tincture of iodine and firm bandaging with a woven elastic bandage. In severe cases the bursa must be tapped.

**HOUSING JOINT.** This joint is one in which the breadth and thickness of the one part is recessed into the other part of the two members, which together form the joint. The simplest example is found in the construction of a bookcase, where upright side pieces are grooved across to receive the ends of the board forming the shelf.

To make the plain joint for a bookcase, the end of the board for the shelf is first cut square across, the ends planed up true, and any ragged parts rubbed off with sandpaper, or preferably left clean from the plane. The depth of the groove is marked on each edge of the upright with a marking gauge, and the exact width of the groove scribed across the face of the upright with a sharp cutting point. Two saw cuts are made with a tenon saw, keeping very closely to the lines, made with the scribe, and the material between the saw cuts is removed with a chisel, working first from one side and then from the other, and levelling the bottom of the groove with a router. The board should fit tightly into this groove and may be secured with glue, by screws from the outside, or by fine nails driven from the inner angle.

The stopped housing is similar to the plain, but instead of the groove passing right across the upright, it stops short of the front face, the board being notched out the corresponding amount. The groove in this case is cut out with a chisel or router, as the saw can only be used at the open end.

The dovetailed housing may be stopped as shown in Fig. 2, or plain; either of these definitely resists any tendency for the upright to separate from the board.

The latter has a dovetail formed on it by sawing across and carefully chiselling out the surplus material. The groove is cut in the upright with a tenon saw, except that instead of making two cuts, at least three are required, two to form the sloping sides of the dovetailed edges, and the third between these two. The wood is cut out with a chisel not wider than the narrowest width of the groove. If this precaution is not taken, the overhanging part of the wood at the dovetail side is liable to be torn as the chips come away, but by cutting down the centre of the groove the chips are better able to free themselves.

*Housing Joints in course of construction. Fig. 1. Plain joint. Fig. 2. Stopped dovetail housing joint.*

*Housing Joint. Fig. 3. Diagram showing details of a draw-bolt joint used in framed timber work.*

A type of housing joint that is of use in framed timber work, such as is required for outbuildings, etc., is the draw-bolt housing, Fig. 3. The horizontal member is grooved into the upright as already described. A hole is drilled through the upright, and lengthwise into the

horizontal member for a distance of at least three times its minimum thickness. The diameter of the hole is slightly larger than the bolt to be inserted in it.

Another hole is then drilled at right angles in the horizontal member, until it meets the bolt hole. This second hole is cut out square and deep enough to admit a square nut. This is dropped to the bottom of the hole, the joint put together, the bolt pushed through the bolt hole, screwed into the nut, and tightened up tightly with a spanner. *See Joint.*

**HOVER FLY.** One of the gardener's friends is the hover fly, so named because it hovers above plants during bright sunshine, seeking a spot infested with aphides or plant-lice, among which it deposits its eggs. These produce larvae of a whitish colour which feed on the aphides. The method by which the aphides are killed is by means of hooklets in the mouth, with which the larvae pierce the bodies of their prey, afterwards sucking them dry. The parent flies are of yellowish colour, shining and metallic, marked with bands of a

different shade of yellow, or orange. They live upon the juices of flowers, and are perfectly harmless. *See Green Fly; Insect.*

*Hover Fly, a useful friend to the gardener. It is shown enlarged.*

**HOVIS BREAD.** To make this bread it is necessary to use Hovis patent flour. Take  $3\frac{1}{2}$  lb of the flour and over  $1\frac{1}{2}$  oz. of yeast,  $\frac{1}{2}$  teaspoonful of castor sugar, and about  $1\frac{1}{2}$  pints of warm water. Warm the mixing bowl before putting in the flour, cream the yeast with the sugar, and stir in sufficient water to make a thin liquid.

Make a well in the centre of the flour and pour in the remaining water, which should be hotter than that used in making white bread. Add the liquid yeast, and make up into a smooth soft dough. Well flour the hands and board when moulding the bread as this dough is inclined to be sticky. Make four loaves out of the quantity, place them in greased tins, and rise them for half an hour. Bake them from 25-35 min. No salt must be used in this bread. *See Bread; Diet; Food.*

**HOW, WHEN AND WHERE.** In this indoor game one player leaves the room while the others decide upon a word, preferably a noun with several meanings, such as chest. This done, the person outside is asked to enter the room. He has to find out what the word is by asking questions of the company in turn. These must take the form of, How do you like it? When do you like it? and Where do you like it? He continues this until, aided by the answers, he is able to guess the word, when another player leaves the room.

**HUB.** The central part of a wheel is the best known form of hub. That part of a Jock through which the spindle passes is also termed the hub, and the word is applied to the peg on to which the rings are thrown in the game of quoits. The hub of a wooden wheel is generally of hardwood, shod with iron or steel hoops; a bicycle wheel has a tubular type of metal hub. *See Ball Bearings; Bicycle; Brake; Coaster Hub; Wheels, etc.*

**HUB BRAKE:** For the Bicycle. These take two forms, the coaster brake, operated by back-peddalling, and another type operated from the handle bar of the machine. The latter resembles the internal expanding brake used on motor vehicles, in which two shoes are forced outwards against the inner surface of the brake drum. *See Brake; Coaster Hub.*

**Hub Gear.** *See Three Speed Gear.*

**HUCKABACK.** A favourite material for towelling, huckaback has a thick, spongy texture which makes it more absorbent than plain, smooth fabrics. Linen huckabacks are to be preferred both on the grounds of absorbency and strength. *See Linen; Towel.*

**HUMANIZED MILK.** For the purpose of infant feeding humanized milk is prepared from cow's milk by many of the large dairies. In cow's milk, as compared with human, there is about the same amount of fat, about twice the quantity of proteins and of salts, and only  $\frac{5}{7}$  the amount of carbohydrate, in the form of lactose or milk sugar.

In a mixture of equal parts of cow's milk and water the protein will therefore be right, and also the salts, but the fat will be halved and the sugar will be further reduced to about  $\frac{1}{3}$  of the desired amount. To rectify this, as much good cream should be added to the mixture as is obtained from the amount of milk used, eg.  $\frac{1}{2}$  pint or more as the case may be in making up the mixture, and milk sugar should be added in the proportion of rather less than  $\frac{1}{2}$  oz. to a pint of mixture. Even then there is a difference from human milk, notably in the relative proportions of the two kinds of protein found in milk, viz. from that which is coagulated by heat and that coagulated by rennet. But the method described, though rough and ready, is easily done at home, and the results are usually good. Strict cleanliness must be observed. *See Baby; Milk; etc.*

**HUMEA.** *Humea elegans* is a vigorous greenhouse plant which has large fragrant leaves and in summer produces panicles of small reddish blooms on stems 5 ft. or so high. It is raised from seeds sown under glass in June and will bloom the following summer. When the seedlings are large enough they must be potted in small pots, using a compost of loam, leaf-mould and sand: repotting must be continued as becomes

necessary until in spring the plants are put in 8 in. or 9 in. pots. During summer they are grown in a cold frame. Decayed manure should be mixed with the compost for the final potting. During winter the plants should be kept in a temperature of 50 degrees. After having flowered, the plants are useless.

**Hump Back.** *See* Curvature; Spine.

**HUNDREDWEIGHT.** This measure of weight, used for coal and other heavy substances, contains 112 lb.; 20 hundredweight make a ton. The usual abbreviation, cwt., is used throughout this work.

**HUNT THE SLIPPER.** For this children's game, more suited for indoors than for outdoors, the players, who may number 20 or more, though 8 or 10 can play it, sit in a circle, except one who stands out. They sit with the feet drawn up and the knees raised, so that the slipper can be passed from under the knees of the participants.

The object of the game is to pass the slipper from one to another in such a way that the odd player who is on the outside of the circle does not know in whose hand it is. His object is to find that person and to touch him when in possession of the slipper. When he does this he takes his place in the circle and the person touched becomes the hunter.

**HUNT THE THIMBLE.** For this game an ordinary thimble is produced, and one member of the party undertakes to hide it, while the others leave the room. It may be hidden anywhere in the room, provided that it is visible without necessitating the removal of anything. When it is hidden the party is summoned into the room, usually with the formula:

Hot beans and melted butter;  
Ladies and gentlemen, come to supper.

They enter, beginning their search from the moment they are inside the door. The hider may direct them when they are warm, hot, or cold, according to their proximity to the thimble. When somebody sees it, he or she moves quietly away and sits down, taking care not to betray its whereabouts by word or gesture. The game continues until each member of the party has discovered the thimble, when the first finder becomes hider.

**HUSBAND:** In Law. In all matters of property a husband's interests are now separate from a wife's. He has no more claim to her property than she has to his. He is not liable for her debts, except that he is bound to provide her with necessary food, lodging, apparel and other things according to his position in life; if he does not provide them, or give her the money to buy them, she can order them on his credit. This right vanishes if she runs away, or if he is obliged to turn her out for misconduct.

A husband is not liable for consequences of his wife's

torts, i.e. wrongs, such as libel and slander, negligence and the like. A wife may, for her benefit, insure her husband's life.

In Scotland a wife is entitled to a life interest in one-third of her husband's property in land and a husband to a life interest in the whole of his wife's property in land. In addition a surviving husband (or wife) has a right, which cannot be taken away by will, to one-third of the movable estate if there are children of the marriage, or one half if there are no children. A wife cannot recover money lent to her husband for his business until all other debts have been paid. *See* Divorce; Intestacy; Separation; Wife.

**HYACINTH.** The hyacinth is a favourite spring flowering bulb suitable for planting in flower beds and borders out of doors, or for cultivation in pots of soil in the greenhouse and in bowls of fibre in the home. The bulbs should be planted out of doors in October, 3 inches deep and 8 inches apart. If several varieties are grouped in one bed, care should be taken to choose those that flower at the same time. The following groups of varieties bloom together: Queen of Pinks, pink, Ivanhoe, violet blue, L'Innocence, white, Primrose Perfection, pale yellow, and Gertrude, rose pink. Grand Lilas, pale lilac blue, Schotel, pale blue, Lady Derby, salmon pink, Duke of Westminster, purple, Marie, dark blue, and City of Haarlem, yellow. Hyacinths in pots of soil are invaluable for the greenhouse in spring.

*Hyacinth Culture.* 1. Water culture: a, charcoal; b, height of water. 2. Too much water. 3. Shading to encourage root growth. 4. When to transfer to light. 5. Bowl culture: a, shingle; b, charcoal; c, fibre. 6. Roman hyacinths in a pot: a, compost; b, sand; c, crocks. 7. Potted bulbs plunged in covered box of fibre: a, fibre; b, shingle. 8. Pot of bulbs excluded from light by means of another pot.

The bulbs should be potted separately in early autumn in 5 in. or 6 in. pots in a compost of loam with which sand, some leaf-mould and a scattering of bonemeal have been mixed. The bulbs should be just

covered with soil, which must not be made too firm, or the bulbs will be forced upwards. The pots of bulbs should be watered, placed on asphalt or some other hard base out of doors, covered with old sifted coal ashes and left there for 6 or 8 weeks; by then they will be well rooted. Ashes fresh from the fire must not be used. After the pots of bulbs are taken from the ashes they should be shaded for a few days before being exposed to full light in the greenhouse.

The earliest hyacinths are the Roman, bulbs which have been specially prepared for forcing, and the cynthella or small-flowered sorts. Bulbs of these should be potted in August and September, those of the large-flowered varieties in October, to ensure a succession of bloom. They must be grown in a greenhouse heated sufficiently to keep out frost. The same sorts are suitable for cultivation in bowls of fibre indoors. They should be kept in a cool dark place for 6 weeks before being set in the room window. Care must be taken that the fibre does not become dry.

*Hyacinth. Bloom of one of the large-flowered hyacinths grown in fibre in a bowl.*

Hyacinths may also be grown indoors in wide-mouthed glasses filled with water; there should be a space of  $\frac{1}{4}$  in. or so between the base of the bulb and the water. They must be kept cool and dark until roots have formed. *See Bulb; Flower Garden; Galtonia.*

**HYDRANGEA.** This splendid flowering shrub (*Hydrangea hortensis*) is hardy in southern counties and in other mild districts, where in sheltered places it forms a large bush. It is also a great favourite for cultivation in tubs and large flower pots for the greenhouse, veranda and terrace; it flowers in late summer.

*Hydrangea. Fine head of the flowering shrub grown as a pot plant for indoor use.*

The normal colour of the flowers is pink; there are also white varieties. Blue hydrangeas, which are the most popular of all, are obtained by the application of a blueing powder to the soil; this can be obtained from nurserymen with direction's for use. Some varieties, when treated with blueing powder, produce true blue flowers; others turn mauve or mauve blue. In some gardens, where the soil is ferruginous, hydrangeas bear blue flowers without any treatment.

Propagation is by cuttings of flowerless shoots taken off in August, inserted singly in small pots of sandy soil and placed in a frame. If grown in a heated greenhouse and repotted in 5 in. pots in January many of these small plants will bloom the same year.

Hydrangeas are easily spoilt by incorrect pruning. When the blooms of pot plants are over, thin weakly shoots should be cut out; the tips of other shoots may be cut off if they are unduly long. Big bushes of hydrangea planted out of doors need little pruning.

*Hydrangea paniculata grandiflora* is a striking hardy shrub which bears large heads of cream white bloom in September. This needs quite different pruning; in spring the past summer's shoots should be cut back to within 3 or 4 in. of the base.

*Hydrangea Culture. 1. Suitable cutting, properly trimmed at a. 2. Same, correctly potted. 3. Sectional diagram of cuttings plunged in frame, with good method of ventilation shown at A.*

**HYDROCEPHALUS.** Popularly known as water on the brain, hydrocephalus is a condition in which a large amount of fluid collects within the brain through blocking of the drainage channels.

In children the disease is recognized easily. The head enlarges, sometimes to such a size that the child cannot raise it from the pillow. The eyes are sunken, there is inflammation of the optic nerve, sometimes followed by blindness. Convulsions are common. As a rule the child is mentally weak or imbecile. Death usually occurs before the fourth or fifth year. Pron. Hy-dro-sef'-al-us.

**HYDROCHARIS.** A native water-plant, also known as frog-bit, the hydrocharis has white flowers and leaves, borne on the surface of pools where there is no flow or motion. It may be collected in the spring and

introduced into cultivated water-gardens, and is propagated by division. It is of value in collections of aquatic plants. Pron. Hy-droch'a-ris.

**HYDROCHLORIC ACID.** Strong hydrochloric acid is known as spirit of salt, and if swallowed acts as a corrosive poison.

The acid is used in medicine in the form of the dilute hydrochloric acid, dose 5 to 20 minims after meals. This is frequently prescribed in sluggish indigestion where the natural hydrochloric acid secreted by the stomach is deficient in amount.

In the type of indigestion accompanied by heartburn and acidity, when the acid is due to an excess of the natural hydrochloric acid, dilute hydrochloric acid given before the meal tends to check the abnormal pouring out of acid into the stomach, and so relieves the disagreeable symptoms. *See* Indigestion.

**HYDROPHOBIA.** The infectious disease known as hydrophobia, or rabies, is communicated to man mostly by the bite of a rabid dog. The poison travels up the nerves to the spinal cord and brain, and produces spasm of muscles, particularly those of the pharynx and larynx, paralysis, and generally death if not properly treated. It has been said that only 15 per cent, of those bitten by mad dogs are attacked by hydro-phobia. The incubation period usually is one to two months. Children are the most common victims. On being bitten by a suspected dog immediately tie a cord round the limb above the wound to promote bleeding. Suck the wound and squeeze as much blood as possible out of it. If hot water is at hand bathe the wound with it to encourage bleeding. Send for the doctor, or go to him immediately, as the wound should be cauterized at once.

*This cauterization should be done as soon as possible; if not done within twenty-four hours after the bite it is probably useless.*

The patient after this first-aid treatment should be sent as soon as possible to an institution where the Pasteur treatment can be obtained. In Great Britain this is carried out at St. Thomas's Hospital, London. Unless a bitten person comes under Pasteur treatment before the disease fully develops, the case is generally hopeless. The dog should not be destroyed at once, but should be shut up and kept under observation to see if it is really rabid. If it is suffering from rabies it will be dead within ten days; if it survives this period, a bitten person need have no fear of hydrophobia.

**HYDROQUINONE.** Quite a slow-acting developer, hydroquinone is particularly useful when negatives with maximum contrast are required, as in copying drawings in line, lettering or similar black and white subjects. For ordinary purposes it is usually made up with another developer, metol, as described under metol-hydroquinone. A formula is made up thus:

Hydroquinone      50 gr.

Sodium sulphite	¾ oz.
Sodium carbonate	1½ „
Water to make	10 „

Dilution with water up to 20 oz. will give softer results. The following two-solution formula with caustic soda gives a more quickly acting developer:

#### SOLUTION 1.

Hydroquinone	80 gr.
Sodium sulphite	1 oz.
Citric acid	30 gr.
Potassium bromide	20 „
Water to make	10 oz.

#### SOLUTION 2.

Stick caustic soda	80 gr.
Water to make	10 oz.

For use take 1 oz. of each solution and add 2 oz. water. Where pure black and white results are wanted the addition of formalin gives excellent results, as in the following formula:

Hydroquinone	65 gr.
Sodium sulphite	3 oz.
Formalin	1½ dr.
Water to make	10 oz.

The Watkins factor for hydroquinone in the first and third formulas given above is 5; in the second it is 4½. In all developers containing hydroquinone the temperature must not be allowed to fall below 60° F. or action will cease almost entirely. The solution must be fresh and contain the full quantity of sulphite, or stains will result. Between developing and fixing, negatives should be well rinsed. *See* Developing Metol-hydroquinone; Quinol.

**Hymenocallis.** This is a bulb plant suitable chiefly for cultivation in a hothouse. The correct name is *pancratium* (q.v.).

**HYMENOPHYLLUM.** This is one of the filmy ferns. It must be grown in a closed case in which the atmosphere is kept thoroughly moist. *See* Fern.

**Hyperacidity.** *See* Acidity; Indigestion.

**HYPNOTIC.** Drugs used to induce sleep are termed hypnotics. All, while useful when taken under the direction of a doctor, are more or less dangerous if self-prescribed. The patient in many cases becomes so dependent upon the drug in order to get a night's rest that finally he cannot sleep without resort to it. Hypnotic drugs lose their efficiency as the patient becomes used to them, so that larger and larger doses

are taken, until finally the safety limit is passed. *See* Insomnia.

**HYPO:** For Fixing Negatives. Hypo or hyposulphite of sodium is used for fixing negatives and prints in photography, and should not be less than the average strength of 4 oz. to 1 pint of water; it may be more, up to 8 oz. to the pint. For bromide and gaslight prints it may be half strength. Too strong a solution will blister some bromide papers.

A convenient and rapid method of dissolving hypo is that described and illustrated under the heading Developer. Solution is further hastened by using warm water.

Hypo solution keeps reasonably well, particularly if an acid solution such as the following is used:

Hypo	4 oz.
Potassium metabisulphite	$\frac{1}{2}$ oz.
Water	20 oz.

This bath should not be used for the P.O.P. papers printed by daylight. Fresh hypo solution should be used for every batch of plates or prints fixed. It is very cheap, and prints and plates are then certain to be properly fixed. A strong stock solution which can be diluted for use is a very satisfactory way of storing hypo. Dissolve 1 lb. of hypo in a pint of hot water. When cool add water to make it up to 32 oz.. Then every 2 oz. of the stock solution contains 1 oz. of hypo, and any strength of solution required for use is readily calculated.

Do not allow drops of hypo solution to fall on the dark-room table or floor without mopping them up, or particles of the dried chemical float in the air of the dark-room and cause spots and blemishes on negatives and papers. *See* Film; Fixing; Washing.

**HYPOCHLOROUS ACID.** The name is given to a liquid with a penetrating odour which is used for removing ink-stains from paper or white fabrics. In ink-erasers hypo-chlorous acid is generated by adding acetic acid or vinegar to a solution of chlorinated lime. To prepare a liquid ink-eraser mix chlorinated lime or bleaching powder, 4 oz., with water 15 oz., shake together for an hour and strain. To the strained liquid add acetic acid 6 oz., and bottle at once. For removing ink-stains the liquid is sponged on the stain, repeating until the stain has disappeared, then rinsing the spot with clear water. *See* Stains.

**HYSSOP.** The hyssop is a hardy evergreen herb, the shoots and flowers of which are used for medicinal and perfumery purposes. The common hyssop, *Hyssopus officinalis*, bears blue-purple flowers and grows to a height of 2 ft. It thrives best in well-drained soil. Planting may be done in April or May, 1 ft. apart each way. Propagation is by seed sown outdoors in April, cuttings of shoots in summer, or by division of roots in spring or autumn. For distilling purposes flowers should be gathered when opening.

**As Medicine.** The dried flowers and shoots are infused for medicinal purposes. The infusion forms an aromatic bitter, and is taken as a tonic and for flatulence. It may also prove beneficent in cases of chronic bronchitis. *See* Bronchitis; Flatulence.

**HYSTERIA.** The symptoms are many and varied. A person may be potentially hysterical without ever exhibiting any symptoms. If, however, a person is subjected to some exceptional degree of stress or strain, his normal element of control may become weakened, and then the hysterical condition develops. Very many examples of severe hysteria were seen among soldiers in the Great War. In civilian life grief, fright, disappointment in love, anxiety, prolonged overwork and sudden unexpected physical shock may be the immediate cause of hysteria.

In cases of hysteria paralysis of one or more limbs is not uncommon. Disturbance of sensation is frequent. Twitching of muscles or groups of muscles may be seen, leading to spasmodic movements of the face or limbs. The special senses, hearing, seeing, tasting, smelling, may all be abnormal. Stuttering is frequent. Some patients exhibit convulsive seizures or fits which may lead to a diagnosis of epilepsy. Mentally, there may be depression, emotional instability, as evidenced by frequent outbursts of tears, nervousness, irritability, dreamy states, unreasonable fears, and attacks of acute anxiety.

**Treatment.** The treatment of hysteria may be palliative, i.e. directed towards relieving the obvious symptoms, or radical, which aims at discovering the fundamental psychological cause of the condition. In mild cases simple measures such as rest in the country, a sea voyage or change of occupation may be sufficient to restore the normal degree of self-control. Paralysis, loss of voice, stuttering, and similar symptoms may be removed by a course of treatment consisting of physical exercises, which are, however, in effect a vehicle for suggestion.

This treatment, however, while removing the physical symptom, is not likely to improve the mental condition, which may indeed become worse after the physical symptom has disappeared. The extreme form of suggestion is hypnotism, and in certain cases this line of treatment has been known to be of great benefit. Undoubtedly, the most satisfactory and radical treatment of hysteria is an investigation of the patient's subconscious mind, with the object of finding out the suppressed motives which, in conflict with the conscious mind, are really responsible for the condition. One of the chief methods of investigating the subconscious mind is by psycho-analysis (q.v.). This method of treatment usually gives the best results in the case of persons below middle age. It is not suitable for elderly people or for those of poor mental development.

**HYSTERICIS.** The fits or convulsions which occur in hysteria are popularly known as hysterics. They

occur most commonly in young women, and are usually preceded by emotional disturbances, bouts of weeping, alternating, perhaps, with wild and unnatural mirth. Sometimes patients complain of feeling a ball rising in the throat, as if it would choke them. There is great restlessness, or the patient may fall down and have a fit which has a close resemblance to an epileptic one.

The patient should be laid comfortably on her bed, all tight clothing being loosened. The room should be cleared, as the presence of a crowd of excited and sympathizing friends tends to foster symptoms of hysteria. A douche of cold water on the face, and an intimation that this is to be frequently repeated, sometimes has a good effect in hysterical attacks. The ammoniated tincture of valerian in dram doses, every 3 or 4 hours, is a good remedy.

**IBERIS.** This is the botanical name of the popular hardy perennial and annual flowers that are better known as candytuft (q.v.).

**ICE: Domestic Uses.** Ice is often impure, and may contain germs of disease, especially of typhoid fever. When used to allay vomiting, to cool beverages, etc., it should be obtained from a reliable source. To keep ice from melting roll it in thicknesses of flannel. It can be chipped with a strong needle or ice pick.

Iced water and other iced drinks should be used moderately, otherwise dyspepsia may result. A small piece of ice allowed to dissolve in the mouth is a good remedy for thirst, and proves very grateful in fevers.

Ice is used largely for keeping food cool in hot weather. It should not be placed in direct contact with fish, but may be used with advantage if the latter is first placed in paper bags and fastened down. *See Frozen Food; Refrigerator.*

### ICES AND ICED DISHES Recipes for Plain and Fancy Varieties

See also the articles on Coffee; Custard Freezer; Genoese Pastry; Icing; Mould; Refrigerator.

Generally speaking, ices can be divided into two classes, cream ices and water ices. Cream ices form the foundation of many dessert dishes such as mousses, coupes, sundaes, ice puddings, moulded fruit ices, etc.

To be correct cream ices should consist of equal parts of sweetened cream and fresh fruit purée; or flavouring essences, such as coffee, chocolate, vanilla, orange or lemon, can be used. In winter, when fresh fruit is not obtainable, jam or bottled fruits can be substituted. These should be made into a purée before adding to the ice. As cream is often highly priced a good rich custard may be substituted, wholly or in part.

The necessary equipment for making ices consists of a freezer and a wooden spatula or bone paper knife. There are many inexpensive freezers on the market for making small quantities of ices. (*See Freezer.*) The vacuum freezers freeze the mixtures without the usual

churning. Ices can also be made in electric or gas refrigerators without churning. An ice cream scoop should be used for serving the ice cream in neat portions (Fig. 1).

*Ice. Fig. 1. Ice cream scoop, a simple device used for serving small circular portions of ice cream.*

To make ices in a freezer a freezing mixture is necessary. This consists of seven pounds of rough ice to one pound of freezing salt. Table salt is no good. The ice should be broken up very small. Pack the ice and salt in layers in the ice container, very solidly, and fix in the freezing vessel while packing, so that a tight fit is obtained. When pressed for time the mixture may be frozen more quickly by increasing the proportion of salt, but when this is done the ice melts more quickly and must be renewed.

Make the ice cream mixture as directed, put it into the freezing pot and close the lid firmly. Then rotate it in the ice. After a few minutes wipe the lid carefully, take it off, scrape down any mixture frozen to the sides of the pot, and beat the mixture until smooth. Use a wooden spatula, or bone paper knife, for this. Put on the lid, churn the freezer again and repeat the whole process until the mixture is evenly frozen all through. Keep the mixture in the freezer until needed and cover it with a piece of wet flannel. Drain off the water now and again, and, if necessary, pack in more ice and salt.

If using a vacuum freezer this churning will not be necessary.

*Fig. 2. Ice pudding mould, which may also be used for moulding ice cream into a fancy shape.*

A substitute for a freezer can be made with a pail and a vessel with a well-fitting lid to contain the mixture. A two-pound golden syrup tin with a lever lid is excellent for the purpose. Put the mixture in the tin, cover securely, stand it in the pail on a bed of ice and salt, pack the ice and salt well around it, and with the handle of the pail twist it round for a few minutes. Repeat the process as described for the proper freezer. When the mixture is thoroughly frozen, cover it tightly and put a piece of blanket, or felt, over the top of the pail, with the ends resting on the ice to absorb the brine. Repack with ice

and salt, if necessary, and allow it to stand at least an hour before using.

**Facts to Note.** Here are a few rules that will make the ices a success:

Never put warm mixtures into the freezing vessel; they take longer to freeze and melt the ice surrounding it.

Too much sugar makes the mixture slow to freeze, sometimes preventing freezing altogether: on the other hand, too little sugar causes the ice to be too hard. The richer the ice the longer it will take to congeal.

Take every possible care to keep the freezing salt from coming in contact with the ice mixture.

Essences should be blended with the custard.

Use pewter or aluminium vessels whenever possible; they are cold and flavourless. Do not use copper moulds for ice puddings as they give an unpleasant flavour and are dangerous to health.

For dessert, cream ices are often packed into fancy moulds of pewter to represent fruits. The ices should then be coloured to correspond with the fruits they represent. If no moulds are available the ice can be made into oblong blocks and served on glass plates (Fig. 3), or the ice can be formed into balls and rolled in chopped nuts or coloured desiccated coconut (Fig. 4). Serve ice cream wafers or petits fours with all forms of dessert ices.

*Fig. 3. Ice cream for dessert shaped into oblong portions and served on glass plates, with wafers.*

*Fig. 4. Ice cream formed into balls and rolled in chopped nuts or coloured desiccated coconut.*

Sponge cakes, or Genoese cakes, are often given a filling of ice cream. The cream is shaped in a high round tin, either fluted or plain. The centre is scooped out and just before serving it is filled with well-flavoured ice cream. A round of cake is placed on the top, and on this is piled some kind of firm fruit which has been previously cooked and kept on ice. Pour some of the syrup around the cake and serve at once.

**Vanilla Ice Cream.** For this take one pint of rich custard, half pint whipped cream, vanilla to taste. Allow the custard to get cold, and flavour it with the vanilla, put it in the freezer and half freeze it. Then add the cream, beat it well in, and continue the freezing as directed. For an economical ice cream the cream may be omitted or less used.

**Strawberry or Raspberry Ice.** To a pound of fresh strawberries, or raspberries, allow half a pint of cream,

four ounces castor sugar, half tablespoonful lemon juice and cochineal to give good colour. Rub fruit through a sieve; mix purée with lemon juice and castor sugar. Whip cream and stir in; add cochineal. Freeze as directed. Apricot cream ice is made in the same way, using fresh or tinned apricots.

**Coffee Ice.** Take half a pint of strong coffee, half a pint of good custard, quarter pint cream and quarter pound loaf sugar. Mix the coffee, hot custard and sugar. Half freeze when cold; then add cream and finish freezing. Serve in separate glasses.

**Neapolitan Ices.** These are composed of various kinds of ice cream frozen separately and then packed into oblong moulds in equal portions. When these are hard they are removed from the moulds and served without cases on small glass plates, as shown in Fig. 3. Moulds can be bought for making these ices. The Neapolitan mixture can also be made into an ice pudding.

**Mousse.** The mousse is a light ice cream mixture usually composed of well-flavoured fruit syrup, or purée, with cream that has been highly whisked. It is then frozen in plain large or small moulds lined with paper. The high whisking makes it light and frothy in appearance. The top should be decorated with berries or pieces of fruit and chopped nuts.

**Sundaes.** Cream ice and fruit sundaes are served in individual glasses. These are almost filled with the cream ice and fresh or tinned fruit in small pieces added. The fruit syrup is then poured over and chopped nuts sprinkled thickly over all. If fresh fruit is used, such as strawberries or raspberries, it should be sprinkled with sugar and allowed to stand for a time. The syrup thus formed can then be poured over the ice cream.

**Coupes.** The coupe is another form of fruit ice, made from either water or cream ice. It is usually served in glasses.

**Coupe à la Milanese** is a lemon-water ice flavoured with cherry brandy, and mixed with enough brandied cherries to allow about three to each portion of ice. Another form of this fancy ice, known as *coupes d'abricots*, is prepared in this manner. Mix a pint of apricot cream ice with 4 tablespoonfuls of tinned apricots cut into small cubes. Flavour them with some liqueur and serve in glasses, putting in first a small spoonful of the ice, then a light layer of powdered ratafias, then more ice, and so on until sufficient ice has been used for a portion. A layer of the ice should be put in last and the top decorated with shreds of bright green pistachio nuts.

**Coupes aux marrons** are prepared by soaking some broken marrons glacés in a little liqueur, and putting small tablespoonfuls of them into some glasses. Fill them up with vanilla ice cream, and decorate the top of

each with a marron glacé and a little whipped cream.

Another similar sweet, known as coupes Jacques, is prepared by half-filling some glass cups with fruit salad, flavouring it with kirsch, and then covering it with one layer of vanilla and another layer of strawberry ice cream. Decorate the top with a grape or cherry. Some slight variation can be provided by using different liqueur for flavouring.

**Pêche Melba.** This is another form of fancy ice, made with cream ice and peaches. The peaches are divided in halves and stoned and steeped in liqueur and a sprinkling of sugar added, or tinned peaches can be used. They are served with a surrounding of rich ice cream and garnished with whipped cream arranged in the centre. A little syrup is poured over. Other Melbas are made in the same way, substituting pineapple, strawberries or pears for peaches.

**Lemon Water Ice.** This requires care to be successful. In lemon water ices the juice of the lemons must be added after the syrup of sugar and water is made and must be perfectly incorporated. Take  $\frac{3}{4}$  pint water, the juice of three lemons, a teacupful of loaf sugar, and the whites of two eggs. Wipe the lemons, then rub some of the lumps of sugar over the outer parts of the peel to get the essence of the lemons. Boil the sugar and water for ten minutes till it forms a thread between finger and thumb. Allow it to cool, then add the strained lemon juice. Pour the mixture into the freezer and half-freeze it, take it out and add the beaten whites of the eggs and beat them well in. Return to the freezer and freeze to the desired consistency. In all water ices the chief point is to draw out the particular flavour of the fruit used. Orange water ice is made in the same way as lemon water ice, substituting oranges for the lemons.

**Sorbet.** This is the water ice flavoured with liqueur and with fruit added. It is served in a goblet in the middle of a formal dinner just before the roast. Russian cigarettes are usually handed round with it.

**Ice Pudding.** Half freeze one pint of rich custard and add 2 oz. mixed glacé fruits, cherries, apricots, oranges, etc., a few finely chopped almonds, pistachio nuts, a dessertspoonful chopped preserved ginger, 2 teaspoonfuls maraschino and half a pint whipped cream. Half freeze as before. Wet the ice mould (Fig. 2) and decorate it with nuts and fruit. Pack in the frozen mixture, put on the lid and cover all the joints, cracks, lid opening, etc., with lard to prevent any salt coming into the mixture, and then wrap the mould in two or three thicknesses of paper. Bury it in the ice and salt and freeze for two to three hours. To unmould, first remove paper and lard, dip mould in cold water, remove lid gently and slip the pudding on to the dish.

**Iced Food and Drink.** Certain foods and beverages, though not ices in the accepted sense of the term, are subjected to a freezing process and are therefore said to be iced. White coffee may be iced by

placing it in a jug resting on ice, and leaving it until it is icy cold. Black coffee is similarly iced, except that the jug is put deep into the ice, a little brandy added, and a lump of ice put in just before serving. Tea that is to be iced should be freshly made and poured off the leaves as soon as it is ready for drinking. Leave it to cool and then pour it into a glass containing some frozen ice, a thin slice of lemon and a little sugar to taste.

**ICE BAG: Its Medical Uses.** A convenient means for applying continuous cold to any part is provided by the use of an ice bag. Ice is broken up into very small pieces and put in an india-rubber bag, so as to half fill it.

In typhoid fever, in the presence of pain or haemorrhage, an ice bag may be ordered to be placed on the abdomen. It proves useful also in early appendicitis, and as the weight of the bag would tend to increase the pain, the bag is slung from a bed cradle so as just to rest on the skin, but no more. An ice-cap or bag to the head is often of great use in lessening the pain in severe headache, such as migraine. Care has to be taken against leaving an ice bag too long in contact with the skin, especially in the old, as a sore may be produced. *See Cold Pack.*

**ICELAND MOSS.** This lichen may be cooked in the same way and used for the same purpose as Irish moss. It has a somewhat bitter taste, but this may be partly remedied by adding a pinch of soda to the water in which it is soaked. *See Irish Moss.*

**ICELAND POPPY.** This very beautiful hardy plant (*Papaver nudicaule*) has long-stemmed flowers in orange, yellow or white, which appear in May and June. In recent years new and improved types with large and more richly coloured blooms have been raised, e.g. the Sunbeam and Coonara poppies. In the latter the flowers are of salmon, fawn, biscuit, apricot, etc. All these varieties are treated as biennials: they are raised from seeds sown out of doors or in boxes of soil in May to produce flowering plants next year. Before the seedlings become crowded they must be set on a reserve border at 6 in. apart until finally planted in October where they are to bloom.

*Iceland Poppy, showing the number of graceful flowers that are produced by one plant. (Courtesy of Amateur Gardening)*

**ICE PAIL.** An ice pail is a simple form of wine cooler. In the shape of a pail, it was made in silver and Sheffield plate, as well as in the cheaper metals. After a time pieces were decorated, ornament taking the form of reeding, usually round the body about a third of the way from the top. The best specimens were made in the 18th century and the early part of the 19th.

**ICE PLANT.** This is another name for *Mesembryanthemum crystallinum*, a showy annual for hot, dry places mesembryanthemum is known also as fig marigold.

**ICE SAFE.** Uncooked foods may be stored safely for several days in an ice box with about  $\frac{1}{2}$  cwt. of ice. It consists of an outer case enclosing a zinc box, the space between them being packed with slag wool, sawdust, or some other material that is an equally good non-conductor of heat.

*Ice Safe. Fig. 1. Simply made safe for storing uncooked food.*

The example illustrated shows the component parts and various details, the dimensions being suitable for a small household, but may be increased or diminished to suit requirements, and the form of the box can be modified. The ice can be obtained from any good-class stores, or sometimes by arrangement with the fishmonger or butcher, who will deliver supplies regularly.

*Fig. 2. Outer case in part section with one end removed.*

The outside wood case can be made with 1 in. tongued and grooved boards dovetailed together at the corners, or nailed together and

reinforced with little straps at iron screwed over the corners. The bottom is of similar material, screwed to the sides. The dimensions are given in Fig. 2. The feet may be turned or made of 3 in. square deal planed to a slight taper, so that they are about  $2\frac{1}{2}$  in. square at the bottom. These are screwed to the bottom of the case with wood-screws passed through from the inside. A plinth of deal, 3 in. wide and 1 in. thick, is glued and screwed round the outside of the bottom, the corners being neatly mitred and the edges chamfered.

*Fig. 3. Detail of outer lid.*

*Fig. 4. Detail of inner lid.*

The lid of the case, Fig. 6, is floor-board and a framework of deal, 4 in. wide and 1 in. thick, screwed, at the corners or dovetailed. If they are screwed, they can be reinforced with iron angle plates screwed to the outside. The lid is hinged to the back of the box. An

alternative method is to make the whole box in one piece, lid and bottom included. Screw the whole together, then mark a line round the outside of the box and saw off to this line, the meeting surfaces being planed up true and flat.

*Fig. 5. Bottom of case with draw-off tap.*

The zinc lining, Fig. 7, may be made from separate pieces, riveted at the corners and soldered. If a large sheet of zinc is obtainable the lining can be made in one piece by bending up the bottom angles, the vertical edges being flanged, riveted and soldered. The upper part is turned over at right angles, mitred at the corners, and soldered. In the centre of the bottom a tap, Fig. 5, is fitted by soldering a bush piece into the bottom of a brass cup, such as can be made from the top of a bedstead knob. This is soldered on to the bottom of the zinc lining, and the tap into the bottom of the recess.

*Fig. 6. Lid.*

The zinc above the brass cup should be pierced with small holes about  $\frac{1}{8}$  in. in diameter, so that it will act

as filter. A hole is cut through the bottom of the wood casing to allow the tap to pass through, and fillets are screwed to the inside of the wood case for the zinc lining to rest upon, as in Fig. 3. The space between the zinc lining and the outer case should be packed with insulating material.

Fig. 7. Inner zinc lining.

To make the zinc-lined lid, fit a fillet round the opening at the top of the zinc case and round off the edges;

then make a plain wooden inner lid that will just fit into the space inside the fillet. Prepare a zinc lining similar to the case, but smaller and only 2 in. deep. Turn a flange on to it and temporarily screw it to the underside of the inner lid (see Fig. 4). Hinge the lid to the top of the outer case, and see that the lining on the lid closes into the case and fits closely. The meeting surfaces round both inner and outer lids can be covered with a good close-grain cloth, as this assists in keeping the joint tight. The interior of the lid lining has to be filled with non-conducting material, for which purpose it must be removed, packed tightly, and replaced.

Internal fittings will be determined by individual requirements, but one or more shelves of perforated zinc on a framework are essential. These are readily made by cutting the parts to size and making soldered joints. The shelves are supported on angle pieces soldered to the sides of the inner lining. Sufficient space must be left for the ice, and a practical arrangement is to have the shelves just a little less than one-third the width of the lining so that they can be arranged in the most advantageous way, omitting the centre one if the block of ice is at all tall and narrow. The whole interior has to be cleaned thoroughly with warm water to remove all traces of the soldering acid.

A good way to finish the exterior is to enamel it, as a coating of paint is an effective method of protecting the woodwork from the effects of the relatively cool interior and the hot, dry exterior. Another advantage of the enamel finish is the ease with which the whole can be kept clean. The ice should be wrapped in a piece of clean sacking or cloth, as this is of assistance in protecting it from the effects of the rush of heated air when the lid is opened. *See Refrigerator.*

**ICHNEUMON FLY.** This insect is beneficial in the garden, as it is destructive to caterpillars and other pests. Actually the flies deposit their eggs in the bodies or eggs of other insects, hatching out larvae which devour the body or egg in which they were developed. The flies may be readily identified by their long, slender, blackish-brown bodies, and are about  $\frac{1}{2}$  in. in length. *See Caterpillar; Insect.*

*Ichneumon Fly. Useful garden insect which helps to keep down the caterpillar plague.*

**ICHTHYOL.** The drug used in medicine under the name of ichthyol is a dark substance obtained from a bituminous quartz containing the fossil remains of fish. The dose internally is 10 to 30 gr., and the drug proves useful for rheumatism, bronchitis, etc. A convenient way to take it is in tablets containing  $2\frac{1}{2}$  gr.

Ichthyol ointment, 5 to 10 or more per cent, spread on flannel is a soothing and heat-reducing application in sunburn, burns, and other inflammatory conditions of the skin.

**ICING.** There are various kinds of icing, differing somewhat in make and consistency. They include almond paste, butter, or Vienna icing, and fondant, glacé, and royal icing. In some of these the method of application varies, both glacé and fondant icing, for instance, being usually poured over the cake; while butter icing, which is used sparingly because of its richness, is allowed to get hard and cold before use, and then spread over the cake, smoothly and evenly, with the flat of a knife.

If glacé or fondant icing is not used in the manner suggested, the cake is dipped into it and coated in this way. Almond paste or icing is used in a thick layer, which is shaped with the hands before being smoothed with a wetted knife. A little marmalade is used to make the paste adhere to the cake.

Royal icing, for which almond paste frequently serves as a base in rich wedding cakes, is hard and white. It can be coloured pink with a few drops of cochineal, or other colours with vegetable colouring extracts. Only one drop at a time must be used, as these are very strong.

Instructions for making royal icing are given under the heading *Cake*. Two or three coats are sometimes used in cakes of an elaborate character, but one coat must always be allowed to dry before another one is put on. Large cakes are sometimes iced only on top, the sides being tastefully decorated with ribbon or fringed paper.

Icing on birthday or party cakes may be of one, two, or even more colours and flavours, but if intended for children it should not be too rich. Additional decorations on iced cakes may be supplied by birthday, Christmas, New Year, or other greetings, or any appropriate design, carried out in icing of a contrasting shade. Forcing pipes will be necessary for this process, which, though more difficult than ordinary icing, merely requires careful practice.

**The Forcing Pipe.** These are made in the form of syringes with detachable funnels of different sizes and designs. If it is desired to ornament the cake with words of greeting, a funnel is placed on the mouth of

the syringe, which has a small round hole. If piping of coloured icing is desired, or a lattice or scroll design, the same funnel is used. A funnel with a serrated edge is used for making rosettes or roses of icing, and a funnel with a flat opening for making ribbons of icing, bows, garlands and other designs.

The icing, which should be of a firm, creamy consistency, not thin enough to run nor stiff enough to stand, should be placed inside the syringe, the handle of which is unscrewed at the top. The syringe is about half filled. The handle, with the pump pulled out as far as possible, is screwed on, and then gently pressed downward. The icing is forced out through the funnel, and takes the shape for which the funnel is designed. A revolving stand is supplied with some icing sets, and this is a great help in icing a cake evenly. The syringe should be held immediately over the spot where the decoration is to fall if roses or rosettes are desired. It should be slanted for writing or ribbons of icing.

*Icing. Forcing machine used for fancy icing. Upon the syringe is a funnel for making ribbons of icing. Of the two detached funnels, that on the left is for rosettes, etc.; that on the right for greetings.*

If a forcing bag is used, the icing mixture is put into the bag, half filling it, and the funnel pressed through the bottom. The icing is then squeezed by the hand through the opening into the funnel. Royal icing, butter icing, or whipped and flavoured cream, can all be used for ornamenting dishes in this way. Entrées and savoury dishes are sometimes decorated with savoury cream by means of a forcing set.

**Glacé Icing.** This is made with  $\frac{1}{2}$  lb. of icing sugar and about half a gill of tepid water. Crush the sugar and put it into a basin, add the water slowly and stir smoothly but do not beat. The icing should coat the back of a spoon and settle smoothly into that in the basin. If necessary, add a little extra water. Colourings and flavourings, such as vanilla or almond, can be added if it is desired.

For an orange or lemon glacé icing use the strained juice of lemon or orange instead of the water, and colour if necessary with a few drops of saffron colouring.

**Feather Icing.** This is used when a rough surface is desired on a cake to give the effect of snow. To make it, prepare a syrup from  $\frac{1}{2}$  pint of water and 2 lb. of loaf sugar and boil it to  $240^{\circ}\text{F}$ . Then pour it on to the slightly whisked whites of 4 eggs, add any colouring required, and whisk the mixture until it thickens. A smaller quantity can be made provided that the same proportions are maintained. This icing is sometimes known also as mountain icing. *See* Almond Paste; Cake; Chocolate Icing; Coffee Icing; Decoration; Fondant, etc.

**Icterus.** *See* Jaundice.

**Idiocy.** Idiocy is extreme mental deficiency which shows itself after birth or develops in very early childhood. *See* Insanity.

**ILLEGITIMACY.** An illegitimate child is one born out of wedlock. Such children are made legitimate if the parents marry after their birth, provided that the parents were free to marry at the time of the birth. This has long been the law of Scotland and in 1926 it was made the law of England also. An illegitimate child usually takes the mother's name.

The chief disadvantage of an illegitimate child is that he or she cannot inherit anything in case a relative, except the mother, dies intestate and from the mother only if she leaves no legitimate issue. Illegitimates must pay legacy duty on money they do inherit at the same rate as strangers in blood, but they are recognized as dependents under the Workmen's Compensation Acts.

The mother of an illegitimate child can compel the father to pay towards its maintenance. A child of a married woman is regarded as legitimate even if the father is not her husband, the law being that such is born in wedlock. The law, however, can declare such a child illegitimate if the husband can prove that it is not his. *See* Affiliation Order; Child; Father; Income Tax; Mother.

**I LOVE MY LOVE.** This is an old game, and can be played anywhere with any number above two. It consists merely in filling in a form of words with the necessary epithets, all of which must begin with the same letter. The form runs as follows: I love my love with an A because he is amiable; I hate him with an A because he is argumentative. He took me to the sign of the Arrow and fed me with anchovies and asparagus. His name is Archibald and he lives at Angmering.

When one person has done this satisfactorily the next takes up the tale, either repeating it with A and supplying a different word for each epithet, or, if preferred, continuing with B. The game goes on until the entire alphabet has been exhausted. X is omitted, and Z will seldom last for more than one player. It can be played either in the masculine or feminine gender.

**IMARI WARE.** The Japanese porcelain shipped from the port of Imari was at first painted in underglaze blue on white, and afterwards in enamel colours and gold. This old porcelain was freely copied in Delft ware, and then in English china, especially at Bow, Derby, and Worcester. Chrysanthemums, peonies, and other boldly drawn and richly tinted blossoms, often highly conventionalized, with dragons, birds, and diaper patterns, are favourite styles. They are painted in grass-green, dull red, lilac-blue and gold. Modern Imari does not equal the old ware, which fetches very high prices, but it is an effective foil to other Eastern furnishings, especially the beakers, square vases, and shallow dishes. Imitation Chinese marks are sometimes used. There is much inferior work, both old and new. *See China.*

**Immortelle.** This is an alternative name for rhodanthe. *See Everlasting Flower.*

**IMPEDANCE.** This is the opposition offered to the flow of an alternating current round a circuit, and is dependent upon the values of resistance, capacity, and inductance. Impedance varies with the frequency of the alternating current, except in cases where the circuit constitutes only a pure resistance. Impedance is expressed in ohms.

**IMPERIAL DRINK.** For feverish patients a beverage known as imperial drink is often prescribed. One simple method of making it is to add cream of tartar to freshly made lemonade in the proportion of a teaspoonful to the pint. The following is a usual recipe:

Saccharin	1 gr.
Oil of lemon	3 minims
Potassium tartrate	1 dram
Boiling water to make	1 pint

Another recipe consists of  $\frac{1}{2}$  oz. cream of tartar, the rind of a lemon, a heaped teaspoonful of sugar, and 3 pints of boiling water.

**IMPETIGO: A Skin Disease.** Impetigo is a highly contagious inflammatory skin disease, characterized by the formation of scattered blisters on the skin, which become filled with matter and dry into crusts. The face, particularly about the mouth, is the commonest site of the disease. There is little or no itching. The disease is chiefly noted among poor and dirty children.

The crusts should be softened and removed with soap and warm water, or, if necessary, by soaking with oil or applying starch poultices, after which the following ointment may be applied to the patches:

Ammoniated mercury	5 gr.
Petrolatum	1 oz.

To prevent new crops of blisters appearing an antiseptic lotion should be frequently sopped on the affected skin and adjacent areas, e.g. saturated boracic solution or corrosive sublimate lotion (1 in 3,000).

**INARCHING: Of Plants.** This is a form of grafting which is not often practised in gardens. It is useful, for example, if it is wished to replace a worthless grape vine with a better variety without disturbing the roots of the former.

The method is as follows: A vine in a pot of the variety wanted is purchased. When growth has started in spring the pot must be raised so that the fresh green shoot can be brought into contact with another green shoot on the old vine. A piece,  $\frac{1}{2}$  in. to  $\frac{1}{4}$  in. deep and about 2 in. long, is cut out of the side of each green shoot, the two shoots are tied together with raffia so that the cut surfaces are in contact, and finally the raffia is covered with moss, which must be secured in position.

*Inarching.* Left, young and old plants joined together; a, bandaged junction; b, where to divide when cohesion is established. Right, showing at a, preparation of stock and scion.

The moss is kept moist by syringing. If the work is successful the two shoots will unite. When it is obvious that union has taken place, during the summer the stem of the young vine should be severed very gradually just below the green shoot. Subsequently, as the new variety of vine makes vigorous growth, the shoots in the old vine can be rubbed off gradually, and eventually the branches may be cut away, leaving the new variety firmly established on the old stock.

**Incarvillea.** The rose-red trumpet-shaped flowers of this hardy herbaceous plant.

**INCARVILLEA.** This plant has thick brittle roots, large leaves and trumpet-shaped flowers in summer.

The favourite is *Incarvillea Delavayi*, with rose-red blooms. It should be planted in well drained sandy, loamy soil in a sunny place. In cold districts the

soil over the roots should be covered with old ashes in autumn, when the leaves have died down. If an increased stock is desired it is best to sow seeds in a frame in spring.

**INCH.** For ordinary purposes the inch is the smallest measure of length, though for special purposes, scientific and other, it is divided very considerably. Twelve inches go to a foot, and the standard inch of the United Kingdom is  $\frac{1}{36}$  of a yard. 144 square inches make a square foot and 1,728 cubic inches make a cubic foot. For it the usual abbreviation is in., which is used throughout this work.

**INCINERATOR.** The best method of dealing with household refuse, which is usually placed in the dustbin, is to burn it on the kitchen fire. In the hot weather the range or independent boiler may be out of use, so that some other way of consuming the refuse must be arranged. In such a case the best way is to destroy it in an incinerator. In one type, which may be installed in kitchen or scullery where a flue is handy, the heat is provided by gas. An incinerator of this kind is perfectly safe to work, and needs no attention beyond feeding in the refuse, giving it an occasional poke, and afterwards emptying the ash. By this agency refuse, wet or dry, tea leaves, egg-shells, vegetable stalks and scraps, rags, cooking waste, etc., can be converted quickly into a relatively minute quantity of ash. This can be deposited in the dustbin or used in the garden as a fertilizer. The use of the appliance for half an hour daily will dispose of all the domestic refuse and the cost for gas is negligible.

A galvanized iron incinerator is handy for use out of doors. It is a cylindrical structure resembling a dustbin, and having a grating, lid, and central flue. A fire is kindled with paper, etc., and the refuse, is placed inside. See Dustbin; Gas; Refuse.

## INCOME TAX: THE LAW EXPLAINED

### How the Taxpayer can Compute His or Her Liability

By the help of this article income tax payers can see for themselves the amounts they are liable to pay. Other articles that deal with the financial liabilities of the householder include Employers' Liability; Rates. See also Insurance; Surtax.

This is a tax of so much in the £ on every £ of income, with certain allowances intended to relieve small incomes. In addition to the income tax proper a surtax is levied on larger incomes, i.e. those over £2,000 a year.

In Great Britain the existing scheme provides for a certain amount of income being free from tax, for the payment of a lower rate on the next £135, and for the payment of the full rate on the balance. In addition, there are various allowances and abatements, so that the actual rate of tax varies, not only with the income but with the responsibilities of the payer. In fact it can be said that each payer has his own rate of tax.

The tax is in most cases payable in two instalments, due on Jan. 1 and July 1 during the year following the one in which the return is made. Weekly wage earners (manual labour) are assessed  $\frac{1}{2}$ -yearly and pay tax every  $\frac{1}{2}$ -year. This concession does not, however, extend to journalists, clerks, typists, and others, even if they are paid weekly. If the income for the year in question cannot be ascertained exactly, a provisional return should be made and the matter adjusted at the end of the period, or as soon, as possible.

**The Procedure.** To ascertain his liability the taxpayer must know the rate of tax and the amount of his taxable income, this being his income less certain deductions. In 1938 the standard rate, as it is called, was 5s. 6d. in the £. It had been raised in 1930 from 4s. to 4s. 6d. and in 1931, the year of the financial crisis, to 5s. In 1934 it was reduced to 4s. 6d., and in the budget of 1937 increased to 5s. The first £135 of taxable income was, from 1935, charged at  $\frac{1}{3}$  of the standard rate instead of  $\frac{1}{2}$ , but for 1938 the reduced rate, as it is called, was continued at 1s. 8d. from 1937. In April the taxpayer should ascertain his total income for the year ending on April 5 and fill up the form which is sent to him. If this is accepted as correct by the authorities, he will receive a demand note for the amount, which he must pay during the following year. If his return is not accepted, the authorities may ask him to make another one or to present them with certain explanations. They may, too, assess his income at a figure higher than the one he returned and leave him to prove that it is incorrect. Appeals must be made within 21 days of the issue of the assessment notice (generally sent in the autumn).

**The Five Schedules.** The income must be entered under one of the five schedules or classes shown on the form. Of these A relates to income from land and house property in Great Britain and Northern Ireland and includes the annual value of the house in which its owner lives. B relates to income from the occupation of land and is charged on the annual rental value. This chiefly concerns farmers, who, if they prefer, can be assessed on their actual profits for the year preceding. C relates to income from War Loan and other securities, the interest on which is paid out of public funds.

The majority of taxpayers probably pay, as far as the bulk of their income is concerned, under the two remaining headings. D relates to profits from every trade, profession or vocation, farming excluded, and also to bank interest, loan interest, interest from foreign and colonial securities and on stocks and shares. In this class, therefore, fall the incomes of all who are in business for themselves, and of those having holdings of stocks and shares in public and private companies. In E fall all salaries, pensions, etc., whether paid out of public funds, or by public and other

companies or by private firms.

**Reliefs and Allowances.** The income ascertained and entered, the taxpayer should next find out what reliefs and allowances he can claim, and by deducting these from his total income he will obtain what is known as his taxable income. As matters stand (1938):

The taxpayer can get relief for the part of his income that is earned, earned in this sense including pensions. This is an allowance of one-fifth of the income; but total relief must not exceed £300, unless taxpayer is over 65.

No income tax is payable on the first £125 of assessable income in the case of a single person or on the first £180 in the case of a married man living with his wife, or wholly maintaining her. This makes all incomes under these amounts free from tax. No tax is payable on wound and disability pensions granted to persons who served in the Forces during the Great War, or on war gratuities, or on educational scholarships, and exhibitions, even if they exceed the limit of £125. Casual and occasional profits and gains, such as that from a sweepstake or from a deal in shares, are not liable to tax, neither are gifts and annuities not payable under a deed. In the case of gifts of this kind the tax is borne by the payer, who gets no allowance for such.

For purposes of income tax the incomes of husband and wife are added together, unless application is made for separate assessment. If a wife earns an income her husband is entitled to an abatement thereon of a sum equal to four-fifths of the amount of such earned income, but the relief is limited to £45. In other words, a married couple in this position can claim relief up to £225 instead of £180.

The next relief is for children. There is an allowance of £60 for each child. Such children, however, must be under the age of 16 on April 6 of the year for which the claim is made, except in the case of those who are in full time attendance at school or college, for whom there is no age limit. This allowance cannot be claimed for any child who has in his or her own right an income of £60 a year or over. Child in this sense includes a stepchild and an adopted child, if such child is maintained by the taxpayer.

**Allowances for Dependents.** Allowances are also made for dependent relatives. One of £25 is granted in respect of any relative who is dependent on the taxpayer or his wife, provided that such dependent is incapacitated by old age or infirmity from maintaining himself or herself and that his or her income from all sources does not exceed £50 a year. If two or more sons or daughters join in maintaining a dependent they are entitled to divide the relief of £25 between them. When the dependent relative is a widowed mother the condition of incapacity is waived. The same relief is granted for a daughter on whose services the taxpayer depends by reason of old age or infirmity.

Allied to this is the allowance granted to widows and widowers for a housekeeper. Relief to the extent of £50 is granted to a widower in respect of a female relative or some other female who resides with him for the purpose of looking after his children. A widow in a cor-

responding position can also claim it. If an unmarried person has living with him a widowed mother or any other female relative maintained by him to look after his brothers and sisters he can claim an allowance of £50.

An allowance is also granted for premiums on life assurance policies. This amounts to an allowance of 7 per cent on the capital sum insured, up to one-sixth of the total net income from all sources, on all sums paid in premiums on his own life and on that of his wife. It is also allowed in cases where a wife takes out a policy on the life of her husband. There are, however, certain restrictions on this form of allowance.

**Trade and Professional Expenses.** Allowances are also granted in respect of certain trades and professions. Ordinary tradesmen and other business men are allowed to deduct all the expenses wholly and exclusively incurred for business purposes. The auditors will usually decide what expenses can rightfully be included in this category, but their decisions may be questioned by the Inland Revenue authorities, who may ask for the production of the books of the business. In these cases much depends upon the nature of the business and special circumstances of all kinds; but the authorities will certainly question heavy expenditure that is not proved to be purely for business purposes.

When an individual resides on the premises at which he carries on his business he is entitled to charge against his profits a proportion, normally two-thirds, of the rent, rates and other outgoings incurred in connexion with the said premises. Other traders who conduct their business from their homes are also entitled to an allowance of the same kind.

Medical men, dentists, and those solicitors who do part of their business at home, are also allowed to deduct from the incomes something for that part of their house that is used for professional purposes. In the case of a clergyman or minister of religion an allowance not exceeding one-eighth of the rent or annual value of the house in which he lives is allowed.

Journalists are allowed a certain amount in respect of professional expenses such as the cost of typewriting and stationery. Artisans and others can obtain allowances for expenses on the tools necessary for their livelihood. Expenses incurred in getting to and from one's work are not allowed as deductions from the amount liable to income tax. A commercial traveller, however, can obtain a deduction for expenses of travelling incurred for his business provided no allowance is made to him by his employers for expenses of this kind.

When a person sustains a loss in any trade, profession, or vocation, he can, upon giving notice in writing to the local inspector of taxes, within twelve months after the year of assessment in which the loss is incurred, apply for and obtain an adjustment of his

liability to income tax by setting the loss against his assessed income of the year and bearing the tax on the balance. When such loss exceeds the assessed income the balance of the loss can be carried forward and set off against the income of six succeeding years.

**Two Examples.** To illustrate the working of the income tax laws two instances may be taken, one very simple and the other somewhat more complicated. A married man with two children under 16 has a salary of £750 a year, his wife has a private income from investments of £40 and himself one of £20. He pays £20 a year in insurance premiums and on this he can claim an allowance of 2s. 9d. in the £, or £2 15s. The total income is, therefore, £810, and the deductions are:

	£
One-fifth of earned income	150
Allowance for himself and wife	180
Children's allowance	<u>120</u>
	450

The taxpayer should therefore deduct £450 from £810, leaving a balance of £360 on which he is to bear tax. Of this £135 is charged at the lower rate of 1s. 8d. in the £ and the balance at 5s. 6d. His total tax will therefore be £73 2 6d., less the £2 15s. mentioned, or £70 7 6d. He has, however, already paid £16 10s., as this amount has been deducted from the dividends or interest paid to himself and his wife, and so the actual amount due from him in cash is reduced to £53 17 6d.

In the other case a professional man returns his earnings at £1,440 for the year. In addition he has a private income of £178, and his wife has one of £260. This gives him a total gross income of £1,878, from which there are various deductions, in addition to the main ones of one-fifth of his earned income and £180 for himself and his wife.

This professional man has three children; one son is over 16 years of age, but as he is still at school the father can claim an allowance for him. He contributes £100 a year to the support of his widowed mother, so can claim relief on £25 in respect of this payment.

His abatements and allowances may be summarized thus :

	£
One-fifth of earned income	288
Self and wife	180
Three children	180
Dependent mother	<u>25</u>
	673

This amount is deducted from the total income of £1,878, making his taxable income £1,205. He pays 1s. 8d. in the £ on the first £135 of this and 5s. 6d. on the balance of £1,070. Thus he is liable for a payment of £305 10s., but as he has already paid, by deduction at the source, £120 9s. on the incomes of himself and his wife, he need only find in cash £185 1s.

**Taxing at the Source.** In these two cases and in many others the taxpayer does not actually himself pay over the whole of the tax due from him. This is due to

the fact that he may obtain part of his income from interest and dividends of various kinds.. These unearned incomes, and also certain classes of earned incomes, are taxed at the source, or before they reach their owner. In other words, the company pays the tax direct to the national exchequer and deducts it from the amount of the dividend.

The same is done by the Bank of England and other banks when paying the interest on consols, War Loans, corporation stocks and other securities of that kind, and also by those who pay interest on mortgages. The only exception is one or two of the War Loans, on which interest is paid without deduction of tax, leaving the recipient to pay the tax if he be liable. The holder of stocks and shares is required to show income on which tax has been deducted in his declaration of income to the tax authorities, but obviously he is not required to pay a second time.

The principle is exactly the same when a company pays its dividends free of tax, as it is called. This simply means that it is paying a higher rate of dividend. To take a simple example: a company that pays 5 per cent free of income tax is really paying something over 6 per cent gross, when the rate of tax is 5s. 6d. in the £. The gross dividend inclusive of tax must be entered on the return by the taxpayer. He must not enter £10, or whatever sum he actually receives, but that sum plus the amount deducted.

In the case we have assumed, that sum is £13 15 10d., because tax on £13 15 10d. at 5s. 6d. in the £ is £3 15 10d., which leaves a balance of £10 for the taxpayer to receive. He is really taxed, therefore on £13 15 10d., and this is the amount of income which he is assumed to have had. This matter is important from the point of view of the Inland Revenue authorities, as the larger amount will, in certain cases, make incomes, otherwise free, liable to surtax. It is also important for a taxpayer who claims repayment because he is entitled to reclaim tax on £13 15 10d., instead of on only £10.

**Claims for Repayment.** These deductions from income are obviously made irrespective of the amounts of the incomes of the various persons concerned, which amounts those making the deductions cannot possibly know. Hence it comes about that many persons with small incomes, e.g. all those below £125 a year and those who, although they have incomes above that amount, are entitled to allowances of various kinds that are equal to or greater than the income itself, find, when they receive their dividends, that they have paid a tax from which legally they are free. Others who are liable to pay something find that they have paid more than they should have done. For instance, a man may be liable for a tax of £10, but £20 may have been deducted from his dividends. Cases of this kind are very frequent.

To remedy this effect of deduction of tax at the source provision is made for returning the excess of tax so deducted. Persons, therefore, who have paid more than they are liable for should take the following steps

to recover the amount, whether they are totally exempt from tax or only partially so. Immediately after the end of the year, which for this purpose is April 5, a claim for repayment should be forwarded to the local inspector of taxes. For this purpose a special form is provided, which can be obtained from the inspector, whose address will, if required, be given by the local collector. This form should be filled up carefully, all the particulars required being clearly entered. It should then be sent to the inspector for examination and verification. Questions may be asked about one or more of the items, but if the claim is in order the overpaid tax will be returned in the course of a few weeks. No claim will be admitted unless it is made within six years from the end of the year to which it relates. This is an important proviso.

**Sending in the Claim.** With this claim should be forwarded the vouchers which are sent with dividend and interest warrants, certifying that the tax in question has been paid. For other kinds of income the authorities will require receipts and letters from the payers certifying that the amount stated has actually been paid by them to the revenue authorities. Repayment will be made, if desired, in instalments as sufficient taxed income is received, without waiting for the full income of the year. The ordinary tax demand is usually sent in December.

**Relief from Double Income Tax.** A certain measure of relief is allowed to persons who are liable to two income taxes on the same income, provided that the two income taxes are charged within the British Empire. For instance, a man may reside in England and receive most of his income from property in Ontario. In such a case the taxing authorities in London will allow relief from the tax charged in Great Britain as the tax has already been paid in Canada. The relief thereon will be at the Dominion rate in the £, or at one half of that person's appropriate rate of tax in Great Britain, whichever be the less.

This arrangement covers the case of the Irish Free State, which, since it came into existence in 1922, has levied its own income tax. On its part the Free State has laid it down that from April 6, 1923, income tax will be deducted from dividends and interest on the stocks, shares, bonds, etc., of any government and company, outside the Free State, including British Government securities, where payment of such dividends and interest is made by or obtained through a bank, paying agent or other person in the Free State.

Exemption from Irish Free State income tax in respect of such dividends or interest is, however, allowable when the owner of the stock, shares, etc., is not resident in the Free State or, in the case of those British Government securities which were issued exempting them from taxation of this kind, where the beneficial owner is not ordinarily resident in the Free State; and payment of the dividends or interest without deduction of Irish income tax can be obtained by persons entitled to such exemption upon the completion of declarations on the correct forms.

The Free State has decided, too, that no deduction of tax will be made from interest on holdings of 5 per cent war loan, 5 per cent national war bonds, 4 per cent war loan, tax compounded, and 4 per cent national war bonds, tax compounded, registered or inscribed on the books of the Bank of Ireland in Dublin; but such interest will be charged with the tax by direct assessment on owners liable to income tax levied by the Free State.

**Protection for the Taxpayer.** A society exists for the protection of income tax payers, and its officials are willing to give expert advice to persons who are unable to recover overpaid income tax and to those who have difficulties with their assessment. Advice on these and kindred matters is also given for a fee by accountants, some of whom specialize in this subject, and by agencies that make a business of recovering overpaid income tax. In the great majority of cases, however, the taxpayer can deal with these matters himself, and any information and assistance he requires is usually given quite willingly by the inspectors and other officials who are responsible for collecting the tax. In case of serious dissatisfaction with his assessment he can appeal to the commissioners, and, from their decision, to the courts of law.

The Income Tax Payers' society, Abbey House, 2, Victoria Street, London, S.W.1, was founded in 1921, and is a non-trading concern. In addition to safeguarding the interests of taxpayers in general, it offers to its members, in consideration of the payment by them of a nominal annual subscription, the advice and assistance of its staff of experts on all matters relating to the law and practice of income tax. It publishes a quarterly Journal which is posted free of charge to all its members and which contains technical and other useful information likely to appeal to every taxpayer.

**Incontinence.** *See* Enuresis.

## **INCUBATORS AND THEIR MECHANISM**

### **Care and Attention Needed to Secure the Best Results**

As the keeping of poultry is a domestic industry, our work contains many articles of interest to the poultry keeper. Such include Brooder; Poultry House. See also Chicken; Duck; Eggs; Fowl; Poultry, etc.

The mechanical stages in the use of a hot water incubator are as follows, assuming that the instrument is in perfect working order: First the water container is filled with hot water, until it runs out of the overflow pipe or appears at the top of the filler pipe. The lamp reservoir is then very nearly filled with kerosene oil of good quality, the wicks adjusted so that the flame burns brightly without smoking, quite steadily and quietly, and generally about  $\frac{3}{4}$  in. in height.

The lamp is inserted in place under the flue opening. To do this the spring base has to be depressed to allow the lamp glass to pass the top of the opening in the chamber. The resultant spring upon it forces the lamp upward, and the top of the glass makes contact with the bottom of the flue and thereby prevents any air getting into it except through the air passages in the burner and the independent air supply separately provided.

The egg drawer is then closed and the thermometer inserted into place. The accuracy of the thermometer should be tested against another of known exactitude, and, if satisfactory, may be put into service. The lamp is then left burning day and night, until the temperature has risen to about 104° F., at which temperature the capsule should expand and lift the control lever. This control lever has, on its outer end, a cap or disk, which hangs over one of the hot-air flues, with the result that when the cap is down, the whole of the hot air will pass to the hot-air chamber and water container, and then be carried into the atmosphere.

*Incubator for hatching hen's eggs. A, water tank, heated by lamp, B. C, egg tray with, beneath, water tray to keep air moist. D, thermostatic capsule, which expands at a prearranged temperature and, by means of a rod and lever, raises damper, E, from chimney, F, permitting hot air to escape without passing through incubator. When temperature drops, capsule contracts and lowers damper. (Courtesy of Spratts Patent, Ltd.)*

When the cap is lifted by the lever and expansion of the capsule, some of the hot air can escape direct to the atmosphere; and consequently the temperature of the incubator falls a few degrees, the capsule contracts, the lever falls, and the cap is automatically replaced at the top of the flue opening. The critical adjustment of the capsule regulating screw governs the temperature at which the lever will rise. By screwing or unscrewing it the lever is raised and lowered. A sliding weight is also used on the lever bar, because with the increase of temperature not only does the capsule expand, but the pressure in it increases with further increase of temperature, hence the moving weight is useful; as by sliding it along the lever a fine adjustment is possible. This will have to be made on the spot for each individual incubator, and the incubator should be run for a sufficient period until the temperature remains constant for 48 hours before the adjustments can be considered safe, as with a hot-water incubator of this

type several hours must necessarily elapse before changes of temperature become apparent.

**Preliminary Experiments.** The water tray will have to be refilled with water from time to time, and various other operations performed when the incubator is at work, according to the period of incubation. When adjusting the incubator for the first time, it is as well to open the drawer occasionally, as if about to turn the eggs, and for about the same length of time requisite to do this, so that an appreciation of the temperature change and the time it takes to recover the normal hatching temperature is ascertained, as a knowledge of this item is very important during the actual hatching.

*Incubator. This apparatus has an egg capacity up to 120 hen eggs. The water tank is heated by an oil lamp which is controlled by a thermostat. (Courtesy of Spratt's Patent, Ltd.)*

The care and attention that should be given to any incubator includes the placing of the incubator in a dry position where the temperature can be maintained at an equable degree. This is a very important matter, as much of the success of incubation depends on the incubator itself being placed in some situation where it will be free from draughts or any violent change of temperature. The incubator should stand upon a firm support, either upon four stout legs with a framework, or upon brackets or any other arrangement that is firm and entirely free from vibration. This is a matter requiring careful attention.

As regards the apparatus itself, the only attention during the hatching period is to refill the lamp and see that the wicks are clean and in good order at regular intervals, say, about every 24 hours. After the lamp has been in use for some time, remember to see that there is sufficient wick to reach well to the bottom of the container, otherwise the lamp may go-out unexpectedly. The asbestos or other washers used to make the airtight joints around the inspection glass and the base of the flue should be examined, and if worn or broken be replaced by new, as any ingress of cold air at those points tends to reduce the heating

value of the lamp.

The internal air passages, or flues, should be cleaned out from time to time with a stiff-bristled brush with a flexible handle. The regulation of the capsule has already been described, and when it is functioning properly it should not be disturbed, as it depends upon chemical action for its functioning, and the action will always take place at the same time in every case. Therefore, when the regulator is properly adjusted it is best to leave it alone, except to see that the pivot bars have not worn and to keep them slightly oiled, so that they may work perfectly smoothly.

If it is desired to vary the temperature, as, for example, at the beginning or near the end of the hatching, the lead adjusting weight may be moved in preference to altering the adjusting screw for the capsule. The drawer, egg tray, water tray, and drying compartment should be kept scrupulously clean and be washed out between every hatch, preferably with hot water, with a small addition of disinfectant, followed by a washing in clean water.

The outside of the cabinet will keep in better condition by the application of a little furniture polish or an oily rag, as this preserves the wood in good condition and makes it less susceptible to atmospheric changes. The little air vent holes should be kept clear, and the water tank examined and the water-level tested between each hatch, making good the deficiency with hot water. After a year's hard work, the water tank should be emptied to free it from sediment which might accumulate.

**INDIAN CLUB.** The practice of various exercises with Indian clubs helps to develop the chest and the muscles, and enables the performer to acquire an erect and graceful carriage. The exercise or drill is well adapted for musical accompaniment if desired. In shape the Indian club resembles a slender, long-necked bottle with a knob at the end. These clubs are usually made of willow or elm. The wrist plays an important part in the exercises, which consist of a series of twists and swings. The clubs are made to turn in circles by the wrist action while they are swung from the shoulders with wide, sweeping movements to right or left. There is an outer and an inner swing. In the former the clubs are raised and swung downward away from the body and back to the starting point; in the latter the swing is upward.

**INDIAN CORN.** The variegated-leaved variety of Indian corn or maize (*Zea Mays*) has long been a popular plant for use among others in summer flower-beds, but improved varieties of the common kind are being increasingly grown for the sake of the cobs, which are cooked in the way described in the article on Maize. This plant needs rich, deep soil and copious watering in hot weather. Seeds may be sown under glass in March and the seedlings set out of doors in May, or seeds can be sown out of doors in the latter month. The rows should be about 2 ft. apart, and the seedlings thinned to 10 or 12 in. from each other. *See* Maize.

*Indian Corn. Leaves of the variegated maize, a plant much grown for its decorative value.*

### INDIAN CRESS.

This is a popular name for the common or garden nasturtium. It is a familiar and easily grown annual which bears showy flowers in many shades of red, yellow, orange, scarlet, and terra-cotta. There are dwarf and climbing varieties. *See* Nasturtium.

**Indian Fig.** Popular name of the *Opuntia* cactus (q.v.).

**INDIAN GRASS.** This is a hardy perennial grass of pretty tufted growth, attractive in mixed borders, its Latin name is *Molinia caerulea*. It will grow in good ordinary soil, in any position, and may be planted from March to June, or during autumn. It bears smooth, rigid leaves of delicate green, variegated with white, 8 to 12 in. in height. Propagation is by simple division of the roots in spring or autumn. *See* Border.

**INDIAN PINK.** This is a popular name of *Dianthus chinensis*, known also as Chinese pink, a favourite summer flowering plant with large fringed blooms in many colours. It is commonly treated as a biennial. Seeds are sown out of doors in June, the seedlings being transplanted once to give them room for development: in October they are put out where they are to bloom the following year. Well-drained soil and a sunny situation suit them best. From seeds sown in a heated greenhouse in January or early February the plants will flower in the summer of the same year if planted out of doors in May or early June.

*Indian Pink. Flower heads of the double variety.*

**Indian Shot.** Alternative name for the canna, a large and handsome summer bedding plant. *See* Canna.

**INDIA-RUBBER PLANT.** This is the popular name of *Ficus elastica*, a favourite room and window plant with large, handsome deep green leaves. The variegated leaved variety is even more attractive. Both thrive if potted in a compost of sandy loam. Careful watering is necessary, as with all room plants. When

the soil is just moderately dry the pot should be filled to the rim with water. An occasional sprinkling of guano or watering with soot water has a beneficial effect on the growth of the plant.

**INDIGESTION.** Pain or discomfort is caused to many persons in consequence of a disturbance of digestion in the stomach or bowels. This may assume an acute form, with headache, nausea, vomiting, and severe pain in the stomach. If the vomiting is not free, the stomach may be relieved of its contents by tickling the back of the throat and giving large draughts of tepid water. The bowels should also be cleared, and for this purpose  $\frac{1}{2}$  oz. of Rochelle salts or 2 oz. of compound mixture of senna (black draught) may be taken. The pain over the stomach may be relieved by a hot-water bottle or by a large mustard plaster.

No food should be given for at least 12 hours, but warm water with from time to time a pinch of bicarbonate of soda in it may be given. Milk, diluted with hot water, soda water, or lime water, may be commenced if the stomach has properly settled; then beef tea, chicken soup, steamed white fish, and so on to ordinary diet.

In the chronic form of this complaint, as in the acute, it is necessary always to bear in mind the possibility of the stomach symptoms being due to some disorder of the digestive apparatus calling for special treatment, or to some general disease. When dyspepsia begins in a middle-aged person whose digestion has hitherto been quite good, medical advice should be obtained.

**Causes and Prevention.** In most cases if inquiry is made as to the state of the mouth, and the habits are brought under review, fairly obvious reasons can be found for the protests which the stomach is making. The mouth is often very septic, and this is responsible for a variety of mischief. Not uncommonly in people who suffer from chronic catarrh of the nose, pus is continually being discharged from the back of the nose and is then being swallowed.

The teeth may be too few for the mastication of ordinary food, leading to the free use of liquid at meals to make the swallowing of the large, partially chewed masses possible. The same result will follow when, either from hurry or reading at meals, sufficient care is not taken to reduce the food to a soft, semi-liquid pulp. The strain on the stomach is increased in the case of the man who feeds with his eyes always on the clock. For half an hour after a meal other functions should be made to go easy. If circumstances dictate a hurried meal it should be small and easy to digest. Taking a meal dry and leaving any beverages to the end greatly helps to promote better mastication. Reading at meals tends to reduce adequate mastication.

Meals should be regular, and casual food between meal-times is to be deprecated. Many people err by taking too many meals, or, even if they take a reasonable number, they load themselves with too much food. The manner in which food is cooked is important. It may be said that things that are fried, that is, cooked in super-heated fat, may strain the digestive

powers too much, and the same applies to meats stewed in the ordinary way in a saucepan or baked in pies. All such, and pastries of any kind, should be eschewed by the dyspeptic. Grilling and roasting, or stewing by the French method on a water bath, are the methods which favour digestibility. Pork, salt or corned meat, cheese (unless of the mildest description), shell fish, nuts, pickles, vegetables if fully grown and tough and stringy, new potatoes, and new bread will do harm.

Intemperance in tea, coffee, tobacco or alcohol may be responsible for dyspepsia. The diet should be as varied as it is possible to make it, and should include some fresh food, tender salad, and a little fresh, ripe fruit if possible, avoiding plums and the stringy parts of oranges. But if these disagree a frequent ration of squeezed orange-juice should be taken for the sake of its vitamins.

The general causes of indigestion are set forth in Fig. 1. In neurasthenic cases symptoms are very variable.

*Indigestion. Fig. 1. Inefficient chewing and improper food are the commonest causes of indigestion, but there are many other causes, set out in the above scheme. Note that indigestion may be only indirectly due to the stomach, the prime cause lying elsewhere.*

#### Importance of Avoiding a Chill

It is important to keep the abdomen warm, and much benefit may be derived from wearing a flannel binder, especially in cold and in damp weather. The feet should also be kept warm, and this fact applies very especially to infants and young children. The general fitness should also be advanced by a sufficiency of open-air exercise. The bowels should be kept regular, and for this purpose one of the preparations of cascara or aloes may be employed. Where there is much distress after a meal a small teaspoonful of the following powder may be taken in a little milk 20 min. before or half an hour after meals:

Bismuth carbonate	2 drams
Sodium bicarbonate	2 „
Magnesium carbonate	4 „

If flatulence tends to be a troublesome symptom, a wineglass of peppermint water with a pinch of bicarbonate of soda or 1 or 2 soda mint tablets will relieve it.

*Indigestion.* Fig. 2. Food may not be properly masticated unless attention be given to the matter. For this reason reading at meals is discountenanced; it may lead to bolting of food.

It is not infrequent for pain to come on in the night. This is known as the hunger pain, and it may be relieved by taking a teaspoonful of bicarbonate of soda or of this combined with bismuth. But as this symptom is characteristic of an excess of hydrochloric acid in the gastric juice, with which a duodenal ulcer is apt to occur, anyone who suffers in this way should put himself immediately in the hands of his doctor.

When bottle-fed babies are not digesting their milk well, as shown by the appearance of curdled milk in the stools, 1 grain of sodium citrate may be added to each 1 oz. of milk used. In older children the starch and sugar consumed may have to be reduced, and a meal or two of Benger's Food each day may be a useful way of meeting any difficulty in digesting starch. Flatulence may be relieved by sips of hot water, a teaspoonful of dill water, or a crushed soda mint tablet. *See* Constipation; Diet; Digestion; Eating; Hydrochloric Acid; Stomach, etc.

**INDIGO.** The blue dye known as indigo produces a dark blue colour on woollen cloth that is fast to light, and on this account the dye is used for all the dark blue cloth employed in the Navy and for dress materials and suitings, etc., of the better qualities in the shade known as navy blue.

The dye bath is a mixture of indigo, lime and fermentable substances such as bran. In this form a colourless liquid is formed. After cloth has been soaked in the dye bath, it is exposed to the air and the blue colour develops. Much of the indigo now used is prepared artificially. *See* Dyeing.

**INDIGOFERA.** The indigo of commerce is supplied by *Indigofera tinctoria*, an East Indian plant. Few species of indigofera are grown in gardens; the most important is *gerardiana*, a shrub which bears rose-red, pea-like flowers in late summer. It is often planted against a sunny wall, where it will reach a height of 10 ft. in the course of time. If planted in the open garden the branches should be cut down each spring to force the development of fresh ones which will reach a height of about 3 ft. Often the branches are cut down by frost. This shrub thrives in ordinary soil in a sunny place and is increased by cuttings inserted in

pots of soil in a frame in September.

**INDUCTION.** When a body charged with electricity produces an electric condition in a neighbouring body not directly connected with it the result is termed induction. A similar effect is observed if the body be charged with magnetism, in which case the magnetic condition is induced in the neighbouring body. Should an electric current be flowing through a conductor, it will induce electricity in another wire brought near.

In internal combustion engines the word induction is used to describe a phase of the suction stroke, and particularly refers to the state of affairs which exists in the pipe or passage connecting the cylinder to the carburettor, generally known as the induction pipe. The difference between the pressures in the cylinder and the carburettor induces a flow of gas from the carburettor to the cylinder. *See* Internal Combustion Engine.

**INFANT.** In English law an infant is one under 21 years of age. An infant is not held responsible for all his actions; for instance, contracts made by him to repay money or pay for goods are void unless they are for necessities. The definition of a necessity depends on the social position of the infant. An infant is not liable to pay a bill of exchange, even if it has been drawn for necessities.

An infant under seven is not capable of committing a crime in the eyes of the law. It is an offence to send printed matter to infants inviting them to borrow money or to bet. Infants cannot act as trustees or executors, nor be made bankrupt. In an allied sense the word is used for a baby. *See* Baby; Child; Guardian; Juvenile Offender.

**INFANTILE PARALYSIS.** The infectious disease named acute poliomyelitis is more generally known as infantile paralysis. It is a serious and not uncommon complaint in childhood, especially during the first three years. The onset may be sudden, with headache, vomiting, fever, and perhaps convulsions. After a few hours, in some cases, the child shows evidence of paralysis, involving the limbs, and perhaps the trunk. The paralysis passes away from the greater number of muscles, but remains permanently in one limb or part of a limb, sometimes in two or more. The paralysed limb becomes shorter; deformities such as club foot may be produced, and the limb is blue and cold.

The disease most commonly occurs in the hot summer months. It is due to the entrance of a germ into the body, the source of which is not quite clear. It may occur in epidemics, and when this is the case milk should be boiled. All cases of this disease should be isolated. Treatment will be in the hands of the doctor. Paralysed limbs must from the beginning be placed in position which will avoid any stretching of the muscles, and the doctor's directions on this head must be

carefully followed.

After the acute stage has subsided, and the degree of the residual paralysis is fully determined, an endeavour must be made to re-educate the muscles of the limb which still have the power of contraction. Thus if a leg be affected the child may require to be taught to walk again by means of a wheeled walking machine which he propels. Surgical appliances and instruments are of great value in enabling the affected joints to be moved, and in some cases great good can be achieved by orthopaedic surgical operations.

**INFECTIOUS DISEASE.** Any disease which is transmissible from one person to another is said to be infectious. Some infectious diseases, such as tuberculosis and ringworm, may be derived from the lower animals. A disease is infectious because it is due to a living organism which can multiply in or about one person, and be discharged and become parasitic in or on another person.

Some parasites, like those of a common cold or influenza, are discharged in the breath, especially when coughing or sneezing, and in such diseases as tuberculosis and pneumonia the sputum teems with organisms which may be dispersed by coughing, or as a fine dust when the sputum dries. The dried crusts of smallpox and chicken-pox are infective, and their dust contaminates the air.

The parasites of other diseases, such as typhoid fever, dysentery and cholera, are chiefly spread by contaminated water, and these are therefore often described as water-borne diseases. Not only may infection come from drinking such water, but from utensils or fresh vegetables or fruit which have been washed with polluted water. Milk may be charged with parasites by being kept in such vessels, or by dilution with the water. Icecream may also convey infection.

Other insects convey infection when they bite; or infected faeces of an insect may be inoculated into the skin by scratching. By the last method typhus, relapsing fever and trench fever are disseminated by the louse. Mosquitoes, by biting, spread malaria, yellow fever, dengue and filariasis; the flea transmits bubonic plague; the bed bug, plague and possibly leprosy and other diseases; the tsetse fly, sleeping sickness; the sand-fly, three-day fever; and the tick, relapsing fever.

Articles of clothing, books and other objects which have been in contact with an infected person may carry the infection, and are referred to as fomites.

Not only may a person actually suffering from a disease be a source of danger to others, but also some who have recovered but still retain a focus of infection in the body. Such a person is called a carrier.

*A person suffering from an infectious disease should be isolated until all danger of communicating the infection has passed.*

It may be possible to isolate a patient at home, but if there is any difficulty in doing so, and especially when the disease is one of the more serious infections, the patient should be sent to an isolation hospital.

#### Room Chosen for the Patient

The room chosen should be at the top of the house, and should have a fireplace. A sheet wrung out of lysol solution, a teaspoonful to the pint of water, or some other antiseptic, and hung over the door, has the advantage of emphasising the fact of the isolation if it does nothing more. Carpets, heavy hangings, and all unnecessary furniture should be removed before the patient goes into the room. Feeding and other utensils used by the patient must be kept for his separate use.

Some person must be told off to attend to him, and should wear an overall when outside the room. Books should not be allowed to leave the sick-room. When the period of infectivity is over, the patient must be properly washed all over and dressed in fresh clothing, and the room and all its contents must be dealt with as described under the heading Disinfection.

Not only must the patient be isolated, but also anyone who has been in contact with him, the duration of this quarantine being regulated by the incubation period of the disease, and estimated from the last date of exposure to infection.

Some infectious diseases must be notified to the Medical Officer of Health for the district, and this should be done immediately the diagnosis is made. A list of such diseases is given under the heading Notification. Responsibility for notifying falls both on the doctor in attendance and on the head of the house or any other person in a similar position, but in practice the notification of a doctor usually suffices. The fine for failure to notify is 40s. The Act applies to boats, tents, vans or sheds used for human habitation, as well as to houses and other buildings. *See* Disinfection; Fever; Fly; Quarantine; Rash.

**INFIRM PERSONS:** Care of. Elderly people left by themselves, either through gradual mental decay or neglect, often get into a dirty and sometimes verminous condition. Particularly is this so where they have only one or two rooms in a house; they then become a nuisance or danger to themselves and the other inmates of the house by their insanitary ways. The position is a very difficult one, and calls for tact on the part of the landlord or chief tenant of the house. In such circumstances the first step is to communicate with the relatives, if any can be traced, and get them to act and make provision for someone to look after the person and to keep them and the room and contents reasonably clean.

If such friends or relatives cannot be found the next step is to communicate with the relieving officer of the local Public Assistance Committee. He will interview the persons and try and persuade them to go into the local infirmary or hospital and be taken care of properly. It frequently happens that they will not consent, but prefer to continue in the old ways and keep their independence and muddle along, to the detriment of themselves and the other inmates of the house.

In such a case the only remedy is to notify the local sanitary inspector, who will make inquiries and refer the same to the medical officer of health. London and some of the larger cities and towns have acquired powers to deal with this problem. After examination of the person, the medical officer of health gives a certificate in writing that he or she is aged, infirm, or physically incapacitated, and resides in premises which are insanitary owing to any neglect on the part of the occupier, or is living under insanitary conditions, or is suffering from any grave chronic disease and is unable to get proper care and attention. Then the medical officer of health makes an application at the police court and gives evidence to the magistrate as to the danger to health and fire to the person and other inmates of the house.

Most of the Acts make the period of detention and maintenance in the hospital or infirmary under the magistrate's order at three months. Application must be made to the court for an extension of this period; ample provision is made to protect the liberty of the person, and every means is taken to get into touch with relatives and friends of the aged person, for it has to be remembered that the person becomes a charge upon the rates.

Before application is made to the court for the removal of the person, three clear days' notice must be given by the medical officer of health of his intention to apply to the court for this removal, and should any relatives be found who will come forward and take care of the infirm person, then, even after the order has been made, the court has power to make a rescission order and allow the person to be taken under the care of relatives and friends. *See Old Age; Old Age Pensions.*

**INFLAMMATION.** When any part of the body is irritated by an injury or the presence of bacteria, there is an increased flow of blood to it, producing the four characteristic symptoms of heat, redness, swelling and pain. Diseases whose names have the termination "itis" are inflammatory diseases, e.g. appendicitis, bronchitis.

In the treatment of inflammation the first thing to do is to remove the cause, if possible; for example, removing a foreign body from the eye. The part should then be put at rest. Pain may be relieved by lessening the amount of blood in the part; by keeping the part raised up, e.g. a whitlow in a finger; by applying cold applications which contract the blood vessels or by using heat to dilate blood vessels at some distance from the site of inflammation, and so draw blood away from this point, as when a poultice is applied to the chest wall to relieve congestion in the lung.

**INFLATION.** In the economic life of motor tires, and also pedal cycle tires, inflation, which is distending or filling with air, is an important factor. Tires must be kept inflated to the correct pressure as stated by the makers if freedom from trouble, e.g. chafing at the beads, is to be avoided. *See Tire.*

**INFLUENZA.** Due to a germ, there is good evidence for believing that the influenza bacillus of Pfeiffer is the one primarily responsible for this disease,

although other germs have been found in association with the disease, and may be responsible for at least some of the complications.

The onset of influenza is sudden, and occurs from one to four days after exposure to infection. Running at the eyes and nose may suggest a bad cold, but usually the fever is higher, there is considerable headache and pain in the back and limbs, and more prostration. Often the throat is sore, and there is a dry, irritating cough. The tongue is furred, and there may be nausea and perhaps vomiting. The brunt of the disease may indeed fall on the digestive organs, and the symptoms be so sudden and severe as to suggest food poisoning. In some instances, it may be added, the onset of the disease is unusual as, without feeling noticeably unwell, a person has dropped unconscious in the street.

Ordinarily, after having persisted from three to five days, the temperature drops, suddenly as a rule. Some complication, however, may supervene. Bronchitis may become severe, developing into broncho-pneumonia. Sometimes the lobar type of pneumonia develops pleurisy, heart disease or Bright's disease. Apart from legacies left by some of its complications, even an apparently simple attack of influenza may have troublesome sequelae, such as considerable mental depression or neuralgia.

The chance of recovering from an attack of influenza is, generally speaking, good except where young children or aged or debilitated persons are concerned. The general treatment is that of the state of fever, but special emphasis must be laid on the necessity for rest in bed, abundance of fresh air, and of sufficient time for convalescence. Aspirin in 10-grain doses is useful for relieving muscular pains and headache. This or salicin, sodium salicylate or quinine may be given at intervals in order to combat the toxæmia of the disease. The patient ceases to be infectious in three or four days after the temperature has become normal.

The infection of influenza is mainly spread by the breath of an infected person, and the danger is increased by his sneezing and coughing.

*During an epidemic an infected person should be given as wide a berth as possible. It is a prudent thing to walk to business, for example, or go on the top of a bus rather than in a closed vehicle, and rooms and offices should be especially well ventilated.*

It may help to lessen the risk to gargle the throat and spray the nose with a weak solution of permanganate of potash twice daily. Should suspicious symptoms make their appearance, 15 drops of essence of cinnamon or of spirit of camphor taken on a lump of sugar may cut them short. Mixed vaccines, containing the influenza bacillus and other germs associated with the disease, are of definite value. *See Cold; Cough; Fever.*

## INGLE NOOKS AND THEIR CONSTRUCTION

### An Old-World Feature Adapted to the Modern House

This article, aided by further information under such headings as Corner Seat; Cottage; Joint; Stain; Wood, tells how an amateur can make an ingle nook for his house. See further the entries Chimney Piece; Fireplace; Settle.

The ingle nook may be described as a large opening fitted with a seat or with two seats, one on either side of a fire and within the chimney breast of the fireplace. Such are only possible in the large fireplaces of Tudor and Stuart times, or in those built in imitation thereof.

In some ingle nooks the seats are built into the walls, but if they are not, the nook can be completed by placing a wooden seat on one or both sides of the fire, care being taken that the distance between it and the fire is sufficient to leave the sitter in comfort. Obviously the seat must not be trimmed in any way.

The construction of an ingle nook will have to be determined; as regards its size and detail, according to the geography of the room in which it is to be constructed, and the purpose for which that room is required. As the ingle nook is a characteristic of the old style house, the construction should be on solid lines, and treated in such a manner that it will retain these characteristics. Generally this is accomplished by the use of rough-hewn oak posts and simple, direct methods of construction. As a typical example, the illustrations, Figs. 1 to 4, show how an ingle was formed in the dining room of a modern house, and suggest a method of construction which may be adopted elsewhere.

*Ingle Nook. Fig. 1. This is built in the dining room of a modern house. The fireplace, a wide brick recess containing a basket grate, is flanked by comfortable settles, with sloping backs and seats.*

**The Work Described.** In the case illustrated the fireplace was a brick recess, spanned by a heavy oak beam and accommodating a wrought iron basket fire mounted on a base of brickwork; but where that arrangement cannot be followed it is, for example, often possible to remove a cast iron register stove and to face up the opening with narrow facing bricks, splaying the jambs and building in a barless fire at the back.

A false oak beam could be fitted across the opening and should be faced with a fireproof material, as, owing to the small space between the fire and the canopy of the chimney, it would not be practicable or safe in the general run of cases to fit an actual wooden beam.

Having arranged the fireplace in the manner described, so that it is in character with the general scheme, the construction of the ingle can proceed, and in general it will be found that this will necessitate the fitting of false beams to the ceiling, unless such a feature is already present, as if there is to be any appearance of realism the design should be based on what would have been in the old days the structural necessities of the case.

In the first case, the seats are simply built up in their place from ordinary building deal, this being easily accomplished by covering the end wall with 3-ply, nailed to rough grounds affixed to the brickwork, or, if the walls are smooth enough, direct to the plaster surface. Alternatively, a plaster wall could be covered with one of the high-grade, oak-grained wallpapers. The legs and a simple framework are then constructed, as shown on the detailed drawing, Fig. 2. Figs. 3 and 4 show the seat in course of construction and completed, the general method being to make up a frame with legs complete and to stand it in its correct position in the corner of the room.

*Fig. 2. Details of legs and framework of the settles shown in the ingle nook illustrated in Fig. 1.*

*Ingle Nook. Fig. 3. This shows the framing in place, with plywood facing in position on wall.*

**Making the Seats.** For comfort's sake the seat should slope backward, being considerably higher at the front than the back, and if the rest, or back, be similarly sloped and rightly adjusted, a really comfortable seat is the result. On no account should the seat and the back be at right angles, for the seats will not then be comfortable.

The next step is to prepare 1 in. tongued and grooved floorboards and nail them on the top of the framework, thus forming the seat. Oval brads should be used for this work, and their heads punched well

below the surface. The front of the seat, or that part of it which faces the length of the room, is prepared from similar boards sawn to the desired shape, lengths of floorboard being cut as nearly as possible to match the curved shape, which may afterwards be worked up by sawing it with a pad saw and finished when in place both with a spokeshave and sandpaper.

These pieces should not be glued together, but should be simply secured by 2 in. oval brads to the face of the framework, or preferably by screws passing through the framework into the side pieces. A dummy upright post, comprising a rough hewn oak plank attached to the wall, may either be grooved to receive the side members, or these may be secured in position by beads on each side; the latter is the simplest way for the amateur.

The next step is to cut a sufficient number of pieces of  $\frac{3}{4}$  in. matchboard to the length requisite to form the back, and to bevel the upper and lower edges so that they are a good fit on to the top of the seat and on the rough ground attached to the wall, respectively. A single crossbar is fixed between the front part and the wall, and also two rough pieces inclined at an angle and attached respectively to the wall and the side piece of the seats, to form a foundation to which the back can be nailed. A capping is then fitted to the top of the front piece and a simple moulding run around the wall on this line, across the back of the seat, along the sides and

terminating at the great beam over the fireplace.

To cover the nail heads and make a neat finish around the seat, sides, and back, a simple  $\frac{1}{4}$  round moulding is glued or pinned in the corners. The whole of the woodwork is stained dark oak colour.

*Ingle Nook. Fig. 4. The seat complete and ready for staining.*

**Dummy Timbering.** If it is desired to fit dummy timbering, a heavy plank about 6 in. wide and about 2 in. or so thick should be rough hewn to represent a beam spanning the two uprights of the back and sides. This is further supported by two roughly shaped and curved members, rising from the capping on the top of the sides and terminating about a quarter the length of the beam from the walls. The false timbering on the ceiling is easily arranged with rough hewn strips of oak, or even plain deal stained to a dark brown colour, and secured to the rafters by oval brads, driving these right through the plaster into the rafters or floor joists.

When two small windows are in existence, or can be provided, one on each side of the fireplace, they add a great charm to the ingle and have a real value in providing light for the seats. They make reading or sewing a practical proposition, as usually the corner by the fire has a tendency to be dark. The ingle can be further decorated by a few judiciously applied strips of rough hewn oak attached to the wall to represent old

timbering.

**INHALATION.** The method of inhalation is used for many drugs, mostly in the treatment of respiratory disorders. Creosote, eucalyptus oil, compound tincture of benzoin (Friar's balsam), menthol, camphor, etc., may be administered in respirators, inhalers, volatilized in steaming water or on respirators, while some drugs to relieve asthma are smoked.

The simplest method of giving medicated steam inhalations is to fill a large jug with a pint of boiling water, 2 parts, cold water, 1 part, add a proper quantity of the drug, cover the head with a towel, and place the face over the jug. One teaspoonful of Friar's balsam used in this way will sometimes cut short a cold, if no time is lost after the first symptoms appear.

**INITIAL: How to Work.** The usual custom of initial embroidery is to choose the first letter of the surname, but this is often varied; as occasion demands, by working instead the first letter of the Christian name, or for a more elaborate device, taking both the first letter of Christian and surname, and grouping them together attractively.

**The Stitches Used.** When working initials it is important to prepare the ground by padding the outline, in order to give a raised effect that is particularly attractive. The simplest method of doing this is to cover the inside part of the outline with rows of running stitches, all of an even length, and fairly close together as shown. It is possible to buy at most fancywork shops some attractive initials made in papier mache that will form a padding, and only require to be placed on the material and closely covered with satin-stitch to secure them in place; but these are not to be recommended for garments that are to go to the wash.

Another method which is very good for fine work on such things as linen handkerchiefs or underwear is to employ a thick thread or fine cord, and lightly sew this to the outline of the initial before covering it with a close oversewing stitch. Satin-stitch should always be worked across the shorter way of the shape to be embroidered. It consists of perfectly straight and even stitches, that should be made to lie quite closely together.

A more elaborate result may be obtained by working the initial in Venetian ladder work, and in this case the padding is unnecessary, as the centre of the shape is cut away. The whole outline is first closely covered with a fine running stitch, and the ladders that connect it from side to side are worked in buttonhole-stitch. With very fine scissors cut through the centre of the shape and turn back the edges to the line of the running stitches. Now closely work round the outline in fine over-sewing or in buttonhole-stitch as desired. Carefully cut away the raw edges of the material when

the embroidery is finished.

Another device for embroidering large initials is to cut out the outline in a contrasting material, and appliqué it to the article. Blanket-stitch is a good medium to use for securing it in place, and it is advisable to choose a material for the lettering which is not easily inclined to fray. Another plan is to embroider the initials in satin-stitch on a fine piece of net, and then to insert the net, shaped into some fancy device such as a circle, square, or oblong.

*Initial. Designs for four single letters and a monogram, showing also methods of embroidering them in Venetian ladder work, padded satin-stitch and cross-stitch, the latter being suitable for the coarser kind of house linen.*

Easy to make and very suitable for towels is the initial worked in cross-stitch as shown in diagram. The stitch is made by taking up equal strands with the needle in a slanting direction, and at right angles to each other, each pair of cotton strands forming a single cross-stitch. It is advisable to work this embroidery on very coarse threaded material, as this helps considerably when the threads have to be counted in order to keep the stitches regular. The simplest way to obtain an outline for the initial is to sketch one on finely squared paper, and then count the squares that are thereby covered, making each square represent a stitch. It will be quite easy to follow this guide on the actual linen. *See Cross Stitch; Embroidery.*

**INK: Its Varieties.** Ordinary black writing ink is made by mixing ferrous sulphate with Turkey or Aleppo galls, which contain gallo-tannic acid, and adding a little gum arabic. There are many recipes, the proportions varying in each, but the best results are said to have been obtained with one part of the sulphate to about 3 parts of the galls. A good black ink may be made by boiling 8 oz. of galls in a gallon of water and adding 6 oz. each of ferrous sulphate and gum, or 6 oz. of galls and 4 oz. each of the sulphate and gum in 6 pints of water.

A special ink is required for the zinc labels used by gardeners. This is made by mixing  $\frac{1}{2}$  oz. of lamp-black with 1 oz. each of verdigris and sal-ammoniac in  $\frac{1}{2}$  pint of water. The zinc should be thoroughly cleaned before the ink is applied.

**Marking Ink.** Marking ink is mainly metallic in composition and is usually prepared with aniline salts, which produce a deposit on the surface of the article marked. It is generally used for marking names or initials on linen, cotton and clothing. The deposit may be obtained by passing a hot iron over the writing, but in some varieties it is possible to dispense with this

process.

**Other Special Inks.** Special inks are made for other purposes, copying and drawing among them. Any ordinary iron gall ink will yield a copy for some time after writing, but in order to get better results a larger proportion of ferrous sulphate, galls and dye should be used. With this should be mixed a small amount of a substance such as glycerin, to prevent the ink from drying too rapidly.

Drawing inks include sepia, Indian ink, and the so-called waterproof ink. Indian ink is composed mainly of fine lamp-black and glue. Waterproof ink consists of a pigment or colouring matter suspended in a liquid medium, e.g. a solution of shellac. Typewriting inks frequently consist of a solution of methyl violet with a thickening agent, such as glycerin or oil. For writing on bottles a suitable ink can be made by dissolving 60 parts of borax by weight in 250 parts of water. Warm the borax and add the water to it, stirring all the time. For colouring, one part of methyl violet can be added.

**INKSTAND.** The inkstands sought by collectors are chiefly articles of silver or Sheffield plate dating from the eighteenth century. They appear to have been first made in England about 1700, and the styles are many, ranging from the boat-shaped one with its pair of silver-mounted bottles to massive silver pieces that are heavily moulded. A popular style is the box-shaped one, which has corners of heavily stamped metal, and in some silver pieces four cast feet. One beautiful silver example, dating from 1770, stands on four claw and ball feet. The tray has a gadroon border, and there are three pierced cages for the three bottles, which are of crystal with silver mounts. Many of these old inkstands are provided with a sandbox, a waferbox, penwiper, and a taperholder in addition to the bottles.

Inkstands are included sometimes in modern writing desk sets of lacquered or painted wood. Opaque glass in a brilliant colour is effective for inkpots, pen tray, ash tray and candlesticks. Other charming inkstands are of flowered china mounted in ormolu with holes at each side of the inkwell to accommodate quill pens in harmonizing colours.

## INLAYING: THE ART EXPLAINED A Pleasing Decoration for Pieces of Furniture

Those interested in this subject should consult the articles on other forms of wood decoration, e.g. Fretwork; Graining; Marquetry; those on the various pieces that are inlaid, e.g. Cabinet; Sideboard; and those on the woods used, e.g. Ebony; Satinwood. See also *Antique Furniture; Furniture; Hepplewhite; Jacobean Style; Sheraton.*

The art of inlaying consists in cutting away or recessing a given ground work to receive a substance cut to a corresponding shape, the inlaid portion being of either different material or different colour, so that

it will thus show in relief against the ground work. Its use, for the main part, is a decorative one, though it can be employed to advantage in a theoretically constructive sense.

*Inlaying. Examples of modern pieces. Left cabinet in figured oak with inlaid lines and applied marquetry panels. Above, oak sideboard inlaid with fancy banding in ebony and satinwood. (Rowley Gallery, Kensington)*

The more advanced work naturally requires a good deal of skill in its execution, and can hardly be recommended to the amateur as a branch of work within his range but among the more simple types of inlaying there is a great deal of scope, and there is no reason whatever why he should not make his work more interesting by decorating it with a simple form of inlay. The methods employed in inlaying may be roughly divided under two headings, that of inlaying a given ground and that of applying a surface piece, already inlaid, to a ground work. This latter is in many respects similar to the method employed in marquetry work, but differs in that marquetry is made from veneers and requires a special cutting arrangement, known as a donkey, and is cut at a right angle to the work; whereas in the method to be explained here a surface measuring anything from  $\frac{1}{16}$  in. to  $\frac{1}{4}$  in. thick is required and is cut at a different angle. Figs 1 and 2 show the two methods employed to give the same effect, Fig. 1 being inlaid directly in the ground, and the other formed on an applied surface. The former is the inlay proper, and is often the only method which can be practicably employed.

**Simple Inlaying.** Fig. 3 represents an inlaid pattern of holly and ebony for an oak ground. The design should be first carefully drawn full size on a piece of paper and an indication made of which portions are to be in holly and which in ebony. The shape of each inlaid portion is then marked out on the corresponding pieces of wood for inlaying (these being about  $\frac{1}{8}$  in. thick) by means of carbon paper, and carefully cut out with a fine fretsaw; all the pieces are assembled on the drawing and fitted together, care being taken to get close joints. Any straight joints may be trued up with a plane, while for the shaped parts a spokeshave or rasp will be useful. They are then all glued to the drawing and together, and another piece of paper glued to the other side, the whole then being laid between two flat

boards and cramped and allowed to set. When dry the drawing is stripped off the back and any surplus glue cleaned from off the edges, and the inlay placed in position on the ground work and scribed round the edges with a pointed tool.

*Inlaying. Fig. 1. Direct inlay. Fig. 2. Surface inlay. Fig. 3. Inlaid pattern in holly and ebony. Fig. 4. Mahogany tray ready for central inlay. Fig. 5. Sheraton ornament for tray. Fig. 6. Method of marking position for inlay. Fig. 7. Edge removed for a wide banding. Fig. 8. Use of cutting gauge for inlaying lines at edge.*

The ground is now cut away to a depth slightly less than the thickness of the inlay, to allow for cleaning off. This is done with chisels and gouges and must be as clean as possible, the bottom of the recess being perfectly flat and equidistant from the surface all over. In the larger portions this is better accomplished with a router.

The inlay must now be made perfectly flat on the underside; the best way to do this is with a toothing plane, which not only levels the work, but makes a series of fine scratches which enable the glue to hold better. It may then be glued in and cramped and left to set for as long as possible, and then cleaned off. If insufficient time is allowed in the setting, it will be found that the inlay will sink.

The same method is followed when it is desired to inlay a piece of marquetry in a solid ground, such, for example, as Fig. 4, which shows a mahogany tray the centre of which it is desired to inlay with a Sheraton ornament, as Fig. 5. These can be bought cut in the form of marquetry.

To begin, the two axes are marked on the oval, and the corresponding centre lines on the tray. These will give the exact position for the oval (Fig. 6). It is then proceeded with as before. It will be found that the marquetry has a piece of paper glued on one side; this must face upward so that the glue will grip the plain wooden side. Glue the inlay in position and heat a flat block of wood large enough to cover the inlay, and cramp this down on to the inlay with a piece of paper between to prevent the block from sticking to the work. The heat of the block will thus re-liquefy the glue and allow the inlay to be pressed right down.

**Bandings and Lines.** Bandings may be made by the worker, but they can be bought quite cheaply. They are made in great variety, some being shown in Fig. 15. For the inlaying of these a special tool is required known as a scratch. This is easily made by the worker and is of the form given in Fig. 16. It consists of a block of wood shaped as shown, cut in two and then screwed together again, so that the two pieces may be loosened at will. A piece of steel for the cutter is then filed to the width of the inlay to be used (a piece of an old saw blade will do) and inserted between the two parts of the scratch at the required distance from the shoulder, and the screws tightened. To use it the shoulder is kept tightly up against the edge of the work and worked up and down (Fig. 17). When working across the grain it will be found advisable to cut in the two sides of the groove with a cutting gauge or chisel to prevent the wood from splitting up.

For wide bandings to be put round the edge it will be found better to cut round with a cutting gauge and then remove the surplus, as in Fig. 7, with a bull-nose or shoulder plane; while for a line to be put at the edge, a gauge may be used on both edges (Fig. 8). The bandings are glued in and pressed well down with the back of a hammer (Fig. 18). In a rectangular shape the corners are mitred. When two lines cross, put the narrow one in first, and scratch the other across it when dry. To put a line round a circular or oval ground such as a mirror frame, the edge is gauged round to form the rebate for the line, as is shown in Fig. 8.

When glueing, put a screw in the inside of the frame and tie a piece of fine string to it and then put in the line, glueing a little way at a time and binding the string round as you proceed until the starting point is reached, when the line is cut off, as in Fig. 9. The joint in an oval should occur in the flattest part of the shape so that the line will not be so apt to spring out. The string, having been damped, will pull the line in tighter. It is then cleaned off in the usual way.

*Inlaying. Fig. 9. Method of binding in glued lines.*

When inlaying a line a little distance from a circular edge, a good plan is to use a gauge having two projections fastened to the fence, as in Fig. 10, to keep the gauge held rigidly in the correct position.

When a line or banding has to be inlaid in such a position that it is not possible to use a gauge or scratch from a parallel edge, as in Fig. 11, a straight-edge should be held down in a line with the required inlay, and the groove scratched out with a narrow chisel or bradawl the same width as the inlay, while for shaped inlays a template of the shape is cut, and this used as a fence against which the tool may be worked, or in the

event of the shape being a circular curve it is sometimes better to file one of the leg points of a pair of dividers for a cutter to the width of the groove and use these, the other leg acting as centre. This is only practicable when the shape is a quick one. It is sometimes necessary when glueing the line to steam it to render it sufficiently pliable to bend round a quick shape. In all cases of lines or bandings use the glue as hot as possible, work in a hot room and proceed with it quickly.

*Fig. 10. Gauge for use with a circular edge. Fig. 11. Method of using straight edge for diagonal line inlays.*

An example of inlay not used for a purely decorative purpose is in the case of a veneered surface, when an inlaid line is put across the grain at the end to prevent the veneer from being chipped off, as in Fig. 12; drawer fronts are often treated in this way, being liable to catch.

*Fig. 12. Drawer front with inlay to prevent veneer from chipping.*

*Fig. 13. Marking out pattern for surface inlay.*

**Applying an Inlaid Surface.** The other method of in-laying, i.e. that of applying the inlaid surface, is done as follows. After making the drawing on paper, the ground is prepared, planed perfectly true, and toothed. Now take the surface background and mark roughly the limits of the inlay, i.e. the extent of ground it will cover.

Next prepare the wood for the inlay the same thickness as the background, and with thin glue and with paper in between apply it to the background in a position to cover all the inlay. When dry, mark out the

design from the drawing with carbon paper (Fig 13 shows the two pieces marked out), and with a fine saw cut round the design, holding the saw tilted at a slight angle so as always to undercut the inlay, as in Fig 14. The tilt of the saw must be always in the direction of the inlay, so that when this is put in position a close joint will show. Having cut the pattern, the two thicknesses are separated, the paper removed from the underside of the inlay and the two portions tried together. They are then glued down on to the ground, cramped between two flat boards and allowed to set, and, when dry, cleaned up in the usual way.

Fig. 14. Showing angle of saw cut in making a surface inlay.

Inlaying. Fig. 15. Lines and bandings employed.

Inlaying. Fig. 16. Home-made scratch for making groove; the steel cutter is filed to the width of the inlay to be used.

Fig. 17. Making the groove in which the inlay fits.

Fig. 15 shows some lines and bandings used in

inlaying. A and B are lines usually made of either box or satinwood; C and D, of ebony or of a cheaper wood stained black to represent ebony. E is a combination of the two. F, G, H, and J are bandings made in various fancy woods, such as kingwood, rosewood, tulip wood, etc. The lines at the edges are not only decorative but strengthen the inlay, binding the whole together.

Fig. 18. Glueing in the inlay by pressing with the back of a hammer.

**INOCULATION.** The act of introducing a disease germ into the body through a breach of the skin or the mucous membrane is called inoculation. The microbe of tetanus may be inoculated; for example, through treading on a dirty nail or through a cut. Vaccination against smallpox is an instance of preventive inoculation, the virus of cow-pox being introduced through the scarification of the skin so that by passing through the milder disease a person may be protected against the more serious. Inoculation is performed by scarifying the skin and rubbing with virus, or, alternatively, by the use of a syringe. *See* Diphtheria; Vaccination.

**INQUEST.** In England an inquest or inquiry by a coroner, with or without a jury, may be held into the death of any person whose dead body is in the district, but no inquest is held as a rule if a medical man gives a certificate stating the cause of death. It is therefore employed in the case of death from violence and also in the case of sudden death when no doctor has been in attendance, and is intended to find out whether or not there has been anything like foul play. Instead of holding an inquest the coroner may now order a post-mortem examination to be made, and if he is satisfied with the report no inquest is necessary. In Scotland the above duties are discharged by the official known as the procurator-fiscal.

Before 1927 it was necessary for a coroner to have a jury to assist him in his inquiry. This is no longer obligatory, unless there is reason to suppose that the death is caused by murder, manslaughter or infanticide, or by a street accident, or that it took place in prison. The jury must number at least 7, but not

more than 11. *See* Death; Funeral.

**INSANITY.** The term insanity covers a great variety of mental disorders which differ in their causation, treatment and outlook for improvement or recovery. The following are the principal forms: manic-depressive insanity, which includes mania and melancholia; acute confusional insanity, a disorder that may follow exhaustion resulting from influenza and other diseases, surgical operations, child-birth, severe anaemia, and excessive mental or physical fatigue; paranoia, in which the patient suffers from systematized delusions; dementia, a general loss of mental capacity; general paralysis of the insane, the primary cause of which is syphilis; and epileptic insanity.

Heredity plays an important part in the causation of all forms of insanity, and other factors are infection with syphilis and addiction to alcohol. A large amount of mental disease is preventable. That due to heredity, however, could only be prevented by suitable marriage. Any person with a neuropathic inheritance should be a total abstainer. Public health measures, by diminishing disease generally, and educational and economic measures which raise the standard of comfort of the poorer classes and lessen the stress of their struggle for existence, will be beneficial.

Some insane persons can safely be kept at home, but when restraint and skilled nursing are needed the expense and worry involved usually makes institutional treatment necessary. This has the further advantage, however, that the routine of an institution generally has a tranquillising effect on a disordered mind. The legal procedure involved in putting an insane person under restraint in an asylum is dealt with under the heading *Lunatic. See* Delusion; Feeble-minded; Hysteria; Neurasthenia.

**INSECT:** In the Garden. The policy of the average gardener is to make an end of all insects he sees, prompted by his belief that they are his enemies. Such an attitude is to be explained only on the ground of ignorance. But no real gardener is justified in remaining ignorant of the forces that help or hinder him in his chosen work.

All the butterflies and moths pass through a caterpillar stage, and with few exceptions all caterpillars are plant-eaters. But all the butterflies and moths do not leave behind a batch of eggs from which the all-devouring caterpillars will issue. Out of more than 60 butterflies on the British list, only the large white and the small white are pests.

With the moths it is different; though some may have come from neighbouring woods and hedges, many of them may have developed in the garden at the expense of the plants.

All caterpillars found upon plants are there for purposes of plunder. The forward-tapering, somewhat flattened larva of the hover-fly may be mistaken for a kind of caterpillar, but the observation that should precede drastic action would show that it feeds exclusively on plant-lice (aphis) and is to be

encouraged. The grubs of the numerous species of sawfly are very like caterpillars; but any mistake in this direction does not matter, for these are all enemies. The larvae of the lady-bird beetles are often mistaken for plant-feeders of some sort, but the error is a disastrous one. They are sluggish creatures of slaty hue spotted with red, blue and black. Their sole food consists of plant-lice.

Any other beetles that may be seen upon foliage should be regarded with suspicion. They gnaw shot-holes in the leaf, not eating them from the edge as most caterpillars do. The large cockchafer and the smaller summer chafer are great delinquents in this matter, continuing the injuries they have inflicted during their long life as grubs underground. The beetles that live in the ground during all their stages may be regarded as valuable allies, for they prey upon foes the gardener may never see.

Dragon-flies, including the large falsely called horse-stingers, are to be welcomed, for their food consists of other insects. The legion of two-winged flies (diptera) are a very mixed lot and require nice discrimination. On the one hand they include the pernicious onion-fly, celery-fly, lettuce-fly, and crane-fly, or daddy longlegs; on the other hand, the helpful hover-flies, already mentioned, and a number of species whose grubs are internal feeders in caterpillars.

**Beneficial Insects.** The insects with four transparent wings (hymenoptera), including bees, wasps and ichneumon-wasps, are, with the exception of the sawflies, beneficial. Bees of all sorts, when they visit flowers for nectar and pollen, are also assisting in the production of fertile seeds by the transfer of some of the pollen; and wasps, though they attack overripe and damaged fruit in autumn, are engaged all the summer in destroying noxious insects for the nourishment of their helpless grubs. Over 1,200 British species of ichneumon-wasps carry out similar useful functions, though in a different way, laying their eggs in or on caterpillars and other insects that their grubs may flourish by consuming the internal substance of the gardener's foes.

Of opposite nature are the bugs (hemiptera) of all kinds, including plant-lice, froghoppers and scale-insects; being all sap-suckers, they are, as a tribe, noxious. Earwigs, though they damage certain flowers by gnawing the petals, also feed partially on insects.

The gardener who wishes to be sure as to the identity and the friendly or unfriendly nature of insects should keep in a pocket of his garden jacket two or three of the glass-bottomed boxes used by entomologists. In these he can imprison insects that are unknown to him, observe them closely and in detail, and arrive at a decision as to his attitude to that species. *See* Beetle; Moth, etc.

**INSECTICIDE.** Insecticides are fluids for destroying certain insect and other pests, and so protecting trees and plants. They may be divided into

two classes, one used against sucking and the other against biting insects.

Washes of the poison type act by poisoning the food of the insects, and are used for all the leaf-eating pests. Arsenate of lead in paste form is recommended, and the formula for making it is  $\frac{1}{4}$  lb. of lead arsenate paste to 5 gallons of water. The wash should be applied in a fine spray, the aim being to wet all the leaves without drenching them, so that when they have dried they will be covered uniformly with poison. Contact insecticides, which are sprayed on to their objective, kill insects, not by poisoning their food, but by contact with their bodies. To attain this, the washes should be applied with as much force as possible with a coarse spray. A wash containing nicotine is advised.

The formula for nicotine soap wash is  $\frac{3}{8}$  oz. of nicotine to  $\frac{1}{4}$  lb. of soap and 5 gal. of water. Both the water and the soap should be soft. If, however, the water is hard  $\frac{1}{2}$  lb. of soap should be used. Dissolve the soap in hot water, dilute it to the required strength, add the nicotine, and then stir it well. Hard soap can be used if soft cannot be obtained.

It should be noted that nicotine and lead arsenate are very deadly poisons. Lead arsenate should not be used where vegetables are grown underneath fruit trees, or on gooseberry bushes if the fruit is to be picked green. If nicotine is applied, a fortnight should be allowed to elapse before the vegetables or green fruit are gathered. Empty nicotine bottles must always be destroyed. *See* Apple; Currant Sawfly; Fruit; Gooseberry; Green Fly; Spraying; Syringe, etc.

**INSERTION: In Needlework.** An insertion is a strip of fancy stitching or lace used to join two pieces of material together, to add a false hem to a garment in an attractive way, or inset for pure decoration. Insertions are very charming when made at the hems of tablecloths, guest towels, pillow cases, lingerie, collars and cuffs and baby linen.

There are various lace stitches which can be successfully used for insertions. One of the most popular is twisted Russian stitch. This consists of diagonal stitches taken between the upper and lower hems, each stitch being twisted round the last one. Overcast or buttonholed plain bars can be used, ornamented with picots or left plain (*See* Embroidery), and if desired elaborate branched bars can be used if the insertion is to be fairly wide. For a broader insertion, make loose buttonhole stitches along each hem, and join the opposite rows of loops with twisted Russian stitch.

**Lace Insertions.** Charming lace and crochet insertions can be bought very inexpensively, ready to set into the material, or they can be made at home. Two examples, knitted and crocheted, are described and illustrated here.

**Knitted Insertion.** Using No. 20 ordinary crochet cotton, and No. 14 steel knitting needles, the knitted insertion works out about  $1\frac{1}{2}$  in. wide. With ordinary

knitting silk and No. 7 bone needles it would be  $3\frac{1}{2}$  in. wide.

*Insertion. Top, hand-knitted insertion.*

*Bottom, example of handmade crochet insertion.*

Cast on 15 stitches. Purl one row. 1st row: Slip 1, knit 1, make 1 (by passing the thread to the front of the needle, so that it passes over the latter when knitting the next stitch, and in the next row this thread is knitted), knit 2 together, knit 1, knit 2 together, make 1, knit 1, make 1, slip 1, knit 1, pass slip-stitch over, knit 2, make 1, knit 2 together, knit 1.

2nd row: Slip 1, knit 2, purl 9, knit 3. Every alternate row is worked in exactly the same way. 3rd row: Slip 1, knit 1, make 1, knit 2 together, knit 2 together, make 1, knit 3, make 1, slip 1, knit 1, pass slip-stitch over, knit 1, make 1, knit 2 together, knit 1. 5th row: Slip 1, knit 1, make 1, knit 3 together, make 1, knit 5, make 1, slip 1, knit 1, pass slip-stitch over, make 1, knit 2 together, knit 1.

7th row: Slip 1, knit 1, make 1, knit 2 together, knit 1, knit 2 together, make 1, knit 1, make 1, slip 1, knit 1, pass slip-stitch over, knit 2, make 1, knit 2 together, knit 1. 9th row: Slip 1, knit 1, make 1, knit 2 together twice, make 1, knit 3, make 1, slip 1, knit 1, pass slip-stitch over, knit 1, make 1, knit 2 together, knit 1. 11th row: Slip 1, knit 1, make 1, knit 2 together, knit 1, make 1, slip 1, knit 1, pass slip-stitch over, knit 1, knit 2 together, make 1, knit 2, make 1, knit 2 together, knit 1. 13th row: Slip 1, knit 1, make 1, knit 2 together, knit 2, make 1, slip 1, knit 2 together, pass slip-stitch over, make 1, knit 3, make 1, knit 2 together, knit 1. 15th row: Slip 1, knit 1, make 1, knit 2 together, make 1, slip 1, knit 1, pass slip-stitch over, knit 3, knit 2 together, make 1, knit 1, make 1, knit 2 together, knit 1. 17th row: Slip 1, knit 1, make 1, knit 2 together, knit 1, make 1, slip 1, knit 1, pass slip-stitch over, knit 1, knit 2 together, make 1, knit 2, make 1, knit 2 together, knit 1.

19th row: Slip 1, knit 1, make 1, knit 2 together, knit 2, make 1, slip 1, knit 2 together, pass slip-stitch over,

make 1, knit 3, make 1, knit 2 together, knit 1. 21st row: Slip 1, knit 1, make 1, knit 2 together, knit 8, make 1, knit 2 together, knit 1. 23rd row: Like the 21st row. 24th row: Like the 2nd row.

Repeat from 1st row for length required for the work.

**Crochet Insertion.** The example illustrated was worked with No. 26 ordinary crochet cotton and a No. 5 steel hook, and measures nearly 2 in. wide. Begin by making 45 chain stitches for the foundation. 1st row: 1 treble into the ninth chain from the hook, \* 2 chain, miss 2 chain, 1 treble in the next stitch, making a space; repeat from \* four more times, then 1 treble in each of the next three stitches, 6 spaces, 5 chain. Turn.

2nd row: 3 spaces (putting the first treble on the second treble from the hook), 6 treble, 3 spaces, 6 treble, 3 spaces, 5 chain. Turn. Turn each row with 5 chain throughout the pattern, and this will form the first space of following row.

3rd row: 3 spaces, 9 treble, 1 space, 9 treble, 3 spaces. 4th row: 4 spaces, 6 treble, 1 space, 6 treble, 4 spaces. 5th row: 6 spaces, 3 treble, 6 spaces. 6th row: 4 spaces, 6 treble, 1 space, 6 treble, 4 spaces.

7th row: 3 spaces, 9 treble, 1 space, 9 treble, 3 spaces. 8th row: 3 spaces, 6 treble, 3 spaces, 6 treble, 3 spaces. 9th row: 6 spaces, 3 treble, 6 spaces. Repeat from the 2nd row for the length of insertion required.

**Embroidery Stitch Insertion.** The simplest form of insertion is a band of embroidery stitches. To prepare the edges of the material, turn under twice the raw edges of the pieces to be joined. Tack the two pieces of material, along the turnings, on to a piece of stout paper, leaving a space between as wide as the required insertion. Then join the two hems by a lace stitch. *See* Crochet; Knitting; Lace.

**INSOMNIA.** Sleeplessness may arise from any of the following minor causes: cold feet, bad ventilation of bedroom; uncomfortable bed, too heavy, too warm, or insufficient bed-clothing, a hot room; hunger, a full stomach, too high or too low a pillow, noise, too much light in the room, tea or coffee taken late in the evening; mental or physical overwork and exhaustion, want of exercise, worry, financial anxiety, domestic troubles; retiring at irregular hours, and from many other small errors which can be corrected.

Habitual insomnia may result from a preoccupation of the mind with the worries and chagrins of the daily life; but it may result also from repressed experiences, whether or not these assert themselves in dreams, arousing the patient to uneasy wakefulness. In these cases psycho-therapy may be of service.

In relief of the condition the following precautions should be observed:

See that the room is well ventilated. It should have a fireplace or an efficient ventilator. The window should be wide open, or the top sash lowered 8 to 12 in. The best temperature for a bedroom is about 60°.

Let the bedclothes be light, but sufficiently warm. For most people a pillow 3 in. high is satisfactory. It is

often a good plan to raise the head of the bed about 2 in. by placing blocks of wood under the legs at that end. This tends to prevent any undue filling of the brain vessels with blood. Never go to bed with cold feet.

As a rule it is well not to eat a substantial meal later than three or four hours before bedtime. On the other hand, the want of food may banish sleep. In this case a glass of warm milk with a few biscuits should be taken at bedtime. Sometimes when one wakes up and cannot get off to sleep again, munching a biscuit proves effective. Strong tea or coffee taken late may prevent sleep.

It is best to cease both mental or physical work at least an hour before bedtime. A tepid bath just before getting into bed is another good remedy, or a hot foot-bath may be effective. A brisk walk is an excellent producer of sleep, even when one is already tired. Massage is one of the best remedies. Sometimes the change from a hard to a soft bed, or vice versa, will effect a cure. Go to bed at regular hours, and just before getting into bed sponge the face with tepid water, and then brush the hair for a few moments. Repeating poetry, counting numbers, picturing peaceful scenes, and many other such devices sometimes succeed in mild cases; and autosuggestion may be useful.

Drugs should only be used when other measures fail, especially in habitual insomnia, and then should never be used except when under the care of a doctor, or a drug habit is formed and difficult to break. *See* Sleep.

**INSULATOR.** This is a substance which offers an extremely high resistance to the passage of an electric current. Insulators are used to prevent the flow of electric currents between conductors, or between a conductor and earth. Such substances as glass, ebonite, bakelite, mica, glazed porcelain, vulcanite, etc., are good insulators.

**Insulin.** *See* Diabetes.

## **INSURANCE: LIFE, FIRE AND ACCIDENT Protection for Property and Provision for Death**

This article deals with the whole subject of Insurance as far as it affects the householder. Insurance against ill-health, the national scheme, is explained in the succeeding article. *See* Burglar Alarm; Fire; Fire Alarm; Motoring.

Insurance is a system whereby for a consideration, usually the premium, an insured person has made good for him, up to the limit of his insurance, loss or damage befalling him through an event insured against. Insurances are usually carried by companies, but sometimes by individual underwriters, and occasionally by mutual associations. The operations of those carrying on insurance are controlled by various Acts of Parliament, so that the interests of the public are fully protected in every way.

**Kinds of Policy.** Practically all the offices now transact all classes of business, varying according as the policy is a fire policy, a life policy, a marine policy, or an accident policy; and, as the accident section of the business includes all the miscellaneous classes of business, the accident policy conditions vary according to the class of risk insured. Policy conditions are in the main an epitome of common law based on common sense.

Those who are insured should appreciate two of the principles lying behind these considerations, viz., good faith and indemnity. Good faith requires that nothing material to the contract into which an insured may enter shall be withheld from his insurer, and if the insurer can prove that something material to him to know has not been disclosed, the policy issued by him is void.

A policy of insurance is a contract of indemnity, i.e. an insured is only indemnified against any loss or damage sustained by him through the happening of the event he has insured against, but no more. If he were to secure more, he would convert his loss into profit, and this by many legal decisions has been held to be contrary to public policy. Personal accident policies and life policies, however, are not strict contracts of indemnity, the sums payable under them being determined by the amount of the insurance, and not, as in contracts of indemnity, by the loss, but always within the limit of the insurance. Insurable interest is also necessary. Possession does not of itself constitute insurable interest, though the householder's comprehensive policy, including, as it does, the property of himself and his household (including his servants), might suggest this.

Practically every contingency to which human life and property are subject may be covered by insurance. The following, apart from the more usual types of insurance, make some appeal to the householder; key insurance, live stock insurance (for other than fire or lightning damage), plate glass insurance, public liability insurance, baggage insurance (a form of marine insurance), and some of these are included in the householder's comprehensive policy described below.

**A Comprehensive Policy.** Originally combined policies for the household were confined to the risks of fire and burglary. Later, when accidents to servants were included under the Workmen's Compensation Acts, a householder's liability in this respect was added to this combined cover, other miscellaneous risks being also included. Now a householder can obtain what is called a comprehensive or "all-in" policy, covering the majority of the risks and liabilities to which he is exposed.

A perusal of the prospectus of any reputable insurance company will give full details of the cover granted by such a form of policy. The policy may cover building or contents or both, and the rates charged are, as regards buildings if all the risks specified are covered, 2s. 3d per cent, if certain risks (earthquake, storm and tempest and others) are excluded, 1s. 9d. per cent, or if the cover is limited to fire, explosion, lightning or

thunderbolt, 1s. 6d. per cent. Contents policies may be obtained at 5s. per cent in respect of private houses, flats, residential chambers and private dwellings forming part of business premises, but for the last an increased premium may be required. From the contents insurance are excluded motor vehicles and accessories, livestock other than horses, and such things as deeds, stamps, manuscripts, etc., unless stated in the policy.

A condition of the policy is that the full value of the property shall be insured, and the insured is required to sign a declaration which he agrees shall be the basis of the contract; if the sum insured is less than the value, his declaration is false, and in this case the policy can be made void.

**Proving a Claim.** An insurance of this description has for the householder, besides its inclusive cover, the added attraction of one policy, one premium, one renewal. In the event of a loss arising, an insured person should promptly advise his insurance office, and they will tell him what to do to prove his claim. In this, as in the effecting of the insurance, the essential thing is that he should observe good faith with his insurance office. In effecting an ordinary fire policy, however, covering fire only, an insured is not required to make a declaration as to value, so that it is possible for him to recover any loss up to the amount insured.

**Life Assurance.** Policies of life assurance differ from other insurance policies in that the latter are in respect to events which may happen, whereas life assurance policies have relation to an inevitable event—death—the common lot. There being no escape from this, the prudent man will provide against it, and this for the man of limited means can best be done by means of life assurance.

In the case of ordinary savings, all that is secured at any time is the actual capital represented by these savings, and any interest accrued, but in the case of life assurance one premium secures a capital sum of from 20 to 40 times the amount of the premium, according to the age at which the assurance is effected, this capital being available at the death of the assured for the benefit of his dependents. Security is thus obtained through the working of two principles: the average duration of a number of lives, ascertained by mortality tables, and the combination of insured lives, so that by regular payments of adequate premiums there is formed the fund from which to provide the capital sums assured as these will necessarily fall due.

**Two Kinds of Policy.** The two most usual forms of life assurance are whole life assurance and endowment assurance; the former provides for the payment of the sum assured at death, and the latter provides for the payment of this sum at a given age, or at death, if this takes place earlier. In the early years of life assurance the latter form of policy was rare or unknown, but to-

day, for every whole life policy issued, two endowment policies are issued. The premium on the whole life policy may be paid annually, half-yearly, quarterly, or in some cases monthly. If it is imperative that the premiums in early years shall be as low as possible, half premiums may be paid for the first five years; or if the policy is with profits the ordinary premium may be reduced by discounting the bonuses.

The premiums on an endowment assurance may also be paid by yearly or other instalments as agreed, and it may be so arranged that for the first five years the premiums are on the scale of a whole life policy, with the option of having the assurance converted into an endowment assurance after five years on payment of the required premiums.

Premiums may also be arranged to be paid for a limited term of years in respect of whole life policies, these policies, if with profits, still sharing in profits, after all the premiums are paid. Such policies carry special privileges as regards surrender values and paid-up values, each premium securing a proportion of the original assurance.

Thus, if the premiums are limited to 20 payments and the assured for any reason does not wish to continue the assurance, assuming he has paid, say, five premiums, he can obtain a paid-up policy for one-fourth the original assurance, and to this is added any bonuses which have accrued. The surrender values of such policies are similarly higher, and the same is true of endowment assurance policies also, both as regards paid-up values and surrender values.

Term assurances may be taken out to meet special circumstances which may terminate after a certain number of years, and such policies if for a sufficiently long term, carry with them the right of having an ordinary assurance, with appropriate premiums for the age, without further medical examination.

#### Relief from Medical Examination

The provision relieving from medical examination is of importance, considering that health itself is uncertain. Other assurances are double endowments, securing to an assured a sum double the sum proposed if the life attains the age proposed; if death takes place earlier than the age proposed only the sum originally proposed being paid. Leasehold insurance is of importance to the householder having only a leasehold property, enabling him for a comparatively small premium to provide the capital sum required for the renewal of his lease; pure endowments are endowments only, i.e. payable only if the age for payment is reached. Usually there is a provision for the return of the premiums if death takes place earlier. Children's endowments are usually of this type.

Since the Great War the volume of life assurance business transacted has notably increased, but even now it is probably not on a scale adequate to the needs of the individual householder. So often at the death of the breadwinner the only provision is a life policy, but this, unfortunately, quite inadequate. It has been suggested that the life assurance policy taken out should amount to, say, five times the annual income.

Some of the newer types of policy endeavour to overcome this by an income plan policy, which can be arranged whether the assurance is whole life or endowment. It provides, in the event of death within 20 years of the date of the policy, for the payment of a capital sum, plus an income of one-fifth of the capital sum for the balance of the 20 years. Schemes in connexion with the operations of building societies and staff assurance and pensions schemes have helped to swell the total business transacted. There has also been a notable advance in recent years in the bonuses declared by life offices, probably mainly because of the increased rate obtained by offices on their investments. Many intending insurers are still attracted to the without profits policy because of the immediate maximum cover secured for the premium they may be paying; for many it is still worth while to take out a with profits policy.

The rebate for income tax increases the value of a life assurance policy, and this is obtainable in respect of premiums on policies on a man's own life or on the life of his wife. The tax payable is reduced by a sum representing tax at half the standard rate or less, up to one-sixth of the total income, but if premiums exceed 7 per cent of the sum assured there is no relief in respect of the excess.

**Benefits for Children.** Other assurances of special benefit for children are educational assurance and deferred assurance. The former may be on the father's own life and provide for payment of a certain sum in the later school years of the children, and it can be arranged that if the father dies earlier the premiums cease. The most recent form of policy combines, with educational benefits for children and family protection, income on retirement and remission of premiums during illness. Children's deferred assurances provide, for comparatively low premiums, policies which may be whole life policies or endowment policies available for the child upon attaining his or her majority.

Proof of age should be submitted at the time a policy is taken out; then all that is necessary to secure payment of the sum assured is the proofs. The proofs of death usually required are registrar's certificate of death, certificate of death signed by the doctor who attended in the last illness, and a certificate of identity from some intimate friend.

A number of policies are taken out for the express purpose of paying death duties, the sum assured being paid over to the Inland Revenue authorities before the issue of probate. This arrangement makes it unnecessary to realize for the purpose of paying death duties any of the property left by the deceased.

**Accident and Sickness Assurance.** There are three classes of policies: one combined to personal accident only, one combining personal accident with certain specified diseases, originally confined to such as are notifiable to the medical officer of health but now extended to about 60 in all, and one combining

personal accident with all sickness or disease. Sickness means any illness requiring the attendance of a doctor. There are two systems of policy in respect of sickness insurance: one an annual contract under which the premiums are the same irrespective of the age of the insured, though policies will not usually be issued to persons over 55; and the other a permanent contract with premiums varying according to age at entry and computed on an actuarial basis. Certain risks, such as motor-cycling, etc., are only covered by special agreement; the policies, except as stated, are annual contracts and terminable by the office on formal notice, and a pro rata return of premium for any part of the year of insurance that is not expired.

Risks from suicide, intoxication, war, invasion, riot and civil commotion, military or naval service, racing or aviation, are excluded; also in the case of a disease and sickness contract, venereal diseases, drug taking and insanity. Medical expenses are payable under the disease and sickness contract, and there is a system of cumulative bonuses increasing the original sum insured by 5 per cent at each renewal up to 50 per cent should a policy remain continuously in force.

Claims should be notified within 14 or 21 days. Women are eligible for this class of insurance if engaged in some wage-earning profession or occupation, at higher rates than are charged for men, and ordinarily such policies exclude risks arising in connexion with child-bearing.

**Property Owner's Insurance.** Property owner's insurance is of importance to house-owners or householders because either the owner or occupier of premises may be liable for any injury or loss caused through defects in the premises to any persons coming lawfully thereon. In addition a statutory liability is imposed on houseowners under the Housing Act 1925 to maintain their premises reasonably fit for human habitation. The Act applies only to small houses. Policies are issued to cover claims by the public or by tenants in respect of:

(a) Personal injury or property damage caused by defects in the buildings insured.

(b) Illnesses arising from any such causes. Private houses may be insured for an indemnity of £1,000 at a premium of 6d. a house, though a minimum premium of 2s. per policy may be required.

This particular form of insurance is included in the householder's comprehensive policy as householder's comprehensive policy as part of the general cover.

## **INSURANCE: THE NATIONAL HEALTH SCHEME**

### **Payments and Benefits that Affect Millions of British Workers**

This subject is of interest both to the employer and employed. Other articles that deal in one way or another with their relations are Employers' Liability; Servant. See also Accidents and the entry on Insurance against unemployment that follows.

In Great Britain and Northern Ireland since 1911 the

great majority of the workers have been insured by the State against sickness, and since 1926 this scheme has been linked with the one giving pensions to insured persons and their wives on reaching the age of 65, instead of waiting until they are 70. The scheme also provides pensions for the widows of insured persons and allowances for fatherless and orphaned children. All these benefits are covered by a single weekly payment.

**The Exceptions.** In general all workers between the ages of 16 and 65 must be insured. Certain classes are excepted, the chief being all non-manual workers who are in receipt of a salary of over £250 a year. Manual workers, whatever their remuneration, must be insured, unless they belong to certain excepted employments. Excepted employment, in this sense, is service under the Crown, a public authority; or a railway or other statutory company that provides benefits for its employees that are not less than those given under the national scheme. A certificate of exemption can be obtained by a non-manual worker who has a private income or is otherwise independent. In these cases, however, the employer must pay his share of the weekly contribution. Otherwise he would be under a temptation to give preference to persons who can obtain exemption from the insurance payments. Persons who need not be compulsorily insured can insure as voluntary contributors. Such pay a smaller weekly premium, if they are not entitled to medical benefit.

**Contributions.** The ordinary rate, of health and pensions contribution is 1s. 6d. a week for men, and 1s. 2d. a week for women. Persons who are employed while they are over the school leaving age, but under 16, must now be insured for medical benefit. The contribution is paid by affixing a health and pensions insurance stamp to a contribution card. Contributions at the above rates cease to be payable when the insured person reaches the age of 65. Where, however, a person is insurably employed after the age of 65, a weekly contribution of 10d. (man) or 7d. (woman) is payable by the employer.

In the case of an employed contributor, a contribution is payable for every contribution week, i.e. from Monday to the following Sunday during the whole or any part of which the contributor is employed

or for which he receives wages, but no contribution is required to be paid for any week during which the member is prevented by sickness from working, whether he receives wages or not.

The whole of the contribution is payable in the first instance by the employer, and must be paid by stamping a card at or before the time of payment of wages for the week for which the contribution is due. The employer is then entitled to recover by deduction from the wages the employee's share of the contributions so paid. The employee's share is ordinarily 10d. in the case of men, and 7d. in the case

of women, but in certain cases of low wage earners the employee's share is less, as explained on the contribution card. No part of the contributions payable for employed persons over 65 is recoverable from the employee. An employed contributor is entitled to be excused arrears for weeks in which he was available for, but unable to obtain, employment on producing evidence of his inability.

**The Benefits.** The ordinary benefits to which insured persons are entitled in return for contributions in respect of health insurance are— medical, sickness, disablement and maternity.

Medical benefit consists of the provision of medical attendance and treatment, including treatment and attendance for tuberculosis and the provision of proper and sufficient medicines and such medical and surgical appliances (and chemical reagents) as are named in the regulations made by the Minister of Health. It does not include medical attendance or treatment in respect of a confinement, which is the subject of a separate benefit.

Sickness benefit means periodical payments during incapacity for work caused by some specific disease or bodily or mental disablement of which notice has been given, commencing ordinarily on the fourth day of such incapacity and continuing for a period or periods not exceeding 26 weeks in all. Disablement benefit is a continuation of the periodical payments at a lower rate in respect of incapacity after the period of sickness benefit has been exhausted. The right to sickness and disablement benefits ceases when an insured person reaches the age of 65, but, subject to the necessary conditions having been satisfied, a contributory old age pension then becomes payable.

The ordinary rates of sickness benefit are 15s. a week for men and 12s. for women (10s. if married), but until a person has been insured for 104 weeks and 104 weekly contributions have been paid sickness benefit is payable at the reduced rates of 9s. for men and 7s. 6d. for women. The normal rate of disablement benefit is 7s. 6d. a week for men and 6s. for women (5s. if married). All these rates are subject to reduction when the member is in arrears with his weekly payments.

Maternity benefit consists of the payment of a sum of 40s. on the confinement of the wife (or, in the case of a posthumous child, of the widow) of an insured man, or of a woman (whether married or unmarried) who is herself insured. The benefit is paid by the approved society concerned. If a woman is herself insured, she is entitled to maternity benefit from her society in respect of her own insurance, and in the case of a married woman this is additional to any maternity benefit payable by her husband's society in respect of his insurance.

Sickness, disablement, or maternity benefit is not payable to any person in respect of a period when such person is an inmate of a hospital or similar institution supported by a charity or by voluntary subscriptions or out of public funds; but it can be devoted to the relief of his dependents or to defraying the expenses of the hospital or accumulated until he is discharged.

**Married Women.** An insured woman who marries

is required to give notice of her marriage to her society within eight weeks thereafter, and any woman who fails to comply with this requirement is liable to a penalty. If owing to the failure of a woman member to notify her society of her marriage more sickness benefit is paid to her than she is properly entitled to receive, the society is entitled to deduct the excess from any benefits which may subsequently be payable to her.

An insured woman who marries and who, immediately before her marriage, had already ceased all work for eight consecutive weeks, or who completes that number of weeks without working within the year immediately following her marriage, comes under special provisions as to health insurance benefits on her marriage or on completion of the eight weeks without working (whichever first occurs). In reckoning this period of eight weeks no account is taken of weeks of sickness of which the society is notified at the proper time, or of weeks during which the woman shows to the satisfaction of the society that she was available for, but unable to obtain, employment.

**The Insurance Card.** Every insured person is required to obtain a contribution card from his society or from a post office, and his employer can demand its production at any time. It must be delivered to the employer on the commencement of an employment and whenever he may reasonably require it for the purpose of paying contributions, or for production to an inspector or to any other authorized person.

There are two methods of arranging for the custody of the card during its currency. The first is for the employer and worker to agree that the employer shall keep the card, in which case he is responsible for its safety; he must stamp it regularly at the proper times and must return it to the worker upon the termination of the employment, or, if the worker leaves without notice, within 14 days; upon the expiration of the period of currency of the card or within six days thereafter; and where the worker at any time so requests within 48 hours after the receipt of the request.

The other way is for the worker to keep the card, and this must be done unless the employer and worker agree that the employer shall keep it. When the worker keeps his card the employer must, on each occasion of stamping, return it to him as soon as he has stamped it. On the death of a worker whose card is then in the hands of his employer, the card should be forwarded to the insurance department of the Ministry of Health as soon as possible.

**Joining a Society.** To obtain the full advantages of insurance it is necessary to join an approved society. An insured person can join a society at any time. A list of approved societies, giving the addresses of their secretaries, may be seen at the office of the local insurance committee, or at any employment exchange, or district office of the Ministry of Health, Insurance Department.

To join an approved society, the first step is to ask the secretary, or agent, of the society selected for a form of application for membership. After this is filled up and sent in, the applicant should receive within a reasonable time a notification from the society that he has been accepted or rejected, as the case may be, and he should make further inquiry if he does not receive notification within one month after application. An insured person who does not join an approved society within a certain time becomes a deposit contributor.

At the end of every half year an insured person must send up his contribution card to his society, or, if he has not joined a society, to the Ministry of Health, Insurance Department, or to the Welsh Board of Health, according to the instructions printed on the card. No credit can be given for the contributions until the card is received by the society or the Insurance Department.

**INSURANCE: Against Unemployment.** The national scheme for insuring persons against unemployment was introduced in Great Britain in 1911. At first it was confined to certain specified classes of workers, but in 1916 many munition workers were brought in. In 1920 there was a large extension, and the scheme now applies to all employees over the school-leaving age, except non-manual workers who receive over £250 a year, and certain other classes.

**Exempted Classes.** Apart from these non-manual workers the chief classes of persons who need not be insured under this scheme are agricultural labourers and domestic servants. Employees of local authorities, of railways and other public utility undertakings, and also persons with rights under statutory superannuation schemes, are exempt if the Minister of Labour grants a certificate. Other industries can set up insurance schemes of their own, and if the minister thinks these are satisfactory the employees therein can obtain exemption from the national scheme. To be satisfactory these schemes must give benefits at least equal to those of the national scheme.

**Weekly Contributions.** The contributions to this scheme are paid in the same way as contributions to the National Health Insurance scheme. Every week the employer must stamp a card for each employee insured. Part of the cost of this stamp falls on himself, but part he can deduct from the wages of the employee.

Contributions cease to be payable when the employee reaches the age of 65, as he or she is then qualified for an old age pension.

There are also allowances for dependents— 10s. for an adult (agriculture 7s.) and 3s. for a child. No contributions are required during periods of unemployment.

To obtain the benefit the unemployed person must prove: (1) That no fewer than 30 contributions have been paid in respect of the two years immediately preceding the date on which application is made. (2) That he or she has made application in the prescribed manner, and proves that since the date of the

application he has been continuously unemployed. (3) That he or she is capable of and available for work. (4) That, if so required, he or she has duly attended an approved course of instruction. The Act of 1930 repealed a condition in the 1924 Act, "that the applicant is genuinely seeking work, but unable to obtain suitable employment."

The weekly contributions are :

	Agriculture		Other Employment	
	Em- ployee	Em- ployer	Em- ployee	Em- ployer
	d.	d.	d.	d.
Men (21 to 65)	4	4	9	9
Women (21 to 65)	3½	3½	8	8
Young Men (18 to 21)	3½	3½	8	8
Young Women (18 to 21)	3	3	7	7
Boys (16 to 18)	2	2	5	5
Girls (16 to 18)	1½	1½	4½	4½
Boys (14 to 16)	1½	1½	2	2
Girls (14 to 16)	1	1	2	2
Men (65 or over)	—	4	—	9
Women (65 or over)	—	3½	—	8

#### Rates of Benefit.

	Agriculture		Other Employment	
	s.	d.	s.	d.
Men	14	0 a week	17	0 a week
Women	12	6	15	0
Young Men (18 to 21)	10	6	14	0
Young Women (18 to 21)	9	6	12	0
Boys (17 to 18)	6	0	9	0
Girls (17 to 18)	5	0	7	6
Boys (under 17)	4	0	6	0
Girls (under 17)	3	6	5	0

**Disqualifications.** A claimant is disqualified for receiving benefit if it is proved by an officer of the Ministry of Labour; (1) that he or she has, without good cause, refused or failed to apply for or refused to accept a suitable situation notified to him or her as vacant or about to become vacant; or, (2) that the claimant has, without good cause, refused or failed to carry out any written directions given him or her, with a view to assisting him to find suitable employment.

A worker is disqualified if he or she is unemployed owing to a stoppage of work which is due to a trade dispute, or if he or she has left his work through misconduct or without just cause. He or she is disqualified, too, if the inmate of a prison or workhouse, or if in receipt of an allowance under the health insurance scheme.

The benefits are paid out at the employment exchanges, or, if the insured prefers, through a trade union. The officials of the exchanges are responsible

for verifying the claims made. Disputes are settled by courts of referees. Both employers and employees have representatives on these courts and the chairmen are appointed by the Ministry of Labour.

**INTARSIA.** This is a way of inlaying wood which is now practically identical with marquetry. In its origin intarsia was the inlaying of one or more colours upon a lighter or darker ground, while marquetry proper is composed of pieces of thin wood or other material of equal thickness laid down upon a matrix and fastened with glue. *See* Inlaying; Marquetry; Mosaic.

**INTENSIFIER: In Photography.** When a negative, whether on glass or on a film, is too thin to give a satisfactory print, it may be subjected to a process of intensification whereby, in suitable cases, a negative which gave a flat print with poor detail may be made to give a quite satisfactory silver print. The amateur, however, should be extremely cautious in using any of the intensification processes detailed below, particularly if the negative is one which is valued.

The mere re-wetting of a negative is frequently attended with risk of stain or other damage. Under the best conditions some intensifiers, particularly those containing mercury, are liable to attack the gelatine, causing holes or reticulation, i.e. a series of wavy cracks in the gelatine of the negative. They also shorten the life of the negative.

Every effort, therefore, should be made to obtain satisfactory prints before resorting to intensification. If it is decided that a negative must be intensified, first make the best print that can be obtained on vigorous gaslight paper to keep in reserve.

It is useless to attempt to improve the printing strength of a negative which gives flat prints because it is fogged; the intensifier will simply increase the fog and make the result worse. If the negative is free from fog the edges which have been held in the dark slide will be seen to be perfectly clear. Make certain that the plate or film has been thoroughly fixed and properly washed; a trace of hypo left in the negative is almost bound to cause irregular stains after intensifying. See that the surface of the negative is free from smears, stains, or a chalky appearance, the latter indicating insufficient washing.

One of the safest processes is the following: The negative is first placed in a solution of 20 gr. of alum to 1 oz. of water to harden and clear it, leaving it in the solution for about ½ hour. It is then washed and placed in a solution made by dissolving 30 gr. of potassium bichromate in 3 oz. of water and adding 1 dram of hydrochloric acid.

The hydrochloric acid should be the pure acid obtained from the chemist, and not spirits of salt; 60 drops can be counted out if a dram cannot be measured. The negative will quickly become white, and the action should be allowed to continue until the bleaching is complete; it is then washed until the whole of the yellow stain is removed, which will take anything

up to an hour.

When it has been thoroughly washed the negative is re-developed in a non-staining developer, such as amidol or metol-hydro-quinone. When it will darken no more, wash well and dry. This intensifier is best suited to cases where the negative has been properly exposed but is under-developed, i.e. it is clear and bright, but thin. If the amount of intensification is insufficient, the process can be repeated, omitting the alum bath.

For a negative that is thin through underexposure and has not been seriously overdeveloped, uranium intensifier will give good results, provided the negative is absolutely free from hypo. The solutions are:

	<b>A</b>	
Uranium nitrate		50 gr.
Water to		5 oz.

	<b>B</b>	
Potassium ferricyanide		50 gr.
Water to		5 oz.

Mix 1 oz. each of A and B, and add 1 dram of acetic acid. After intensification wash in several changes of water (not running water) until all stain is removed.

For a plate that is over-exposed but not over-developed, i.e. it is thin but has a veiled and flat appearance, the mercury and ammonia intensifier may improve matters. It is liable to cause pinholes and discoloration after a time; as explained above, it should be used with caution. The bleaching solution is made up of:

Mercuric chloride (corrosive sublimate)	50 gr.
Hydrochloric acid	25 min.
Water to	5 oz.

The hydrochloric acid is dropped on the powdered mercuric chloride, and the water then added.

*Note that the solution is extremely poisonous.*

The negative, being soaked as before in clean water, is placed in the above solution and the dish rocked until the back of the plate appears quite white. Wash thoroughly in running water for about ½ hour, and then blacken in the following solution:

Ammonia (strength •880)	20min.
Water to	1 oz.

It may also be blackened in hydroquinone, pyro-ammonia, or ferrous oxalate developer. *See* Developing; Fixing; Hypo; Washing.

**INTERFERENCE.** In a wireless receiver this is the interruption caused by unwanted signals, e.g. undesired broadcast transmissions, atmospherics, induction from electrical machinery, etc., on the wavelength to which the set is tuned. *See* Selectivity.

**INTEREST.** Interest is money paid for the use of money. It is calculated at so much per cent, i.e. per hundred, and varies according to the standing of the borrower, the state of the money market, and other matters.

As it is occasionally necessary to calculate interest in household matters—for instance, when a house has been bought or built by the aid of a mortgage—the following method may be found useful: Divide the amount of the loan by 100 and multiply the answer by the rate of interest. Thus, if a man borrows on his house £450 at  $3\frac{1}{2}$  per cent., he should divide £450 by 100, i.e.  $4\frac{1}{2}$ , and multiply the  $4\frac{1}{2}$  by  $3\frac{1}{2}$ , i.e. the annual interest will be  $15\frac{3}{4}$ , i.e. £15 15s. It is well to remember that 5 per cent is exactly a shilling in the £, and  $2\frac{1}{2}$  per cent is sixpence.

Interest is usually paid half-yearly or quarterly, and the borrower is usually entitled to deduct income tax from the amount he pays. Income tax, however, is not deducted from the interest on bank overdrafts, but the amount paid can be deducted from the income when the return is sent in. Interest on these overdrafts is charged quarterly. *See* Banking; Building Society; Mortgage.

### INTERNAL COMBUSTION ENGINE.

There is an essential difference in the working of the internal as compared with the external combustion engine. With the latter, the fuel may be consumed away from the engine, which is the actual power producer. In the steam engine, for instance, fuel is consumed under the boiler, thus raising the water to a sufficient heat to give off the steam, which is conveyed to the cylinders.

With the internal combustion engine the conditions are entirely different. The fuel is gaseous, or is rendered so by vaporisation, and is burned in the engine. We may take the petrol engine as the type. Through the medium of the carburettor the fuel is drawn into the cylinder in a semi-liquid form, composed of a mixture of air and sprayed petrol. This is turned into a highly explosive petrol gas as it enters the engine, and is exploded through the medium of the high tension spark that is caused to jump the points of the sparking plug at precisely the right moment.

Fig. 1 illustrates the Otto, or four-stroke cycle of operations. The diagram shows the four strokes of the piston that go to produce one power impulse, namely, induction, compression, explosion or power stroke, and exhaust. As the piston has to descend and ascend during one complete revolution of the crankshaft, two complete revolutions of the crank go to make one cycle of operations. No matter whether the engine has one or a dozen cylinders, the cycle of operations will be the same for each; the only difference is the firing-periods.

In the cycle of operations the chief factor is the valves, two of which are employed, an inlet and exhaust valve, for each cylinder of the engine. The inlet opens at the commencement of the induction stroke and closes at the end; the exhaust valve remains on its seating. Both valves remain closed during compression and the firing or power stroke. Finally the exhaust valve opens on the

exhaust stroke, the inlet valve remaining on its seating; at the end of the exhaust stroke the inlet valve again opens, and so the operation goes on. The valves are operated by the camshaft. Ignition is carried out usually by a high tension magneto, driven at crankshaft speed, or by a coil and accumulator.

*Internal Combustion Engine. Fig. 1. Diagrammatic drawing showing the Otto or four-stroke cycle.*

**Two-Stroke Cycle.** The difference between the two-stroke engine and the four-stroke is that the former has one power stroke at every downward stroke of the piston, and the latter at every alternate down stroke. There are three main working parts, the piston, connecting rod, and crankshaft, no valves, timing gears, camshaft, and tappets being required. The half-compression valve or decompressor shown in the diagram is provided to facilitate starting the engine.

The cycle of operations is shown in Fig. 2. The initial induction and compression of the fresh charge takes place below the piston and in the crankcase. There are four ports positioned in the cylinder walls and controlled by the movement of the piston, the sequence of operations being as follows:

The piston rises and creates a partial vacuum in the crankcase. On rising further, the inlet port is uncovered, thus allowing the fresh charge to enter, assisted by the vacuum created. On the completion of the up stroke the piston descends and compresses the charge in the crankcase, and just before the stroke is completed, uncovers the transfer ports, allowing the compressed charge to pass via these to the top of the piston.

After the piston has risen a little way the transfer ports are closed, and the further rise of the piston

compresses the charge that is now on top of the piston in readiness for the explosion to take place immediately the piston commences the down stroke. During the down stroke the same cycle of operations is going on below the piston in readiness for the opening of the transfer ports. This cycle is common to all two-stroke engines.

Fig. 2. A, induction and compression; B, transfer to cylinder; C, explosion; D, exhaust.

As the fresh gases enter the cylinder when the burnt gases are passing out through the exhaust ports, a certain proportion of the fresh gas is bound to mix with

and pass out with the exhaust residue. This fault is guarded against as far as possible by the provision of a baffle cast on the piston head that tends to deflect the fresh gas to the top of the cylinder, thus keeping it for as long as practicable from coming into contact with the exhaust. Figs. 3 and 4 show a two-stroke stationary engine. See Big-End; Camshaft; Carburetter; Crankshaft; Lubrication; Motor Car; Motor Cycle, etc.

**INTESTACY.** An intestate is a person who dies without having made a valid will disposing of all his property. The property of an intestate is used first in payment of the funeral and other expenses and debts, and the residue is distributed in accordance with certain rules. In English law no distinction is now made between real and personal property. If the intestate leaves a husband or wife he or she takes all the personal chattels of the intestate—i.e. such things as furniture, silver, jewelry, motor cars and the ordinary contents of the home, and in addition a sum of £1,000 absolutely. After this payment has been made any residue left over will, if the intestate has left no descendants, be held in trust for the husband or wife for life—i.e. he or she will receive the interest on the money, but not the capital sum.

If there are descendants the husband or wife will get a life interest in half only of this residue and the descendants will take the whole residue subject to that life interest upon what are called the statutory trusts. That means that the children will divide the property equally, each becoming entitled to his or her share on attaining the age of 21 or marrying before that age. If a child of the intestate has predeceased him or her, any children of that child living at the death of the intestate will take the share to which their parent would have been entitled had he or she survived.

If the intestate leaves no descendants the following classes take in order, subject to a life interest to any husband or wife: (1) The parents or parent. (2) Brothers and sisters; (3) Half brothers and sisters; (4) Grandparents; (5) Uncles and aunts of the whole blood; (6) Uncles and aunts of the half blood. In each class, any child living at the death of the intestate of any deceased member of that class will take the share the parent would have taken had he or she survived.

If no member of any of these classes exists all the property will go, not for life but absolutely, to any husband or wife and, if there is none, then to the crown.

If the intestate was illegitimate and leaves neither husband nor wife nor descendants all the property will go to the crown. In such cases the crown will, as a rule, provide for any dependants of the intestate and for any persons to whom the intestate might reasonably have been expected to leave the property had he or she made a will. It will be noticed that the effect of the present law is to make it impossible for anyone more distantly related than a cousin to succeed to an intestate.

**INTESTINE: Its Ailments.** The bowel or intestine is a long muscular tube, lined with mucous membrane, which extends from the pyloric end of the stomach to the anal opening and is about 28 ft. in length. The first 10 in. is called the duodenum, the next 8 or 9 ft. the jejunum, and the following 12 to 13 ft. the ileum. These three divisions constitute the small intestine. The remainder, 4 to 7 ft., is the large intestine and consists of the caecum, the colon, and the rectum. The vermiform appendix, inflammation of which constitutes appendicitis, is a narrow tube emerging from the wall of the caecum. It communicates with the bowel, but is closed at the other end. The important role of the intestine in the processes of digestion is dealt with under that heading.

The intestines are subject to a large number of diseases. Inflammation may attack the intestine as a whole (enteritis), and also involve the stomach (gastro-enteritis), or affect only a part of the intestine, as the caecum (typhlitis), the colon (colitis), the appendix (appendicitis), the rectum (proctitis). It may be acute or chronic, a mild catarrh, or a severe ulcerative form.

Improper diet is one of the chief causes. Tainted meat, unripe fruit, bad beer, the frequent use of irritating purgatives, chilling of the abdomen, may all set up inflammation. The common symptoms are griping, colicky pains, diarrhoea, thirst, nausea, and loss of appetite, headache, languor, and prostration.

In cases due to errors in diet two to four grains of calomel may be given at once, or else from two teaspoonfuls to a tablespoonful of castor oil, with ten minims of laudanum added. Let the patient rest in bed. The food must be warm and liquid—skimmed milk, boiled arrowroot, well-beaten eggs, strained gruel. To relieve the pain, a large mustard plaster, fomentations or linseed poultices may be placed on the abdomen until the pain is easier. If diarrhoea is severe or is prolonged, a doctor should be called in.

#### Sagging and Obstruction

Sagging of the intestines is known as enteroptosis, and is generally associated with descent of stomach, kidneys, and sometimes liver and spleen. The common causes are poor development, a rapid loss of fat, tight-lacing, many pregnancies, etc. Flatulence and constipation, neurasthenia, and a large variety of other symptoms may be present. Keep the bowels regular by means of laxatives such as two to four grains of cascara at night or liquid paraffin. A well-fitting abdominal belt often gives relief. Strengthen the abdominal walls by massage.

Obstruction of the intestines may arise from a large number of causes outside, in the wall of, or within the intestine. In an acute attack severe pain is suddenly felt, perhaps after a violent muscular effort. At first the pain comes in spasms, and commonly in the region of the navel; then it becomes continuous and agonizing. Vomiting soon appears; at first the stomach contents, then of bile, and finally of faecal matter. The doctor must be summoned instantly. Purgatives are most dangerous, and should never be given.

Tuberculosis of the intestine may occur through

infection by ingested milk or other food, or may accompany tuberculosis of the lungs. It occurs frequently in cases of the latter. The prominent symptoms are colicky pains and diarrhoea, with perhaps some blood and pus in the stools.

Duodenal ulcers occur, as a rule, in males between twenty and forty years old, and are usually preceded by months of more or less constant dyspepsia. Pain, three or four hours after meals, may be felt in the stomach region. It frequently assumes the character of hunger pain, which comes on just as the patient is beginning to be hungry, and is relieved by taking food. There is generally blood in the stools, though it is not always obvious. Vomiting is common, and the vomit may contain blood. In some cases medical treatment may be advised instead of operation. *See* Appendicitis; Colitis; Constipation; Diarrhoea; Digestion; Piles, etc.

**INULA.** These vigorous hardy herbaceous plants, rather coarse in appearance, bear large yellow daisy-like flowers in late summer. They flourish in ordinary soil and are increased by division in autumn or by seeds sown out of doors in May. *Glandulosa*, *Hookeri* and *Royleana*, all about 2 feet high, are the best; *ensifolia*, 9 in. high, is suitable for the rock garden.

**INVALID COOKERY.** The actual diet will be prescribed by the doctor, but the cook must be able to present it attractively and with sufficient variety to tempt the patient's appetite. Hot food must be served really hot, and cold food quite cold.

Much depends on the serving. A patient may refuse a dish which, if more attractively served, he would eat with enjoyment. Jellies, puddings and moulds are more appetizing served complete than as a helping, and soups, etc., more attractive in a dainty bowl than in a cup or soup plate. Highly flavoured things are to be avoided.

It is a mistake to send up large quantities of food to a sick-room, as the patient's appetite will probably disappear at sight of it.

Low diet consists of slops, and it is almost entirely fluid. A little bread or toast will represent all the solid part of it. For such diet the cook should send up some kind of liquid food at two-hourly intervals, varying her menu between milk, beef tea, gruel, Benger's food and such things. A liberal supply of barley water and lemonade is generally appreciated.

Light diet is usually understood to include fish, eggs, chicken, and milk puddings, thus giving the cook a wider scope for her ingenuity. Lightly-boiled or coddled egg and poached egg are suitable for invalids, while scrambled eggs are appetizing as well as wholesome. Both fish and chicken are best steamed, but as the patient progresses he may have the chicken roast and the fish baked.

Full diet will include everything eaten by the normal person, with the reservations mentioned at the beginning of this article.

Among vegetables suited to invalid diet are potatoes

(most digestible when mashed or baked), cauliflower, vegetable marrow, well-boiled onions, spinach, asparagus, stewed tomatoes, and stewed celery. Of meats and fish the most digestible are chicken, turkey, pheasant (the breast especially), most kinds of birds, mutton, lean, tender beef, whiting, brill, soles, plaice, halibut, trout, turbot.

With specialized diets for definite diseases such as diabetes, chronic rheumatism or certain forms of heart disease the doctor will issue detailed instructions, for the cook to follow implicitly. *See* Beef Tea; Diet; Gruel; Imperial Drink, etc.

**INVENTORY.** An inventory is a detailed list in writing of furniture and other goods, usually drawn up for a particular purpose. When a furnished house is let it is usual to make an inventory of the furniture and utensils left therein, and when a house changes hands an inventory is made of the fittings, etc., which the incoming tenant is taking over. Such inventories are best made by an estate agent.

Sometimes an inventory of property and other possessions is made in connexion with the proving of a will, while an inventory of the personal possessions of the borrower must be attached to a bill of sale. *See* Executor; Furnished House; Will.

**INVISIBLE MENDING.** This term is used for a kind of mending which not only repairs the rent or hole, but removes all traces of its presence. It is generally left to tailors and others who make a speciality of it, but can be done, with varying degrees of success, at home. *See* Mending.

**INVITATION.** All formal invitations are written and answered in the third person. The usual form runs as follows: "Mrs. S. requests the pleasure of the company of Mr. and Mrs. K. on Saturday, Nov. 10, at such and such a time." If an answer is required it is usual to put R.S.V.P. in the right-hand corner; but in any case it would be extremely bad manners not to answer.

The reply would run thus: "Mr. and Mrs. K. have "(not "will have")" much pleasure in accepting Mrs. S.'s kind invitation for Saturday, November 10," or "regret they are unable to accept." It is to be noted that an invitation should be answered to the person from whom it is sent as designated by him or herself. For example, if it comes from Mrs. Arthur Walker, the reply should be addressed to Mrs. Arthur Walker. The reply should be prompt. Much inconvenience is caused by people who forget or neglect to answer invitations until the last moment.

Wedding invitations are sent out by the bride's family. They are sometimes printed in silver, and are usually on a folded sheet of good notepaper. The wording is as follows: "Mr. and Mrs. Arthur Walker request the pleasure of Mr. and Mrs. Robinson's company at the marriage of their daughter, Mary Elizabeth, with Mr. Richard Kent, at St. Peter's Church, Eaton Square, on Saturday, November 10, at 2 o'clock." If the wedding is to take place out of London

some people add a note in the corner giving times of trams, the nearest stations, etc. *See* At Home; Bridge Party; Dance; Dinner Party; Etiquette; Evening Party; Wedding.

**IODINE.** A non-metallic element occurring in dark lustrous crystals, and procured largely from the ashes of burnt seaweed, is called iodine.

As a counter-irritant the tincture, the strong tincture, and the ointment are frequently used in chronic inflammations of the joints, swollen glands, pleurisy, etc. Painted on a bunion or chilblain, tincture of iodine sometimes markedly reduces the pain and swelling. The colourless tincture of iodine or iodine ointment is suitable for exposed parts.

Iodine is a powerful germicide. Accidental wounds may be painted or daubed with tincture of iodine, the surrounding skin also being dealt with. There is some smarting, but this quickly passes off.

For iodine poisoning give an emetic (q.v.), and immediately send for the doctor.

It is useful to remember that a weak solution of photographic hypo will remove iodine stains from clothing.

**I.O.U.** An I.O.U. is a piece of paper in this form:

March 1, 1938.

To Mr. John Smith

I.O.U.

Twenty pounds.

(Signed) W. Jones.

This is an acknowledgment of indebtedness only, and is very strong evidence that Jones owes Smith £20, but not that the transaction was necessarily a loan. But it is not a contract or agreement. Nor is it like a bill of exchange or promissory note, which is negotiable; nor does it need to be stamped, as those documents do. If the I.O.U. goes on to say, "I promise to pay you the money on the 1st of June," it is a contract or promise to pay, and must be stamped as a promissory note or with a sixpenny agreement stamp, or as a promissory note. *See* Promissory Note.

**IPECACUANHA.** The dried root of a Brazilian plant yields the drug ipecacuanha. The dose of the powdered root is one half to 2 grains when used as an expectorant, 15 to 30 grains when used as an emetic.

Ipecacuanha is a reliable emetic, but it acts slowly. As such, one of its chief uses is to clear out the clogged-up air passages in chest diseases in children who have not yet learned to cough. The vomiting induced by the ipecacuanha, together with the expectorant effect of the drug, causes the accumulated mucus, etc., to be thrown out of the bronchial tubes. The compound powder of ipecacuanha (Dover's powder) is frequently prescribed as a diaphoretic in slight fever.

**IPOMOEA.** These are quick-growing climbing plants. Some of them may be grown out of doors, while others are suitable only for a heated greenhouse. *Ipomoea rubro-caerulea*, which bears beautiful blue flowers in summer, is raised from seeds under glass in spring and may be grown in the greenhouse or planted out of doors in a warm sunny place in late May. *Coccinea*, bright red, and *versicolor*, red and yellow, are others that may be grown in a similar way. The correct name of the common Morning glory (*Convolvulus major*) is *Ipomoea purpurea*. *Horsfalliae*, rose coloured, and *Learii*, blue, must be grown in a hothouse. *Bona-nox*, white, is suitable for the greenhouse.

**IRESENE.** This plant, which is grown for the sake of its coloured leaves, is a favourite for summer bedding and is also useful in the greenhouse. It is easily increased by cuttings of the young shoots in spring in warmth under glass; if subsequently potted in 3-inch pots they will be well rooted by early June when, after having been hardened off, they may be planted out of doors. A compost of loam, leaf-mould and sand is suitable. The favourite kinds are *Herbstii* and *Lindenii*, with dark red leaves, and *aureo-reticulata* which has red and yellow leaves.

*Iresine.* Decorative coloured leaves of the greenhouse variety, *lindenii*.

**IRIS.** This is one of the most important groups of garden plants; a selection of the best kinds will provide flowers from early spring until late summer. The chief types are the May and June flowering bearded irises; the beardless irises and the Japanese irises which bloom in summer; and the early and late bulb irises which are at their best in spring and summer respectively.

The bearded flag irises are beautiful plants distinguished by sword-shaped leaves and large flowers of brilliant and varied colouring, in May and June. The common purple flag iris (*germanica*), the best known of these, will thrive in partial shade, but the finer varieties need a sunny place. They may be planted from July to September in well dug soil to which lime has been added if necessary; they do not flourish in soil which lacks lime. An application of superphosphate of lime, 2 oz. per square yard, to the soil is beneficial. Care must be taken not to bury the rhizome or root stock deeply: it should be only partially covered with soil.

A few of the best of the numerous varieties now available are (May-flowering) *Florentina*, white, *Kharput*, purple, *Zwanenburg*, bronze and yellow, *Queen Flavia*, pale yellow, and *Charmant*, blue purple. Of the June flowering varieties these are exceptionally fine: *Rhein Nixe*, crimson purple and white, *Alcazar*, mauve and purple, *Archevêque*, purple, *Albert Victor*, avender blue, *Caprice*, rose-red, *Lord of June*, lavender-blue, *Standard Bearer*, rose-crimson, *Ma Mie*, white with blue margin, *Ambassadeur*, crimson bronze,

and *Darius*, yellow. The dwarf bearded irises (*pumila*) which bloom March to May are valuable plants for the rock garden and for sunny borders.

*Iris.* Left, early-flowering Spanish; right, bearded or common flag.

Among the beardless irises (which have no crest or beard on the falls or lower petals) are the lavender blue *Siberian iris (sibirica)*, *aurea*, yellow, *Monnieri*, yellow, *orientalis*, blue, the common yellow flag (*pseudacorus*) and the monspur varieties of several colours; all these like deep moist soil and are suitable for borders and the waterside. The beautiful *Algerian iris (stylosa)* which bears lavender blue blooms in winter is in this group; it should be planted in spring at the foot of a sunny wall in well drained soil containing mortar rubble.

The Japanese irises (*Kaempferi*) bear large, flattish, brilliantly coloured flowers in summer; they should be planted in moist soil by the waterside and must have a sunny place.

**Bulb Irises.** Among the bulb irises the Spanish and English are favourites. The former bear blue, white or yellow flowers in June, the latter open in July, the flowers being shades of mauve, purple and rose. The proper time to plant the bulbs is in October, those of the Spanish irises being set 2 inches deep and 4 inches apart, those of the English irises 3 inches deep and 8 inches apart. The miniature bulb irises which are in full beauty in spring are very charming in the rock garden or for cultivation in pots in the cold greenhouse: *reticulata*, violet, *Danfordiae*, yellow, and *histrio*, blue, are some of the best. The bulbs should be set in rather light well drained soil in September.

In addition to those named many species or wild types are cultivated and the *oncocyclis* or cushion irises which need special treatment—a sunny position, a raised bed of well drained gritty soil and suitable protection in winter—have many admirers.

**Iris Diaphragm.** See F. Number; Stop.

**IRISH HEATH.** This is a beautiful flowering shrub about 15 inches in height, with drooping, crimson-purple flowers. There is a beautiful white variety, *alba*. Its culture is the same as for the heaths.

(Continued in page 1145)

Purple and red English

Early-flowering Spanish

Jacquiniana, or common "Flag"

Hybrid double Japanese

# **IRIS: FOUR VARIETIES FOR BRITISH GARDENS**

Instructions for the choice and culture of irises are given under the heading Iris.

**'H,' 'I,' AND 'J' RECIPES: SHOWN IN COLOUR.**

Haddocks, grilled with Tomatoes. Follow instructions for haddock, adding tomato. Jelly Orange. A variant of the sweet called Orange Basket. Italian Jelly. Make some raspberry or strawberry jelly and when nearly set half-fill a mould with it. When this has quite set add a narrower layer of stiff, almond flavoured cornflower blancmange. Spread a little jam thinly over this, and add another layer of blancmange, coloured green and flavoured vanilla. Herring Roes, baked. Fry 3 or 4 soft roes lightly in butter, lay in greased pie-dish with 2 tablespoonfuls chopped mushrooms, of chopped parsley, and 2 chopped shallots. Bone and fillet 3 anchovies, add these with squeeze of lemon-juice and season well. Pour the butter used in frying over the roes and cover with brown sauce. Put greased paper over dish and bake for 5 min.

Its botanical name is *Daboecia polifolia*. See Heath.

**IRISH JIG.** Each of the 9 steps in the Irish jig takes 8 bars, and with repeats 16 bars. It may or may not be danced with a partner. The jig step starts by striking one foot against the back of the other leg while turning in a circle, this being repeated seven times, finishing by stamping twice with each foot. A shuffle is done in the next-step, first with the right foot and then with the left, and repeated. The dancer next steps to one side and hops, while striking one foot against the other leg, finishing with a double shuffle. Other movements include turning in a circle while carrying one leg raised in front, and tapping one foot against the heel of the other, finishing with the single shuffle and stamping of the feet. The last step is similar to the second, but brisker at the finish. A shillelagh is often carried.

**IRISH MOSS.** Irish or Carrageen moss is best known as a remedy for chest complaints, but it also possesses certain nutritive properties. It should be washed thoroughly and should be soaked for several hours before being cooked. It is usually taken as a drink, which is prepared by simmering  $\frac{1}{2}$  oz. of moss in a quart of cold water for about 4 hours. Then strain the liquor, sweeten it to taste, and, if liked, add a little lemon juice.

Irish moss is used as a substitute for isinglass in blancmange and jellies, and is also employed in making sizing and lager beer.

**IRISH STEW.** This popular dish is very cheaply and easily made. Cut 1 lb. neck of mutton into chops, and put it, with 1 lb. sliced onions and  $\frac{1}{2}$  pint water or stock, into a stewpan or casserole, and simmer it for about 1 hour.

Then add  $1\frac{1}{2}$  lb. potatoes, whole, if small, or cut into thick slices, and salt to taste. Continue to simmer the stew for about an hour, when it will be ready to serve. If cooked in a casserole three hours should be allowed in all, and the stew should be served in the casserole.

*Irish Terrier. Prize-winning specimen of a favourite breed of house dog.*

**IRISH TERRIER.** This rough-coated dog is most devoted to his own people, and can be trusted fully with

the care of little children, whose exigent demands upon his attention are not resented. He should be wholly of some tint of red, save for a black nose, and, perhaps, a spot of white on the deep chest; the head should be long and square-looking, carried on a fairly long neck, which broadens to the shoulders and the straight back.

The small, intelligent eyes are of a dark hazel colour; and the small V-shaped ears fall forward to the

cheeks. He wears a thin beard. The hard, wiry coat is straight and flat, and, in spite of its length, neither shaggy nor curled. He is smaller than the Airedale, and his weight should not exceed 27 lb. See Dog; Terrier.

**IRISH WOLFHOUND.** The Irish hound attains a greater stature than any other dog, some having been exhibited that measured 37 in. at the shoulder. Assuming that Oliver Goldsmith measured to the top of the skull instead of to the shoulder, as we do, he may have been right in putting the height at 4 ft.

*Irish Wolfhound, the largest breed of sporting dog, much valued as a guard.*

The Irish wolfhound is powerful and active, with a wiry coat, similar in colour to that of the deerhound. The few breeders find a steady and remunerative market in the United States and the Dominions, the dog being prized as a guard or for hunting wild animals, his size and strength making him incomparable. See Dog.

**IRON: General Uses.** Iron in its simplest form is known as wrought iron, and is obtainable in large sheets, strips, round, squared, and flat strips, or bars, angle irons, or "L" shaped section bars, and similarly in "T" shaped and other various sections. Thin strip iron is used for packing-cases, being known as hoop iron, and also used in a similar way for securing the staves of a barrel.

Wrought iron can be welded or brazed without difficulty, and in addition can be drilled, or cut with a hack saw. It is inferior to steel, both as regards strength and the ease with which it can be turned in a lathe.

Iron, when melted and poured into a mould, is moulded to most intricate shapes, and is then known as cast iron, being used in this form in the making of innumerable articles, but, as it necessitates a high temperature to melt it, the process of making iron castings is scarcely practicable to the amateur. See Bent Iron Work; Casting; Forging; Soldering; Steel, etc.

**IRON: Medicinal Uses.** In the maintenance of health iron is of the greatest importance. It occurs in haemoglobin, the red colouring matter of the blood, which is necessary to the carriage of oxygen throughout the body. In order to maintain the stock of haemoglobin iron must be taken in food, the largest quantities being found in yolk of egg, red meat, oatmeal, and spinach.

It is, therefore, in anaemia that the administration of

iron preparations is obviously necessary. In debility such as follows acute diseases, or resulting from overwork or strain, or in chronic diseases such as tuberculosis, iron may be given with happy results.

The astringent preparations of iron, the perchloride and the sulphate, are used to arrest bleeding. When taken internally they may upset the digestion, produce constipation, headache, and irritability of the bladder. To avoid this they may be combined with purgatives, e.g. magnesium sulphate, or, if necessary, a change may be made to a blander form, such as the citrate of iron and quinine, or of ammonium. Iron also tends to blacken the teeth, and the astringent forms may injure them. For this reason it is a good thing to suck liquid iron mixture through a glass tube.

Among the most popular and widely used preparations of iron for its tonic effect are Bland's pills, the scale preparations, and Easton's syrup. A course of any of these preparations following on convalescence after any illness or when in a generally run-down state frequently gives most gratifying results.

Iron may also be taken in natural iron waters, such as are found at the chalybeate springs at Tunbridge Wells, Harrogate, and other places.

## IRONS AND IRONING IN THE HOME

### Describing Electric, Gas-heated, and other Types

For related information on this subject the reader is referred to the article on Laundry. The entries on Box Iron; Clothes Line; Copper; Gas; Goffering; Labour Saving; Mangle; Pressing, should also be consulted.

The irons in general use include the flat iron, the iron heated by gas, and the one heated by electricity; but there are also other varieties, such as the fuel-charged box, the spirit iron, and special goffering and polishing iron.

Flat irons weigh, as a rule, from 2 to 8 lb., the heaviest being used for pressing such materials as tweeds. For ordinary purposes, sizes 5, 6, and 7 are the most useful, though it should be remembered that the larger and heavier the iron the longer it will retain the heat.

Flat irons may be heated over a gas ring, on top of a stove, or before an open fire. In the last case the iron is placed in an upright position against the bars of the grate. Irons should never be put on the fire itself, for this tends to blacken them and also, to destroy their smooth surface. Special stoves for heating irons can also be obtained, but these are not necessary unless a great deal of laundering is done. But, whatever the method of heating used, an iron slipper or shield should be fastened on immediately before ironing to prevent the clothes from becoming soiled. When this is not done, the iron will require careful cleaning by rubbing it on a thick sheet of brown paper nailed to a board or table and sprinkled with powdered bathbrick. A little beeswax may then be applied with a soft cloth, and the iron finally polished and dusted.

The heat of an iron may be tested by dipping the finger into water and then dabbing it lightly on the surface of the iron. If the water dries immediately and leaves no mark, the iron is hot. Old pieces of cloth may also be used for testing. During ironing a stand or trivet should be placed on the table so that the iron may rest upon it when not in use. This will prevent unnecessary scorching of the ironing cloth. An iron holder, thick enough to prevent the heat of the handle penetrating through, must also be provided. Irons should be put away in a dry place, for damp rusts them.

The gas iron has a tube attachment which connects it with the burner and a tap for regulating the heat. The electric iron is commonly used where electricity is installed, and is heated by attaching the connexion to the wall plug or electrolier, having made sure by examining the number on the bulb that the voltage of the iron and that of the house supply agree. These irons are sold usually in 4 or 5 lb. weights, and have their own particular stands. The current should be turned off when the iron is sufficiently hot and turned on again as required. The electric iron is the cleanest of all.

*Iron. Left, adjustable voltage iron for use during holidays or travelling. Right, electric iron which concentrates additional heat in the point. (Courtesy of Hotpoint Electric Appliance Co., Ltd.; and of Edison Swan Electric Co., Ltd.)*

To the traveller the adjustable voltage is a real boon, owing to the widely varying supply voltages to be found in different towns. Another useful iron has an automatic device for controlling the temperature by cutting off the current when this exceeds the correct heat for efficient ironing. In that illustrated on the right heat can be concentrated in the point for pressing pleats and small work.

The charcoal and the methylated spirit irons, which the electric and gas irons have done much to supplant, find votaries amongst people who have neither current nor gas in their homes. The charcoal iron has a cavity in which lumps of hot charcoal are placed, and the outfit includes a small pair of tongs for dealing with the fuel. Goffering irons should never be placed in the fire, but may be heated under a flat iron on an ordinary stove. Tailors' irons are long and narrow, and are usually heated by gas or electricity.

**Ironing.** The old rules still obtain with regard to the ironing of various materials and garments. Piqué must always be ironed upon the back, and when ironing

embroideries upon sheets and pillow-slips, mats, children's dresses, etc., the embroidery should be placed face downward on a thickness of flannel and be ironed in that position upon the back while they are damp. This raises the design. Coloured silks or wool embroideries should also be ironed on the wrong side when nearly dry after having been washed.

Iron shantung, Japanese, tussore, and pongée silk on the wrong side when dry, and use the iron only moderately hot. Any white silk ironed with a hot iron is turned a yellow tint. Other silks and satin ribbons should be ironed on the wrong side when just damp, which they will be if they have been rolled in a Turkish towel and squeezed out after their last rinsing. Cretonne also must be ironed on the wrong side when damp.

Crêpe-de-Chine, crêpe, georgette, and the cotton crepons, after a right-side ironing when damp with a hot iron, usually come out beautifully. A gloss is given to knitted and crocheted silk if ironed on the wrong side when damp with a moderately hot iron. Silk stock-ings should, therefore, not be ironed if required to keep a dull surface. Artificial silk garments should be ironed with only moderate heat. It is advisable always to test the iron before use on a piece of material, or hold it to the face, not near enough to scorch the skin, or wet the iron and listen for the fizzle that indicates considerable heat.

Children's cambric frocks and other garments should be ironed damp on the right side, and to prevent scorching a damp cloth may, for the first ironing, be placed between the material and the iron. Keep all frills that have been set in pleats carefully ironed to their original state. Use goffering tongs for the narrow lace edgings and frills of clothes and bed linen. Lace collars should be ironed lightly on the wrong side with a cool iron, and there should be a piece of muslin between the iron and the lace. Then iron again without the muslin, having previously pulled the edges into shape. Finally pull out with the fingers any raised flower petals, and so forth, that there may be in the design.

When ironing a pleated garment tack the pleats in place or iron them carefully two at a time, placing a damp cloth between the material and the iron. Pressure and a very hot iron will probably be necessary.

Men's linen collars of the turned-over type and the straight are ironed flat, first on the back and then in front. Some men like their turn-over collars glazed both back and front, in order that the tie may slip easily between the folds. They have preferences, too, in the case of the shirt collar-band, some calling for a stiffened band and others a soft one, for which reason the laundries have a plan of using coloured threads that denote exactly the fancies of their customers.

To keep irons polished and clean is an absolute necessity, and the ironing board cover should be washed, especially if iron-moulded, for this mark is catching and can be communicated by the iron to a fresh fabric.

**Ironing Board.** A board can be prepared for ironing purposes by taking a smooth piece of wood 3 or 4 ft. long and about 9 in. wide and covering it with blanket

or felt. This material must be stretched tightly enough to produce a smooth surface, and over it a length of white linen or cotton material should be pinned when ironing takes place.

A specially shaped board of this kind is used for ironing skirts, petticoats, and frocks. It should be narrower at one end than at the other, so that the garment can be fitted over it. Other boards shaped so as to facilitate the ironing of sleeves and shirt fronts are covered in the same way.

**Ironing Cloth.** The blanket and sheet used to cover a table while ironing is in progress are together known as an ironing cloth. They may be of one, two, or more thicknesses, but the main point is to see that they are perfectly smooth and free from creases. If preferred, a piece of felt may be used instead of the blanket. The sheet must be white, otherwise there will be a danger of damp clothes ironed on it taking the dye.

**Ironmould.** This is a stain produced by ink or rusty iron. It can be removed from most materials by means of powdered oxalic acid or some salts of lemon and hot water, but if either of these acids is used, the article so treated must be washed immediately afterwards to prevent the acid from causing holes. Salts of lemon may be applied two or even three times on strong white materials, but oxalic acid needs to be used more sparingly.

If salts of lemon is used on coloured materials it should be made into a fairly weak solution with hot water, and the affected part only dipped into it and taken out again before the colour begins to fade. Then put the material into a basin of cold water to stop the bleaching action of the salts and the stain should have disappeared. This process may be repeated, if necessary, but it must be done rapidly and the cold water used afterwards on each occasion.

**IRONSTONE.** This is an impure iron ore with a heavy proportion of clay. In districts where it can easily be obtained, it may be used for decorative purposes in the garden. It is also used in the pottery industry for the manufacture of some classes of cooking utensils and earthenware.

**ISINGLASS.** The purest kind of gelatine is known as isinglass. Colourless and without smell, it melts quickly in hot water and is used mainly for jelly making, etc. It is often adulterated with ordinary gelatine, and may be tested by dropping some of it into cold water or vinegar. In cold water, isinglass becomes white and cloudy, while gelatine remains clear; in vinegar it swells and becomes jelly-like, while gelatine hardens.

An invalid dish made from isinglass is prepared by dissolving an ounce of isinglass in  $\frac{1}{2}$  pint hot

water, and adding  $\frac{1}{2}$  gill white wine and the juice of a lemon. Sweeten all to taste; then add the beaten yolks of 3 eggs, and thicken the whole over the fire. Pour it into a basin, and when cool, but not set, turn into a mould. *See Gelatine; Invalid Cookery.*

**ISLE OF WIGHT DISEASE.** This malady of bees, prevalent for more than 20 years in Britain, has been found to include several parasitic diseases. The name is therefore obsolete. The bees lose their power of flight, gradually or suddenly, and the use of one or more pairs of legs. Sometimes they are very vicious and use their stings freely, but at other times they are quite the opposite. The combs may be soiled with excrement.

Bee-keepers who notice any of these symptoms, or indeed any general indication that their bees are disinclined to work, should at once examine their stocks and if they have any doubts should consult an expert or communicate with the Ministry of Agriculture.

No certain remedy has been discovered for this disease, but in Bulletin 9 the Ministry of Agriculture and Fisheries gives a few suggestions for preventing its spread and mitigating its severity when it appears. Cleanliness is of great importance in this connexion.

After an outbreak of disease, the inside of the brood chamber and the floor board of all movable comb hives should be charred with a painter's lamp. All skeps, quilts, combs and honey that have come in contact with the affected colony should be burnt, together with all dead bees, and the soil round the hive should be sprinkled with petrol and ignited. After the fire has subsided the ground should be dug over and covered with quicklime.

Bee-keepers should endeavour to see that no stagnant water is left in the neighbourhood of their apiaries, especially when there is any disease in the neighbourhood, and should endeavour to supply their bees with a pure supply at a short distance from the hive. The drinking fountain should have a sheltering board about one foot above it to prevent the flying bees from soiling the water with excreta which they void when on wing. In the spring very thin syrup could be given in the ordinary feeders, as this lessens the demand for water. Some authorities advise supplying them with salt water, especially in the spring.

Bee-keepers who live in districts which are free from disease should on no account purchase swarms or driven bees from an infected district. There is no surer way of spreading disease than to transfer bees from one district to another, for swarms, even from apparently healthy stocks, sometimes develop disease when placed in new hives. *See Bee.*

**I SPY.** This outdoor game is a variant of hide and seek. The player chosen to be the spy stands with closed eyes at the place fixed upon for the goal, while the others scatter and hide. He counts up to 100 or some other agreed figure and then starts upon the chase, going warily lest a player should dart out and reach the goal before him. As soon as he catches sight of a player, he must shout his name, run back and touch the goal.

The player who has been seen, however, has also this

right, and if he touches the goal first he is not caught. The other players can also run for the goal, but if they are seen and named the spy may be able to get there before them. If the spy calls out a wrong name, the player wrongly named and also the one whose name was actually called are both free to return to the goal.

A game ends when all the players are caught, or all have succeeded in reaching the goal. In some parts of England this game is known as lurky and there are other localized names for it in various parts of the country.

**ITALIAN CREAM.** To make this sweet, prepare a custard with a pint of milk, the yolks of 3 eggs, and sugar to taste, flavouring it with the thinly peeled rind of a lemon and a little cinnamon. Stir in  $\frac{3}{4}$  oz. gelatine previously dissolved in a little water and a dessert-spoonful of strained lemon juice. Let the whole stand until it cools and begins to set; then add the stiffly beaten whites and put the mixture into a mould rinsed with cold water. When firm, it may be turned out and served with stewed fruit made into a puree.

**ITALIAN GARDEN.** Although there are examples of this style of gardening to be found in England, its principle of subservience to architecture is too pronounced for English tastes. The free and natural growth of plants, which nowadays is such a feature of British gardens, is absent; the stately Italian garden, is distinguished by stereotyped beds of glowing flowers and ornamental plants, balustrades and statuary.

The design is formal, with carefully ordered beds laid out in geometrical shapes. Paths intersecting the beds are paved with stone, or loosely gravelled. Effort must be made to maintain a succession of the most brilliant flowers from spring to autumn, but difference of climate makes it almost impossible to grow many of the striking trees and plants prominent in the gardens of Italy.

Agaves, yuccas, aralias, and dracaenas can be brought into the scheme during summer months, together with specimens of topiarian art. Sculpture, in the form of an ancient wellhead or Venetian cistern, a fountain or stone seat, if possible, should find a place.

Modern gardening regards the plants as of most interest, but old Italian gardens were designed as an ornamental extension of the architecture of the house. *See Loggia.*

**ITALIAN GREYHOUND.** This miniature edition of the English greyhound has the appearance of great delicacy and fragility, and in consequence has been treated by its owners too often as one of the expensive pets of the drawing room. Gentle and affectionate, of exquisite form and beautiful colour, some shade of fawn, he should be given proper opportunity for exercise.

The head should be long, flat, and narrow, tapering to the fine muzzle and dark nose, set upon a long and gracefully arched neck and long, sloping shoulders; back curved to the hind quarters and the long tail; fore-legs straight with small bones; feet long and hare-like. The small, soft ears should come close together behind the head; the eyes large, bright, and expressive. For

show purposes there are two classes: those under 8 lb. in weight and those of heavier build. *See Dog.*

*Italian Greyhound. Prince Ivanovitch, a champion of the breed of strong but fragile-looking dog.*

## ITALIAN

**LINING.** Available in many qualities and in colours to tone with all the materials ordinarily used in tailored clothing, Italian lining is smooth-faced, and is the chief lining used for men's coats and waistcoats. The best qualities have a strong cotton warp, hidden on the surface by a close texture of fine Botany wool, which lends warmth to the garment. In poorer qualities less wool is used, and in the larger part of Italian cloths there is no wool at all.

Cotton Italians vary in weight from light to heavy, and can be had with guarantees as to the fastness of the colour and permanence of the lustrous finish. Linings tend to polish themselves in wear, and too much insistence should not be made upon their original brightness. A high and permanent lustre is often obtained by methods which rob the cloth of its natural strength.

## ITALIAN RENAISSANCE WORK

### Modern Simplified Form of an Interesting Old Handicraft

The articles on Gesso Work and Lacquer Work should be consulted in connexion with this, as there are points of resemblance in methods and materials employed. See also Lampshade; Leather Work; Papier Mâché; Stencilling

The original method of applying this ornamental craft was a long one and entailed great skill and patience. It was largely employed in the interior decoration of churches and other buildings and many famous examples are to be seen in Italy. As with gesso work, a paste is employed, and this was used thickly, layer upon layer, and when hard the design was carved out and gilded or coloured. In this article the work is only dealt with from the point of view of the amateur, for the decoration of small articles, but in its antique form it enriched large surfaces.

It is not practicable on metal or glass, but can be used on wood, papier mâché, and even cardboard. As

the paste fills in cracks and dents it is an excellent method for re-decorating a wooden box or blotter, or for book ends which have become shabby. It is also largely used for decorating white wood articles, which are obtainable in great variety in most good art departments, together with the materials required for this work.

If the article to be decorated is old it should first be thoroughly cleansed with soap and water and dried. A wooden surface, if smooth, may be sandpapered quickly and just sufficiently to roughen it. A coarse sandpaper should be used, or the surface may be scratched up with a pointed instrument.

**Method and Materials.** A small box is a simple article to begin experiments with in this craft, which is an ideal one for quickly making decorative objects for a bazaar stall at little cost. A special form of paste, called renasco paste, is employed for the raised decoration. It is easier to apply than barbola paste, which requires expert modelling to obtain good results, or than gesso, used for lacquer work, which requires to be exquisitely smooth. Decoration may consist only of the raised paste work done in conventional scrolls all over the article with a spoon-shaped modelling tool supplied with an outfit. Practice is required, but the work in its simple modern form is especially suited to those who cannot draw or paint.

More effective work is done by utilizing a panel as shown in the examples of finished work in Figs. 3, 4. Such panels may be original designs drawn and painted by the worker, in which case the craft may be raised to the standard of an art, or a picture may be cut out and glued to the article and coloured with barbola colours. Photographs and picture postcards can be used and tinted with transparent oil colours. The panel on the blotter in Fig. 4 is a photograph of a well-known picture, those on the tea caddy in the same illustration were cut out from a painting book.

The materials required besides the paste are tubes of vandyke brown, emerald green oil colours, yellow, blue, crimson and mauve barbola colours, a special medium and turpentine, gold and silver bronze powders, a sable, a fitch and a hog hair brush, one or two modelling tools, china saucers for mixing colours, and other bronze powders and oil colours which may be needed for a particular piece of work, and are obtainable separately. Metal glue is the best adhesive for sticking on panels and strips of cardboard which may be utilized to form a raised framework round the panel and should be affixed before the renasco paste is applied. Such a framework has been used to surround the photograph panel on the blotter.

To decorate one of the boxes illustrated in Fig. 3, the space which the panel will fill must first be decided on and then the design must be drawn, traced, or the photograph, card or picture must be glued into place. Where it has been decided to decorate this panel design with barbola colours, portions of the design, trees, birds or figures can be slightly raised with the paste

reduced with water to the consistency of a thin cream, and allowing it to dry before applying any colour. The actual painting of the panel is left until the remainder of the decoration of the box is finished. While the panel is drying the rest of the box is covered with the paste, using a hog hair brush. Apply the paste unevenly, covering any strips of cardboard or of wood which may have been glued or nailed into position round the panel. The paste should not be allowed to spread on to the latter.

This first coating of paste is left to set for twelve hours, unless the weather is very damp, when it may take longer. For the second coat the paste is used of a consistency which, when the brush is raised, flows from it in sufficient thickness to make coils. Only the paste is allowed to touch the surface of the first coating, not the brush, which is kept moving in circles, figure eights, or leaflike formations to cover the box with raised decoration. The scroll work design on the right-hand box of Fig. 3 is done with a spoon-shaped modelling tool instead of the brush.

*Italian Renaissance Work. Fig. 1. Above, gilding the paste; a squirrel brush is used and the gold powder is mixed with renasco medium. Fig. 2. Below, removing excess of oil colour with a clean rag. (Courtesy of Winsor & Newton. Ltd.)*

**Gilding and Colouring.** When the second coating of the paste is dry, the whole article, except the portion

reserved for the panel, is gilded and coloured. A squirrel hair brush is best used for this purpose. Gold bronze mixed with the special medium is painted over the paste (Fig. 1); when this gilding is dry it is in turn painted over with vandyke brown oil colour thinned with turpentine. This is allowed to dry for a short time and then with a piece of clean rag the colour is reduced in places to give an antique look (Fig. 2). A greenish shade may be obtained by mixing emerald green oil colour with the vandyke brown.

*Italian Renaissance Work. Fig. 3. Above, three boxes showing raised designs coloured in barbola colours.*

*Fig. 4. Below, blotter and box. (Courtesy of Winsor & Newton. Ltd.)*

By the time all this has been done, the raised portion of the panel design will be quite dry. Barbola colours look well on this work as they are somewhat suggestive of the old tempera colours used for this form of decoration in the time of the renaissance. Sable brushes are best for painting and water for thinning. As little shading as possible should be used, the colour being applied, except for details, in flat washes. When raising, the paste should be used more thinly than for the rest of the decoration. Gesso powder is quite suitable for this purpose as applied to the handkerchief box described previously. The object in the first case is to provide a smooth surface in very slight relief; in the second, a rough surface in bolder relief. For raising the panel design use a sable brush and twist it to avoid brush marks and to make the paste lie correctly. Instead of cardboard strips the framework-round the panel can be formed by drawing the paste along and turning the brush while working. It is important to remove or raise the lids of boxes before applying paste.

The edges can be trimmed with a sharp penknife when the paste is dry.

Candlesticks and wooden table lamps can be successfully decorated in this method. On the white wood blotter and tea caddy illustrated in Fig. 4 the panel pictures are merely coloured and no raising paste has been applied to them. After glueing on the panels a rubber roller should be employed in order to remove any bubbles which spoil the appearance of the work.

For the blotter thin strips of cardboard are glued

round the panel to form the frame and the back of the blotter is gilded all over. Paste is not used for this as the back is required to lie flat on the table. A pretty effect is gained by mixing silver with the gold bronze powder for painting the paste and introducing a little vermilion and vandyke brown oil colours, wiping the latter off, as shown in Fig. 2, so that the metallic lustre is not lost. When the paste work on the front is painted, the photograph is coloured with transparent oil colours, using megilp as the medium for this decoration.

The white wood tea caddy is decorated with five pictures cut to fit sides and top. When these are firmly glued to the wood the box is covered with the paste. Opening the lid, do the sides first and the top last. Bronze powders are used to colour the paste, a good effect being gained with copper instead of gold, the brown oil colour being left only in the unraised portions. If picture postcards are used to decorate the box, they must be tinted with oil colours; if drawings or cutout line illustrations, these can be worked up with barbola colours.

Many of the materials in the various handicrafts to which the reader is referred can be utilized to make variety of designs and colourings when the worker gains experience, and in this way original pieces are produced. Barbola work, for instance, in a floral design could be used instead of a panel, or for an edging on a box decorated with renaissance work. Stencils can be employed when painting small panels at the base of candlesticks covered elsewhere with relief work.

**ITCHING.** Itching of the skin, or pruritus, may be transient and easily controlled, but it is sometimes so severe and continuous as seriously to affect the general health. It accompanies many skin diseases. It may also be the result of irritation by fleas, lice, scabies, or by coarse woollen underclothes. In nettle-rash or hives, often found in indigestion, the chief symptom is intense itching.

Where the sensation is localized, bathing the part with a one in forty solution of carbolic acid sometimes gives relief. Another useful lotion for sopping on the skin to relieve localized itching is the following:

Carbolic acid	1 dram
Bismuth carbonate	1 „
Rectified spirits of wine	2 oz.
Water, enough to make	8 „

Make into a lotion, sop on to the itching skin, and allow to dry. These lotions are poisonous if taken internally.

General pruritus without apparent cause may be benefited by Turkish baths (if the doctor approves) or hot baths, and to the latter might be added bran or oatmeal, 2 lb., or carbonate of soda, 2 oz., to the 30 gallons. *See* Scabies.

**IVORY.** There are four kinds of ivory: Indian, African, walrus, and mammoth, and to the experienced eye each has its distinguishing features. Indian ivory is recognized by its intense whiteness, also its small size, and by its very slight graining. African ivory is the

choicest and commands a considerably higher price. The tusks of the African ivory grow to a very large size. The graining is much more pronounced than in the Indian, whilst the colour is a rich light cream. A variety of the African known as soft ivory is much paler in colour than the choicest African ivory, but it has a very similar graining.

Mammoth ivory is mostly found in Siberia, and is obtained from the remains of prehistoric animals. It has not a great commercial value, and is largely used for making the cheaper varieties of ivory ornaments, bead necklets, etc. The colour is very white, and the tusks, when found, are mostly damaged and cracked; when exposed to the light it cracks on account of its dryness. Ivory from walrus tusks is similar in appearance to mammoth ivory.

Ivory articles that become discoloured should always be placed in expert hands, as it is impossible for ivory to be cleaned without damage except by those who are accustomed to handle it. Any slight discoloration can be removed by wiping the ivory with soft wool or rag moistened with hydrogen peroxide and placing it in the sun, which will whiten it. On no account should ivory be washed with soap and water. Some ivory has dark yellow or brown markings. These are mostly found on small beads, and are the result of too much bark being left on the ivory; the dark colour can be bleached by wiping it with wool slightly moistened with hydrogen peroxide.

Ivory is mostly used in European countries for the manufacture of piano keys, billiard balls, knife handles, brush and mirror backs, combs, powder boxes, silk bag frames, and, when in fashion, bead necklets. The most popular of these ornaments are undoubtedly the round and oval bead necklets, which are made of best West African ivory. The best beads are made from the points of the tusks; they have pronounced graining and are cream in colour. Bangles are made in ivory with inlaid gold. They are often engraved with Chinese and Indian figures, and carved with floral and other designs.

Articles made of walrus or vegetable ivory are inferior in quality and appearance. Vegetable ivory is chiefly used for buttons, and although it is generally described as ivory, the material actually is cut from a nut, the nut ivory button industry being quite large in certain Italian manufacturing districts. These articles of nut ivory are easily distinguished by their whiteness and almost bone-like colour, and the absence of graining such as is seen in tusk ivory. The walrus ivory is mostly obtained from the tusks of the Baltic sea lions, and as these are small the chief use for this ivory is in making bead necklets and other small articles. It is more fragile than elephant ivory; also it has not the lustre, and it cracks very easily. It is usual for it to be bleached, and the chemical action frequently causes cracks to appear.

It is advisable when purchasing ivory goods of any description to inquire whether the ivory is elephant,

walrus, or mammoth. The last two are comparatively cheap. From the description given above it should be possible to distinguish the fine qualities from the less expensive.

*Carved ivory comb of Italian workmanship of the 14th or 15th century. (National Museum, Florence)*

*Ivory. Walrus ivory tau-head fixed to the top of a walking-stick. Northern Europe, 12th century. (By permission of the Director, Victoria & Albert Museum, S. Kensington)*

If ivory is to be silvered, put it into a weak solution of nitrate of silver and leave it there until it has acquired a deep yellow colour. Then wash it with water and expose it to sun for about three hours, or until it turns black. Vigorous rubbing will then produce the desired silvery effect. Preparations, together with directions for staining ivory red, blue, green purple, yellow, and other colours can be obtained from most chemists.

**Antique and Decorative Pieces,** For the purpose of home decoration the classes of ivory carvings most readily available are statuettes, plaques and caskets. The first include works of great excellence produced by modern artists more freely in Belgium and France than in England. In some instances they are set off by other materials, such as metal, ebony and gems. Some of the antique Chinese statuettes are highly valued by collectors and are of great beauty. Plaques and caskets are usually carved in low relief. A fine example of such carving on ivory is seen in the illustration of the mirror case.

*Ivory. Carved ivory mirror-case depicting a hawking scene. French, 14th century. (British Museum)*

In acquiring old ivories it is essential to avoid anything not pleasing in itself. Admirable work has been done in all ages in walrus ivory and in the horns and bones of various animals. Some of the choicest pieces of antique ivory,

especially the Romanesque, Byzantine, and medieval diptychs, or folded tablets, have been reproduced in waxed plaster-casts called fictile ivories. For purposes of art study they are quite desirable.

A large industry in modern carvings has developed in India, China, and Japan for the Western market. They are often tawdry and lacking in attractiveness, because they do not interpret native feeling.

Ivory carvings which retain the mellowness of age should not be washed, but polished with soft leather. A bath of turpentine, followed by exposure to sunlight for a few days, is sometimes advantageous and quite harmless. Some forms of artificial discoloration can be detected by applying a damp cloth. Old specimens should be kept under glass, away from the sun.

*Ivory. Chinese statuette, 17th century. (Victoria & Albert Museum, S. Kensington)*

**IVY.** The common ivy (*Hedera helix*) is an invaluable evergreen shrub of climbing or trailing growth, it is one of comparatively few self-clinging climbing plants and is thus often used for the purpose of covering walls. If planted in such a position it should be cut hard back annually in April to get rid of the old leaves and straggling shoots. Ivy thrives in ordinary soil and is propagated by cuttings set in a frame in August or out of doors in October.

The variegated ivies are more attractive than the common green-leaved form: a few of the best are *Crippsii*, *Lee's Silver* and *variegata elegantissima*. The golden-leaved ivies too are favourites, and there are some distinct varieties among the small-leaved ivies, such as *Caenwoodiana*, *crenata* and *gracilis*. Some of the best large-leaved ivies are *canariensis* (Irish ivy), *dentata* and *amurensis*. The leaves of *purpurea* are green in summer but take on a purplish tint in autumn.

A curious trait of ivy is that as soon as it reaches the top of its support it loses its climbing or trailing form of growth and becomes what is called a tree ivy. It develops a bushy habit of growth and bears flowers and fruits. Ivy makes a good ground covering beneath trees and in very shady places where little else will grow.

**IVY LEAVED GERANIUM.** The type of *pelargonium* known as the ivy-leaved geranium is useful in the garden in summer flower beds and in vases. It is valuable for covering greenhouse walls, for hanging baskets under glass, for window boxes and balconies.

Propagation is by cuttings taken in August and kept under glass until spring, when they are transferred singly to 4 in pots, points of main shoots being nipped a few days later to make stocky plants and to ensure prolific flowering. *Madame Crousse*, pink, and

Souvenir de Charles Turner, carmine rose, are two favourite varieties. *See Pelargonium.*

**IXIA.** This is a bulb plant which bears flowers of many brilliant colours in early summer. It is not very hardy and should be grown in pots in the greenhouse or be planted in well-drained soil in a sunny sheltered border preferably at the foot of a wall. The bulbs are potted or planted in September: if out of doors they should be covered with 2-3 inches of soil and protected by old ashes in winter. If grown in pots they must be dried off gradually after the flowers are over and re-potted in autumn. The green and black ixia (*viridiflora*) is very handsome; numerous others named in catalogues have blooms of scarlet, rose, crimson, and yellow. They are propagated by offsets.

**IXIOLIRION.** This is a rather uncommon bulb plant from Persia which, when grown in British gardens, needs a sunny sheltered place in a well-drained compost of loam, leaf-mould and sand. The bulbs should be set in autumn 1-2 inches deep; a covering of old ashes should be put on the soil early in winter. *Pallasii* (*tataricum*) is the only kind usually grown; it bears blue flowers in early summer.

*Ixiolirion, or Ixia Lily.*  
*Delicate tubular flowers of an uncommon bulb plant.*

**IXORA.** These are beautiful hot-house shrubs, known also as the West Indian jasmine. They form bushes of glossy foliage, surmounted by lovely panicles of flowers, either white, yellow, or red. Ixoras like a compost of two parts of rough loam, one part leaf-mould, and one part fibrous peat, with a good sprinkling of sharp sand.

Propagation is effected by means of cuttings. For this purpose fairly mature shoots which show no signs of bloom should be inserted singly in small pots, in sandy peat, and plunged in a propagator. After the cuttings have been rooted, remove the tops, as this will conduce to a bushy habit. The plants should be potted on until 6 in. pots are reached. After flowering give the plants a rest in a temperature of from 55° to 65° during the autumn and winter months. The time for repotting is when growth is just starting.

*Ixora.* Flower head and glossy foliage of the beautiful hot-house shrub.

**JABORANDI.** Dried

jaborandi leaves are important in medicine because they contain certain alkaloids, especially pilocarpine. Both jaborandi and pilocarpine are largely used as outward applications to the hair to stimulate and promote its growth. Taken internally, they cause an increased flow of perspiration.

**JABOROSA.** A hardy perennial plant allied to the mandrake, this is one of those curious freaks of horticulture which are said to shriek when their roots are torn from the ground. Jaborosa grows in any warm soil in a sheltered situation, and has white Lapageria-shaped flowers about 2 in. in length and very fragrant.

The plant rarely attains to a height of over 1 ft., and is propagated by separating its long, creeping stems. It is during this process that the noise called shrieking occurs. *See Mandrake.*

**JACINTH.** This semi-precious stone is transparent and bright in colour, varying from a dark red to orange. The best stones have a lustre and are pretty, but not valuable.

**JACK: For Lifting.** A jack, or a lifting jack, is a mechanical device for raising weights or for exerting great pressure. It usually takes the form of a strong metal casting, broad at the base and tapering towards the top. Through its centre passes a rod with a square sectioned screw-thread cut upon it. A steel nut with actuating handle turns upon this rod and rests upon the top of the body of the jack. Consequently, when the nut is rotated the steel rod is forced upward, and the head, or pad piece, which is affixed to it bears against some convenient part of the object to be lifted, thereby forcing it upward.

When using a screw jack for lifting operations, it is important to see that the foot of the jack rests upon a solid base; if it is tilted to one side it is liable to slip when the load is brought to bear upon it. Similarly, the head of the jack should bear upon some firm, solid part of the object to be raised, the essential thing being that the pressure is exerted in a straight line.

A jack is very convenient if it is desired to force an object along for a few inches, as the jack can generally be laid in a horizontal position, with the foot bearing upon a solid piece of wood which butts against the wall of the house, or any other sufficiently strong resistant structure.

A convenient type of jack has a worm and wheel to rotate the screw-nut, and this permits of still easier operation of the jack, and, to avoid the necessity of approaching near to the jack, a long extension handle may be employed to rotate the worm, as in Fig. 1.

A lifting jack is an indispensable part of the equipment of the motor car, and there are numerous types. Important points are that the jack be of such size that it can be inserted under the axle when the tire is deflated, that the base is adapted to stand firmly on the ground, and that there be an extension handle. The jack should be capable of lifting the weight of the car

when fully loaded. Vehicles that weigh  $1\frac{1}{2}$  tons or so should be provided with a double-lift jack, that is, one in which a separately movable part is provided; this is raised by hand, thus leaving only the car itself to be raised by the jack.

*Jack. Fig. 1. Example of a jack in use, showing convenience of the long handle.*

*Fig. 2. Component parts of a lifting jack.*

For garage use a regular garage type of jack is preferable, as it can be wheeled about from place to place; the base has one or two wheels mounted upon it; the lifting is on the lever principle, and only calls for the depression of a long handle to raise a heavy car, the jack being held in position by a ratchet device.

*Fig. 3. Self-locking garage jack, operated by a long lever. (Courtesy of Harvey, Frost & Co., Ltd.)*

**JACKDAW.** No bird is more easily tamed than the jackdaw, and once it gains the affections of its owner, it will attach itself firmly to him. It has a strong partiality for bees and beetles, and will devour mice.

The food usually provided for the bird in captivity consists of bread and milk, oats, insects of all kinds, and scraps of meat. The jackdaw may either be kept in a cage, which should be large, or allowed the run of the house. As it has thievish propensities, bright objects, such as rings, brooches, etc., should be kept out of its reach.

**JACK PLANE.** This name is given to a type of long plane used to prepare the surfaces of timber. It is an indispensable tool for all workers in wood, as by its aid the rough and uneven wood is planed to a true

surface.

Jack planes are made in several sizes, varying in width from 2 in. to  $2\frac{1}{2}$  in., and from about 14 in. to 15 in. or so in length. Most are made of beech wood. This type of plane is generally sold with an open or single handle, others have a try-plane type of closed handle, another variety has a single handle or horn at the front, but the most usual has the handle at the back, and this type is to be preferred for amateur use. They are to be had with a single or a double iron, the latter being preferable, as it is easier to use.

*Jack Plane. Sectional drawing showing construction.*

The iron is secured by a wooden wedge, which has to be removed to withdraw the iron for sharpening purposes. This is accomplished by grasping the plane in the left hand with the fingers on the face, and the thumb in the throat pressing on the iron; a blow is then struck on the top front of the plane; this is repeated if necessary, and releases the iron, which is then withdrawn, the two parts separated by unscrewing them, and the cutting iron sharpened on a grindstone in the usual way. The iron is replaced and secured by driving the wedge back into its place with a hammer. See *Amateur Carpentry; Plane*; also illus. Above.

### JACOBEOAN STYLE IN FURNITURE The Famous Classical Period of English Oak Pieces

The Jacobean Style is further described under the headings *Antique Furniture; Armchair; Chest; Chimney Piece; Door Furniture; Grandfather Clock; Grate; Guilloche; Hall; Oak Panelling; Settle*, etc. See also the styles preceding and following the Jacobean; *Tudor; William and Mary*.

The term Jacobean used in reference to decoration and furniture applies to the period between 1603 and 1688 and thus embraces almost the whole of the 17th century. French and Italian influences greatly swayed the taste in British furnishing during the reigns of Charles II and James II, so that the purer forms of English Jacobean style, directly evolved from the Tudor, are to be found in the oak furniture made before 1660.

After the Restoration walnut was used, and by the end of the 17th century, with this new wood, a different style of furniture had come into fashion for the homes of the rich.

The Jacobean period was not distinguished for a great diversity of pieces. Furnishing in a comfortable manner was only beginning to be thought about during the reign of Elizabeth, and the first half of the 17th century saw improved workmanship and more elaborate decoration and carving, but few innovations. Furniture in a wealthy household would include a carved four post bed with bulbous supports and having probably a bedspread and curtains of linen, embroidered with crewel work in one of the conventionalized designs which are to-day reproduced in furnishing fabrics labelled Jacobean style. The dining table might be of the type seen in Fig. 1, with stretcher rails, richly carved frieze and the legs showing the Elizabethan bulbous formation, which continued far into the Jacobean period, or of the draw-leaf type, which had two leaves, one at each end, to draw out from beneath the top, centre leaf, which then dropped to the same level. Many reproductions are still made of this draw-leaf table. The gate-leg table was introduced during the commonwealth, and an early form is illustrated in which the legs show the baluster style of turning; the barley sugar twist was introduced later.

*Jacobean Style. Fig. 1. Beautifully carved oak table, dating from the 17th century. The top is fixed and the bulbous legs are supported upon stretcher rails. (By permission of the Director, Victoria & Albert Museum, S. Kensington)*

Seats included stools like the one illustrated in Fig. 3, heavy forms, chairs with arms, upholstered sometimes in hide, or having loose velvet cushions, and high-backed benches or settles. A beautiful example of a carved settle is shown in Fig. 4. The monk's bench or table settle was made at this period, a piece with a movable back which is adjustable to form a table and is reproduced for the Jacobean style of hall furnishing to-day.

Chests of the 17th century were often beautifully decorated. Buffets were a development of these set on stands and were the earliest attempts at sideboards. A court cupboard and a livery cupboard would be found in the dining hall of the day, a courting seat, or double armchair, might be seen there towards the end of the Jacobean period. A bible box and a mirror, pillows, tapestries, curtains, and carpets were accessories and amenities which softened the otherwise austere utilitarian appearance of the wealthiest home.

*Fig. 3. Oak stool, middle 17th century; height, 1 ft. 10 3/4 in.; length, 1 ft. 6 in.; width, 1 ft. 1 in. Fig. 4. Oak settle with finely carved and panelled back. (Fig. 3 by permission of the Director, Victoria & Albert Museum; Fig. 4 courtesy of Gill & Reigate, Ltd.)*

Panelling was extensively used for interior decoration, and plaster work of great beauty is seen on friezes and ceilings of the period. Examples of rooms can be studied at the Victoria and Albert Museum, South Kensington. The small oak panel of the Jacobean period had sometimes an inlay of coloured wood and the moulding of its frame was often elaborate. Small panels were also a feature of the heavy oak doors.

*Jacobean Style. Fig. 2. Oak gate-leg table, 17th century; height 2 ft. 3 3/4 in.; width, 3 ft. 2 1/2 in. (By permission of the Director, Victoria & Albert Museum)*

#### Inlay and Carving.

Jacobean furniture is not cabinet maker's work as now understood. It is the work of a joiner, and is very simply put together. Its main appeal is on account of the decorative treatment, which is distinctive and easily recognized. Where inlay was used it was in geometrical or floral patterns. Sycamore, holly, and box were favourite woods for inlay; and sometimes ivory, bone, and mother of pearl were used on chests and more elaborate pieces. On these and on wall panelling relief carvings are also seen; otherwise carving in the main is incised. Guilloche strap work and arabesque ornament were frequently carved on chests, settles, and buffets. Architectural shapes were given to panels by applied mouldings. Relief carving enriched this style and, where genuine, the piece decorated with it is of great value.

Jacobean styles continued to be made in oak and cheaper woods for the furniture of middle-class homes and farmhouses well into the 18th century, and often where the carving is somewhat crudely incised on a genuine antique this may be found to be a later piece of farmhouse furniture, the decoration having been done by the joiner and not by a carver.

For these commoner pieces perfectly straightforward patterns were incised into the wood by the V-tool and gouge. It was a common custom to sink the ground and leave the pattern flat, with a little relief introduced by gouge and V-tool veinings. Many chests

of the period have a diamond form incised in the width of the panels, and a few gouge cuts put in the corners or centre or on the edges of the rails give a little relief. Frequently a date occurs on a chest or court cupboard, but many plain chests of the Cromwellian period and later have had earlier dates put on, so that it is unwise to take dated furniture at face value. Rails enclosing panelling were not as a rule mitred, and the upper moulding was often scratched on.

Jacobean carving of this type has usually an amateur look. It is common to see furniture of the period carved all over the front—in the case of chests, buffets, and dressers—and only a little plain space left here and there. Welsh settles and chests are seen quite crudely treated in this way, the ornaments being often merely a flat, conventionalized dragon or the acanthus leaf form.

The armchair of the period was a very clumsy article. It consisted of heavily turned legs and arm supports, a square panelled back finished sometimes with a crest rail, and rails connecting the lower part of the legs and occurring immediately beneath the plain, flat, wooden seat. The back sloped back a little, and it was common for ornamentation to be introduced in the form of incised leaf ornamentation and possibly strapwork.

**JACOBINIA.** This South American tropical plant requires ordinary hothouse treatment. It is propagated by cuttings taken in spring-time, and needs a compost, loam, peat and sand. Two of the finest sorts are *chrysostephana*, which bears orange yellow blooms in winter and spring, and *carnea*, with rose coloured flowers later in the year.

**JACOB'S LADDER.** This hardy herbaceous perennial grows about 18-24 in. high and bears blue or white flowers in summer.

They flourish in ordinary soil and are easily grown. The best are *Polemonium caeruleum*, blue; *alba*, white, and *himalayanum*, blue. The last named sows itself freely. All can be grown from seeds sown out of doors in spring.

**JACONET.** Plain cottons, usually white but sometimes dyed, jaconets are some 40 in. in width and in pieces of about 20 yd. in length. They are a kind of calico somewhat finer than longcloth and coarser than madapolam, sometimes given a hard finish, but procurable also in a soft finish like nainsook.

**JACQUARD.** To produce large figured patterns such as are seen upon brocades, damasks, and tapestries, or to weave monograms and lettering into cloths, a special attachment had to be fitted to the loom. This mechanism bears the name of its inventor, and the goods woven are also described as jacquard.

The process is slower than ordinary weaving, making the goods more costly to produce. To obtain a more perfect result cloths are sometimes jacquard-woven although they could be produced upon a less complex machine.

The designs in Brussels and Wilton carpets, damask tablecloths, flowered bath robes and bath mats, are

jacquard. In many fabrics jacquard weaving can be detected by the fact that the back and face of the cloth are a perfect replica, but in reversed colourings.

The name has nothing to do with the kind or grade of material, for silk, wool, cotton, and linen may all be woven by this means. Using fine enough thread and a sufficiently elaborate jacquard machine, portraits and coloured pictures can be reproduced quite successfully and faithfully in woven cloth. *See Loom; Weaving.*

**JADE.** Jade is a very hard mineral, and appears in various shades of green, greenish white, and yellowish grey. Jadeite is brighter in colour.

Large quantities of jade and of its imitations are now used in Europe. It is worn in the form of carved ornaments and beads and is chiefly valued on account of its beautiful colouring. Genuine carved Chinese pieces of good workmanship and colour are, however, intrinsically valuable.

**JAM.** Jam can be made from many kinds of fruit, although some kinds are more suitable than others. Some fruit, e.g. the apple, goes well when mixed with certain other fruits, but does not itself make good jam.

Dried fruit is sometimes used, but fresh fruit makes a much better article. When jam is made from dried fruit, the fruit must be soaked overnight in water which covers it well, and fruit and liquid boiled together the following day.

The chief fruits used for jam making in Great Britain are raspberries, strawberries, gooseberries, currants (red and black), plums, damsons, and apricots. Rhubarb is used chiefly to mix with other fruit, and apples go well with blackberries. Quinces, pineapples, and cranberries are among the other fruits used. Marrow jam is made, and ginger is also used to flavour other fruits.

For jam the fruit must be sound, and most of it should be rather under-ripe. The jam will not keep or set well if over-ripe fruit is used. A mixture of one-third ripe and two-thirds unripe fruit will produce a jam of good flavour and good setting qualities. Green gooseberries are used. The colour may be intensified with a little green vegetable colouring, or the jam may be reddened with cochineal.

**The Process Described.** The preparation of the jam depends to some extent upon the kind of fruit used. Gooseberries must be topped and tailed, currants must have their stalks removed, raspberries must be hulled, and so on. All bruises and blemishes must be removed. Some fruits are stoned for jam, but this is not essential, even in plums. All fruit, except soft fruits such as raspberries and strawberries, should be washed in cold water. These should be tossed lightly in a clean towel, to remove any dust. Iron or tin utensils should not be allowed to come in contact with raw fruit. It should be prepared with a silver or stainless

steel knife; stirred with a wooden spoon and boiled in an aluminium or enamel-lined preserving-pan. All fruit should be weighed before boiling.

This done, the fruit should be put into a thoroughly and recently cleaned preserving pan. If it is hard fruit, sufficient water must be added to start the cooking, but if it is soft fruit no water is required. In the former case about a pint of water to 10 lb of fruit is an average quantity, but very under-ripe fruit may require more. As for sugar, white granulated should be used, and from  $\frac{3}{4}$  lb. to 1 lb, allowed to each pound of fruit. The sugar should be warmed before adding to the fruit. Ripe fruit requires slightly less sugar than unripe. Gooseberry jam, for instance, will require 1 lb. of sugar to each pound of fruit in order to bring out the flavour of the berries. This jam is also an instance of one which requires more water,  $\frac{1}{2}$  pint being necessary to each pound of fruit.

The fruit should then be boiled. First stir it over a moderate heat until its texture is broken down. Then add the sugar and stir the fruit until all of it is dissolved. The jam should then be boiled rapidly until it sets when tested. The preserving-pan must be large enough to allow of rapid boiling without fear of the jam boiling over. The jam must be stirred in order to prevent burning. Scum should be removed after the sugar is added.

The jam should be tested frequently by placing a little of it on a cold plate. If, on cooling, the consistency is firm, it has boiled sufficiently. If it is boiled too long it will not set, and it will be syrupy. When it is boiled, pour the jam into heated jars, and place on its surface, while still hot, wax papers, and tie on a cover of parchment paper. Store the jars, when cold, in a cool, dry place.

Some fruits, such as strawberries and some of the sweeter varieties of raspberries, require the addition of a small amount of citric or tartaric acid, or of acid fruit juice, for instance, that of red currant, to produce a jam that will set. An average amount of acid is  $\frac{1}{2}$  oz. to every 8 lb. of fruit. It should be dissolved carefully in as small a quantity of water as is possible, and should be mixed thoroughly into the jam before the sugar is added. If acid fruit juice is used, about a pint should be added to every 4 lb. of fruit.

If less than  $\frac{3}{4}$  lb. of white granulated sugar is used to each lb. of fruit, or if it is insufficiently boiled, it will not keep, nor if stored in a damp cupboard or in too warm a place.

Although usually made from fresh fruit, jam can also be made from fruit pulp which has itself been made from the fresh fruit. The advantage of this pulp is that it can be kept until it is required for the jam. Apples, plums, damsons, goose berries, and raspberries are especially suitable for pulping. Fruit pulp can be bought from any large store, so that it is possible to make jam all the year round.

**Jam Containers.** Containers for preserves are obtainable in various sizes to hold 1 lb., 2 lb., 3 lb., or 7 lb.; larger sizes are also made, particularly for the

marmalade. These jars or pots are made of glazed earthenware or glass, the latter being preferred by many, partly for its appearance, and also because it enables any trace of mould on the preserve to be detected without removing the cover.

To prevent the jars from cracking while the hot jam is being poured in, make sure they are absolutely dry, and warm them a little beside the stove. Of the various kinds of patent covers used to keep jam jars airtight, the most easily adjusted are those with clips or flanged rims or screw tops. If bladders are used, the jam should first be covered with a round of white paper, the bladder washed in warm water, partly dried, and then stretched across the top of the jar and tied down tightly with string. Parchment paper or greaseproof paper can also be used. Packets of tissues and gummed covers can be bought in various sizes to fit the jars. *See* Blackberry. Gooseberry, etc.

**Jamaica Pepper.** *See* Allspice.

**JAMB.** This term is often used in architecture and building construction to describe the side posts of a doorway, the side of a window opening or of a fireplace. The word is better understood if it is remembered that, in substance, the door, window frame, or grate is jammed or compressed into the opening of the surrounding brickwork, although the framing may be built into position.

The part of the wall that remains visible after the door frame, for example, has been fitted is known as the reveal, for the reason that the jamb is visible or revealed. The casing around the opening is known as the jamb lining, the upper part as the jamb head.

The decorative treatment of window jambs comprises facing the jambs with thin oak, nicely figured, wax polished, and possibly decorated with applied mouldings. In the case of a thin-walled building, considerable improvement can be effected by extending the jamb linings beyond the wall face and hanging casement curtains in the opening. The jambs in a room treated in a severe style may well be painted or stencilled, a floral design being suitable. *See* Door; Hinge; Window.

**JAMESIA.** This is a hardy deciduous shrub, allied to the hydrangea. The Jamesia is a native of the Rocky Mountains, and is a member of the saxifrage order. It requires good, well-drained soil, and reaches a height of about 3 ft.

*Jamesia.* *Hardy shrub called after an American botanist. It is allied to the hydrangea, and is very effective grown in a large sunny garden. (Courtesy of Amateur Gardening)*

Plant from autumn to spring, and when necessary prune directly after its white flowers have died down. Propagation may be by seed, but the best method is to insert cuttings of ripe wood in sandy soil under a cold frame during autumn.

**JAM PUDDING.** Some suet pastry and jam of any kind are needed to make the following jam pudding. Use a little of the pastry to line a basin, put in a spoonful of jam and then cover it with a round of pastry. Continue these layers until the basin is full, making the last layer one of pastry. Cover the pudding with a greased paper and steam it for 2½-3 hours.

A baked jam pudding is made by mixing together ¾ lb. of flour, 6 oz. of sugar, a teaspoonful of baking-powder, 6 oz. of finely chopped suet, and the grated rind of one large or two small lemons. Work in gradually 2 well-beaten eggs and ½ pint or more of milk. Have ready a greased pie-dish, and into it put 4 tablespoonfuls of jam. Pour the mixture over it, and then bake the whole in a moderately hot oven until it has risen and is quite firm. This is sufficient for about seven persons.

**JAM RISOLE.** To make these 2 oz. of margarine, ½ teacupful of water, 4 teacupfuls of flour, and a little jam are required. Melt the margarine in a saucepan; then add the water and bring them to the boil. Move the pan to the side of the fire and let its contents cool till they are just warm; then work in the flour and mix all to a fairly soft paste, adding more water if necessary.

*Jam Rissole. Dish of a favourite sweet somewhat similar to doughnuts.*

Knead the paste on a floured board until it is smooth, roll it out to the thickness of ¼ in., and cut it into rounds with a tumbler. Put in the centre of one round about one teaspoonful of jam, damp the edge of the pastry all round, and lay another piece on top of it, pinching the edges well together. Have ready a deep pan half full of smoking hot fat, put in the rissoles and fry them to a golden brown colour. Drain them well on paper, roll them in castor sugar, and serve at once. They can be made with far less trouble from a good short pastry.

**JAM ROLL.** This roll is made according to the directions given for jam sandwich, except that the mixture is poured to a depth of ¼ in. into a flat oblong-shaped tin lined with paper. When baked, it is sprinkled on one side with castor sugar and the other side is spread with warm jam. The cake is then rolled up quickly and left on a wire stand to cool. This is

sometimes also known as a Swiss roll.

**JAM ROLY POLY.** This favourite kind of jam pudding is made by rolling out some suet pastry to an oblong shape and spreading it with jam except for a margin of ½ in. all round. Wet the edges and roll up the pastry. Wrap and tie the pudding securely in a scalded and floured pudding cloth, and boil it for about 1½ hours. Jam roly poly is also baked, but in this case a short pastry is used.

**JAM SANDWICH.** The cake known as a jam sandwich is made by whisking together for 15 minutes 6 oz. of castor sugar and 2 eggs. Into a separate basin sieve ½ lb. of flour and 1 teaspoonful of baking-powder and in a saucepan over the fire melt 2 oz. of butter. Fold the flour lightly into the eggs and sugar, and add the melted butter and the grated rind of half a lemon.

Grease two sandwich tins, pour half the mixture in each, and bake them in a very hot oven for 10 min. Place them on a sieve until they are cold, then split each sandwich and spread it with jam. Sprinkle castor sugar over the top and cut each cake into eight pieces and serve.

**JAM SAUCE.** This sauce is especially well suited to baked and boiled suet puddings. To make it blend a teaspoonful of cornflour with a little water, and boil what remains from ½ pint of the latter with 2 tablespoonfuls of any jam. Pour these on to the cornflour, and boil all for 5 min. Add the juice of a lemon, and then it is ready to serve. Syrup or treacle sauce can be made in the same way, two tablespoonfuls of syrup or treacle being used instead of jam.

**JAM TART.** Small jam tarts can be made by lining some patty pans with short or puff pastry, filling the cases with rice in order that they may not rise, and then baking them in a hot oven until they are lightly browned. They may then be filled with warm or cold jam of any kind, and served either hot or cold. A large open jam tart can be made in the same way, the pastry lining being pricked with a fork. If liked, some narrow twisted strips of pastry may be laid across the tart, but in a case of this kind the jam should be put in before the tart is baked.

*Jam Turnover. Dish of the appetising pastry sweet sometimes known as jam puff.*

#### **JAM TURNOVER.**

Make 8 oz. flaky pastry and roll out about ¼ in. thick. Shape it into small rounds with a fancy cutter, and on half of each place a teaspoonful of any kind of jam.

*(Continued in page 1160)*

# JANUARY

## What to do in the Garden

### Flowers

Plant leaf-losing trees and shrubs in mild weather

Press down all outdoor plants raised out of the ground by action of frost

Plant roses in open weather

Patch bald spots in lawns with turf

Protect autumn-sown annuals, if necessary

Make alterations in directions of paths or shapes of flower beds

Sow seeds of tuberous begonia and gloxinia in the greenhouse

Take cuttings of perpetual-flowering carnations

Sow seeds of sweet peas under glass

Take cuttings of chrysanthemum

Maintain a minimum temperature of 45° to 50° in the greenhouse in cold weather

Give geraniums a shift into larger pots

Keep the hothouse at a minimum temperature of 50° at night, 70° maximum by day. The ordinary heated greenhouse may be at least 10° lower with safety

### Fruit

Spray fruit trees out of doors with one of the tar-oil washes or with caustic soda solution

Prune fruit trees out of doors and vines under glass

Plant fruit trees and bushes when the weather is mild

To ensure ripe grapes in summer vines should

be started into growth in a temperature of 45°-50°

Strawberries in pots to provide early fruits should be placed under glass

### Vegetables

Sow seeds of onion under glass

Sow carrots and radishes in a frame

Early potatoes may be started in frames

Give the asparagus bed a top dressing of farmyard manure, if available

Go over stored root vegetables carefully, and remove all specimens which show symptoms of decay

Look up all vegetable articles in this Encyclopedia for instructions to obtain early crops

## Food in Season

### Fish

Barbel; bream; brill; carp; cod; dory; eels; flounders; gurnet; haddock; hake; halibut; herring; ling; mackerel; perch; pike; plaice; mullet (red); salmon (Dutch and Canadian); skate; smelts; soles; sprats; tench; turbot; whitebait; whiting

### Shellfish

Crab; crayfish; lobster; mussels; oyster; prawns; scallops; shrimps

### Meat

Beef; house lamb; mutton; pork; veal; venison

### Game & Poultry

Capons; capercailzie; chicken; duck; fowl; geese; hares; landrails; larks; partridges; pheasant; pigeons; pintail; plover; ptarmigan; pullets; quails; rabbits; snipe; teal; turkey; wild fowl; widgeon; woodcock

### Vegetables

Artichokes (globe, Japanese and Jerusalem); beetroot; broccoli; Brussels sprouts;

cabbage; cardoons; carrots; celeriac; celery; chervil; chicory; cress; cucumber (forced); endive; horseradish; leeks; lettuce; mushrooms (cultivated); onions; parsnips; potatoes; radishes; salify; savoy; Scotch kale; tomatoes; turnips; turnip tops; winter spinach

### Fruit

Almonds; apples; bananas; Brazil nuts; chestnuts; cob nuts; cranberries; grapes; lemons; limes; medlars; oranges; pears; pineapple; rhubarb; walnuts

## Notes for the Month

JAN. 1. New Year's Day. Bank Holiday in Scotland

JAN. 1. Stock Exchange closed

JAN. 1. Dog and Establishment Licences to be renewed

Damp the edge of the round and then fold over other half, pressing edges well together. Brush the turnovers with milk, and bake them on a greased baking sheet in a hot oven for about 15 min. The pastry should be made according to the directions given in the article on that subject. *See Pastry.*

**JAPANESE ANEMONE.** This valuable, hardy herbaceous perennial bears white or coloured flowers on stems 3-4 ft. high in September. It should be planted in autumn or spring in deeply dug and manured soil in sunshine or partial shade; it becomes established slowly and should remain undisturbed for years. It is a good plant for the shady border. The

botanical name is *Anemone japonica*. Some of the finest varieties are alba, white; Queen Charlotte, rose-pink; Mont Rose, rose; Lord Ardilaun, double white and Lorelei, double rose pink.

*Japanese Anemone. Delicate, long stemmed blooms of the autumn-flowering white variety.*

## JAPANESE

**CUCUMBER.** This type of cucumber is very similar to the ridge variety. It is perhaps more productive, and may easily be raised from seed. It should be grown in rich soil in a sunny place out of doors, from seed sown in May.

Fruits grow up to a foot in length but, as the habit of the plant is really a climbing one, help must be given with branches or stakes so that tendrils may have good support. A four-foot trellis is excellent for the purpose. It must be understood that this variety does not compare with the frame cucumber either for quality or size. *See Cucumber; Frame.*

## JAPANESE GARDENS AND GARDENING With Instructions on Making a Dish Garden

The articles in this work that deal with the garden in one form or another include Garden; Italian Garden; Rock Garden. See also the entries on the various plants; also Path.

Ample space and a congenial position are essential to secure an artistic Japanese garden. The ideal position is near a running stream. Artificial hillocks and knolls or pools and shallow waterways may be constructed when missing from a position otherwise desirable.

Harmony must be maintained by using furniture and material of Japanese character for such adjuncts as a summer or tea house or a bridge over a lake. Typical Japanese trees and shrubs in pots and tubs will be attractive, with groups of the dwarfiest kinds planted here, and there in hillocks and knolls. Quaint bridges should span narrow waterways, the shallow parts of

which may be crossed by causeways of grey stepping-stones, while footpaths wander deviously through varying heights of ground. Where the soil itself is of a moist character, irregular slabs of stone should be placed to form a path. Aquatic plants are one of the greatest charms in Japanese gardens, and a home for these water-loving specimens, together with a pool for water lilies, must be included in the general scheme of the garden.

**Screens and Hedges.** The wistaria and Japanese roses should be utilized, as these are indispensable for covering structures, or hedging out an undesirable aspect. A boundary or screen of Japanese flowering trees, hardy bamboos, and evergreens is necessary where a natural one does not already exist. Near the centre of the garden there should be a dominant hill, with lesser hillocks, banks, and knolls, suitably placed in the picture. The path, perhaps, may complete a circuit, winding in and out, up and down, until eventually it rejoins at the point where it began, with a connecting path running to the centre. True circles and straight lines must rigidly be excluded from any ground plan.

There should be a lake consisting of two pieces of water joined by a narrow, curving bottle-neck channel: and as much of the charm of a Japanese garden is derived from its quaintness of detail, this bottle-neck, spanned near its middle by a bridge approached by an informal setting of grey, flat stones, may very well be one of the most fascinating spots. When excavation is necessary to make a lake, the soil removed may be used with advantage to form rising ground.

Bridges play an important part, and there are many curious and effective examples in wood and stone. Some are elaborate like the roofed bridges with their clustering wistaria, others just simple structures of faggot and bamboo covered with soil or turf. Another

type is the familiar full-moon bridge, erected in a semi-circle, the reflection in the water beneath completing a circle, and thus creating the idea of a full moon. Where the watercourse is very narrow a simple slab of stone may be used.

At one end of the lake rockwork with alpine should be placed, while along its banks aquatics and water-loving plants may find their home. If possible, a garden well should be included, also a guardian tree of either bamboo, pine, or plum. An attractive adjunct is the square or octagonal lantern.

The lake, in most cases, will be the chief difficulty, but beyond a good deal of hard work, its formation is not insuperable; and being in close proximity to the proposed hill, or hillock, in the top left-hand corner the soil excavated may very well be used in order to form the rising ground.

**Miniature Japanese Gardens.** A fascinating pursuit which children can enjoy is laying out a little Japanese garden in a flat dish. Such a garden may

measure anything from 6 in. to 2 ft. or even more across. A shallow brown earthenware baking dish measuring, say, 12 in. by 7 in., is a useful size with which to make a start. The dish may be oval, oblong, square, or round, but an oblong is easiest to plan out successfully. The first thing is to decide on a rough plan

of the garden; for instance, on the position of the little hill on which the pagoda is to stand, and the lake or pool, without which no Japanese dish garden is entirely complete.

*Japanese Garden. Corner of this artistic and fascinating type of garden, with stepping stones leading between aquatic plants to the miniature pagoda.*

Fill the dish with finely sieved and well-damped garden mould to just above the rim pressing it down firmly, and arrange a good hillock on one side. Next start out armed with a basket and a short, blunt table-knife in search of some fine vivid green cushion-moss with which to turf it. An old wall, or bridge, will often yield just the specially fine kind required. Add some tufts of rather coarser moss to serve as bushes and a few minute flowering plants. Low-growing Alpine rock plants sold at 6d. each are suitable. Moss can also be bought if it is not possible to obtain this on a country walk; quite a large piece is obtainable for 2d. Tiny imitation pine trees can be bought cheaply.

Children who live in the country can search in the shrubbery for minute seedling hollies or firs. The paddock or hillside will often produce tiny, dwarfed oak trees and beech trees, with miniature leaves, where the acorns and nuts have sprouted on very poor soil—just the thing for the dish garden. Failing these a small asparagus fern, costing sixpence, stripped of its lower fronds to leave a single tall stem makes an excellent Japanese acacia tree while a small plant of fine white heather will suggest a bush of white flowering broom.

A slab of rock such as is used for a rock garden, which can be flaked with a blunt knife, will provide flights of stone steps and miniature rocks beside the water's edge. Stones may be utilized taken from the roadside or garden.

#### How to Arrange the Garden

First thoroughly damp the moss, and, having damped and drained the mould in the dish (which, of course, has no bottom drainage), plant any trees with good balls of their own earth round their roots, and proceed entirely to turf the landscape, running the moss right up to the stems of shrubs and trees, and to overhang the lake or pool in the garden. Press it well down and make any necessary undulations in the surface. The trees should be perched up on the hill, to

give it height, with the pagoda just beneath their shade.

Arrange a winding flight of steps down the hillside to the water's edge, and one or more finely gravelled paths to meander between moss bushes and flowering shrubs round the outside of the garden. Shell gravel (procurable at any bird-seed shop for a few pence a tiny sack) scattered from a penny pepper pot with rather large sprinkler, or sand spread from a piece of paper made into a cone-shaped poke and used as if icing a cake, allowing the sand to trickle out of the hole at the end, can be used to make a level surface for the paths.

If space allows, place a rocky island in the centre of the lake, cementing it to the bottom of the small oblong glass or china dish used for this purpose, which must be lined with dull green plasticine (a penny stick will do) and covered with shell gravel before the water is poured in, planting a tuft of rushes beside the tiny landing stage formed of a scrap of rock half embedded in the turf.

Connect the island with the mainland by an arched bridge made of a short strip of straw-punnet, stained dull green with water-colour paint, or formed of several minute brown twigs, wired with dull brown florist's wire to lie side by side. More elaborate bridges can be bought.

For a larger garden a real Japanese dwarf tree is often employed, and the tea house is placed under its shade. More elaborate gardens can be made in a corner of a conservatory and built up on a large tin tray.

If real water for the lake is objected to, substitute a piece of clear glass (a well-polished stripped negative glass does) over the top of the prepared hole, in which a minute toy goldfish has been arranged, with a tiny moss water plant, to add a touch of realism, or make no excavation, merely pressing a strip of looking glass on to the soil at just below dish-level, bringing the turf right over on to the surface to make irregular green banks. A bridge thrown over the water and a tiny, flat bottomed punt afloat upon the lake or pool complete the illusion.

*Japanese Garden. Miniature Japanese Garden, the materials for making which are inexpensive and readily accessible.*

Swinging lanterns are easily made from a vivid-coloured oval bead, with a smaller bead of contrasting colour on either side of it, arranged to swing from an iron stake formed of part of a bent hairpin.

Tiny figures, birds, tea houses, pagodas, boats, steps, summer houses, red bridges, and a variety of suitably tiny plants can be bought at a sixpenny store.

A fountain which will play in the centre of the real water lake is an additional attraction to the garden. For this a small oblong tin makes a good tank, with a hole bored in the bottom, to which a length of fine indiarubber tubing long enough to go from the bottom of the tank (fastened to the wall, or to the top of a stout garden stake, thrust into a flower pot, at least eighteen inches above the level of the water), and passed over the edge of the dish and under the turf along the bottom of the lake, to emerge from the centre of a tiny rockery (made from scraps of rock cemented together), with the nozzle of the glass tube (bent at right angles) fitted to the end of it, the join being carefully plastered with plasticine to prevent leakage. When in play the fountain will throw a water jet several inches high into the air.

To cut the glass tubing to the necessary length saw it half-way through with a three-sided file—it will then break easily at the point required. Point the end to be used as mouthpiece for the fountain by holding it obliquely in the flame of a powerful lamp, or in a gas jet, twisting it round and round in the flame, so that it may thicken evenly all round as the glass melts, and continue this until only a tiny hole in the centre of the tube remains. To bend it at right angles, hold it straight across the flame at the point at which the bend is needed; as it gets hot it gradually melts, and, bending with its own weight, falls downward at right angles.

For a waterfall make a second hole in the tank, with a second length of tubing concealed beneath the turf to appear at the top of a rocky gorge, beside the pagoda, down which the waterfall can play. The mouthpiece of glass tubing must be melted to a fine point, as for the fountain, but need not be bent. The garden must be watered with a dolls' watering pot, and then tilted to drain about every other day, to keep the mossy turf green.

**Japanese Golden Bell Flower.** This is the popular name of *forsythia* (q.v.), one of the most beautiful spring-flowering shrubs.

**JAPANESE MAPLE.** A number of low-growing trees or shrubs, varieties of *Acer japonicum* and *Acer palmatum*, are known as Japanese maples. They are suitable for planting out of doors except in cold districts, for the rock garden, and for cultivation in pots in the greenhouse. The spring and autumn leaf colouring of some sorts is very beautiful. The following are some of the best varieties. Of *Acer japonicum*—*aureum* and *laciniatum*. Of *Acer palmatum*—*roseo-marginatum*, *sanguineum*, *Osakazuki*, *septemlobum* and *dissectum* are noteworthy. Miniature trees of the Japanese maples are sold by dealers. *See Dwarf Trees.*

**JAPANESE QUINCE.** This is the popular name of *Pyrus* (*Cydonia*) *japonica* (sometimes called *japonica*), a shrub which bears red flowers in spring. *See Pyrus Japonica.*

**JAPANESE SPANIEL.** This little snub-nosed, straight-haired, silky dog is a comparatively recent introduction to the list of ladies' toys in Britain, but in

Japan they have enjoyed popularity for centuries. It bears a certain resemblance to another type of Eastern dog, the Pekinese, which has also found favour in England. It has a relatively large, broad head, short, wide muzzle, large, dark, lustrous eyes far apart, and small, V-shaped and feathered ears. The body is short and square-looking, the dog's length being equal to its height, which is about 10 in. at the shoulders.

*Japanese Spaniel, a popular toy breed with a long, straight-haired, silky coat.*

The spaniel has a profuse, rather silky coat, the long straight hairs with a tendency to stand out. The small legs, thighs, and tail are well feathered, and there is a thick ruff around the neck. The colour is clear white, with patches of black or some bright tint of red over the body, cheeks, and ears. It should weigh between 4 lb. and 9 lb., the lighter weights being more highly esteemed than the heavier. Its constitution is by no means robust, and great care is needed in the feeding of it. *See Dog; Spaniel.*

**JAPAN LACQUER.** This is a liquid made of shellac, or some similar resin, metallic oxide, turpentine, and linseed oil. It is used to a considerable extent as a medium when grinding and mixing colours, and as a drier to hasten the setting and hardening qualities. It is reputed to have originated in Japan. Virtually a hard black varnish, it is applied as such, and dries with a glossy and smooth surface. *See Lacquer; Varnish.*

**JAPAN WARE.** Articles treated with an application of Japan lacquer are known as Japan ware. The latter is used in the home in the form of tea-trays, bread-pans, candlesticks, etc., its main virtue being the ease with which it can be kept clean. Luke-warm water should be used for washing, and a soft cloth for drying and polishing. A smeared surface caused by grease should be sprinkled with a little flour and then rubbed with a soft cloth; hot water should not be used, as this invariably produces cracks.

**JAPONICA.** This old and favourite shrub usually may be found in nurserymen's lists either under *Cydonia japonica* or *Pyrus japonica*. *See Pyrus Japonica.*

**JAP SILK.** A great deal of silk is made in Japan and consequently that country is noted for the supply of cheap, plain and usually un-dyed silk, which is used very largely in Great Britain for blouses, dresses and linings, and for cutting and sewing into handkerchiefs and many other articles.

This silk is made in standard widths of 19½, 22½, 27 and 36 in. and in pieces mostly 50 yards long. The weight is designated by mommes, a Japanese unit of weight; the thinnest are 2 mommes and suitable for lining hats; 5 mommes silk is medium, and the heavier kinds run 8½ mommes and upwards.

The fabrics are mostly handwoven and made from comparatively unworked silk. When thicker silk is wanted the threads are not twisted together, as is usual in European cloths, but are gummed together and woven.

After weaving the cloths are boiled and the gum and paste are thus taken out of them, so improving the colour; they are made a still better white by being dried in the sun. They are sprayed next with gelatine to stiffen them, and are ironed or calendered between heated steel rollers. They are often irregular, containing minor defects, but are so cheap that small imperfections are overlooked. The silks are graded according to their quality.

When Japanese silk is washed for the first time some loss of weight and substance may be expected, consequent upon the removal of the gelatine stiffening. This cannot readily be replaced in a made-up garment, and the attempt is likely to lead to cloudy patches. Soda in more than very small quantities is bad for silk and weakens it. The best soap should be used for washing, and if a good heavy quality of silk is bought the lost weight will not be missed. A little vinegar should be used in the last water. The whiteness will be increased by drying outdoors.

Jap silks are dyed extensively in Great Britain by professional silk dyers and in colours to suit the demands of the season. Before dyeing, the pieces are well washed to remove the gelatine, which would cause unevenness of shade. They are treated, after dyeing, generally with some kind of starch to make them feel fuller, and so that they shall not be too stiff the starching is broken up by rubbing and brushing the cloth by machine. If a garment is to be re-dyed at home it should be beaten lightly to remove dust, be washed perfectly clean, and silk dye should be used on it. Jap silks are often printed in colours in Britain or in France, to befit them for dress materials, linings, and hat and neck trimmings. *See Dyeing; Silk.*

**Jargoon.** This translucent, colourless or smoky variety of zircon, found in Ceylon, is sometimes used to make imitation diamonds.

**JASMINE.** Two of the most popular hardy climbing plants are *Jasminum nudicaule*, which bears bright yellow flowers in winter, and *Jasminum officinale*, with white, sweet-smelling flowers in summer. The former is suitable for a sunny wall; it

should be pruned as soon as the flowers are over by shortening the side shoots of the past summer's growth to within an inch or so of the base. The white jasmine should be planted to cover a trellis, arch or porch. It is difficult to prune this shrub systematically, because its long, slender shoots intertwine freely, but these ought to be thinned out in spring.

Both these jasmines nourish in ordinary soil, and as they are grown in pots they may be planted at any time, preferably in spring or autumn.

They are propagated by cuttings in a frame or out of doors in autumn. Other climbing jasmines are *Beesianum*, red; *primulinum* and *revolutum*, yellow. They are suitable for planting against a sunny wall. *Gracillimum*, white, must be grown in a heated greenhouse.

*Jasmine. Flowering sprays of the yellow winter jasmine.*

**JASPER.** This opaque stone, a variety of quartz, is widely used for ornamental purposes. Several kinds are known, some being red, brown or yellow, while others have various markings, such as stripes and spots.

**JASPER WARE.** The hard, dense and vitrified biscuit ware which Josiah Wedgwood perfected in 1776 and called jasper is one of the triumphs of English pottery. For twenty years, until his death, the output was very large, especially of tiny cameos, generally portraits and classical scenes in white relief usually on a blue ground, although in various tones. A number of other colours were also employed as backgrounds.

Cameos were often set in gold and steel mountings for finger rings, brooches, buckles and other personal ornaments. Larger medallions, tablets, and plaques sometimes as much as 27 in. wide, were separately framed, or inserted in the fronts of cabinets and mantelpieces. During his last ten years Wedgwood produced some superb vases, whose exquisite finish was due to lapidary work after the firing. Of this the collector can hardly hope to secure the larger examples except at a substantial outlay.

*Jasper Ware. Choice example of a vase of Turner jasper ware, height 12 in. (British Museum)*

Wedgwood jasper is still produced in the original designs, and may be recognized by some differences in the mark, such as the addition to the word Wedgwood, after 1891, of the word England. In 1907 the date was fixed by a mark consisting of the figure 3, to denote that it was in the

third of the alphabetical cycles started in 1846, with a capital letter for the workman and another for the year, that for 1907 being J. The old mark Wedgwood & Bentley used on plaques, medallions and portraits during the period 1768-80 is not found on pieces with an olive, sage, pink, lilac, yellow or black ground, and not on blue-ground vases.

Jasper ware should be kept clean with soft leathers and a sparing use of plain water, because otherwise the unglazed surface tends to become streaky and discoloured.

Some of Wedgwood's pupils and rivals turned out jasper more or less according to his designs and recipes. Of these collectors prize the work of John Turner, whose blue ground is rather violet, and also of William Adams, whose descendants still produce a jasper-looking semi-porcelain. Foreign imitations and counterfeits of old jasper are usually poorly done and readily recognized. *See* Wedgwood.

**JAUNDICE.** This is a condition in which the colouring matter of the bile circulating in the blood gives a yellow hue to the skin, the mucous membranes, and also to the urine and other secretions. Jaundice is not itself a disease, but a symptom for which a cause must always be sought. The yellow colour is at first noticeable in the eyes.

It may be caused by gall stones or parasites obstructing the bile ducts, or by a tumour of the stomach, pancreas, or liver, etc., pressing on the bile duct. A very common cause of obstruction is catarrh of the bile ducts, and this may be produced by indigestible or ill-masticated food, a chill, excessive consumption of alcohol, etc. This catarrhal form of jaundice may pass away in a fortnight, and it rarely lasts more than six weeks.

Jaundice may occur in fevers and in poisoning by phosphorus and other substances. It may follow a severe fright, or a fit of anger, or other violent emotion, in which case it comes on suddenly and goes as quickly.

The treatment of jaundice will obviously depend on the cause, and the diagnosis should be made by a doctor. *See* Gall Stone; Liver.

**JAVELLE WATER.** An excellent bleaching agent prepared from chlorinated lime and pearlash, javelle water is much used for whitening discoloured clothes, and also for removing various kinds of stains. It can be purchased in a prepared form from chemists, or made up at home in the following way. Shake together in a bottle 30 oz. of water and 2 oz. of chlorinated lime or bleaching powder and, when they are well mixed, add a solution consisting of 4 oz. of carbo-nate of potash (pure pearl-ash) and 10 oz. of water.

When the mixture has been allowed to stand for a few days separate the clear liquid from the sediment by means of filtration. White clothes only should be treated with javelle water, since the latter contains certain properties which destroy colour. For bleaching purposes about a cupful should be added to a copperful of water, and the clothes should soak in the solution overnight.

If used for removing stains, either from clothes or paper, the liquid should afterwards be washed off with clean water, otherwise the material may rot. Grass and ink stains and scorch marks on linen or cotton goods may be treated with javelle water; but in the case of a scorch alternate applications of oxalic acid solution are required.

**JAZZ.** The word is of American negro origin, and refers more to the music which is played in syncopated time than to the steps of a dance. There was nevertheless a rolling step known as the jazz, which formed part of the fox-trot; also a straight jazz step. The term "jazz band" is now out of date; instead, "dance orchestra" is generally used. Full-sized dance orchestras consist of piano, saxophones (sometimes clarinets), trumpets, trombones, and occasionally strings, with a percussion outfit and a Spanish guitar.

**JEAN: The Material.** Overalls can be made in jean, which is an especially strong cotton twill used in lining leather boots and in making corsets.

## JELLIES AND THEIR MAKING

Strawberry, Lemon and Other Attractive Varieties

Recipes for other sweets for the table are given throughout this work under such headings as Ices; Trifle. *See* also Cherry Jelly; Children's Party; Mould; Sweets

Jelly is the name given both to the fruit jelly used as conserve and to the moulded table jelly. To make jelly the general principles are as follows:

The fruit should be on the under-ripe side, as pectin, the jellifying substance, is only fully present in under-ripe fruit. As pectin will only work in conjunction with acid, very sweet fruits should either have citric acid or the juice of more acid fruits such as apples, lemons, rhubarb, added.

The fruit, carefully picked over, should be put in a preserving pan with just enough water to keep it from burning. Very slow heat should be used to extract all the juice. Boil it gently until the fruit is pulped, then pour it into a jelly bag, and leave it overnight in order that the juice may drip through into a basin. Do not press the bag or the jelly will be cloudy. Measure the juice back into the preserving pan, and add the sugar, the proportion of which varies with the kind of fruit, but is usually about 1 lb. to 1 pint of juice. It is important that the quantity of sugar should be exactly right. With too much sugar the jelly will not set; with too little it will be tough, so test for the quantity with a small amount of juice. If the jelly will not set, add a little citric acid or lemon juice until the desired consistency is reached, and then add the acid in the same proportion to the juice in the pan.

Boil the syrup again until a little jellies when dropped on a cold plate. If it is boiled too long, the jelly loses flavour and becomes dark and sticky; if not

boiled enough it will not set. Pour it into warmed jars and tie down at once. The pulp left after the juice is abstracted can be mixed with apples or some other juicy fruit for making jam.

**Jelly Bag.** This device for straining the juice from the fruit in the making of jelly is a cone of felt or of strong flannel with loops of tape at the mouth, by which it is hung while the fruit is straining. In making a bag remember that it must be large enough to hold all the fruit likely to be converted at a time. Double-sew the seam, so that no juice escapes through filtration. A clean coarse cloth is often used instead of flannel.

A stand can be obtained to which the jelly bag is fastened, but can easily be improvised at home, the loops on the bag being hung on to the backs of two chairs. A quickly improvised jelly bag can be made as follows: Turn a kitchen chair upside down on the edge of the table, then tie the corners of a square of strong, new flannel to the four legs. A large bowl is then stood upon the inverted seat to catch the juice. The jelly bag must always be moistened with hot water before the fruit is poured in.

The jelly bag illustrated is very useful for making small quantities of jelly. An ordinary basin is placed on a table where it will not be disturbed, and the jelly bag fixed over it.

*Jelly Bag for straining small quantities of jelly.*

A jelly bag should not be washed with soap. As soon as it has been used put it into a basin of boiling water, and stir it about with a stick. Change the water once or twice as it becomes dirty, then add some cold, and wring it out. Rinse it well, then dry it in the open air, but be sure that it is quite dry before putting it away.

**Table Jellies.** These are made either with gelatine and fruit flavourings or by pouring boiling water on to a preparation obtained in crystal or powder form, or as a lump of very solid jelly, which is cut up into squares.

In making a fruit jelly of the first kind, the quantities and methods of preparation vary with the different fruit. The following simple recipes give some instances:

**Strawberry Jelly.** Strawberry jelly is made without boiling the fruit. One pint water and  $\frac{1}{2}$  lb. loaf sugar are boiled with  $\frac{1}{4}$  pint red currant juice, and this syrup is then poured over  $\frac{1}{2}$  lb. carefully picked strawberries. When cool, 1 oz. gelatine, dissolved in a little water, is added, and the whole is poured into a mould.

**Lemon Jelly.** Lemon jelly is made thus: Dissolve  $\frac{1}{2}$  oz. gelatine in 1 pint water, then add the grated rind of 4 lemons and the juice of 2, and  $\frac{1}{2}$  lb. loaf sugar. Then,

to clarify the jelly, add the white of an egg, and the shell, crushed in the hand. Put the whole on the fire and whisk it continuously until on the point of boiling. Then strain it and pour it into a wet mould to set. This jelly is usually clarified. Orange jelly is made in the same way, but needs only 5 oz. sugar.

**Wine Jellies.** To make wine jellies, such as claret cherry or port wine, use 1 oz. gelatine to one bottle of cheap wine and  $\frac{3}{4}$  lb. loaf sugar. Simmer until gelatine and sugar are melted, and then boil for 5 min. Add a little carmine or cochineal in order to give a better colour if necessary. Strain into a mould and leave to set.

To decorate a table jelly with fruit it is necessary to line the mould with jelly to keep it in place, before the bulk of the jelly is put in. This is done by taking two moulds of the same shape and pattern, but one slightly smaller than the other. Let a little cool jelly mixed with fruit set in the bottom of the larger mould. Then put the smaller one inside it, and fill up the spaces with fruit and jelly. When this is quite set pour a little hot water into the inner mould which can then be removed without difficulty.

In making a packet jelly with the addition of fresh fruit it should be remembered that less water is needed; fruit and water together should measure only a pint.

**Jelly Mould.** There is a large variety of moulds for table jellies, both as to shape and size. They are made of tin, aluminium, china, or glass, and are usually ornamented with some raised design which is reproduced on the jelly. Frequently the design is of fruit, and in that case it is desirable to use a jelly of the same flavour. A pineapple jelly, for example, may be set in a mould decorated with a pineapple, and a jelly flavoured with port or claret in a mould with a bunch of grapes upon it.

The mould should not be very deep in comparison to the width, or the jelly may break upon being turned out. Some moulds are made with a deep indentation in the bottom, the corresponding hollow in the jelly being then filled with whipped or clotted cream or with chopped fresh fruit or a purée of fruit.

Before using a jelly mould, make sure it is quite clean, then fill it with cold water and let it stand for a few minutes. When the jelly is ready to pour into it, empty out the water, but do not dry the mould.

**Jelly Fingers.** These quickly prepared sweets are made from half a dozen sponge fingers, a pint of raspberry jelly, and an ounce of almonds. Pour a thin coating of the jelly in a shallow glass dish, and when it has set arrange the sponge fingers on top, leaving about 1 in. of space between each.

Soak them with a small quantity of jelly, and cover the top with the almonds, blanched, skinned, and each split into three or four pieces. Pour over the remainder of the jelly, taking care to keep the biscuits in position,

and leave it to set. Then cut out the fingers with a sharp knife and arrange them tastefully on a glass dish.

**Jelly Trifle.** A trifle made from sponge cake and jelly, and decorated with almonds and whipped cream, is prepared thus: Cut 4 large sponge cakes into halves, and arrange them in a dish with the cut sides downwards. On the top of them stick 1 oz. of blanched, skinned, and halved almonds, and pour over a pint of strawberry jelly. Leave the whole until it sets, then decorate it with a gill of whipped cream, sweetened to taste. A layer of pineapple or sliced peaches may be placed under the sponge cakes and the cream ornamented with crystallized violets and angelica strips.

**JERSEY WONDER.** These fried cakes are made as follows: Rub 3 oz. butter into 1 lb. flour, and then add 3 oz. castor sugar, and a little ground nutmeg, ground ginger and grated lemon peel, and mix to a stiff dough with 4 well-beaten eggs, and, if liked, a few drops of brandy. Turn the dough on to a floured board, and roll it out to a thickness of about  $\frac{1}{2}$  in., and then cut it into oval shapes, about 4 in. by 3 in.

Two slits should now be cut down the centre, not cutting through the ends. Pass one side of the cake through the slit in the other side, and drop it at once into a pan of boiling fat. Turn it in about 2 min. time, and in another 2-3 min. it will be done, and nicely risen. Take it out with a fish slice, and drain on kitchen paper. Several of the cakes can be cooked at the same time.

**Jerusalem Artichoke.** An easily cultivated plant belonging to the sunflower family, with edible roots. *See Artichoke.*

**JERUSALEM SAGE.** This is the popular name of *Phlomis fruticosa*, a half-shrubby plant about 3 ft. in height, with sage-like leaves, and yellow flowers in summer. It thrives best on light soils, and is propagated by seed sown in spring, or by cuttings during the summer.

**JET: For Wear.** The best hard jet is very tough, and can be carved and then polished with jeweller's rouge. Formerly almost the only jet ornaments available were massive and funereal-looking brooches and necklets. For modern neck ornaments jet is often used in bead form with crystals.

Imitation jet is really a variety of coal, cannel coal, highly polished, and so skilfully cut that it is difficult on inspection only to detect the difference between it and the more costly genuine jet.

Besides being made into jewelry, imitation jet, which is a composition of black glass, hard black wax and other substances, is used for trimming dresses.

To clean jet, wash it in warm, soapy water, and dry in sawdust, but if it is regularly brushed with a soft brush each time after use it will not be necessary to wash it very often. This is an advantage, because although the jet itself is not affected by washing, the material on which it is threaded deteriorates when wet, so the

process should be avoided as much as possible.

**JEWELRY.** Fashion plays a great part in the wearing of jewelry. One year it is correct to wear precious stones in the daytime; another year, except at the smartest afternoon functions, they will be seen only in the evening. In any case good taste is governed by a certain simplicity. Pearls and coloured stones are seen to best advantage without any mixture except diamonds. For instance, a sapphire and diamond pendant should not be worn with ruby or emerald bracelets or brooches, or it will lose its distinction.

Where a particular gem is liked, it is a good plan to collect the various pieces of jewelry to form a set, choosing a simple artistic design unlikely to go out of fashion, and the stones themselves for colour rather than size. If a large piece of oriental or modern art jewelry introducing a number of coloured gems set in filigree gold or worked silver be worn, it looks best, as brooch, clasp or pendant, without other ornaments.

The same isolation may be observed with carved Chinese pendants of chalcedony, amber or jade, into which further colour is often introduced by the threading of amethyst, coral or carnelian beads on to the loop of the pendant; also with the long chains of semiprecious beads which in themselves provide a trimming for a dress.

Pearls are always fashionable, either real or counterfeit, many of the finest imitations and artificially cultured specimens defying detection except by the expert. Single pearls, or pearl hoops and tassels, are favourite forms of earrings, and old seed pearl ornaments look well worn with a black evening dress, though they need careful handling.

For modern jewelry French settings are, as a rule, most admired. Yellowish or greyish tinges in diamonds detract from their value; sapphires should be of a rich royal blue or they lose their beauty at night, appearing to be black. The finest Burmese rubies are of the coveted pigeon blood colour; emeralds are rarely without a slight flaw. These four stones are well imitated in paste, some of the old French examples being set with exquisite finish, and in the case of coloured paste often mounted with real brilliants. Modern paste has a fine lustre when new, but it deteriorates, and it can always be distinguished by the expert on account of its comparative softness. Another form of imitation gem sometimes sold in cheaper jewelry is the doublet, a thin piece of real stone cut to form the front, while the back is paste.

Rubies, sapphires and emeralds are cut in the same ways as diamonds or en cabochon, that is, with a rounded surface, which has a beautiful effect in rings when the coloured stone is surrounded by brilliants. For opaque or semi-opaque stones such as turquoise, cat's eye or opal, the cabochon form of cutting is always used. The beauty of turquoise lies in its lovely blue colour, but it is liable to turn green and the stones should be kept from contact with grease or perfume.

The opal suffers from the persistent superstition that it is unlucky, but a fine specimen possessing brilliant flashes of fire always holds its place in public favour. The opal is a soft gem and easily dulled by scratching after much wear. This defect can be removed by a jeweller and the surface brilliancy entirely restored.

**Victorian Styles.** Many of the less precious coloured gems are exceedingly beautiful, such as peridots of soft, transparent green; topaz, pink and yellow; aquamarines, sea-coloured, as their name implies; tourmalines, red, pink, green and brown. Victorian pieces of garnet jewelry have returned to favour with the cameo and onyx. The last named, which is chalcedony stained to a black, has been used with diamond workmanship for exclusive designs in jewelry of all kinds.

Earrings are probably the most valued of Victorian pieces of jewelry, as many of these show fine quality of workmanship. Filigree or chased metalwork settings for black or blue enamel or turquoise are sought after. Much Victorian jewelry was made of, or set in, pinchbeck, a metal which was composed of a mixture of zinc and copper and practically untarnishable. Pinchbeck was an invention of a 17th-century jeweller of that name. Only those pieces of pinchbeck jewelry made before the 19th century have value for the collector.

Amethysts, never out of fashion, are best when of a deep purple. The alexandrite possesses the quality of appearing by daylight a rich green and by artificial light changing to red. Moonstones with their silvery semi-opaque shimmer are very pretty set in conjunction with coloured stones, especially red. In the 20th century the fashion has been for geometrical designs in the setting of jewels rather than the copies of birds, insects, flowers, etc., favoured during the latter half of the 19th century.

All kinds of semi-precious stones and also ivory, amber and coral are formed into beads for necklets and long chains. Lapis lazuli is popular on account of its deep blue colour, and it is imitated in stained agate. Jade, either green or white, is not imitated so successfully. Jet, though chiefly used for mourning jewelry, is effective when combined with crystal for necklets. Jewelry for men, now that the wristlet takes the place of the watch chain, resolves itself into pearl studs for evening wear, cuff links, and a signet ring. *See* Bracelet; Brooch; Diamond; Emerald; Earring; Pearl; Ring; Ruby.

**JEW'S MALLOW.** This is the common name of *Kerria japonica*, a hardy Chinese shrub, about 3 ft. high, which has yellow flowers in spring. The double variety, which bears much larger flowers, is more vigorous and an excellent wall shrub; it is one of the few shrubs that do fairly well on a wall facing north. It thrives in ordinary soil and is increased by cuttings placed in sandy soil in a frame in August. Pruning should be done as soon as the flowers have faded by cutting out the oldest branches or parts of them. If grown in pots, the Jew's mallow is very useful for the

cold or slightly heated greenhouse in spring.

**JIGSAW PUZZLE.** To make one of these puzzles it is best to start on a small puzzle for practice. For this a suitable coloured picture on thin paper can, as a rule, be found in an old magazine or weekly paper. A picture with a shiny surface should be chosen, as dull-surfaced paper becomes so quickly soiled with handling when fitting the puzzle together.

The more definite the picture the easier it will be to put together. A puzzle with a wide expanse of clouds and sky, or of softly shaded fields, for instance, is much harder than one with a scene depicting huntsmen and hounds in full cry, or a dog study.

Experienced jigsaw puzzle solvers delight in a really difficult puzzle. One of the most successful ways of gratifying their desire is to choose a large figure subject which fills most of the picture, and to cut away the background, leaving the puzzle solver no clues in the shape of straight-sided border pieces and the eagerly sought-for corners.

**Making a Puzzle.** The tools needed in jigsaw puzzle making are few. A small fretsaw and frame, a set of extra blades, and a wooden cutting-table—a metal cutting-table is apt to blunt the blades—and clamp, to enable it to be fastened to the edge of any convenient steady table. It is essential to use proper fretsaw wood on which to mount the pictures, as other kinds will be found to split. Good quality 3-ply wood is the right thing to use. Satin-walnut wood is also excellent, and there are other kinds of good thin wood which fretwork material outfitters will recommend. From 3/16 to 1/4 in. thick are the best widths.

To start, make some good strong paste from a tablespoonful of flour, mixed to an absolutely smooth cream with a little cold water, and made up to half a pint by the addition of boiling water, poured in slowly, stirring the mixture all the time. The paste should gradually thicken and clear, becoming semi-transparent; if necessary, turn it into a small saucepan, and stir over a low flame to attain this result. Set it aside to cool; when cold it is ready for use. Trim the picture carefully, removing any white margin, and, placing it face downward upon a sheet of clean, white kitchen paper, brush it over with paste, and then leave it for five minutes to expand.

Brush it over with paste a second time and, lifting it up carefully by the two top corners, place it face upward upon the fretwood, and press it down until absolutely smooth with a pad of white cotton rag. Make sure that it lies absolutely flat, and that any air bubbles have been smoothed out, before placing a sheet of white paper over it and putting it under a pile of heavy books to press until it is quite dry. Meanwhile, fix the cutting-table to the edge of any steady table of convenient height for fretsawing, and when the picture is absolutely dry proceed to cut it out to the exact edge of the margin.

Now take a pencil and, placing the picture face

downward, mark out the pattern of the jigsaw pieces into which you intend the puzzle to be cut. In doing this, remember to avoid sharp points or too thin waists to the individual pieces, as these are liable to break off when the puzzle is in use. Count the number of pieces marked, and note down the number.

For the first attempt it is as well to keep the pieces of fair size, and of not too intricate a pattern. Place the picture face downward on the cutting-board, and proceed to twist it about with the left hand to bring the line to be cut into contact with the cutting edge of the saw, which works up and down perpendicularly in the hole in the cutting-table provided.

When once the knack has been obtained, the work usually goes very swiftly, and soon the puzzle is cut out. Gather the pieces up carefully, counting them to make sure that none are missing, and mark each piece on the back with the same small device—a star, a heart, an arrow head—in water colour, so that if accidentally mixed with the pieces from another puzzle they may easily be re-sorted. Pack them into a small cardboard box, upon the lid of which a label should be neatly pasted, giving the title of the picture and the number of pieces it contains.

When mounting a picture that is printed on rather thick paper it is a good plan to well damp the back with a sponge squeezed out in cold water, leaving it for five minutes, and repeating the process a second time, and again leaving it fully to stretch before brushing it with paste and mounting it in the usual way. If a picture is brushed with paste and mounted without waiting for it to stretch, it is apt to dry into countless minute wrinkles which it is impossible to smooth away, and the picture is ruined. *See Fretwork.*

**JOB'S TEARS.** The name of Job's Tears is given to a half-hardy grass, *Coix lachryma Jobi*, 2-3 feet high, which is attractive when mixed with cut flowers by reason of its drooping clusters of pearly seeds. It requires rich light soil and a sunny position. Seeds may be sown in a temperature of 60° in spring, transplanting seedlings during May.

**John Dory.** *See Dory.*

## JOINERY: ITS GENERAL PRINCIPLES

### The Choice of Materials and the Tools to Use

A knowledge of joinery is indispensable to those who wish to make the many woodworking articles about which directions are given in this work, such as including Bureau; Cabinet; Cupboard; Dresser and many others. *See also Amateur Carpentry; Bench; Joint; Wood, etc.*

Joinery is that branch of woodwork concerned with the preparation of the more ornamental parts of a building, and particularly the art of joining wood to form a strong structure, durable and pleasing in appearance. Joinery is allied to carpentry; but although many of the tools used are common to both, carpentry is, generally speaking, a rougher class of woodwork.

In addition to a knowledge of the various timbers in common use, it is necessary for the joiner to know the limitations of his material. Joinery becomes ineffective in general for three particular reasons: first, by warping or splitting of the material; secondly, owing to failure of the joint due to the expansion and contraction of the wood; and thirdly, as a result of the natural process of decay. In good joinery all parts should be framed together in such a way as to allow for shrinkage or expansion, at the same time proportioning the thickness and breadth to prevent warping. Another point is that the work should be put together so that no end grain, or the minimum of end grain, is exposed to the weather. The end grain is the most liable to attack, because it virtually consists of a series of small pipes conducting moisture to the interior. To reduce shrinkage, all exposed parts should be as narrow as possible, this applying mostly to those members which happen to be framed up.

**Choice of Material.** It is a counsel of perfection to specify that all material should be thoroughly seasoned; that the wood should be chosen from the heart of the tree, and that sapwood, the portion of the tree which surrounds the heartwood, should be rejected.

Wood employed in joinery comprises battens or scantlings, measuring from 2 in. to 7 in., boards ranging from 7 in. to 9 in. wide and up to 2 in. thick, and planks, that is, stuff wider than 9 in. Deal is the name given to sawn timber 9 in. wide and from 2½ in. to 4 in. thick. The name does not necessarily apply to yellow deal only, and the term is frequently used to distinguish different kinds of timber, though it properly only means any timber cut to the sizes specified above. Thus the name white deal is commonly used to mean spruce, because this tree is cut into deal for export. Quartering is another name by which certain sizes of sawn timber are known; it is applied to stuff approaching the square in section, as 3 in. by 3 in. or 3 in. by 2 in. All timber should be subjected to a second seasoning after it has been sawn into boards or planks, and from the joiner's point of view this second seasoning is the more important one.

A useful wood is American whitewood, which is obtainable in various widths and thicknesses and is free from knots. It is susceptible of effective treatment with stain and takes a good polish. Mahogany, walnut, and similar ornamental hardwoods are also employed, but for most work ordinary softwoods are used. Of these pine, particularly yellow pine, is the most serviceable for many purposes in the home.

For the provision of panels and all places where large pieces of thin boarding are required, a useful material for the amateur joiner is plywood. Its use saves much trouble in planing, and it has the added advantage of not being liable to warp or shrink when in position.

**Tools for Joinery.** The tools required by the joiner include planes and saws, together with a good selection of firmer, paring, and mortise chisels, and firmer and scribing gouges of different sizes, brace and bits, hammers, pincers, and oilstone. A well-equipped workman will need a quantity of special planes, such as a plough, a fillister, rebate planes and beads, moulding and compass planes, hollows and rounds. Much joinery work is done by machinery. Accurate planing is done by thicknessing machines, moulding and beads are cut by formers, curves are cut by handsaws, and mortises and tenons and dovetails are cut by special machines. The setting out of intricate pieces of work calls for skill and experience and the accurate use of the rule, square, and bevel, even if the work is partly done by machine.

A solid work bench is essential, and should be about 6 ft. in length and 2 ft. in width. A heavy kitchen table provided with a bench top may be used; but the best work requires a properly constructed bench provided with a strong vice.

The amateur woodworker who takes up joinery should commence by making a careful study of joints and the methods of making the various kinds. Many of these are specifically dealt with under their respective headings, and a general article on the subject follows the present one. Amongst them may be mentioned for special notice the housing joint, the mortise and tenon, the mitre dovetail, and the various classes of halved joints.

It is an excellent plan to begin by practising on a piece of softwood, and in this way to acquire some degree of skill in planing and sawing to a line, for it is little use trying to make even the simplest joint unless the wood is accurately planed, marked out, and sawn. The tools must be kept in the best condition. The plane should be sharpened and set to take a fine shaving. The saw should be sharp, and the thickness of the cut made by it noted; neglect of this precaution will spoil a joint. Chisels should have keen, sharp edges, obtained by grinding and sharpening on an oilstone.

Care must be taken to guard against bruising the wood, for which purpose the use of a mallet is preferable to a hammer. When knocking the parts of a joint together, it is helpful to interpose a rough piece of wood between the mallet and the joint. It is also desirable when erecting the work to see that it does not come into contact with the tools, as if the wood is badly bruised it will be difficult or impossible to eliminate any defects that are made.

Generally the operations involved in joinery include sawing, planing, edge and end grain shooting, rebating, grooving, moulding, and mitreing, in addition to the construction of joints and frames. The proportioning of panelling is an important part of joiner's work, as are the relation of the panel to the width of stiles, rails, and muntins and the size and shape of the mouldings and beads, while the effect of light and shade on the surface calls for skill and experience. All joinery requires a good surface finish and neat accurate joints. The latter are obtained by careful workmanship, and the former by diligent scraping and glasspapering and leaving the work in a suitable state from the plane. Scraping is

done with a specially prepared piece of steel, which is held at an angle to the work and operates by removing fine shavings from the surface. The use of the scraper is essential when dealing with hardwoods, because it is almost impossible to plane the surface without leaving some marks. With the exception of knots on the surface of softwoods, it will generally be possible to obtain a smooth surface with glasspaper, but if the wood contains many knots it will be advisable to use the scraper.

## JOINTS: IN WOODWORK

### An Important Detail of the Woodworker's Craft

Supplementary to this general article are shorter entries on the various joints, e.g. Butt; Dovetail; Halved Joint; Housing Joint; Mortise; Rule Joint.

Reference should also be made to the entries on Bookcase; Bureau; Cabinet Making; Drawer; Glue; Table, etc.

For the sake of convenience, many of the best-known and specific joints are dealt with in this work under their respective headings.

Joints are used in woodwork generally for one of two reasons. Either the size of the material available is insufficient for the purpose, in which case a joint is necessary; or joints are made so that the various components can be arranged to the best advantage from the point of view of the direction of the grain of the wood and the relative proportions of the various pieces. In the former case the joint is often effected by simply glueing both pieces of the material and clamping them together while the glue sets hard. The second case comprises all those structural joints, such as the mortise and tenon, in which one part is shaped to fit into a hole made in the other part. Essentials of any joint of this character are (a) that the fitting surfaces of the wood shall be accurately shaped, so that when assembled the joint is virtually solid wood; and (b) that the one part is flat or true with the other, since a very small error in the shaping of the joint faces causes the one part to take a different direction relative to the surface of the other, with the result that the finished job will be distorted or in the state known as winding.

One of the simplest joints in woodwork consists merely of placing one piece of wood upon the other and glueing and screwing them together; or in the case of light work, sticking them together with an adhesive cement or glue. When these joints are effected by nails or screws, they are generally known as butt joints.

In constructional work, or when it is desired to effect a strong joint between two pieces that will be called upon to resist considerable strain, the joints are often effected by shaping the ends of the faces so that to some extent they interlock. They are further secured by means of nuts and bolts.

Still another series of joints is effected by cutting recesses or grooves to receive the other parts, and this

series of joints is generally known as housing joints. Dovetail joints are adapted to resist strain in certain directions, that is to say, the grooves or holes in the one part are so shaped that the leg or end of the other part can be pulled out only in one particular direction. There are many varieties.

A form of joint extensively used is that in which the one part, such as a panel, fits in a recess or groove in a frame. In the former case a portion of the edge of the framework is cut away, either with a cutting gauge or with a rebating plane, the space so cut away being known as a rebate. The joint is in this case effected by placing the panel in position and securing it with a bead or fillet. When the panel fits into a groove, the latter is produced with a plough plane.

Sliding joints are sometimes necessary in woodwork to provide for the shrinkage or expansion of the material according to the humidity of the atmosphere. These are all more or less in the form of a ploughed groove or a long slot of some kind, to hold the material from warping or twisting, but to allow it freedom of expansion and contraction in the direction of its greatest breadth. The jointing surfaces of wood may be secured by an adhesive, by nails, screws, bolts and nuts, pegs, and also by means of a variety of special fasteners, such as corrugated fasteners and drawbolt fasteners. To tighten up the joint surfaces, a commonly used plan is that known as draw-boring (q.v.), in which a peg is arranged so that it draws the faces of the joint together very tightly.

Joint. Figs. 1 and 2. Hinged and shutting joints in plan.

Another class of joint includes the varieties known as hinged and shutting joints. In good-class work the joint is rebated and provided with a dust or draught bead, Fig 1, and is then a combination of several joints. When a door is hung on a centre pin, the joint surfaces have to be curved, as in Fig. 2.

Fig. 3. Internal hinging joint used in cabinet work.

Many pieces of furniture are made with internal hinging joints, such as the section shown in Fig. 3, which shows how each piece of material has to be shaped to allow for the rise and fall of a flap, as in a bureau.

Among miscellaneous joints is the device known as pocket screwing, Fig. 4, which consists in boring a hole obliquely through the rail or similar part, and gouging out a recess or pocket in the side of the rail. This allows the screw to be inserted, and provides a flat surface for the head to bear upon. This device is used for fixing table-tops.

Fig. 4. Pocket screwed joint in part section.

Fig. 5. Buttoning joint; right, sectional end view of assembled joint.

Another type of joint is known as cleating or clamping. It is simply a batten screwed to the separate parts to be joined together. Fig. 5 shows a buttoning joint, which comprises a rectangular block of wood rebated to fit into corresponding grooves formed in the rail or fixed part of the construction. The button or wood block is then screwed to the table-top or elsewhere, bringing it firmly into position. It is an excellent joint for fixing a table-top on to the side rails of the table. Slot screwed is another form of joint which is easily carried out and effective in use. It consists of cutting a slot through one of the parts to be jointed and securing it to the other with a screw.

Dowelled joints comprise all those forms where the two jointing faces are flat, and kept in position by one or more pegs fixed firmly into one part, with a portion of the dowel projecting, which fits into the hole formed in the other part of the joint. The dowelled joint may be permanent or detachable, as desired.

**JOINT: Of the Body.** Joints are fixed, as those of the skull; partially movable, as those between the vertebrae; or freely movable, as the hip, shoulder, etc. In the movable joints the ends of the bones are covered with smooth cartilage, and the joint is surrounded by a sheath of fibrous tissue lined with the synovial membrane which exudes a lubricating fluid into the joint. Inflammation in a joint may be synovitis, when it is mainly this membrane which is affected, or arthritis (q.v.), when all the structures of the joint are involved. Other diseases and injuries to which joints are subject will be found under appropriate headings. *See* Ankle; Dislocation; Elbow; Hip Disease; Knee; Rheumatoid Arthritis; Shoulder; Sprain; Wrist, etc.

**JOINT: Of Meat.** The parts into which animals that are killed for human consumption are cut up are known as joints. The names of the various joints are

given under the headings referring to the different animals. The names given are those in general use, but the names and the methods of cutting differ somewhat with the locality. *See* Aitchbone; Bacon; Beef; Carving; Lamb; Pork; Veal, etc.

**JOINTER.** This term is used to describe two entirely different tools. In the one case it refers to a large plane, resembling a jack-plane, used when planing the edges of boards preparatory to jointing them together.

The bricklayer's jointer is composed of a cast steel blade, tapered at one end and having a handle attached at about an angle of 45° to facilitate its use in pointing in brickwork. It is used to smooth or finish the pointing or joints between brickwork, particularly the type known as flush pointing. *See* Plane; Pointing.

**JOINTING RULE.** This implement, used by plasterers and bricklayers, consists of a batten of wood about 5 ft. long, 3 in. wide and 1 in. thick, bevelled on one edge. It is used for floating or levelling the surface of plaster in the angle of a room, or for working the surface of a screed on a wall, or any other place where a flat surface of plaster is to be built up. It is also used by bricklayers in the jointing of horizontal and vertical joints in brickwork, particularly in the pointing operations.

The amateur can easily make such a tool from a piece of ordinary clean deal, but it is imperative that it be planed up perfectly true and straight and sandpapered, as any roughness on its edges would be transferred to the surface of the plaster. Its form and method of use are illustrated in the article on plastering.

**JOIST.** The word joist is applied to horizontal supports for floors or ceilings, and in domestic work joists are generally composed of timber, although the use of rolled steel is common, especially in connexion with ferro-concrete constructions. Joists are further described by the addition of the name of the part of the structure to which they act as a support.

For example, the floor joists support the floor, ceiling joists carry the ceiling, and sleeper joists are placed upon the honeycomb sleeper walls under the floor, and act as an intermediate support for the other floor joists. Dovetailed sleeper joists are often embedded in the concrete of a floor as a convenient means of attaching the floor covering in the form of boards, which are nailed into the sleeper joists.

The joists should be of adequate strength for the load they will be called upon to sustain, and for the ordinary type of small house the ground floor joists, which are supported by sleepers at about 3 ft. centres, may be 4 in. deep and 2 in. in thickness. For an upper floor the joists must be much larger, dependent upon the span of the building, but in the case of an ordinary sized house where the joists have a span width of 12 ft., a convenient size is 7 in. deep and 3 in. in thickness, or 9 in. deep and 2 in. in thickness. In the former case there is no necessity for intermediate strutting between the joists, but in the latter it is desirable to fix diagonal

struts of light section, about 2 in. deep and 1½ in. in thickness, to prevent the joists twisting sideways. The average spacing of the joists is about 15 in. for the ordinary 1 in. floorboards.

Ceiling joists usually average 4 in. in depth, and 2 in. in thickness, spaced about 14 in. apart, and are strengthened and supported by longitudinal members, so that the span does not exceed 5 to 6 ft. *See* Floor; Roof.

**JOLLY MILLER.** This game can be played either indoors or outdoors. Each man of the party, with one exception, chooses a lady for his partner. The excepted one stands in the middle of the room, while the others in couples walk round him singing:

There was a jolly miller who lived by himself,  
As the wheel went round he made his wealth;  
One hand in the coffer and the other in the bag,  
As the wheel went round he made his grab.

At the word grab everyone must change partners, and while they are doing this the miller tries to seize one of the ladies. If he succeeds in this, the man who is left without a partner takes the place of the miller and so the game continues.

**JONQUIL.** Bulbs of the common sweet-scented jonquil, a variety of narcissus, should be planted 3 in. deep and about 6 in. apart in autumn. They are equally valuable for forcing or for planting as a woodland flower. Double campernelle is a particularly

noteworthy variety of this flower. There are several fine modern varieties with large, bright yellow flowers, e.g. Buttercup and Golden Sceptre. *See* Daffodil; Narcissus.

*Jonquil. Large-flowered variety of this sweet-scented member of the narcissus family.*

**JUDAS TREE.** This is a hardy summer-leaving, ornamental tree, *Cercis siliquastrum*, about 15 ft. in height, with purplish-pink, pea-shaped flowers in late spring. The flowers are out before the leaves have fully developed.

The tree is common in Judea, and Judas is said to have hanged himself on one. It is grown from seed sown in spring. Propagation by layers in autumn may also be practised if there are branches situated in convenient positions.

**JUDICIAL SEPARATION.** This used to be called divorce a mensa et thoro (from table and bed), to

distinguish it from divorce *e vinculis matrimonii* (from the bonds of matrimony). A judicial separation may be obtained either by husband or wife on any grounds on which a petition for divorce might have been presented or for refusal to obey an order for restitution of conjugal rights. It is an absolute bar to a suit for judicial separation that the petitioner has committed adultery since the date of the marriage.

Separation orders may also be made by magistrates for adultery, cruelty, desertion, or such drunkenness or conduct as compels the wife to leave the husband. Coupled with such magistrates' orders are provisions that the husband shall pay anything up to £2 a week for his wife's maintenance. An order for judicial separation comes at once to an end if the husband and wife cohabit again. *See Divorce; Maintenance; Separation Order.*

**JUG.** Among the jugs sought by collectors are the chocolate jug of Queen Anne's time and the wine jug of a century or more later, both types being fitted with lids. These jugs are usually of silver, but they were also made in Sheffield plate.

Two beautiful examples are illustrated, the first being a silver vase-shaped jug in an Adam design, and the second a Sheffield plate chocolate jug. These shapes are frequently reproduced to-day for hot milk jugs. In the chocolate jug shown in the illustration, the knob in the centre of the lid is removable, thus enabling the contents of the jug to be stirred without being cooled by exposure to the air.

*Jug. Left, silver jug with London hallmark, 1777-8, 12 in. high.*

*Right, Sheffield plate chocolate jug, 1772. (Left. Victoria & Albert Museum, S. Kensington; right, courtesy of Chapell & Mantell. Ltd.)*

Some of the antique silver jugs copied to-day stand on three feet, while others have one circular base. Some of them are finely chased with scrollwork and other decorative features, including beading and gadroon. A form of jug much sought after by collectors is the Toby jug. Old lustre jugs are also valued. Antique brass, copper, or pottery ewers and pitchers form decorative vases for flowers. *See Cream Jug; Crockery; Glass. Pewter; Sheffield Plate; Silver; Toby Jug.*

**JUICE.** This is the name given to the liquid part of fruits, and also of vegetables and meats. Juice is extracted from fruit in the making of jellies, drinks, syrups, sweets, etc., and also, as is the case with lemons and oranges, for flavouring purposes. *See Apple; Beef; Lemon, etc.*

**JUMBLE CAKE.** These small cakes can be flavoured in a number of ways. To make some, cream together 2 oz. butter and 3 oz. sugar, then beat in an egg and add the strained juice and rind of half a lemon. This is then thoroughly mixed with 8 oz. sifted flour. Turn the dough on to a floured board, and roll it out lightly to a thickness of not more than half an inch. Cut it into fancy shapes, and take in a moderate oven, sprinkling the cakes over with castor sugar when they are done. Instead of lemon, orange might be used as a flavouring. Candied peel, chopped almonds, caraway seeds, or spice are also alternatives that would give a pleasing variety.

**JUMBLE SALE.** A jumble or rummage sale is a practical and popular way of raising money for charity. Notice should be given some little time beforehand, say a month, or at least a fortnight, in order that the wealthier members of the community may collect such things as they feel disposed to send. These need not be confined to clothes; almost any discarded article, especially in the way of usable household goods and linen are saleable. If possible, it should also be arranged that all contributions will be called for a couple of days or so before the actual sale. Boy Scouts or Girl Guides are usually only too willing to do this, and a message or postcard from the person having articles for sale will be promptly attended to.

When all have been collected, the next task is to sort, tidy, and price the various things. The pricing should be as low as possible. It must be remembered that the sale involves no initial expenditure, but that every penny taken is clear profit; also, that besides bringing in money for whatever charity fund is concerned, it may be a very real charity to provide poor people with good clothes for a few shillings, and will be far more appreciated than if those same clothes were given away in the ordinary haphazard fashion.

Prices should be clearly marked on tickets and either sewn or gummed on the articles for sale. As far as possible, the garments should be arranged in stalls according to their nature; if there is a large assortment of other things they may be divided into classes or put together on a variety stall.

The sale should be fixed for a day when it is thought that most of the poorer women will be able to attend—probably the local early closing day will suggest itself—and should be open from the early afternoon until 8 or 9 p.m. Many people prefer to hire a hall for the occasion, but a jumble sale can be held very successfully in a large loft or outhouse if there are no suitable rooms in the house.

**JUNE BERRY.** This is the common name of a beautiful small flowering tree, *Amelanchier canadensis*. It reaches a height of 15 feet or more, has white blossom in April and May, and autumn-tinted

*(Continued in page 1175)*

# JULY

## What to do in the Garden

### Flowers

Plant the bulbs of meadow saffron, autumn crocus and the Belladonna lily and the corms of autumn-flowering hardy cyclamen

Bud rose trees on briar stocks planted in the previous autumn or winter

Layer clematis, rambler rose and other shrubs

Save seeds of lupin, delphinium, geum, and other flowers and sow as soon as they are ready

Take cuttings of snapdragon, pansy, mauve catmint, and pink

Sow winter flowering stocks for the greenhouse

Sow seeds of hollyhock, gaillardia, musk, snapdragon, viola, and pansy

Layer the shoots of border carnations

Stake and tie dahlias securely

Keep carpet bedding plants nipped down closely

Cleanse and paint interiors of houses

### Fruit

Layer strawberries to ensure well rooted runners for planting in August

Destroy American blight by means of a brush dipped in linseed oil

Cut out and burn

branches of plum trees attacked by silver leaf.

Summer prune apple, pear, cherry, and plum trees

Prune raspberries as soon as the fruits are gathered

### Vegetables

Finish planting celery and leek

Sow turnip seed to provide roots in autumn

Finish the planting of winter greens

Make the first sowing of spring cabbage

Sow seeds of early carrot to provide small roots in autumn

Cut mint and other herbs for drying

## Food in Season

### Fish

Bass; bream; brill; carp; dory; eel; flounder; gurnet; haddock; hake; halibut; herring; mackerel; mullet (grey and red); perch; pike; plaice; salmon; shad; soles; tench; trout; turbot; whitebait; whiting

### Shellfish

Crabs; crayfish; lobster; prawns; shrimps

### Meat

Beef; lamb; mutton; veal; venison

### Poultry & Game

Capons; chickens; ducklings; fowls; goslings; hares; ortolans; pigeons; pullets; quails; rabbits; ruffs and reeves; turkey poults; wheatears

### Vegetables

Artichokes (globe); asparagus; aubergine; beetroot; broad beans; broccoli; cabbage; carrots; cauliflower; chervil; cress; cucumber; endive; French beans; horseradish; leek; let-

tuce; mushrooms; onion; parsnips; peas; potatoes; scarlet runners; spinach; tomatoes; turnips; vegetable marrow; watercress

### Fruit

Apples; apricots; bananas; cherries; currants (red, white, and black); figs; gooseberries; grapes; melons; nectarines; oranges; peaches; pears; pineapple; plums; raspberries; rhubarb; strawberries

## Notes for the Month

JULY 1.—Dominion Day, Canada

JULY 4.—Independence Day, U.S.A.

JULY 15.—St. Swithun's Day.

# JUNE

## What to do in the Garden

### Flowers

Cut off faded flowers to ensure a prolonged display

Water the garden in the evening during hot dry weather

Spray plants with insecticide to destroy pests

Hoe the soil frequently to keep down weeds and promote growth

Take cuttings of pink, arabis, yellow alyssum, evergreen candytuft, and other rock plants

Cut back vigorous rock plants which have passed out of bloom

Pot chrysanthemums in large pots for autumn blooms under glass

Remove the faded blooms from rhododendron

Prune the flowering

currant, weigela, and mock orange when the blossoms are over.

If necessary, lift spring flowering bulbs when the leaves have died down.

Cut rose blooms with long stems to ensure fresh strong shoots which will flower later

Place azalea and other spring shrubs in pots out of doors for the summer

Stake and tie herbaceous plants

Keep surplus bedding plants ready for making good failures

Thin out shoots of tall-growing herbaceous plants

### Fruit

Spray fruit trees frequently to keep down pests

Layer strawberries to provide plants in pots for forcing

Water fruit trees on walls in hot, dry weather

Pull up surplus raspberry suckers

Ventilate the vinery freely in hot weather

Mulch newly planted fruit trees with manure

### Vegetables

Plant winter greens, celery and leek

Cease cutting asparagus

Plant tomatoes on a warm border or against a sunny wall or fence

Make a final sowing of French beans and dwarf early peas

Sow endive, turnip, globe beetroot, and an early variety of carrot

## Food in Season

### Fish

Bass; bream; brill; dory; eel; flounder; gurnet; haddock; hake; halibut; herring; mackerel; mullet; perch (after 15th); plaice; salmon; shad; sole; tench; trout; turbot; whitebait; whiting

### Shellfish

Crabs; crayfish; lobster; prawns; shrimps

### Meat

Beef; lamb; mutton; veal; venison

### Poultry & Game

Capons; chickens; ducks and ducklings; fowls; guinea-fowls; goslings; hares; hazel hens; ortolans; pigeons; pullets; quails; rabbits; ruffs and reeves; turkey poults; wheatears

### Vegetables

Asparagus; artichokes (globe); beans (broad and French); beetroot; cabbage; cardoons; carrots; cauliflower; chervil;

chervil; cress; cucumber; endive; horseradish; leeks; lettuce; mushrooms; onions; parsnips; peas; potatoes (new); radishes; seakale; sorrel; spinach; tomatoes; turnips; watercress

### Fruit

Apples; apricots; bananas; cherries; currants; gooseberries; grapes; lemons; melons; nectarines; oranges; peaches; pears; pine-apple; raspberries; rhubarb; strawberries

## Notes for the Month

JUNE 16.—Close season for fresh-water fish ends

JUNE 24.—Midsummer Day; Quarter Day

leaves. It thrives in ordinary soil and can be increased by seeds. A variety named *oblongifolia* grows only 5 or 6 feet high and bears white flowers freely in spring.

*June Berry. White spring flowers of this beautiful small tree.*

**JUNIPER.** The juniper is a most important family of hardy evergreen shrubs and trees of many habits and ranging from 1 ft. to 40 ft in height. They are particularly useful as lawn trees and in shrubberies, while lovers of the rock garden should take special note of the dwarf varieties.

The junipers thrive particularly well in chalky soil, and are propagated by cuttings taken in late summer and inserted in a frame. The plants may also be raised from seed. One of the best for general planting is the Chinese juniper (*Juniperus chinensis*); *aurea*, with golden leaves, and *Fortunei*, with grey-green leaves, are attractive varieties.

*Juniper. Specimen of the silvery leaved Chinese Juniper (chinensis), effective either in the shrubbery or in a large rock garden.*

The common juniper (*communis*) is a spreading bush or small tree, but the variety *hibernica* (Irish Juniper), of slender column-like form, is a particularly graceful tree. The dwarf variety, *hibernica compressa*, is one of the most popular miniature conifers for the rock garden. The red cedar or American juniper (*virginiana*), which provides wood used in the manufacture of lead pencils, is an attractive tall tree; the silvery-leaved variety *glauca* is beautiful.

**JUNKET.** This dish is made in the following way: Heat a pint of new milk to about 98° F., which is its natural heat. Then pour it into a dish and add a dessertspoonful of white sugar and 2 teaspoonfuls of essence of rennet. After this let it set, the time needed for this being from 1½ to 2 hours. When it is set, sprinkle it with powdered nutmeg, and then cover it with a layer of clotted or whipped cream.

The rennet for making the junket can be obtained in tablet or powdered form. In the latter case it is sold under the name of junket powder, and directions as to the quantities required are printed on the packet. The powder is sometimes preferred to the liquid rennet because the latter varies in strength, more being needed to turn the milk at one time than another, as climatic and other conditions vary.

If the milk does not solidify with the first addition of rennet or junket powder it can be reheated and more powder or rennet added. A pinch of salt should always be added. The milk used for junket should be perfectly fresh and sweet; if there is the least suspicion of sourness it will not clot, but form into flaky curds. The milk should not be diluted with water, nor fruit juice used for flavouring. Spirits or highly concentrated essences should be used for this purpose, but only sparingly, so that they will not have a curdling effect on the milk.

For flavouring junket brandy is often used, but either whisky or rum makes a good substitute, while on the top cinnamon may take the place of nutmeg. If spirits are not liked, some such flavouring as vanilla or almond essence can be employed. It may be left to set in a room of ordinary or even warm temperature, a cool place such as is required for jelly being unnecessary and unsuitable. A bowl of junket must be handled carefully, as it separates at once if shaken. It makes a light and nourishing dish at all times, but is especially suitable for invalids who cannot eat solid foods. See Clotted Cream; Invalid Cookery; Rennet.

**JURY: Liability to Serve.** With certain exceptions, men and women who are qualified as householders or property owners are bound to serve upon a jury if called upon to do so. Men liable are those between the ages of 21 and 60 who possess land of the clear value of £10 per annum, or who are assessed in the valuation list for a house valued at not less than £30 in Middlesex and £20 elsewhere. Women who possess the same qualifications are liable, but husband and wife must not serve on the same jury. The names of jurors are taken from the lists of voters. The chief classes exempted from this duty are peers, members of Parliament, judges, clergymen, lawyers, doctors, officers of the army, navy, and air forces and Territorial Army, and chemists.

When a jury is required the sheriff or clerk of the peace chooses the names from the list of persons liable and sends by post notices to them. This must be done at least six days previous to the meeting of the court. Jurymen are required for assizes and quarter sessions, and also in London for the sittings of the central criminal court and for certain civil actions heard at the law courts. It is usual to summon more persons than are required, and if the reasons given are deemed adequate a man called can be excused from service. Jury men who fail to attend the court on the appointed day can be fined. They are not paid, except that small fees are given to common jurors and to members of coroner's juries. In some cases refreshments are provided at the expense of the sheriff.

Juries are either grand, petty, coroner's, special, or common. A special jury is one called to hear certain civil actions. Special jurors are taken from those who occupy houses above a certain rental value, usually about £60 a year. Juries in Scotland and Ireland are similar to those in England, although in Scotland the methods of procedure are somewhat different; for

instance, there are no coroners, and hence there can be no coroner's jury.

**Women on Juries.** By the Sex Disqualification (Removal) Act, 1919, women are enabled and bound when summoned to sit on juries. The presiding judge may, however, either at his own instance or on an application made by one of the parties, order that the jury shall be composed of men only, or of women only. A woman may also apply to be excused from serving on a jury in a particular case, and if the nature of the evidence to be given or the issues to be tried make it reasonable that she shall be exempted the judge may exempt her if he thinks fit to do so.

If a woman who receives a jury summons is pregnant, or suffering from some feminine condition or ailment, she should apply to the summoning officer or the under-sheriff, enclosing a medical certificate, and asking to be excused from attendance. This should be done within three days after the jury summons has been received.

**JUVENILE OFFENDER.** In English law a juvenile offender is one who is under the age of 17 years. When a person apparently under that age is arrested, the police superintendent or inspector must let him out on bail, unless the offence is homicide or some other grave crime, or unless it is in the interests of the offender to remove him from some reputed criminal with whom he is associating. If he is not released on bail he must not be put in a prison but in some other place of detention until his case can be dealt with. The object of these provisions is to prevent juveniles from being exposed to the risk of contamination from older criminals.

**Juvenile Courts.** Special courts are held for the trial of juveniles. They may or may not be held in the ordinary police courts but if they are, they must be held at different times from ordinary sittings; and from these courts all are excluded except persons connected with the case and bona fide pressmen. Juveniles are not to be mixed up with ordinary prisoners. In London the Home Secretary appoints for each juvenile court, to assist the regular police, magistrate, two other justices one of whom must be a woman.

In dealing with juvenile offenders, the powers of punishment are restricted. No juvenile can be sentenced to death or penal servitude. He may be whipped or sent to a reformatory or industrial school, or he or his parents may be fined, or he may be handed over to the care of a welfare missionary, or his parents may be bound over to see that he behaves himself for the future. He cannot, however, be sent to prison in default of paying a fine or the costs of the trial, as an adult can. The power that the courts have of fining parents for the offence of a child is the only instance of vicarious punishment known to the English criminal law.

A child under 14 cannot be sentenced to imprisonment, but for certain grave offences may be ordered to be detained for a period such as would formerly have been the period of imprisonment. If

convicted of murder, a juvenile may be ordered to be detained during his Majesty's pleasure. If a juvenile is ordered to be detained, the court may make an order that his parent or putative father shall contribute to his maintenance. *See Child.*

**KAFFIR LILY.** The bulbous-rooted perennial plant known as Kaffir lily, or winter gladiolus (*Schizostylis coccinea*), has long, iris-like leaves, and scarlet flowers on a tall spike in early autumn. It is not very hardy and is generally grown outside in a sunny sheltered position, in a compost of loam, leaf-mould and sand. The bulbs, or rhizomes, may also be placed in pots in early spring. After being established in the cool house or frame they may be stood out of doors during the summer months and taken in for an autumn display inside. Propagation is by division in spring. There is a beautiful pink variety named Mrs. Hegarty.

*Kaffir Lily. Scarlet blooms and iris-like leaves of the winter gladiolus.*

**KALANCHOE.** These are greenhouse perennial flowering plants with thick fleshy leaves. The best are *Kalanchoe flammea* from Somaliland, which bears scarlet flowers in summer; and *Blossfeldiana*, cerise. They should be potted in sandy loam and kept safe from frost. Propagation is by cuttings.

**KALE.** Of this hardy and useful green winter vegetable there are many varieties, e.g. cottager's, asparagus, curled and Drumhead. Seeds are sown out

of doors in April, and the seedlings are planted out in summer at about 2 ft. apart. *See Curly Kale.*

*Kale. Fine head of a variety of this green vegetable known as asparagus kale.*

**KALMIA.** These beautiful hardy evergreen flowering shrubs thrive in peaty or lime-free loamy soil. The best is *kalmia latifolia*, the calico bush, which grows 3 to 5 ft. high and bears pale rose coloured flowers in early summer. *Glauca* 18-24 in., and *angustifolia*, 2-3 ft., both have rose coloured blooms. An important detail of cultivation is to remove the faded flowers to prevent the development of seeds. These shrubs are propagated by seeds, though the seedlings grow slowly.

**KALOSANTHES.** This greenhouse plant, which is classed as a succulent because of its thick fleshy

leaves and stems, is not very commonly grown, but one species, *Kalosanthes (crassula) coccinea* is very showy. It grows about 20 in. high and bears clusters of scarlet tube-shaped flowers in summer. It should be potted in a compost of loam and sand and during winter needs a temperature of 45 to 50 degrees. Propagation is by cuttings in summer. *Kalosanthes lactea* bears white flowers in winter.

**KAPOK.** The vegetable down obtained from the thistle and other plants, and used for stuffing cushions, pillows, etc., is known as kapok. *See Down.*

**KAULFUSSIA** (Cape Aster). This is a pretty hardy annual from South Africa, which grows 6 in. high and bears small daisy-like blue, white or crimson flowers, according to the variety chosen. It is suitable for sowing as an edging. From seeds sown out of doors in April the plants bloom in summer.

**KEDGEREE.** This is an Indian dish prepared mainly from rice and fish. To make it, melt 1 oz. of butter in a stewpan and add to it ½ lb. of boiled rice, ½ lb. of any cold cooked fish broken into flakes, and the coarsely chopped whites of 2 hard-boiled eggs. Season the whole with salt and pepper to taste, make it thoroughly hot, and then pile it up on a hot dish. Garnish the kedgerree with the yolks of eggs rubbed through a sieve, and some chopped parsley.

**KEESHOND.** Breed of dog, popularly known as the Dutch Barge dog. In some respects the Barge dog is similar to the pomeranian, chiefly differing in size and colour. The colour should be like that of the wolf, namely fawn, either light or dark, the long hairs being tipped with black, but the colour on the muzzle, around the lips and on the legs and tail are of a lighter shade. The coat should be very profuse excepting on the head, ears, and front parts of the fore and hind legs where it is smooth. The ears are erect, eyes dark, with a foxy expression, and the head of fox-like conformation. The body should be short and compact, the chest deep, and the tail carried over the back like a plume. The keeshond is about 18 in. in height, and makes an excellent companion as well as a good watch dog. It is a distinctly hardy breed.

*Keeshond.  
Specimen of  
this excellent  
breed of dog,  
closely  
resembling a  
Pomeranian.*

**KENNEDYA.** This greenhouse climbing plant bears pea-shaped flowers in spring or summer. The favourite kind is *Kennedya comptoniana*, with purplish blooms in spring. Another is *Marryattae*, which bears

scarlet flowers in summer. These plants, which are not often grown nowadays, thrive in large pots filled with sandy loam and need a minimum temperature of about 50 degrees. Pruning should be done after flowering.

## KENNELS AND THEIR CONSTRUCTION

### How to Provide Accommodation for the Watchdog

This article suggests a reference to the entry on Dogs, and also to those on the various breeds of dog, e.g. Bloodhound; Spaniel; Terrier. See also the entries on the materials used in the making of a kennel, e.g. Board; Hinge; also Amateur Carpentry; Concrete; Shed.

Kennels are of several kinds, but certain general principles are common to all. All alike should possess roominess and warmth and accessibility, the last mentioned quality being necessary in order that the kennel may be cleaned, as it should be, at least once a week. Attention should be paid to the situation of the door, in order that the dog may escape draughts, while, if possible, a south or south-western aspect should be selected. More necessary perhaps is it that the ground should be dry, for damp is very favourable to disease. Sunshine, fresh air, adequate drainage, and good ventilation are as desirable in the case of kennels as they are in that of houses.

If it is necessary to confine the inmate in the daytime, on no account put him on a chain. A small run can be attached to his kennel, either of railings which are sold for the purpose, or very stout wire netting fixed to posts. Bedding may consist of straw, pine shavings, or sawdust. The latter is a good thing for long-coated animals in winter-time, because of the manner in which it will absorb the wet. The ideal arrangement would be to have an inner sleeping compartment bedded with straw, and an outer compartment littered deeply with sawdust.

*Kennel. Fig. 1. Wooden kennel suitable for a terrier or other dog of medium size.*

### Making a Kennel.

The kennel shown in Fig. 1 is suitable for a terrier or similar dog. Elevations with suitable dimensions are shown at Figs. 2 and 3, and details of the framework at Fig. 4. Deal is a suitable wood to use throughout.

The corner posts (A) are 2 in. square, and the side and end rails (B and C) 1½ in. square. The rails may be tenoned into the posts, as in Fig. 5, or lapped, as in

*(Continued in page 1179)*

*Fig. 2. Side elevation.*

*Fig. 3. End elevation.*

*Fig. 4. Framework.*

*Fig. 5. Mortise and tenon joints in corner post.*

*Fig. 6. Simpler method of securing rails.*

*Fig. 7. Half-lapped joint for rafters.*

*Fig. 8. Door strengthened with battens.*

*Figs. 9 and 10. End sections of kennels suitable for larger dogs.*

## KENNEL

Fig. 6. The joints in either case should be painted before fixing, the tenons being secured with wood pins, or the lapped joints with screws. The rafters (D) are 1½ in. square, half lapped together (Fig. 7) and nailed or screwed to the framing. It will be a good plan to paint the framework before fitting the bottom or covering the side and roof.

The bottom is of ¾ in. grooved and tongued matchboard, fitted around the corner posts, and nailed to the top edges of the bottom rails. The sides and ends are covered with similar boards. An entrance is arranged at one side, being about 1 ft. 2 in. high by 10 in. wide. It will be convenient for cleaning purposes to have a door at one end. The door should be battened together, as shown at Fig. 8, and hung with a pair of long flap hinges. The boarding above the door opening should finish in the middle of the top rail, so that the top edge of the door may shut against this rail as well as against the bottom rail. Weather boards are very suitable for covering the roof. They should overhang 3 in. all round, and the roof is finished with a ridge roll at the top. The kennel should be painted with three coats, or treated with a preservative.

For a retriever or similar dog the kennel should be 3 ft. 3 in. long, and of the section shown at Fig. 8, while for a still larger dog, such as a St. Bernard, the length should be 4 ft., with a section similar to Fig. 10. Their construction will be similar to that already described, only the framing and boarding may be stouter to correspond with the increase in size, and it may be advisable to add a couple of rafters across the middle of the roof.

**KENTIA.** This graceful palm is suitable for a heated greenhouse. It may also be grown in a room window during the summer months. Belmoreana and fosteriana are the favourite kinds, the former being less vigorous than the latter and better suited to cultivation in small pots. A compost of loam, peat, and sand suits these palms, which need a minimum temperature of 50-55 degrees in winter.

**KEPHIR.** This is a form of fermented milk, like koumiss. To make fermented milk, put boiled cow's milk into strong pint bottles, leaving a small part empty; add ¼ oz. of white sugar and a small piece of yeast about the size of two peas to each bottle. Cork, wire, and place the bottles on their sides. Shake them every morning and every evening. The milk will be ready for use in a week. *See Milk.*

**Kerosene.** This name is used for the oil obtained from bituminous coal and petroleum. It is used for lamps. *See Lamp; Oil.*

**Kerria.** Alternative name for the shrub better known as Jew's Mallow (q.v.).

**KERRY BLUE TERRIER.** In size this terrier stands midway between the red Irish terrier and the Airedale. They are rugged fellows with a shaggy, soft

coat and dark, intelligent eyes.

They have a reputation for high courage in tackling vermin and are devoted guards. With children they are said to be very gentle, and they are capable of retrieving or scenting a wounded hare or bird. At present the term blue applied to this terrier admits of a liberal

interpretation, the colour appearing in various gradations. *See Dog.*

*Kerry Blue Terrier. Princeton Hell-of-a-Fellow, champion of this shaggy-haired breed. (Photo, Thos. Fall)*

**KERSEY.** One of the earliest woollen-fabrics made in England, kersey is coarse-spun, like blanket and twill-woven, and usually white or checked. Kerseys are used for horsecloths. Cheap kersey cloths are used for floor scouring.

**KETCHUP.** Ketchup is a sauce made from mushrooms, walnuts or cucumbers.

**Mushroom Ketchup.** To make mushroom ketchup, gather the mushrooms before the sun has discoloured them, and break them very small into a basin. Sprinkle them with salt and let them stand 3 days; then boil and strain them. They must be simmered till all the juice is out. After straining boil up the liquor again with the whites of 1 or 2 eggs to fine it, and then strain. Return the liquor to the fire, adding to every quart of juice 6 shallots, ¼ oz. whole black pepper, ¼ oz. ginger, 1 tablespoonful grated horse-radish, 6 or 8 allspice, and 1 laurel leaf. Simmer about ¾ hour; then skim and strain into bottles and cork them well.

**Cucumber Ketchup.** To make cucumber ketchup, pare the cucumbers and slice them as thinly as possible into an earthenware bowl and cover them thickly with salt. Cover closely and let them stand until the following day; then strain the liquor into a stewpan. To every pint of liquor add ½ pint of white wine vinegar and a teaspoonful of peppercorns, and simmer gently for from 20 minutes to ½ hour. Then allow it to go cold, strain it into bottles, cork it tightly and store in a cool, dry place.

**Walnut Ketchup.** For walnut ketchup the walnuts must be very young, green and tender. To every 100 walnuts allow one quart vinegar, 3 oz. salt, 4 oz. anchovies, 12 chopped shallots, ½ stick grated horse-radish, ½ teaspoonful each of mace, nutmeg, ground ginger, ground cloves and pepper and a pint of red wine. Bruise the walnuts slightly, put them into a jar

with salt and vinegar and let them stand for 8 days, stirring them daily. Drain the liquor into a stewpan, add to it the rest of ingredients and simmer very gently for 40 minutes. When cold, strain into bottles, cork and store in a cool, dry place.

**KETTLE:** Choice and Care. Kettles are made in tin, aluminium and copper and enamelled ware, while more ornamental ones are in silver, electro-plate and brass. The latter, however, are only for use with a small spirit stove, not for the ordinary task of boiling water on a fire. Kettles of aluminium, tin or block tin are the cheapest and for kitchen purposes most suitable. They can be bought to hold 2, 3, 4, 5, 6 or 8 pints, or even more. Copper kettles are more expensive, but their durability is much greater. Some kettles are fitted with wooden handles, which do not get as hot as the metal ones. Others in aluminium are fitted with patent insulated iron handles always cool to the touch.

An aluminium kettle is provided with a cup which fits over the kettle top and can be used to poach an egg in the steam. Another kettle is obtainable with a grooved base so that it forms a lid to a saucepan and serves a dual purpose. Square kettles in aluminium economise space and gas on a gas cooker if used in conjunction with square saucepans. Both kettle and saucepan can be packed neatly together over one burner and no heat escapes between them to be wasted. Absolutely flat bottomed kettles are made for use on electric cookers.

Another kettle is made to hang on a stand, with a heating apparatus in the form of a small spirit stove, while another rests upon a small oil stove. A kettle with folding handle is made for the use of travellers and picnic parties, some of these having a corrugated bottom as an aid to boiling. Bronchitis and fish kettles are amongst those which are made for particular purposes.

Kettles of enamelled ware should be of good quality, for the cheaper makes are apt to chip and to become a source of danger when used for heating drinking water. They may be washed in hot soapy water, and, in case of stains, cleaned in the same way as other enamelled goods. Electric kettles fitted with a heating apparatus and a cord for connecting with the electric wires can be used in any room containing a plug or lamp holder. They have many advantages, among these being the fact that they are easily kept clean, and their contents may be heated on the tea-table itself and kept hot throughout the meal.

**Kettleholders.** These may be made of almost any non-conducting material, from the asbestos ones, which can be bought at most ironmongers, to pieces of serge or woollen cloth from the scrap-bag. Among the most popular are those worked in cross-stitch with bright coloured wools.

Unless at least three thicknesses of material are allowed, the kettleholder will not serve its purpose efficiently. A small loop at one corner is useful, as the kettleholder can then be hung up on a hook by the stove; 6 in. sq. is a satisfactory size for such an article.

*See* Brass; Bronchitis Kettle; Electricity; Kitchen; Silver; Soldering; Tin.

**KEY:** In Engineering. This is the name given to the specially shaped piece of cast steel that is fitted into keyways cut to receive it on the shaft and the part that is to be mounted on the shaft and secured from turning. The key shown in Fig. 1 is the type commonly used in general engineering. To fit this pattern the outer part is first driven home on the shaft with the keyways dead in line, and the key cut very slightly taper from the head on the faces marked *a* and *b*. This taper will be cut to correspond to the amount of taper already given to the keyways. The key when driven home with the hammer should protrude from the shaft, as shown, by not less than  $\frac{1}{8}$  in. This point is essential, if trouble is to be avoided when removing the key.

*Key. Type of key commonly used in general engineering.*

If a key is allowed to become slack, movement will take place between the outer part and the shaft, which, through friction, will very quickly destroy the smooth faces of each, making repair a costly matter. Fig. 2 shows a

key properly fitted to a keyway in a shaft, securing a flywheel.

*Key: in Engineering. Fig. 2. Close-up view of a key fitted to a keyway in a shaft, showing how it fits closely into the boss of the flywheel.*

**KEY:** In Woodwork. In joinery and woodworking, keys of various kinds are used in different varieties of joints, some of which are referred to under separate headings, but in general a key in joinery is a piece of wood which fits into a dovetailed groove to allow the framing to shrink but prevent it warping. A keyed beam is one that is built up similarly to an indented beam, but provided with keys in place of the indents. Keyed mitred joints are those which are strengthened

by inserting thin strips of wood called keys into saw-cuts or grooves cut across the mitre. They may take the form of thin strips converging so as to form a kind of dovetail, or a thick piece known as a false tenon.

*Key: in Woodwork. Showing a keyed joint in carpentry suitable for thin trusses in small roofs.*

A keyed joint in carpentry suitable for thin trusses in small roofs is illustrated below; it shows a rafter keyed to a beam. The key is simply a piece of hardwood accurately fitted into slots cut in the meeting faces of the beams, which are usually further held together by a bolt or strap. *See Joint.*  
Key-cutting. *See Lock.*

**KEYHOLE:** How to Cut. This operation can easily and quickly be done with the aid of a small brace and bit and a keyhole saw. The correct position for the keyhole should be found, this being done by placing the lock-case in position against the door, and passing a scribe or other convenient article through the keyhole in the lock-case, and marking its outline on the woodwork of the door.

Having obtained the correct position of the keyhole, the next thing is to bore a hole of a sufficient diameter to admit the keyhole saw. All that is now required is to cut around the marked outline with the saw. Generally the keyhole is covered by an escutcheon, that is, a metal flap, hinged to the wood or metal work, over the head of the keyhole, so arranged that it can either be lifted up or, as is more generally the case, pushed on one side. This should prevent draughts passing through the keyhole. *See Door; Lock.*

**Keyhole Saw.** This tool is specially adapted for the cutting of keyholes in wood. It comprises a narrow tapered saw with fairly fine teeth with considerable set, to ensure freedom in cutting to the various patterns. A wood or metal handle is used, the former being slotted to allow the saw blade to pass down through it. The blade is secured by set screws in the ferrule. The saw illustrated has a metal handle made of malleable iron and provided with two clamps for holding the saw perfectly square. Spare blades or blades of different lengths and fineness of teeth are procurable.

*Keyhole Saw, a tool special-ly adapted for cutting a keyhole in a wooden door, and other purposes.*

In using the keyhole saw it is necessary to push the saw perfectly in line with the blade, otherwise it is very liable to buckle or break. Too much pressure must not be put on the saw for the same reason, but if these two points are borne in mind the keyhole saw will be found extremely useful for cutting out all manner of shapes in wood up to about 1 in. in thickness. In ordinary work a hole is bored, through which the saw may be passed, and the various shaped portions sawn away.

When working, it is particularly necessary to see that the saw-blade be kept at right angles to the face of the work, otherwise the edges will be tapered and badly shaped. This saw can be sharpened and set in the ordinary way. *See Saw.*

**KID:** Its Uses. A light kind of leather used for

gloves, shoes, and fancy articles, kid is prepared either from goat or sheep skin.

Thorough wetting in water shrinks kid. Certain kinds of heavy kid gloves are sold as washable, but it is safer merely to sponge the surface while the gloves are on the hands. Special glove soap can be used on the sponge. After being semi-dried by rubbing with a soft cloth, sponged gloves should be taken off and left to dry slowly in the air. Rust and ink stains on kid can be removed with oxalic acid applied with a flannel. *See Glove.*

**KIDNEY:** In Cookery. Both sheep's and calf's kidneys can be cooked separately and according to the same directions. Sheep's kidneys, either grilled or stewed, are a favourite breakfast dish, and are also made into curries, pies, etc., while ox kidneys are used mainly for soup-making and stewing. Pig's kidneys may be broiled in the same way as sheep's kidneys, but will require more time.

To prepare grilled kidneys and bacon, remove the rind and lightly fry 6 rashers of bacon. Then put them on a dish in the oven to keep hot while the kidneys are being cooked. Skin and cut 3 sheep's kidneys into halves, and remove the cores, place them in the pan with the cut side down, and cook them gently, turning them once. Dish the bacon, putting half a kidney on each piece; season and place a small lump of butter on each.

Stewed kidney and bacon are prepared from the following ingredients: 1 lb. ox kidney, 3 oz. fat bacon, 2 small onions,  $\frac{1}{2}$  oz. flour, a seasoning of pepper and salt, and  $\frac{1}{2}$  pint water.

Cut up the kidney and wash it well. Place it in a saucepan with the bacon cut into slices, the water, and the sliced onions. Simmer all gently for two hours. Mix the flour, salt and pepper to a thin paste with 2 tablespoonfuls of cold water and add them carefully to the stew, stirring all the while. Boil up the whole, cook it for 5 min., and then serve.

**Macaroni and Kidneys.** Kidneys and macaroni make another savoury dish. Skin and halve 4 sheep's kidneys, sprinkle them with salt, jaegger, and powdered herbs, and then fry them in a pan containing 2 oz. of butter. When they are cooked on both sides, pour off a little of the butter and add  $\frac{1}{2}$  pint of tomato sauce to what remains in the pan. Heat the whole thoroughly; then turn it on to a hot dish and garnish it with a border of boiled macaroni cut into pieces an inch long. On each kidney place a quarter of a hard-boiled egg, and just before serving dust over the whole some grated cheese.

**Mushrooms and Kidneys.** Melt  $\frac{1}{2}$  oz. of butter in a saucepan, stirring in 3 level teaspoonfuls of flour, and then adding  $\frac{1}{2}$  pint of stock. Stir the whole until it boils; then add 2 teaspoonfuls of chopped ham, 2 teaspoonfuls of chopped mushrooms, and a teaspoonful

each of mushroom ketchup and chopped parsley. Mix these well, add seasoning to taste, and then 2 sliced tomatoes. Cook the whole gently for 5 min., and in the meantime skin, halve, and grill 4 sheep's kidneys. Add them, and then reheat the contents of the pan, but do not let them boil. Turn the whole on to a hot dish with sippets of fried bread.

**Kidney Cassolette.** Cassolettes of kidney may be prepared by cooking 2 sliced sheep's kidneys in a little melted butter, adding a finely chopped shallot and a few button mushrooms cut into small pieces. When they have been allowed to fry for a few minutes, add a small teacupful of any good brown sauce and a little sherry. Cook the mixture slowly for 20-30 min., season it, and heap it into some small batter cases for serving.

**Kidney Croquette.** Croquettes of kidney and bacon are made by lightly frying 3 sheep's kidneys and 3 oz. of streaky bacon, and then chopping them finely. Melt an ounce of butter in a pan, stir in smoothly  $\frac{1}{2}$  oz. of flour, add  $\frac{1}{2}$  pint of stock, and stir all until they boil. Put in the bacon and kidney, season the mixture, and then turn it on to a plate to cool. When cold, shape it to form small corks, dip these in egg-and-breadcrumbs, and fry them a golden brown. The croquettes should then be drained on paper, and served with fried parsley and tomato sauce.

**Kidney Soup.** An ox kidney is used to make this soup. Wash and dry it, and cut it into small pieces, removing the fat from the centre. Dredge the pieces with flour and then put them into a pan containing 2 oz. of melted butter or margarine. Fry the kidney until it is brown, then add a large onion cut into dice, and brown that also. Pour in 3 pints of cold water or stock, bring it to the boil, skim it, and then add a carrot and a turnip, cut into dice, and some green celery tops chopped up coarsely. Simmer the whole slowly for 2 hours, then strain and return the liquor to the pan. Blend a tablespoonful of flour smoothly with a little cold water, add it to the liquor in the pan, and stir the soup until it boils. Simmer it for 5 min., season to taste, and then serve. If preferred, this may be served as a stew, with thick gravy and a border of rice or macaroni.

**Kidney Toast.** Either a calf's or sheep's kidney, previously cooked, may be used to make kidney toast. Mince it finely, season to taste, and then heat it up in any good brown sauce. Serve the mixture heaped on slices of hot buttered toast. If liked a little chopped parsley and shallot may be added to the mince. A few small mushrooms are also an improvement to this dish, and a little sherry to flavour. *See* Batter; Steak.

**KIDNEY BEAN.** Varieties of French beans, the seeds of which are shaped like kidneys, are known as kidney beans. They are cooked according to the general directions given for French beans. *See* Bean; French Bean.

## KIDNEYS: Functions and Diseases.

Situated one on either side of the spine, the kidneys are partly covered behind by the last ribs. Their function is removal of the nitrogenous waste products in the form of urea, uric acid, etc., and of other substances from the blood. The essential elements of the kidney are arteries to bring blood containing waste material; urinary tubules to separate this latter, together with a large quantity of water, from the blood; and veins to carry back the purified blood. While the healthy kidneys separate water, urea, uric acid and certain salts from the blood, they do not allow sugar or albumin to pass. In disease they lose this selective power, and great quantities of sugar may pass into the urine in diabetes, and large quantities of albumin in Bright's disease and other maladies. On the other hand, they may fail to remove the urea, etc., and thus give rise to symptoms of uraemia.

Abnormalities are sometimes found. There may be only one kidney, or the kidneys may be united at their lower ends, forming what is called a horseshoe kidney. In some people, and especially women, the kidneys may be more or less freely movable. This has no disagreeable effects, as a rule.

A renal calculus, or stone in the kidney, may exist for a long time without giving rise to symptoms. A dull pain in the loin is common, however, and there may be frequency in passing urine and this may contain pus and blood. Should a stone of any size pass into the ureter it gives rise to renal colic, spasms of excruciating pain which shoot down to the front of the thigh. Associated with this there is shock and vomiting. The doctor should be summoned and meanwhile the patient is placed in a hot bath for ten to twenty minutes. Failing a bath, apply hot fomentations or a large linseed poultice.

Inflammation of the kidney substance, or nephritis, is described under the heading Bright's Disease. Septic infection may involve the organs; this is called pyelonephritis. From such an infection an abscess may form. Tuberculous disease may affect one or both kidneys. The symptoms rather resemble those of stone in the kidney, but a proper examination of the urine will reveal the presence of tubercle bacilli. *See* Bright's Disease; Diuretic, etc.

**Kidney Vetch.** This is another name for the hardy herbaceous perennial better known as lady's finger (q.v.).

**KILOGRAMME.** This is a measure of weight in the metric or decimal system. It consists of 1,000 grammes, and is equal to 2-1/5 pounds avoirdupois. *See* Metric System.

**KILOWATT.** In electricity this is the name given to a unit of power. It is the commercial unit by which electricity is sold, and is the equivalent of 1,000 watt hours. *See* Electricity; Watt.

**KING CHARLES SPANIEL.** Although bred in the present day especially as lapdogs, the King Charles were formerly used for sporting purposes, and they still make excellent house dogs. They are very gentle and affectionate, though their demeanour to intruders may be quite the reverse.

Under the name of King Charles are also included the varieties that breeders and fanciers distinguish as tricolour, Blenheim, and ruby spaniels; but the difference between them is only one of colour, and it is quite possible that one litter might comprise examples of each. The following points apply to all of these varieties.

The head has a semi-globular dome, the turned-up nose is short and broad with a black tip. The large dark eyes have horizontal lids, and are always more or less weeping. The heavily feathered ears are set low on the head, hang flat to the cheek, and reach nearly to the ground when the dog is walking. The body is compact, the back short and broad, the chest wide, the legs stout and strong. Some of these points are hidden by the long silky coat, which should be wavy, not curling. The feet, the backs of the legs, and the tail are all feathered. For show requirements the tail is docked to 4 in.

*King Charles Spaniel. Specimen of the silky-coated breed of pet dog, formerly used for sport.*

The King Charles proper is glossy black with some rich tan on the legs and below the root of the tail, also on the cheeks and over the eyes. The tricolour is white with patches of black, the inside of the ears tan, and the usual spots of that colour on the cheeks and brows. The Blenheim also is white with patches of chestnut or ruby red, and cheeks and ears red, and from nose to above the forehead a long patch of white with a clear spot of red in the upper part. *See Dog.*

*King Post in domestic architecture. Centre upright in a roof truss.*

**KING POST.** This is the centre or principal upright post in a king post roof trust, of which examples are found in many forms of domestic architecture. The roof truss comprises the horizontal member called a tie beam, which reaches from one side of the building to the other and rests upon the walls. The principal rafters are framed into this tie beam, and their upper ends abut on the top of the king post, which stands upon the tie beam. It is connected to the latter by either joints or straps. Braces are then disposed from

about the middle of the rafters to the foot of the king post, with the result that when all these joints are properly constructed and then strapped together, the roof truss is a strong and rigid structure suitable for buildings with a span up to about 30 ft. *See Roof.*

**KING'S SPEAR.** This is a popular name applied

to the giant asphodel or eremurus (q.v.) and to *Asphodelus ramosus*, a hardy tuberous-rooted perennial with narrow grass-like leaves and white summer flowers on stems 4 ft. high. *Asphodelus*, or asphodel, thrives in ordinary soil, and may be increased by lifting and separating the roots in spring.

*King's Spear. Pink flowers of the dwarf variety imperialis.*

**KIPPER.** Certain fish, such as herrings, salmon, or mackerel, are preserved by the process of kipping, which is carried out by splitting the fish open, salting them, and drying them in wood smoke. Most commonly the word kipper is applied to herrings.

The kippers may be cooked in the oven, or broiled in front of the fire. It improves them if they are plunged for a minute in boiling water before cooking them. If no double gridiron is at hand they may be toasted or hung in a Dutch oven. Before broiling, trim the fish, and after they are cooked rub them with butter. Another way is to put them in a casserole with a little butter or good dripping, cover them tightly and cook in a hot oven 10 to 15 min. In this way no smell of cooking escapes into the house. The same method may be used for kippered mackerel, but they will take longer. *See Fish; Herring.*

**KIRMAN RUG.** Persian rugs of the Kirman type can be obtained in carpet sizes. Their soft and harmonious tones, in blue, green, fawn, rose and old gold, and their naturalistic designs of bouquets and vases, show up exceptionally well with 18th century period furnishings. They should be examined for their cotton warps, their fine, closely woven and slightly lustrous woollen naps, and the rich reds and blues of their three or more border-strips.

The design usually includes a large central medallion, sometimes scalloped. Among the devices used are the tree of life, the eight-petalled lotus, birds, gazelles, and other animals. The old patterns are reproduced at Tabriz and elsewhere. The carpets known as Turkey Kirmans are coarser, being fabrics of less merit. *See Persian Carpet; Rug.*

**KIRSCH SAUCE.** This is made by mixing

together and then boiling  $\frac{1}{2}$  pint of water and 2 teaspoonfuls of arrowroot. When they have boiled for two or three minutes, sweeten them to taste, and add about a gill of kirsch. If liked, cornflour may be substituted for the arrowroot.

## KITCHENS AND THEIR ARRANGEMENT

### Suggestions for Suitable Furniture, Fittings and Equipment

An article on the Kitchen, which is the domestic workshop, suggests reference to its fittings, e.g. Cooker; Cupboard; Dresser; Range; Refrigerator; Sink; to the practice of cooking, on which there are hundreds of articles in the work; and to the entries on Electricity; Gas. See also Chair; Cottage; Door; Flat; House; Labour Saving; Larder; Scullery; Tile.

Compactness is a great advantage in any kitchen and the disposition of cupboards, sink, range, electric or gas cooker should be thought out with a view to minimizing the number of steps taken in the various duties to be performed. A small kitchen saves much walking about, but it is more difficult to work in, as constant tidying up is necessary, if muddle is to be avoided. Even in the largest kitchen compactness can be achieved by careful consideration of the disposition of furniture and fittings, placing the working equipment close together and reserving extra space for comfortable chairs and a table for meals. Adequate ventilation is most necessary. A grating high in the wall or over the outer door is desirable, as this permits the escape of the hot, stale air that rises when cooking is in progress.

A north light is best, and the larder should be on the north side, so that this is the proper location for the kitchen. The relative positions of the sink, kitchen cabinet or dresser, and stove should be such as to minimize the number of journeys between them. The range or cooker should be well placed with, if possible, a cross light. A convenient cupboard may be on the left and a kitchen cabinet, or fitted dresser, on the right. The sink should be under a window, or at least well lighted, and easily accessible from the work table. If possible there should be an electric light or gas fitting above the sink. In a house where the kitchen adjoins the dining room a service hatch saves labour and a lift is a great convenience for service from a basement kitchen to a dining room on the floor above.

It is most important that a kitchen should be bright, light, and as airy as possible; that it should have as many simple labour saving devices as are compatible with its size and the required amount of cookery to be done; and that the home worker who spends a good deal of time in the kitchen should have a comfortable corner in it, if no other sitting room is available. An attractive kitchen is no more expensive to decorate at the outset than a drab one.

Where there is a scullery it is often better to concentrate all the rough work there and let everything that is to do with food and the preparation of food, except vegetables, be done in the kitchen. For this reason many people find it better to have a small white

porcelain sink in the kitchen as well as the larger one in the scullery. If all cookery equipment is in the kitchen the labour and steps involved in going in and out of the scullery for water and also for many of the utensils required can be avoided. The perfect sink to wash up in is about a foot deep, fixed at a convenient height, which does not necessitate stooping, with draining boards on either side. Large sinks are sometimes divided for washing and rinsing with swivel taps or a double set of hot and cold. A plate rack over the draining board and, if possible, a tiled splash back to the sink are obvious advantages.

Where several servants are kept a pantry between kitchen and dining room containing glass and china cupboards, service hatch and a sink is a great convenience. A separate washhouse is a useful feature where much laundry is done at home. Kitchen quarters must be adequate for the size of the family to be cooked and catered for, also the number of servants kept must be a consideration. A scullery and pantry mean simply extra labour and cleaning for one maid, but it is almost impossible to do without them and be comfortable if both a kitchenmaid and scullery maid are kept, or if a large household has to be cooked for and the work entails a great deal of washing up and preparation of food. A good sized kitchen is often a practical necessity in the case of the housewife with young children. She wishes to have them under her eye, but not under her feet while she is working. Some of the newer houses are provided with an alcove for meals in the kitchen which is a great asset and can be utilized as a playroom for the children during the morning's work. Where a maid is kept such an alcove forms a pleasant sitting room recess.

**Walls and Ceiling.** The decoration of the kitchen has advanced of late years in practical and yet attractive fashion. Washable papers, good enamel paint, tiles and their substitutes are well employed in a room where hygienic cleanliness is the first consideration. There is no need for too much white in a kitchen. If on the northern or sunless side of house, or flat, in spite of the glow from cooker or range, an all white kitchen will look cheerless. On the other hand, there is something suitable about a cool scheme, such as blue or green with black and white. Glossy effects are excellent in a kitchen. A dado of white tiles with white enamelled walls and ceiling is refreshingly clean if the rest of the woodwork is painted blue, a black and white linoleum being chosen for the floor, and black and white check gingham curtains for the window. The paintwork can be picked out with black and the architrave of the door can also be black to give character to the room if a large one. The saucepan stand and various containers could be enamelled blue, a gaily coloured pattern chosen for the dinner service on the dresser, while rush mats would add further brightness to a cheerful scheme.

There is an excellent and inexpensive substitute for wall tiles. This is an enamelled zinc product of British manufacture and may be used for wall tiling or for lining a cooking recess and for a sink surround. These tilings need not be necessarily in white, but are obtainable in attractive tints. Another form of imitation tiling which enables the housewife to produce a charming effect at a small cost is obtainable in sheets which are applied to the walls in the same way as an ordinary paper. This tiling substitute can also be washed and wears excellently. It is infinitely more pleasing than the old-fashioned varnished papers which are still obtainable in tiled patterns.

*Kitchen. Fig. 5. A well arranged small kitchen with tiled walls, recessed gas cooker, convenient shelves for saucepans above it, and ample cupboard accommodation. (Humphrey & Vera Joel)*

Another suitable wall decoration is a washable paper which has a mat surface and is waterproof. Stains can be removed from such a paper by means of a damp cloth. It is made in a variety of colours and patterns. There is a preparation for rendering any wallpaper washable, which can be used by a decorator without affecting the appearance of the wall covering. Ceilings are best treated with enamel, but, failing this, one of the flat wall paints will be found more durable than ordinary whitewash.

**Furnishing and Floorings.** Where a kitchen is well lighted and also used for meals, built-in furniture should be painted to match walls. Windsor chairs and table can be of painted wood, but a porcelain enamelled top may be fitted to the table if it is to be used for culinary preparations. Such tops are obtainable in white or in colours, very practical kitchens are equipped with these tops, made to measure for the table surfaces of dressers, draining boards, shelves, window sills, wall slabs, cupboard tables and larder shelves. The surface is especially prepared to withstand hot plates, dishes or cookery utensils. No scrubbing is required for cleansing, but merely a rub with a damp cloth.

Where space saving is important a meat safe and table combined is a good idea. In some flats the larder is merely a shallow cupboard with shelves and not well ventilated. The provision of a meat safe table, with steel enamelled top and having a cupboard below which is

zinc lined, with a ventilation regulator, is therefore an excellent solution for storage of hot food, which must never be put into a refrigerator. The latter piece of kitchen furniture has become more usual of late years. Models are obtainable which can be run by gas or electricity and some by paraffin oil, making it possible for people in the country to have refrigeration in their kitchens where neither gas nor electric power is available. The more costly pieces of kitchen furniture are obtainable by paying a small sum down and then by monthly instalments. The all-important matter of the range or cooking stove is discussed in detail under the various headings, Cooker, Range and Stove. The use of fuel or power is frequently dictated by local conditions and where electric power is cheap it has certain advantages on the score of cleanliness though in a large country kitchen the range provides a cosy centre to the home. Modern coal ranges are excellently equipped and there is also a cooking stove which burns small coke or anthracite. This is an efficient stove and needs only to be filled once and riddled twice in twenty-four hours. It also provides about ten gallons of hot water for washing up.

*Kitchen. Fig. 6. Showing a kitchen cabinet in oak fitted with flour bin, extending porcelain table, cupboards and drawers, conveniently placed near the larder.*

**Kitchen Cabinets.** Kitchen cabinets have increased in number and practical advantages. The one

illustrated in Fig. 6 takes the place of a store cupboard and has an extending porcelain table, which is ideal for pastry making and requires no scrubbing. The position of the cabinet in this case has been determined by the larder, which is seen on the right, and within easy reach of culinary operations. Additional side units, as seen in Fig. 7, make a kitchen cabinet quite complete with ample accommodation for all cleaning requisites on one side and cookery utensils on the other. Cabinets may have vegetable racks, metal-lined bread drawers, egg racks, flour bins, and baize-lined cutlery containers. One model has an automatically sealing bread and cake bin and also a detached steel enamelled top table with extra chopping board. This table can be folded away inside the cupboard when not required. Such cabinets may be in oak or finished in enamel to match the woodwork of the kitchen. In any case, the inside is finished with glossy white enamel.

Where there is good cupboard and larder

accommodation the kitchen cabinet is often dispensed with. The dresser may be made more practical by having the upper shelves fitted with glass doors so that the dinner service need not be exposed to the dust of the kitchen. Cupboards underneath the dresser are also a space-saving idea and provide shelf room for kitchen crockery and tools. For storage purposes, if wall space permits, a long shallow cupboard is better than a narrow deep one. In the former it is possible to see at a glance what is on the shelves, whereas in the latter type of cupboard articles get pushed to the back out of sight. A washing up machine is very useful, but almost indispensable within reach of the sink is the plate rack, with compartments of various sizes, made to hold cups and saucers as well as plates and dishes. Another essential article is a clock. Washable porcelain kitchen scales are more hygienic than the old-fashioned type.

*Kitchen. Fig. 7. Another type of cabinet in oak, with side units. The left-hand portion has shelves for cookery utensils, that on the right is made for vacuum cleaner, brooms and brushes. (Courtesy of Triumph Cabinet Works, Ltd.)*

A good method of disposing of rubbish is a vital point of kitchen equipment especially in a flat. A sanitary receiver which is always covered is almost a necessity even where the private dustbin is located just outside, as constant going to this causes delay and is tiresome in bad weather. One with a detachable interior pail and an outer case of white enamel to which the lid is attached is a convenient refuse receiver. The lid opens by means of a foot pedal. A vegetable rack and a tripod saucepan rack are inexpensive items which should be provided. Pans should never be stored in a cupboard, but kept where a current of air reaches them.

In many modern houses jointless composition flooring is laid in a plastic state which has a surface that is easily cleaned. Tiled, brick or stone floors are all attractive and cleanly, but they are cold to the feet, and rush or other suitable mats should be provided. Rubber floorings and inlaid tiled linoleums of a good quality are suitable for boarded rooms. Plain dark colours are not a good choice for these last as they show marks and footsteps. Curtains can be of any washable material, but glazed chintz, gingham or coloured linen always look well. There is also a liking for rubberized material and for American cloth for casement curtains.

Unless the kitchen is of the old-fashioned picturesque country type, or is used as part living-room, when the real domestic workshop is the scullery, a certain severity is best in furnishing accessories. Only practical curtains should hang at the windows unless the kitchen is overlooked when starched muslin glass curtains may be provided, preferably with rods top and bottom to keep them tautly in place. Checked American cloth is a good material for table covers and terry cloth for chair cushions.

**Illustrated Suggestions.** Our first photograph is of a kitchen in a small country house fitted with modern labour saving convenience and yet retaining a cosy look with its oak coloured woodwork, tiled flooring and chintz curtains. The porcelain sink possesses a double draining board. Electric power being available, there is an electric cooker and kettle. In the tiled recess beside the cooker is a boiler for the hot water services and small radiator system. A little sitting room for the maid opens out of the kitchen. The dresser is fitted with cupboards below, has sliding glazed doors above and a shelf specially fitted to take the row of gilded containers for dry ingredients. There is ample other cupboard accommodation on the wall not shown in the illustration.

Completely equipped with electric labour-saving devices the kitchen depicted in Fig. 2 is admirably designed to make the most of a small space. It possesses a British made refrigerator, an electric cooker, boiling plate, water heater, washer and iron. The conveniently deep sink is well lighted; the plate rack is on the wall at right angles (not seen in the photograph), and the vitreous porcelain kitchen table is just discernible on the left. Green enamel surmounts the dado of glistening white tiles on the walls. A kitchen cabinet opposite the window with cupboards to contain china, glass, silver and drawers for cutlery and a fitted cupboard for brooms complete a compact and thoroughly efficient furnishing scheme.

#### An Efficient Town House Kitchen

A larger kitchen of a town house is shown in Fig. 3. The range has been removed to make room in the now tiled recess for two boilers. One of these is for the domestic supply of hot water and the other for central heating. The enamelled gas cooler is provided with a ventilating canopy. There is a seven-tiered saucepan stand and the porcelain sink is under the window. Beyond, not visible in the picture, is a teak-wood draining board and a plate rack. The kitchen table top is half of marble, which provides an ideal surface for pastry making. The enclosed dresser is opposite the window and there is a white enamelled clock and an enclosed electric light ceiling fitting.

A most efficient domestic workshop is shown in Fig. 4. With its spotless tiling, generously-proportioned

*(Continued in page 1188)*

# Kitchen.

Fig. 1. Small country house kitchen with maid's sitting room adjoining. In the recess by the electric cooker is a boiler for hot water services.

Fig. 2. The all-electric equipment in this kitchen includes a refrigerator, water heater, washer, iron and boiling plate.

Fig. 3. A larger town house kitchen with two boilers installed respectively for domestic supply and central heating. The range has been removed and replaced by a gas cooker.

Fig. 4. An efficiently planned domestic workshop with ample cupboard space, long drainage boards which can be used for various purposes, modern gas cooker and attractive tiling.

(1. Humphrey & Vera Joel; 2. Veale & Co., Bristol; 4. Margaret Currant Studio)

drainage boards for the sink which lend themselves to every sort of kitchen use in addition to washing-up, this arrangement seems to radiate cleanliness and practical compactness. Comfort is provided for by a little stool which can be stowed away with other articles in the ample cupboard space beneath the sink. Other useful devices which can readily be incorporated into almost any kitchen plan include a meat-safe-table, which should be placed near a window; it is usually zinc lined with a vitreous porcelain top impervious to heat. Gas radiators also find a place in these quarters—to warm the kitchen when the cooker is not in use. A central kitchen table of the modern dual purpose type, with fitted drawers for cooking implements and cutlery, and an extra deal leaf which renders it suitable for pastry-making on the porcelain surface or for chopping on the wooden one is another idea.

An attractively designed small kitchen is shown in Fig. 5, which is suitably furnished for a flat. The cooker is recessed, the pot shelves are conveniently arranged, the taps are porcelain finished and there is excellent cupboard accommodation. The tiled walls could be less expensively treated by one of the imitation tilings mentioned earlier in this article. The flooring is a jaspé linoleum. In light grey this tones well with pale blue tiling, dark grey enamelled woodwork and aluminium saucepans.

**Culinary Requisites.** Besides decoration, and the more important furniture, there are a number of service aids and cooking utensils to be thought of when equipping even a small kitchen. Aluminium has taken the place of other metals to a great extent, but an iron frying pan is a convenience, as iron will stand a greater amount of heat than other metals, and boiling fat reaches a very high temperature. Fireproof china and glass are also used extensively in cooking, and these wares have the advantage that they can be brought to the table, thus obviating the necessity for extra dish washing.

The articles required for equipping the kitchen must vary with individual needs. It is a wise rule, however, to have a few things and renew these as occasion demands, and to have the simplest equipment possible.

For a small family the following equipment is suggested as a minimum: A set of pans, one of each size; a small and a large frying-pan; a preserving-pan, if preserves are to be made at home; a medium-sized fish-kettle, which can also be used for boiling hams and large puddings; a couple of kettles, an earthenware casserole, some oven glass ware and one or two small fireproof dishes. A set of basins and jugs for milk, two or three pudding dishes, a jelly mould, wooden spoons for mixing, a soup strainer, colander, mincing machine, grater, pastry board and rolling pin, with various-sized cake tins and a Yorkshire pudding tin.

**Cutlery and Containers.** Knives, spoons and forks for kitchen use and special culinary purposes should be included in the equipment. A stainless steel saw edged tomato slicing and lifting knife, a fruit and vegetable

slicing knife, an apple parer, a meat chopper, tin opener, grape fruit cutter and corer, kitchen scissors, a juice extractor and a variety of pastry and vegetable cutters are a useful collection. There are many other devices which can be acquired as need and occasion arise, such as fruit slicing, bread cutting and potato mashing and peeling machines, but these are only essential in the larger household.

Glass containers for dry ingredients are excellent for use in a store cupboard, as their contents are quickly seen, though they should also be clearly labelled. Enamelled or gilded containers look well, when bought to match, in a row on a shelf or on the chimney piece. The newest and most attractive, however, for the small or less severe type of kitchen are the ones illustrated in Fig. 8. In creamy white highly glazed earthenware, decorated with quaint designs and delightfully shaped, these are obtainable for dry ingredients and for condiments.

*Kitchen. Fig. 8. Kitchen containers in glazed earthenware obtainable for both dry and liquid ingredients and for condiments.*

## KITCHEN GARDENS AND ALLOTMENTS

### Details and Plans of Two Serviceable Plots

Associated with this subject are the articles on the vegetables and fruits grown in a garden of this kind, e.g. Apple; Beans; Cabbage; Potato. See also Digging; Fruit; Insecticide; Manure.

The successful management of vegetables depends chiefly on thorough cultivation of the land, a correct rotation of crops, and the choice of kinds and varieties which will maintain an unbroken supply of produce. Those who cultivate vegetables to perfection for exhibition purposes trench the land from 2 to 3 ft deep, but that is costly and laborious work and unnecessary to ensure vegetables for an average household.

Cropping a vegetable garden is a most important operation. The principle of rotation is simplicity itself, being merely a system which prevents the growing of crops belonging to the same natural order repeatedly year after year in the same ground. The potato, however, is an exception to the rule, because good crops of potatoes may be raised from the same plot year in, year out, always provided there is a change of seed tubers every second season. An easy way to ensure proper rotation is to divide the ground into four portions. Planting will be as follows:

#### PLOT 1.

First year. —Peas, beans, celery, leeks.

Second year.—Carrot, parsnip, beetroot.  
 Third year.—Cabbage, cauliflower, kale, broccoli, Brussels sprouts, onion, lettuce, turnips.  
 Fourth year.—Potatoes

#### Plot 2.

First year.—Parsnip, carrot, beetroot.  
 Second year.—Cabbage, cauliflower, kale, Brussels sprouts.  
 Third year.—Potatoes.  
 Fourth year.—Beans, peas, celery, leeks.

#### Plot 3

First year.—Cabbage, cauliflower, kale, Brussels sprouts.  
 Second year.—Potatoes.  
 Third year.—Peas, beans, celery, leeks.  
 Fourth year.—Carrot, beetroot, parsnip.

#### Plot 4

First year.—Potatoes.  
 Second year.—Peas, beans, celery, leeks.  
 Third year.—Carrot, beetroot, parsnip.  
 Fourth year.—Cabbage, cauliflower, Brussels sprouts, kale, turnip, onions, lettuce.

It will be noticed that in the diagrams accompanying this article departure has been made from the above by suggesting a three-course cropping system. This scheme will be found equally satisfactory, and gives opportunity for devoting one of the four centre beds to the cultivation of small fruits. If the four-course system is preferred, however, ample space will be found in the marginal or outside borders for growing the small fruits shown in the plan.

Planting of vegetables is another matter which should receive much care. Endeavour to plant in showery weather, always use the garden line to guide sowing or planting in straight lines, and do not cramp distances between rows or plants. Much good seed is wasted by thick sowing, and it is far better to sow thinly and save unnecessary thinning out. Seedlings, whether sown in drills or seed-beds, should have a first thinning when they have formed their third leaf, thus giving up their room to allow greater development of the remaining plants. Never leave seedlings in a bed to mass together, but transplant early and secure better crops.

It is not possible in this article to include sowing quantities and planting distances for all vegetables, but the following instructions for popular kinds will be found useful. In all cases the estimate is given for a 25 ft. row.

Artichoke (Jerusalem), 3½ lb.— Plant spring or autumn, in drills 5 in. deep and 1½ ft. apart, with 8 ft. between rows.

Beet, ½ oz.—Sow 1 in. deep in early May, 1 ft. between rows.

Broad Bean, ½ pt.—Sow during Feb., 3 in. deep and 2 ft. apart in rows.

Broccoli, cabbage, Brussels sprouts, kale, and all

winter greens, ¼ oz. sown during spring will produce hundreds of plants. Plant not less than 2 ft. apart all round. Four crops of cabbage may be produced, sowing times being August, March, April, and May. When transplanting green crops always nip off the end of the tap root of seedlings, as this will often prevent bolting.

Carrot, ¼ oz.—Sow in Feb. to April 1 in. deep in drills 1 ft. apart.

Cauliflower, ¼ oz.—Sow April, 1 in. deep in drills, and transplant carefully to rows 2 ft. apart.

Lettuce, ½ oz.—Sow at intervals of 3 weeks to maintain succession.

Onion, ½ oz.—Sow thinly in fine shallow soil during March, and roll firm. Use thinnings for salads.

Parsnip, ¼ oz.—Sow seeds in threes at intervals of 9 in. during March, thinning out to strongest plant.

Peas, ½ pt.—Sow varieties for succession from Jan. to July, 2 in. deep in rows of 1½ ft. more between the rows than the height of the variety.

Radish, ¼ oz.—Sow broadcast, or in drills, from Feb. to Oct. Sow sufficient only at one time for small gathering, and rely upon frequent sowings, otherwise they get woody and run to waste.

Shallots, 1 lb.—Plant in fine and firm soil in early March, 8 in. apart, in rows 12 in. apart.

Spinach, ½ oz.—Sow from March onwards, in drills 1 in. deep and 15 in. apart, at intervals of a fortnight to maintain supply.

Turnip, ¼ oz.—Sow monthly from Feb. to July, ½ in. deep, in drills 15 in. apart.

The two diagrams at page 1111A and B define the possibilities of kitchen gardens measuring respectively 148 x 96 ft., and 132x83 ft., either of which may be modified as re-quired. The root principle of each is the four central divisions to accommodate the rotative system of cropping. The encircling borders shown can be devoted to the crops, frames, and fruit trees, suggested in the diagrams; but it is unwise to depart from the plan given for the four central beds.

Allotments. The allotment may be regarded as a kind of kitchen garden. An allotment 10 rods in extent will supply a small family with vegetables all the year round, while a 20-rod plot will provide sufficient vegetables for a large family.

The following information is in Bulletin 90 issued by the Ministry of Agriculture. For an allotment a width of two rods (11 yards) is generally adopted. The length of a 20-rod allotment of this width is 55 yd. and of a 10-rod plot 27½ yd. The areas are respectively ⅛ and 1/16 acre. The ends of the plots should point east and west, and the end of the rows north and south.

Here is an estimate of what a first-class allotment of 10 rods may be expected to accommodate at mid-June. It is assumed that the plot is 27½ yd. (82½ ft.) long and 11 yd. wide.

Greens can be put out in June, during showery weather. Beetroot and French beans need not be sown

before mid-May, and it is possible to get a crop of radishes and even turnips off the ground before then. Spinach can be sown early in March, on a site near that which is to accommodate the scarlet runners, because the runners need not be sown before mid-May.

A reserve piece of ground for a seed bed is exceedingly useful. A strip 3 ft. wide with a length of 33 ft. is a great convenience, because, apart from accommodating such permanent crops as rhubarb and herbs, it affords plenty of room for seedlings of various kinds.

By the middle of August the following crops have probably been cleared off the ground: early potatoes, peas, broad beans, spring cabbages, early turnips, early salads, spinach (not spinach beet), and shallots. Early varieties of pea are best for small plots. The places of the early crops have been taken by winter greens, autumn cauliflowers, leeks, late turnips and vegetable marrows. There may be a piece of neatly raked ground sown with spring cabbages, autumn onions, and lettuces.

Now let us look at our table for the second half of the season.

On a 20-rod plot everything is easy as far as allotting space is concerned. There can be 10 rods of potatoes, with a change of ground every year. Practically everything suggested for the 10-rod plot can be carried out, but on a larger scale.

*(See also page 1191)*

**KITCHENMAID: Her Duties.** A kitchenmaid is, for all practical purposes, an assistant to the cook, and her duties are mainly confined to the kitchen and the preparation of meals. In large establishments two or more kitchenmaids are kept.

Her duties vary with the size of the household, but she is generally expected to cook the vegetables and such foods as do not need a high degree of skill, and to prepare the materials which the cook needs. Much of the washing-up usually falls to the lot of the kitchenmaid. In some establishments the cooking for the other servants is done by her. Many girls who aspire to become cooks gain their early experience in this way, and a kitchen-maid who has served under the cook of a famous establishment will find the training there valuable if she seeks a post of that kind for herself.

Kitchenmaids can be obtained, like other servants, by advertising in the newspapers, or by visiting a registry office. They should be insured against accidents that may happen to them in the course of their work, and also under the National Health Insurance scheme. *See Cook; Insurance; Servant.*

**KITCHEN RANGE.** This contains an enclosed fireplace, with one or more ovens at the side, and a flat top, wherein are a number of holes, with removable covers; this structure enables the fire to be fed and cooking utensils to be placed thereon. There is a great variety of ranges, and they are made to suit all types of houses, from the largest to the smallest. Some firms make a speciality of ranges suited for the tiny kitchens found in flats and small dwellings generally. *See*

*Cooker; Range; Stove.*

**KITCHEN TABLE.** Fig. 1 is probably the simplest method of construction for a kitchen table, since it involves no mortise and tenon joints. Dimensions are given in Figs. 2 and 3. The legs are cut from 2 in. deal squares to the height of the table, less the thickness of the top. At the top end of each leg on two adjacent sides mark with a square the width of the rails, and with a gauge set to half the thickness of the rails, i.e.  $\frac{1}{2}$  in., mark the ends of the legs, thus indicating the width and depth of the shoulders to be cut to take the rails.

The two surplus portions of the legs may be cut away with a tenon saw, as is shown in Fig. 4, and the legs then tapered from below the shoulder  $\frac{1}{4}$  in. on each side. The rails should then be prepared from 1 in. stuff, cutting them off square at each end. Note that the side rails reach only as far as the recessed portion of the leg (Fig. 4), while the end rails are sufficiently long to line up and cover the end grain of the side rails. The undersides of all rails are bevelled off as shown, and holes to take the screws bored, those in the end rails being farther away from the end so that all the screws will go into the leg. The whole is screwed together, fixing the side rails on first (Fig. 4), and corner blocks glued in for additional strength. The top, of course, will have to be jointed up to obtain the width. One-inch stuff should be used, and this should be fastened down to the framework by pocket screwing, as shown in Fig. 5.

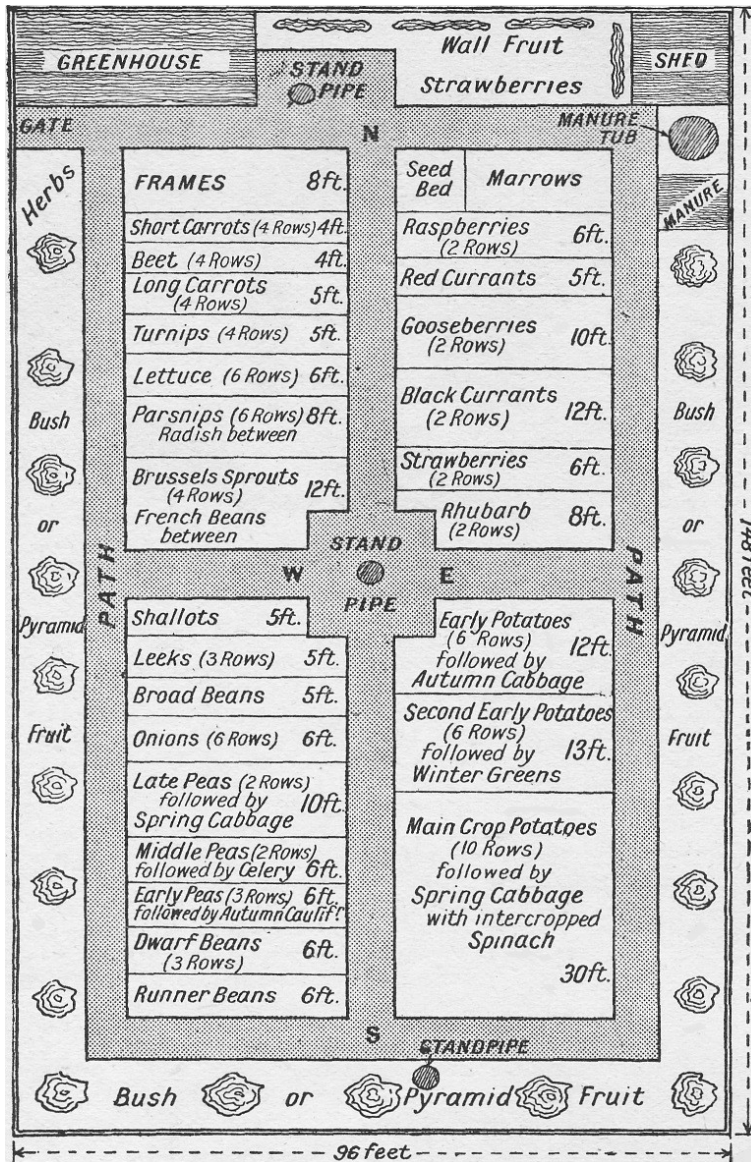

**Another Type of Table.** The table in Fig. 6 has a better appearance and is fitted with a drawer, though this may be omitted. The necessary dimensions are indicated in Figs. 7 and 8. The legs are cut off, and the top ends marked out for the mortises. If a drawer is not required, all four legs will be marked alike, otherwise the drawer end will be fitted with two rails, as in Fig. 9, the lower one being tenoned in and the top dovetailed. These two rails should be about  $\frac{1}{2}$  in. wider than the legs, and are cut round the latter as shown.

When all the joints have been carefully cut, the whole is glued together, taking the two sides first, and allowing them to set before glueing the remainder. When dry, runners are fixed, Fig. 10, being nailed, glued, and further strengthened with corner blocks rubbed in at the top. These blocks should be planed to width so as to line up with the inner surface of the leg and act as guides. The drawer may be dovetailed or rebated. The top is fixed as before with screws fastened from underneath. *See Drawer; Table.*

*(For kitchen table diagram see page 1192)*

**KITE: How to Make.** The best-known simple kite is the pegtop pattern, shown in Fig. 1. It is of fairly small size and covered with tissue paper gummed to the frame; such a kite, a foot long, can be flown on

*(Continued in page 1193)*

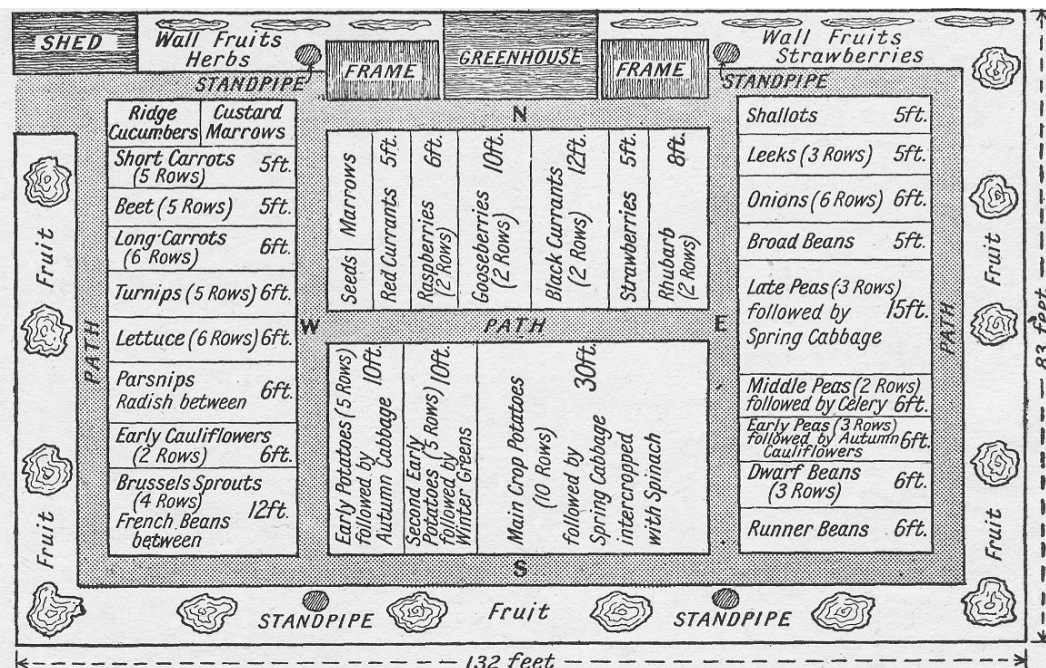

**Kitchen Garden.** How to lay out a garden which measures 132 by 83 ft. Three plots are devoted to vegetables, while in the fourth are grown small fruits, such as currants and gooseberries.

Left, suggestions for planting a kitchen garden measuring 148 by 96 ft., showing a similar rotation of crops and fruit.

Crops at mid-June		Feet run
Potatoes, 8 rows, mid-early,	2½ ft. apart	20
Potatoes, 8 rows, late,	3 ft. "	24

**Kitchen Table.**

- Fig. 1. Simplest form of kitchen table.  
 Figs. 2 and 3. Side and end elevations, giving measurements.  
 Fig. 4. Detail of joints.  
 Fig. 5. Method of fastening table top to framework.  
 Fig. 6. Another type of table, fitted with a drawer.  
 Figs. 7 and 8. Side and end elevations.  
 Fig. 9. Detail of drawer fitting.  
 Fig. 10. Banners and corner blocks in drawer aperture.

stout thread as a line. The frame consists of a relatively stiff wooden backbone, and a thin, flexible piece of split cane bent to a semicircle by a string arranged like a bowstring. The centre of the bow is lashed to the top of the backbone, and strings are run from the horns of the bow to the bottom of the backbone; these strings, however, are not too tight, as the strain is to be taken on the bowstring.

After the frame is covered, a piece of string double the length of the kite has its two ends tied to the backbone, one near each end. This is the bridle, and the kite line is tied to it so that the upper arm of the bridle is shorter than the lower. The rig of the kite is completed by a tail, to which convention consigns the form of a string two or three times the length of the kite, tied to the bottom of the backbone and having screws of paper tied to it at intervals; a strip of fabric, however, answers the purpose equally well, being more durable and less trouble to fix.

Home-made pegtop kites sometimes have a rigid wooden member instead of the bowstring. This is a mistake, as it tends to prevent the horns of the bow

from bending backwards under the air pressure, as they must do to give the dihedral angle effect needful for stability.

The adjustments that have to be made consist in varying the amount of tail carried and the point of the bridle at which the line is tied on; the kite will not fly unless these adjustments are made suitable to the speed at which the wind is travelling.

*Kite. Fig. 1, Pegtop pattern.*

*Fig. 2. The Eddy Kite. Directions for making both are here given.*

The pegtop pattern is inconvenient in large sizes, as it cannot well be taken to pieces for travelling. A modified form of it is therefore used in which the bow-string is replaced by a straight and particularly flexible stick and the bow omitted, the frame thus consisting of two wooden members arranged in the form of a cross, with a surrounding edge of string tied in succession to the four ends of the sticks. If this frame is covered with a light cotton fabric it can easily be arranged so that the sticks may be removed and the whole rolled up for

transport. The same adjustments as in the case of the pegtop kite are needed in order to secure for it a satisfactory stability.

**An Eddy Kite.** A more ambitious form of portable kite is the Eddy type. In this the frame consists of two sticks of equal length arranged in the form of a cross, the two being lashed together at their meeting point, which is one-fifth of the length of the backbone from the top end; a surround string is fitted as usual. The dihedral angle effect in the Eddy kite is obtained by bending the ends of the transverse stick backwards and holding them in this position by a bowstring, which, of course, lies clear at the back of the kite. The cotton covering is made rather wider than the frame, so that it is rather baggy, and bellies out like a sail when the kite is flying. When properly adjusted these kites do not require a tail at all; the adjustments consist in varying the point of attachment of line to bridle, and in regulating the tension in the bowstring at the back of the kite.

**Box Kite.** Named from its rectangular form, the box kite is an excellent flyer, and can easily be made. The sizes given have proved successful, but can be modified to suit individual requirements. Constructional and other details are made clear from Fig. 3.

*Kite. Fig. 3. Diagram illustrating the various parts of a box kite and how they are fitted together.*

The longerons or corner pieces, A B, are made from  $\frac{3}{8}$  in. square stripwood, obtainable at most model shops, or may be cut from a piece of pine  $\frac{3}{8}$  in. thick, and planed up true. These pieces should measure 42 in. long. The diagonal struts, C, are approximately 26 in. long and made from similar material, but these  $\frac{1}{2}$  in. wide and  $\frac{1}{4}$  in. thick. The two bands, E F, can be made from any very light material such as cambric or madapolam. Cut two pieces each 6 ft. 3 in. long and 13 in. wide. Turn a hem on each side, and sew it twice to give the greatest strength. Take care not to cockle the material; the flatter the bands the better they will be. When hemmed, the bands should measure exactly 12 in. in width. Now overlap the ends and sew them together very strongly, thus making two endless bands.

Lay them flat on the table and then flatten them out, creasing the folds. Have one fold at the joint of the ends. Next fold over again, thus dividing the piece into four and again press at the folds. These 4 creases will show just where to fix the 4 longerons, one being tacked on with 5 brass tacks to each corner or crease, and on the inside of the band.

Notch the ends of the diagonal struts, and glue a bit of tape around them near the ends, to prevent splitting. The length of these struts should be such that when they are in place they will be slightly bowed, and thus keep the bands taut. Tie the struts together at the centre with thin string, and to prevent them slipping from their position glue or nail some little blocks of wood to the longerons. By leaving the struts loose the kite is easily dismantled for transport purposes.

A bridle of stout string is securely tied to one of the longerons, 6 in. from either end. The kite line is attached to the bridle with a reef knot and bowline knot to permit of its being adjusted on the bridle, the best positions being found by experiment. In general, the lighter the wind the shorter the front line of the bridle. In a very strong wind it might be advisable to attach the kite line directly to the longeron, just behind the front band.

**KLONDIKE.** This is a card game for one or more persons. It is played with the ordinary full pack of 52 cards. The cards are shuffled and cut in the ordinary way, and the first card is turned face upwards on the table. To the right of this card, but face downward, are placed in a row six cards. Immediately below the left-hand card of this row of unexposed cards is placed another card, face upward, and five more cards to the right of it, below the top row and face downward. So the next row has one faced card and four face downward, and so on until there are seven faced cards and twenty-eight cards in all on the table in the form of a right-angle, apex downward.

Any aces which have been exposed are taken from the lay-out and placed elsewhere on the table to form the foundations on which to build. Upon them are placed cards in sequence, two, three, four — king. When any card of the lay-out is uncovered by playing away the bottom of the row, the next card in that vertical row is turned face upward. Cards in the lay-out are built in descending sequence, king, queen, jack, etc., to the two, and alternate red and black suits. The remainder of the pack not put down in the layout is dealt out one at a time, and any card exposed may be used either on the lay-out or on one of the foundations. Spaces in the layout can only be filled with kings. If there be more than one card at the bottom of a row showing, all must be moved together or none.

A player pays fifty-two counters for his pack and receives five counters for every card he succeeds in getting on the foundations, running through the pack once only.

**KNAPSACK.** This is a form of bag used by soldiers, scouts, and travellers on a walking tour, to hold the necessary articles of food and clothing. It is

carried on the back, supported by shoulder straps, the usual type being equipped with a long, loop-like strap, attached to the top of sides, to pass under the armpits and over the shoulders round the back of the neck.

**Knapweed.** The common name of the perennial *Centaurea*. *See* Cornflower; Sweet Sultan.

**KNEE.** This joint is formed by the junction of the lower end of the thigh-bone, the femur, with the upper end of the large legbone, the tibia. The patella, or kneecap, glides over the front of the joint. The bones are held together by a number of ligaments.

The knee is much exposed to injury, and this may be followed by synovitis with an accumulation of fluid in the joint, on which the kneecap is felt to ride or float. This requires rest and perhaps painting with iodine to promote absorption. The knee should also be firmly bandaged with a flannel or a woven elastic bandage. Very often it happens that when one gets up and about the swelling recurs, but with the daily application of the bandage this gradually diminishes and disappears.

Not uncommonly one of the cartilages is displaced, in football or similar accidents. The knee is locked in a bent position and is very painful. When put right it may easily recur, and a protective cap should be worn. *See* Dislocation; Housemaid's Knee; Knock Knee.

**KNEELING PAD.** Pads or mats used to kneel upon while floors are being scrubbed serve to protect the knees from cold, damp, and soreness. They are especially necessary on tiled floors, and should be thick enough to prevent the cold from penetrating through. Several thicknesses of felt or some similar material make a good pad, but the rubber kneeling mats obtainable in kitchen equipment departments of stores are the best for indoor and outdoor use, being dampproof.

**KNIFE: For the Table.** It is claimed for some of the newer types of stainless steel table knives that they never require re-sharpening. These have serrated edges and include dessert and bread knives.

Stainless steel knives which are not thus guaranteed need a special form of sharpener. The best is one which has two grooved revolving rollers. The edge of the knife is placed between these two rollers and drawn backward sharply. Stainless steel will become scratched somewhat easily. To clean blades of the stain-less variety they should only be dipped in water and wiped. The placing of handles of knives in hot or cold water should be avoided, as this usually causes early discoloration.

Hardened steel knives which are not stainless are to be had in various qualities. The cheap varieties are fitted with what is known as single-shear steel blades, but the higher priced and more durable qualities are fitted with double-shear steel blades, which are cross-rolled.

**Handles for Knives.** The best handles for knives in everyday use are those which very closely imitate ivory. There are many materials which give quite an excellent reproduction of ivory, but as long as cutlery is purchased from some well-known firm that specializes in Sheffield-made cutlery there need be very little fear regarding the discoloration of handles, as all the best firms use a reproduction of ivory which will neither discolour nor split, whereas with real ivory handles, unless of the finest grain and quality, there is always a risk that the ivory will crack owing to the expansion or contraction which is caused by varying temperatures.

A simple test can be applied to assure oneself of the quality of a metal-handled knife. The end of the handle of the knife should be held lightly between the finger and the thumb, and the point of the knife should be sharply tapped on some hard surface, such as china or glass. If the blade is hard soldered to the handle the metal will ring almost like a silver or gold coin when it is tested. If a knife is fitted with an inferior tang, and the metal blade is filled with a composition, there is a dull sound when the above test is applied.

Metal handles for knives are made in Georgian styles; also many continental styles of knives have come into vogue. The difference between these and the usual English patterns is that the continental styles of knives are usually fitted with shaped blades.

**Cleaning the Knives.** Knives which are not of stainless steel can be cleaned with a damp rag dipped in powdered bathbrick or by means of a knife board or cleaner.

The latter is preferable; but a specially prepared powder should be used with the board. It is well not to wash knives in hot water, as if the blades are heated the metal tangs expand and the handles may split. Many persons try to avoid this by immersing the blades only.

Ivory and bone handles should never be washed with soap or in lukewarm water, as this causes discoloration. It is better to wipe them with a soft cloth that has been moistened with peroxide of hydrogen, and afterwards place them in the sun, which will whiten the ivory or bone.

**Repairs to Knives.** The handle of a carving or table knife may possibly become slack, and when it does it should be immediately seen to. If the blade can be removed from the handle, it will be evidence either that the tang is broken, which can be seen by inspection, or that the holding pins have sheared or broken. If the latter is the case, carefully punch out from the handle the remaining portions of the pins, and do likewise from the tang, and test to see that it is straight and true. Next prepare some cement composed of melted resin, pour this into the hole in the handle, and having previously warmed the tang, insert it in place and hold it in position until the resin has set. Then drill out the resin from the pin holes and make them all secure with new pins of brass or German-silver wire. They only need very slight riveting in order to make them secure.

Xylonite-handled carving knives and forks frequently have serrated tangs, which are difficult, if

not impossible, to remove. Other types have through tangs, which are often riveted on to a washer or cap at the end of the handle. This has to be removed before the knife can be repaired. A slight slackness can be taken up by further riveting the end cap. If the knife or fork is of rustless steel it will need especially careful handling, as this material is much harder and more prone to break while being repaired. Drilling is more laborious, and requires plenty of lubricant on the drill to keep it cool and cutting freely. Otherwise similar methods can be applied. This second style of case is illustrated in Fig. 2. It is constructed of satinwood and beautifully painted.

*Knife Box. Fig. 1. Example with marquetry of satinwood, mahogany and sycamore. Fig. 2. Urn-shaped box in painted satinwood. Both of 18th cent. English workmanship. (Victoria & Albert Museum)*

**KNIFE BOX.** In the 18th century knife cases were made in two distinct styles. Fig. 1 shows the type with a sloping hinged lid and a moulded front; the interior being divided into compartments raised one above the other for the knives, etc. Many of these are made of satinwood and some of mahogany, the wood being often veneered on oak; others were inlaid or edged with sycamore and boxwood. During the classical period Adam, Hepplewhite and Sheraton also designed many of the rarer and more elaborate knife urns.

Knife boxes were frequently seen on the sideboards in the 18th century. They stood on the pedestals that flanked many of these pieces designed by Sheraton and other makers. *See* Carving; Cutlery; Draw Knife; Ivory; Paper Knife; Pocket Knife; Pruning Knife; Sideboard; Steel; Table Laying.

**KNIFE REST.** Rests for supporting the carving knife and fork on the table are made in pairs in silver and electro plate, and also in glass. Each consists of a bar raised above the table by two supports. The supports take various forms, some being plain and others ornamental. They may represent an animal or some other kind of figure. *See* Carvers; Silver; Table Laying.

**KNIGHT'S TOUR.** This is a useful pastime for an invalid or a child. All that is needed is a chessboard and 64 counters. The object of the game is to place all the counters on the board, the positions being those that a knight would take up at chess. The player can begin on any square, and his aim is to place the counters on the board so that the whole of the 64 squares are filled up. *See Chess.*

**Kniphotia.** This is a hardy perennial, known also as red hot poker, torch lily, and flame flower. *See Red Hot Poker.*

## KNITTED AND STUFFED TOYS

### Instructions for Making Nursery Favourites

Other articles in our work which deal with the construction of playthings for small children are Dolls and their Homes; Noah's Ark; Toys. For related information consult also Crochet and the subsequent entry under the heading Knitting.

To knit delightful, inexpensive and cuddlesome toys which really appeal to babies and very young children and are also most saleable articles on the nursery stall at a bazaar requires no special skill in arts and crafts and only a simple knowledge of knitting, which can be quickly acquired by studying the article on that subject which follows this one. The success of a stuffed toy depends largely on the way it is stuffed. Kapok is used for these, and 1 lb. bags cost from 1s. 6d. to 2s. It is astonishing how much stuffing is required in order to make a toy really hard wearing and nicely shaped.

The five toys illustrated and described can be made up in other colours and the sizes varied. We have to thank the Best Way Series for kind permission to reprint some of their excellent ideas here. The abbreviations used are K., knit; tog., together; st., stitches, inc., increase; p., purl; Ips., loops; rpt., repeat.

**Wilfrid the Rabbit.** The first toy is that well established favourite Wilfrid. He costs about 3s. 6d. to make and requires 2½ oz. of pale blue and 1 oz. of white teal wool; one pair of knitting needles (steel) size 11, 2 black shoe buttons. Kapok for stuffing.

The work begins at the base of the body. *1st row:* With the blue wool cast on 14 st., k. 30 rows. *31st row:* Inc. in first st. (15). *32nd row:* Inc. in last st. (16). Rpt. these 2 rows 6 times (28). *45th row:* K. 30 rows. *75th row:* K. 10 st., place these on a safety-pin. Cast off 6 st. for armhole, k. remaining 12 st. *76th row:* K. 13 rows on these 12 st. *89th row:* Inc. in first st. (13). *90th row:* K. Rpt. these 2 rows once (14) and put these on a pin. *93rd row:* Pick up the 10 st. from the safety-pin, join wool to where the 6 st. were cast off and k. 13 rows. *106th row:* K. Inc. in last st. (11). *107th row:* K. Rpt. these 2 rows once (12). *110th row:* K. Pick up the 14 st. from the pin and k. them (26). *111th row:* K. *112th row:* K. 2 tog., k. 8 st., k. 2 tog., k. to end of row (24). *113th row:* K. Rpt. these 2 rows 3 times (18). *120th row:* K. 2 rows. *122nd row:* Inc. at beginning, middle, and end of needle (21).

K. another in the same manner.

*Ears.—1st row:* With blue wool cast on 7 st. K. 4 rows. *5th row:* Inc. in first and last st. (9). *6th row:* K. Rpt. these 2 rows twice (13). *11th row:* K. 44 rows. *55th row:* K. 2 tog. in middle of row (12). *56th row:* K. Rpt. these 2 rows once (11). Cast off. K. another ear in blue wool and 2 in white wool.

*Arms.—1st row:* With blue wool cast on 12 st., k. 10 rows. *11th row:* Inc. in first and last st. (14). *12th row:* K. 5 rows. Rpt. these 6 rows 3 times (20). *35th row:* K. 2 rows. *37th row:* Inc. in first st. (21). *38th row:* Cast off 8 st., k. to end of row (13). *39th row:* K. 12 rows. *51st row:* K. 2 tog. at each end of needle (11). *52nd row:* K. Rpt. these 2 rows once (9). Cast off. K. another in the same manner.

*Tail.—1st row:* With blue wool cast on 7 st., k. 4 rows. *5th row:* Inc. at each end of needle (9). *6th row:* K. Rpt. these 2 rows twice (13). *11th row:* K. 12 rows. *23rd row:* K. 2 tog. in middle of row (12). *24th row:* K. Rpt. these 2 rows 3 times (9). Cast off. K. a similar piece in white wool.

To make up the rabbit, with a wire brush brush up each piece of knitting. Sew up the two pieces of the body, beginning at the throat over the face, head, and along the back, leaving about 3 inches open for stuffing. Sew in the white front of body, beginning at the throat, and along the sides. Sew up the blue leg and white inside, sew into the body. Sew up the arms and sew into armholes. Turn the work. Stuff well with kapok, making the animal look shapely. Sew up the opening. Sew one blue and white ear together, and sew on in position. Sew the two pieces of tail together, and sew on to animal. Sew in the black shoe buttons for eyes. Mark the nose and mouth with fine pink wool. For whiskers use white bristles from a brush. Smooth the rabbit down with the wire brush.

*Knitted Toys. Fig. 2. Black Sambo and Jumbo. These little figures are in simple knitting and stuffed with kapok.*

**Black Sambo.** Seen on the left of Fig. 2 is a fascinating doll known as Black Sambo. He costs about 2s. to make, and requires 1 oz. each of white, brown, red, and royal-blue wool (4-ply); one pair of knitting needles (size 11); a little black wool for the shoes; kapok.

The work begins at the head. *1st row:* With brown wool cast on 12 st., k. *2nd row:* Increase in first and last st. (14). *3rd row:* P. Rpt. these 2 rows twice (18). *8th row:* K. and p. for 10 rows. *18th row:* K. 2 st. tog. at each end of needle (16). *19th row:* P. Rpt. these 2 rows once (14). *22nd row:* Join on red wool for collar, k. Inc. in first and last st. (16). *23rd row:* K. Rpt. these 2 rows twice (20). *28th row:* Join white wool. Cast on 2 st., k. (22). Rpt. this row once (24). *30th row:* K. 30 rows. *60th row:* Join blue wool for trousers, k. 12 st., place the remaining 12 on a cotton for other leg. *61st row:* K. 23 rows. *84th row:* Join brown wool, k. 2 tog. at each end of needle (10). *85th row:* K. Rpt. these 2 rows once (8). *88th row:* K. 6 rows. *94th row:* Join red wool, k. 2 rows. *96th row:* Join white wool, k. 8 rows. *104th row:* Join black wool, k. 4 rows. *108th row:* K. 2 tog. at each end of needle (6). *109th row:* Cast off. K. another in the same manner.

**For the Arm.**—*1st row:* With white wool cast on 3 st., k. *2nd row:* Inc. in first and third st. (5). *3rd row:* K.

Rpt. these 2 rows five times (15). *14th row:* K. 16 rows. *30th row:* Join red wool, k. 4 rows. *34th row:* Join brown wool for hand, k. 2 rows. *36th row:* K. 2 tog. in first and last st. (13). Rpt. this row three times (7). Cast off. K. another in the same manner.

**The Cap.**—*1st row:* With red wool cast on. 30 st., k. *2nd row:* K. 1 and p. 1 to end of row. Repeat this row four times. *7th row:* Inc. in every other st. (45). *8th row:* P. Rpt. these 2 rows once (68). *11th row:* K. and p. for 12 rows. *23rd row:* K. 2 tog. 12 times at even distances along the row (56). *24th row:* P. Rpt. these 2 rows three times (20).

Break off a length of wool and thread through all stitches on the needle, and draw up tightly and sew up the cap.

To make up the doll, sew up the work, leaving an opening at one side for the stuffing with kapok. Sew up the opening, seam up the arms, stuff and sew on to doll. To make the nose, make a stitch about  $\frac{1}{2}$  inch in the middle of face, and draw up tightly. Mark the eyes with white wool, and work the pupils with fine, black wool, and the mouth with red wool. Work the buttons down the front with red wool. Sew on the cap.

**Jumbo.** For the elephant Jumbo, which costs only 1s. 6d., 2 oz. of grey 4-ply wool are required, with a little red wool for the saddle-cloth and yellow Sylko No. 5; one pair of steel knitting needles, size 11; one steel crochet hook size  $2\frac{1}{2}$ ; two black shoe buttons.

*1st row:* Cast on 15 st., k. 2 rows. *3rd row:* Inc. 1 in first st., k. to end. *4th row:* Cast on 20 st., k. to end. *5th row:* Inc. 1 in first st., k. to end. *6th row:* K. Rpt. these 2 rows five times. *17th row:* K. 3 rows. *20th row:* Cast off 19 st., k. to end. *21st row:* K. 20 rows. *41st row:* Inc. 1 in first st., k. to end. *42nd row:* Cast on 19 st., k. to end. *43rd row:* Inc. 1 in first st., k. to end. *44th row:* K. Rpt. these 2 rows once. *47th row:* K. 11 rows. *58th row:* Cast off 25 st., k. to end. *59th row:* K., knitting last 2 st. tog. *60th row:* K. Rpt. these 2 rows once. *63rd row:* K. 2 rows. *65th row:* K. 2 tog. at beginning of row. Inc. 1 in last st. *66th row:* K. Rpt. these 2 rows twice. *71st row:* K. 2 tog., k. to end. *72nd row:* Cast on 12 st., k. to end. *73rd row:* K. 2 tog. twice at beginning, k. to end. *74th row:* K. Rpt. these 2 rows once. *77th row:* K. 2 tog. at beginning, k. to end. *78th row:* K. to the last 6 st., k. 2 tog. three times. Cast off. Knit another piece in exactly the same manner.

**Underbody.**—Cast on 2 st. *1st row:* K. 2 rows. *3rd row:* Inc. 1 in each st. *4th row:* K. *5th row:* Cast on 23 st. for forelegs, k. to end of row. *6th row:* Same as 5th row. *7th row:* K. 14 rows. *21st row:* Cast off 19 st., k. to end of row. *22nd row:* Same as 21st row. *23rd row:* K. 20 rows. *42nd row:* Cast on 19 st., k. to end of row. *43rd row:* Same as 42nd row. *44th row:* K. 14 rows. *58th row:* Cast off 20 st., k. to end of row. *59th row:* Same as 58th row. *60th row:* K. 2 tog. at each end of needle. *61st row:* K. Rpt. these 2 rows once. Cast off.

**Soles.**—Cast on 3 st. *1st row:* K. *2nd row:* Inc. 1 at each end of needle. *3rd row:* K. Rpt. these 2 rows once. *6th row:* K. 2 rows. *8th row:* K. 2 tog. at each end of needle. *9th row:* K. Rpt. these 2 rows once. Cast off. K. three more in exactly the same manner.

**Ears.**—*1st row:* K. Cast on 8 st. *2nd row:* Inc. 1 at each end of needle. *3rd row:* K. Rpt. these 2 rows twice. *8th row:* K. 8 rows. *16th row:* K. 2 tog. at each end of needle. *17th row:* K. Rpt. these 2 rows three times. *24th row:* K. 1, k. 2 tog. twice, k. 1. Cast off. K. another in exactly the same manner.

**Tail.**—Cast on 8 st. *1st row:* K. 24 rows. *25th row:* K. 2 tog. at each end of needle. *26th row:* K. 2 rows. Rpt. these 3 rows once. Cast off.

**Saddle Cloth.**—Cast on 20 st. in red wool. *1st row:* K. *2nd row:* P. Rpt. these 2 rows for 5 in. With the steel hook and yellow Sylko, work a double crochet all round the cloth.

**Tusks.**—Use two strands of 3-ply white wool. Make a line from the side of the face to the trunk, then work buttonhole fashion along the mark. Work the other side in the same manner.

To make up the animal, sew the two profile pieces together, leaving about 2 inches open in the middle of the back for stuffing. Sew on the underbody, beginning at the throat, along the forelegs, etc. Sew in the four soles. Now turn the work and stuff well with kapok, beginning at the trunk and head, making the trunk curl in at the end. Stuff the legs firmly, so that the animal will stand. Sew up the opening in the back. Sew on the ears and tail, using the black shoe buttons for eyes; mark the tusks, and stitch the saddle cloth at the four corners.

Fig. 3. *Teddy Bear*, knitted in fawn teazle wool.

Fig. 4. *Koko the Monkey*, made in brown and fawn wool, with a scarlet cap.

**Teddy Bear.** No nursery seems quite complete without this old-fashioned friend. Materials to knit one of a popular size cost only about 3s. It requires 2½ oz. of fawn teazle wool; 2 black shoe buttons; one pair of steel knitting needles size 11; ¾ yd. green ribbon 1½ in. wide for his necktie.

The work begins at the base of the body. *1st row:* Cast on 7 st., k. 18 rows. *19th row:* Inc. in first st. (8). *20th row:* K. Inc. in last st. (9). Rpt. these 2 rows twice (13). Break off the wool and put these 13 st. on a safety-pin. Now k. from 1st row to 24th row. Pick up the 13 st. from the safety-pin, and k. them. You should now have 26 st. on your needle. This makes the opening for the legs to be sewn in. *25th row:* K. 2 rows. *27th row:* Inc. at each end of needle (28). *28th row:* K. Rpt. these 2 rows once (30). *31st row:* K. 20 rows. *51st row:* K. 13 st. Put these on a safety-pin, cast off 4 st. for armhole, k. remaining st. (13). *52nd row:* K. *53rd row:* K. 2 tog., k.

to end (12). *54th row:* K. 3 rows. Rpt. these 4 rows once (11). *61st row:* K. 4 rows. *65th row:* Inc. in first st. (12). *66th row:* K. Rpt. these 2 rows twice (14). Place these on a safety-pin, pick up the 13 st. from the safety-pin, that were left for the front of chest. *71st row:* Joining wool to where the 4 st. were cast off, k. 1 row. *72nd row:* K., knitting last 2 st. tog. (12). *73rd row:* K. 3 rows. Rpt. these 4 rows once (11). *80th row:* K. 4 rows. *84th row:* K. Inc. in last st. (12). *85th row:* K. Rpt. these 2 rows twice (14). *90th row:* K. 2 tog., k. to end of row. Now pick up the 14 st. from the safety-pin, and k. them, knitting last 2 st. tog. (26).

*91st row:* K. *92nd row:* K. 2 tog. at each end of needle (24). *93rd row:* K. *94th row:* K. 2 tog. at beginning, middle, and end of needle (21). *95th row:* K. Rpt. these 2 rows once (18). *98th row:* K. 2 rows. *100th row:* Inc. at beginning, middle, and end of needle (21). Rpt. this row once (24). *102nd row:* Inc. in first st. (25). *103rd row:* K. Rpt. these 2 rows 3 times (28). *110th row:* K. 10 rows. *120th row:* K. 2 tog. at each end of needle (26). *121st row:* K. Rpt. these 2 rows 4 times (18). *130th row:* K. 2 tog. at each end of needle (16). Rpt. this row 3 times (10). Cast off. K. another piece in the same manner.

**Headpiece.**—*1st row:* Cast on 3 st, k. 2 rows. *3rd row:* Inc. in first and last st. (5). *4th row:* K. 3 rows. Rpt. these 4 rows 3 times (11). *19th row:* K. 22 rows. *41st row:* K. 2 tog. at each end of needle (9). *42nd row:* K. 5 rows. Rpt. these 6 rows twice (5). *59th row:* K. 12 rows. *71st row:* K. 2 tog., k. 1, k. 2 tog. (3). *72nd row:* K. Cast off.

**Leg.**—*1st row:* Cast on 22 st., k. 8 rows. *9th row:* K. 2 tog. twice at each end of needle (18). *10th row:* K. Rpt. these 2 rows once (14). *13th row:* K. 2 rows. *15th row:* Inc. at beginning, middle, and end of needle (17). *16th row:* K. Rpt. these 2 rows 6 times (35). *29th row:* K. 16 rows. *45th row:* K. 5 st., place these on a safety-pin. Cast off 3 st., k. to end of row (27). *46th row:* K., knitting last 2 st. tog. (26). *47th row:* K. 3 rows. *50th row:* K. 2 tog. at each end of needle (24). *51st row:* K. Rpt. these 2 rows 5 times (14). *62nd row:* K. 2 tog. at each end of needle (12). Rpt. this row once (10). Cast off. Now pick up the 5 st. from safety-pin, k. 2 rows, k. 2 tog., k. 1, k. 2 tog. (3). K. Cast off. K. another piece in the same manner.

**Arms.**—*1st row:* Cast on 15 st., k. 2 rows. *3rd row:* Inc. at beginning, middle, and end of row (18). *4th row:* K. 7 rows, *11th row:* K. 2 tog. at each end of needle (16). *12th row:* K. 3 rows. *15th row:* Inc. in first and last st. (18). *16th row:* K. 3 rows. Rpt. these 4 rows twice (22). *27th row:* Inc. in first and last st. (24). *28th row:* K. Rpt. these 2 rows twice (28). *33rd row:* K. 2 rows. *35th row:* K. 5 st., put these on a safety-pin. Cast off 3 st., k. to end of row (20). *36th row:* K., knitting last 2 st. tog. (19). *37th row:* K. 3 rows. Rpt. these 4 rows once (18). *44th row:* K. 2 tog. at each end of needle (16). *45th row:* K. Rpt. these 2 rows twice (12). *50th row:* K. 2 tog. at each end of needle (10). Rpt. this row once (8). Cast off. Now pick up the 5 st. from the safety-pin, and k. 2 rows. K. 2 tog., k. 1, k. 2 tog. (3). K. Cast off. K. another piece similarly.

*Ears.*—*1st row:* Cast on 6 st., k. 1 row. *2nd row:* Inc. in first and last st. (8). *3rd row:* K. Rpt. these 2 rows twice (12). *8th row:* K. 10 rows. *18th row:* K. 2 tog. in middle of row (11). Rpt. this row 3 times (8). Cast off. K. another in the same manner.

To make up the bear, brush up each knitted piece well with a wire brush. Sew the two pieces of body together, beginning at the base of the front. Sew along the neck to the nose. Sew in the headpiece, placing where the 3 st. were cast on to the nose, and sew along the top of head to neck. Sew along the back, leaving about 2 inches open for stuffing. Sew up the arms and sew into armholes. Sew up the legs and sew into openings. Turn the work, and stuff well with kapok, pressing the stuffing well into the legs and arms with a knitting needle to make them firm. Sew up the opening that was left for stuffing. Sew on the ears. Sew in the two shoe buttons for eyes. Mark the nose and mouth with fine black wool, also mark the feet and paws. Smooth the bear down with the wire brush. Tie the ribbon round his neck.

**Koko the Monkey.** For this toy, which costs about half a crown, 1 oz. of pale fawn 4-ply wool; 3 oz. 4-ply brown wool; ½ oz. 2-ply red wool; one pair of steel knitting needles size 11, and 2 black shoe buttons are required.

The work begins at the base of body. *1st row:* With brown wool cast on 6 st., k. 10 rows, *11th row:* Inc. in last st. (7). *12th row:* K. 11 rows. *23rd row:* Inc. in first st. (8). *24th row:* K. Inc. in last st. (9). Rpt. these 2 rows twice (13). Put these 13 st. on a safety-pin. Now k. another piece from 1st row to the 28th row. Pick up the 13 st. from the safety-pin, and k. then. You should have 26 st. on your needle. This makes the openings for the legs to be put in. *25th row:* K. *26th row:* Inc. in first st. (27). *27th row:* K. Rpt. these 2 rows once (28). *30th row:* K. 26 rows. *56th row:* K. 12 st., put these on a safety-pin for the chest. Cast off 4 st. for armhole, and k. the remaining st. (12). *57th row:* K. 13 rows. *70th row:* Inc. in first st. (13). *71st row:* K. Put these 13 st. on a pin. *72nd row:* Pick up from the safety-pin the 12 st. that were left for the chest. Joining wool to where the 4 st. were cast off, k. 13 rows.

*85th row:* K. Inc. in last st. (13). Pick up the 13 st. from the pin and k. them (26). *86th row:* K. *87th row:* K. 2 tog. at beginning, middle, and end of row (23). *88th row:* K. Rpt. these 2 rows once (20). *91st row:* K. 2 rows. *93rd row:* K. 2 tog. Inc. in middle and end of needle (21). *94th row:* Inc. in first and middle st., k. last 2 st. tog. (22). *95th row:* K. 2 tog., k. to end of row (21). *96th row:* K. Rpt. these 2 rows 5 times (16). *107th row:* K. 2 rows. *109th row:* Inc. in first st. (17). *110th row:* K. Rpt. these 2 rows twice (19). *115th row:* Inc. in first st., k. last 2 st. tog. (19). *116th row:* K. Rpt. these 2 rows twice. *121st row:* K., knitting 2 tog. in middle and end of needle (17). *122nd row:* K. *123rd row:* K. 2 tog. at beginning, middle, and end of needle (14). Rpt. this row twice (8). Cast off. K. another piece in the same manner.

*Leg.*—The work begins at the foot. *1st row:* Cast on 36 st., k. 6 rows. *7th row:* K. 2 tog. at each end of needle

(34). *8th row:* K. *9th row:* Cast off 10 st., k. to end (24). Rpt. this row once (14). *11th row:* Inc. in first st., k. 2 tog. in middle of row. Inc. in last st. (15). *12th row:* K. Rpt. these 2 rows 11 times (26). *35th row:* K. 2 rows. *37th row:* K. 2 tog. at beginning of row. Inc. twice in middle of row, k. last 2 st. tog. (26). *38th row:* K. Rpt. these 2 rows 4 times (26). *47th row:* K. 2 tog. at beginning. Inc. twice in middle of row, k. last 2 st. tog. (26). *48th row:* K. Inc. twice in middle of row (28). Rpt. these 2 rows 3 times (34). *55th row:* Inc. in first st. (35). *56th row:* K. 5 st., put these on a safety-pin. Cast off 8 st., k. the remaining st. (22). *57th row:* Inc. in first st., k. last 2 st. tog. (22). *58th row:* K. Rpt. these 2 rows once (22). *61st row:* K., k. last 2 st. tog. (21). *62nd row:* K. 3 rows. Rpt. these 4 rows once (20). *69th row:* K. 2 tog. at each end of needle (18). Rpt. this row 6 times (6). Cast off. Now pick up the 5 st. from the pin, joining wool to where 8 st. were cast off. K. 2 rows. K. 2 tog., k. 1, k. 2 tog. K. Cast off. K. another in the same manner.

*Arms.*—*1st row:* Cast on 4 st. with brown wool, k. *2nd row:* Inc. in first and last st. (6). *3rd row:* K. Rpt. these 2 rows 6 times (18). *16th row:* K. 28 rows. *44th row:* Join fawn wool for hand, k. *45th row:* P. Rpt. these 2 rows once. *48th row:* K. 2 tog. at beginning, middle, and end of row (15). *49th row:* P. Rpt. these 2 rows twice (9). Cast off K. another in the same manner.

*Ears.*—*1st row:* With brown wool cast on 9 st., k. *2nd row:* Inc. in first and last st. (11). *3rd row:* K. 4 rows. *7th row:* K. 2 tog. at each end of needle (9). *8th row:* K. Rpt. these 2 rows once (7). Cast off. K. another in the same manner.

*Tail.*—*1st row:* With brown wool cast on 4 st.; k. *2nd row:* Inc. in first and last st. (6). *3rd row:* K. Rpt. these 2 rows 4 times (14). *12th row:* K. 16 rows. *26th row:* K. 2 tog. at each end of needle (12).

*27th row:* K. 14 rows. Rpt. these 15 rows twice (8). *55th row:* K. 2 tog. at each end of needle (6). *56th row:* K. 6 rows. Cast off.

*Soles for Feet.*—*1st row:* With fawn wool cast on 4 st., k. These are worked in stocking-stitch. *2nd row:* P. *3rd row:* Inc. in first and last st. (6). *4th row:* P. Rpt. these 2 rows once (8). *7th row:* K. *8th row:* P. Rpt. these 2 rows 4 times. *19th row:* K. 2 tog. at each end of needle (6). *20th row:* P. Rpt. these 2 rows once (4). Cast off. K. another in the same manner.

*Face.*—*1st row:* With fawn wool cast on 6 st., k. This is worked in stocking-stitch. *2nd row:* P. *3rd row:* Inc. in first, middle, and end st. (9). *4th row:* P. Rpt. these 2 rows 5 times (24). *15th row:* K. *16th row:* P. Rpt. these 2 rows twice (24). *21st row:* K. 2 tog. at beginning, middle, and end of needle (21). *22nd row:* P. Rpt. these 2 rows 3 times (12). *29th row:* K. 2 tog. 6 times (6). *30th row:* P. Cast off.

*Cap.*—*1st row:* With red wool cast on 60 st., k. 28 rows. *29th row:* K. 2 tog. to end of row (30). *30th row:* K. 3 rows. *33rd row:* K. 2 tog., k. 5 st. Rpt. this to end of row (25). *34th row:* K. *35th row:* K. 4 st., k. 2 tog. Rpt. this to end of row; k. 1 st. (20). *36th row:* K. *37th row:* K. 2 tog., k. 3 st. Rpt. this to end of row (17). *38th row:* K. *39th row:* K. 2 tog. to end of row, k. 1 st. (9). *40th*

row: K. Break off a length of wool and thread through all the 9 st., and draw up.

To make up the monkey, sew up the body to the throat. Sew over top of head, and along the back, leaving about 2 inches open for stuffing. Sew in the fawn face, placing where stitches were cast on to the neck. Sew along the sides. Sew up the arms and sew into armholes. Sew up the legs and sew in the fawn soles. Sew legs into the openings. Turn the work. Stuff well with kapok, pushing the kapok well into the head and limbs with a knitting needle. Sew up the opening that was left for stuffing. Sew on the ears. Sew in the shoe buttons for eyes, mark the nose and eyebrows with fine black wool. Mark the mouth with red wool. Sew up the tail. Stuff lightly with kapok, and sew on to animal. Mark the hands with black wool. Sew up the red cap, drawing all the stitches together. Make a tassel of a few strands of black wool. Stitch the cap on to the monkey's head.

### KNITTING: STITCHES AND PATTERNS

#### How to Obtain Both Simple and Fancy Effects

This general outline of the principles of knitting suggests reference to the entries on Glove; Stocking; Sock. See also the companion articles, Crochet and Needlework.

Knitting consists of loops or stitches formed by means of two needles when working a flat piece, or four or more needles when working in a round. Through connecting the stitches in one continuous piece an elastic fabric can be produced. In its earliest stage knitting was practically limited to making stockings in a flat piece on two needles, which were afterwards sewn up; from this, knitting stockings in a round was evolved, avoiding the back seam, and fastening off at the toe.

The first process is casting on the stitches. Hold the short end of the wool in the left hand, take the main length in the right hand and pass the latter over the short end, so that it forms a loop. Bend the main length of wool under this loop, keeping the latter in position with the thumb and forefinger of the left hand, and pass it up through the loop so that it forms a complete stitch, as in Fig. 1. Pass this loop on a knitting needle and draw up the wool closely until the loop just fits the needle. Hold this needle in the left hand, and take the working needle in the right hand. Twist the length of wool round the third finger of the right hand, and allow it to pass over the first finger of that hand as the work proceeds. The tightness or looseness of the wool and how it is held over the third finger determine the tension of the knitting, and it is only by an even tension that good work can be produced.

One stitch is now on the needle. To make further stitches, put the right-hand needle from left to right through the loop on the left-hand needle, pass the wool round the point of the right needle, bring it through the single loop, Fig. 2, and draw it out until it is long enough to pass it over the point of the left-hand needle, when another stitch will be produced. Continue this

operation until enough stitches are on the needle.

*Knitting. Fig. 1. How to make the first stitch out of a loop in casting on.*

*Fig. 2. Making the second stitch with the needles. This also shows how the right-hand fingers regulate the tension of the wool during work.*

*Fig. 3. Plain knitting, producing garter stitch, in progress.*

*Fig. 4. Purl stitch, first stage, with working thread in front of needle.*

**Plain and Purl Stitches.** To work the first row of plain knitting, take the needle containing the stitches in the left hand; put the right-hand needle into the first stitch from left to right, and pass the wool round the right-hand needle as described for casting on. Draw the loop through, and with the right-hand needle pass the first stitch off the left needle, as the new stitch now remains on the right needle. Repeat this action to the end of the row, and if these rows are continued little ridges will be seen on the work, two rows making one ridge. Fig. 3 shows this stitch, known as garter stitch, in progress. To make a neat edge on a piece of knitting, work the first row through the back of the loops.

The next form of knitting is known as purling. This is used to produce the reverse side of the stitch just explained. If stocking web is wanted (smooth on the front side, not ridged on both sides, as with garter stitch), the back row must be purled. Put the right-hand needle through the stitch from right to left (Fig. 4), with the working thread to the front of the needle. Pass the thread over and round the right-hand needle and back to the front again; then let the right-hand needle pass through the loop of the stitch, while the latter slips off the left-hand needle. Fig. 5 shows the

second action with the wool round the needle.

*Fig. 5. Purl stitch, second stage, wool round needle.*

*Fig. 6. Casting off.*

**Casting Off.** The chief method of casting off the stitches is shown in Fig. 6. Knit two stitches as usual, then put the point of the left-hand needle, left to right, through first stitch knitted, and lift it over second stitch and point of the right-hand needle, letting it drop right off needles. Knit next stitch on left needle, so that you again have two stitches, on right needle, and again pass the first one over the second. Repeat until there is only one stitch left; then cut wool and pass it through remaining stitch and fasten in the end with a darning needle.

If a loose casting off is wanted, knit two stitches together by inserting the needle from right to left through the two stitches together instead of one only; then knit them in the ordinary way, when one stitch will result on the right-hand needle. Now pass this stitch back again to the left-hand needle and knit it together with the next stitch, and again pass the resulting stitch back to the left-hand needle, and continue to the end of the row, when a loose edge will be the result. This particular edge bears a resemblance to a cast-on edge as near as possible.

**Increasing and Decreasing.** The next step to learn is how to increase and decrease stitches for the purpose of forming a piece of knitting into a different shape, such as the leg of a stocking that has to be narrowed towards the ankle. There are two methods of decreasing. At the beginning of a row the decrease is generally formed so that it turns towards the centre of the row, thus: slip one stitch by simply passing it off the left-hand needle on to the right, without passing the thread round it. Knit the next stitch, when there will be two stitches on the right-hand needle, and lift the slipped stitch over the knitted one with the point of the left-hand needle. This is usually referred to as the slip, knit, and draw-over method.

If a decrease is wanted at the other end of the same needle, two stitches should be knitted together as described above, and these are usually the second and third stitches from the end, so that there will be one stitch to knit at the end after the decrease. If possible, avoid decreasing right at the end of a row, as it makes

an uneven edge, and in the case of a jumper or similar garment does not make a neat seam when the two edges are sewn together. Fig. 7 shows a piece of stocking web knitting decreased at both ends of the row.

*Fig. 7. Piece of stocking web decreased at both ends.*

*Fig. 8. Pattern resulting from made stitches with stocking web between.*

To increase, a stitch can be knitted into twice to make one extra. Knit in the usual way through the front of a stitch, then knit again through the back of the same loop before passing it off the left-hand needle, and two stitches will result. Another method is to lift up the loop immediately under the first stitch on the left-hand needle and knit it; or knit one and purl one in the same stitch.

A "made" stitch is not really an increase, as this term should be used in fancy patterns only, to produce a hole, and usually a stitch is decreased directly after it to restore the balance of the stitches. To produce a made stitch before a knitted stitch, simply bring the wool to the front of the needle, so that it passes over the latter when knitting the next stitch, and a straight loop results on the right-hand needle. When working the next row this made loop is knitted like an ordinary stitch, and a complete new stitch results. To make two stitches in this way the thread is passed round the needle twice, then when working the next row a stitch must be knitted and purled in the made loop, otherwise one of the made stitches will be lost. Fig. 8 shows an openwork design based on made stitches with stocking web between.

When knitting in a round for such articles as stockings or children's gaiters without side seams, the stitches must be divided equally on three or more needles, and a fourth one taken for the working needle. At the end of the round the wool must be drawn up very closely so that a gap does not occur between the needles, and when beginning a new needle put the latter in the first stitch of the next needle behind the needle that has just been worked, otherwise a little gap will appear at the beginning of every fresh needle, and this would produce a ladder right down a stocking. A flexible circular wire with points at both ends is often used for knitting jerseys and other tubular garments.

When knitting in rounds, stocking web is obtained by working every round in plain knitting, instead of plain and purl alternately.

Fig. 9. Specimens of single and double ribbing, for tops of stockings.

Ribbed knitting is used for the tops of stockings, hems and necks of jerseys, for sleeve edges, and for any position where contraction is required, as the ribs cause the knitting to fit closely. In the case of stockings that are ribbed all the way down, the welt, usually about 3 in. deep is worked in a different rib from the rest of the stocking, generally a single rib of knit one and purl one alternately. Double rib is two knitted and two purled stitches worked alternately, and a variety of rib designs can be formed. Fig. 9 shows specimens of single and double rib.

**Joining Wool.** In the course of a large piece of work, joining new wool or thread is sure to be done. When the first ball is getting near the end, stop when there is about 8 in. left, take the new ball and lay the two ends together, knit one stitch with the two ends, then knit the following stitches with the new and the old ball alternately. In knitting stockings or any stocking web in a round, this join will only be visible on the inside, so on a flat piece of stocking web, worked on two needles, the join should be done when working a right-side row so that the alternate threads are passing on the wrong side.

Another method of joining is by twisting the new thread over the first as each stitch proceeds. Put the needle in the stitch of knitting, then, holding the end of the new ball down with the fingers on the left hand, pass the short end under, then over, the new wool, so that the latter is encircled with the old end, then use the new wool to knit the stitch. Twist the old wool over the new ball for about 12 stitches and leave the short end of wool to be sewn down afterwards.

The only place in which a knot is allowed is at the end of a row when a fancy pattern is being worked, and which would be spoiled with an ordinary joining. If the knot is tied right up to the edge of the knitting it can be hidden when joining up the side seams. A knot is never allowed in stocking knitting.

To make a chain edge on a piece of flat knitting, the first stitch must be slipped purl-wise, and the last stitch should be knitted through the back of a loop instead of through the front in the ordinary way. This edge is used on the flap of a stocking heel, each chain being picked up afterwards when turning the heel to represent one stitch. It can be employed on the armholes of jumpers, if the sleeve stitches are to be picked up in the same way.

Double knitting is done on two needles, and is

worked so that when the flat piece is completed it has two distinct halves that can be pulled apart like a bag, but they are caught all round the edges. It is a useful pattern for scarves where extra warmth is required, as stitches can be cast on for any width and the piece continued for any length. Two stitches are usually knitted single at the beginning and end of each row, so an even number of stitches should be cast on to begin with.

Knit one plain row, then proceed thus: Knit two stitches, bring the wool to the front of the needle, slip a stitch as if for purling, pass the wool back again, and knit the next stitch. Repeat these two stitches alternately to the end of the row, except the last two stitches, which are knitted plain to match the beginning. Continue this row for any length required, and it will be noticed that in the second row the slipped stitch is knitted, and vice versa, which thus causes the two distinct sides of the bag.

**Fancy Designs.** Brioché knitting is a fancy rib, and for this the number of stitches cast on must be divisible by three. To work it, bring the wool to the front of the needle and slip one stitch purlwise; knit together the next two stitches, and repeat this alternate movement to the end of the row. Every row is worked in the same manner, and in succeeding rows the two stitches that cross each other are always knitted together.

Two-colour knitting is chiefly stocking web, using two colours of thread in the same row to form a design. Sometimes six colours or more are used in one design, but two are usually confined to one row, as the different colours have to be carried along the row during the work. The first movement is shown in Fig. 10. The second wool which is not in use is held over the first finger of the left hand as for crochet, and in the first step it is passed over right-hand needle, before the working wool is passed over that needle to knit the stitch. This catches the spare wool in with the stitch. The second stitch is knitted in the ordinary way, but holding the spare wool on the left finger away from the stitch. The wool not in use passes through every alternate stitch, and is only slightly visible at the back.

When working coloured stripes in ribbing, say at the hem of a jersey, one plain row should be worked with the new wool on the right side of the work each time the colour of the wool is changed. This plain row will sink in the ribbing and give the work a neater appearance where change of colour is effected.

Knitting in two colours. Fig. 10. First position, with second wool passed over right-hand needle before working wool.

*Fig. 11. Second position, showing second wool held on left forefinger away from stitch.*

**Grafting.** Two pieces of knitting can be joined together so that the join is quite invisible, and quite flat. It is usually employed for finishing off the toes of socks and stockings.

In the case of a stocking toe the stitches would be equally divided on two needles, one being placed behind the other, with wrong sides facing. The thread should be cut off, leaving about 18 in. hanging for a stocking toe, or longer, according to the number of stitches to be grafted together. Pass the thread into a darning needle and, beginning on the front row—that is the row nearest to the worker—put the darning needle in the first stitch as if for knitting, pass the stitch off the knitting needle and draw up the thread, but not too tightly. Put the darning needle in the second stitch as if about to purl, draw the thread through while this stitch is on the knitting needle, and do not slip it off.

Go to the back needle and reverse the action. Put the needle in the first stitch as if about to purl, draw the thread through and slip this stitch off the needle; put the needle in the second stitch as if about to knit, and draw the thread through, but do not slip the stitch off the needle. Repeat until all are taken off. The thread must not be drawn tightly.

The method of grafting above described can be memorised thus: knit and slip off, purl and keep on; purl and slip off, knit and keep on. This includes the two needles.

**Knitting Needles.** Knitting needles are sometimes referred to as pins or wires. They are divided into two classes: steel needles, which are made in the finer sizes, and bone needles for the coarser sizes. The latter includes aluminium, celluloid, ebonite, and amongst patent materials are metal tubings coated with nickel silver or other material.

Knitting needles are made in standard sizes and can be tested on a bell gauge (q.v.), No. 1 being very coarse, No. 2 slightly less coarse, and so on. The higher the number the finer the needle. The usual sizes employed for knitting jumpers and dresses range from No. 8 to No. 12, but for very thick wools sizes coarser than No. 8 may be employed. The average sizes used for knitting socks and stockings are from No. 12 to No. 15. For very loose meshed knitting, there are needles in sizes larger than No. 1, No. 0, for instance, being larger than No. 1, and No. 00 larger than No. 0. These "outsize" needles

are usually in wood or cane.

Steel knitting needles are sold in paper packets in sets of four, and bone in pairs of two and sets of four, some with knobs on for flat pieces of work, and the sets with points at both ends for knitting round or tubular garments. Thicker needles can be bought in a variety of colours, so it is well to use dark needles for light thread and vice versa.

When buying bone needles they should be carefully inspected to see that there are not any flaws, as the tiniest chip will split silk and wool. When a flaw does occur it can be smoothed away with fine glasspaper. This also applies to the point of the needle, which should not be too sharp.

Wooden needles can be treated with glass-paper and given a perfectly smooth finish. Celluloid needles are always smooth, but should not be used for very heavy work as they bend easily. Aluminium needles soil light wool, and should be used only for dark materials; those made from brass tubing coated with nickel silver are light in use, and do not soil the work.

Knitting shields can be bought cheaply for protecting the points of the needles when not in use. They are made in pairs attached by elastic or a spring. In shape the shield resembles a thimble, into which the needles fit.

**Knitting Wool.** All wools have a certain ply, whether it be 2, 3, or 4 ply, and so on, the word ply meaning the number of threads which compose the thickness of the wool in each case; but a 4-ply fingering produces a garment about half the size of a 4-ply thick wool, using exactly the same number of stitches and following also the same directions. There are numerous fancy wools on the market, but the following are the main standard kinds:

Fingering, which is the kind in most general use, is divided into Scotch, super-fingering, and the cheap varieties. All these are employed for stockings, children's dresses and coats, jumpers and underwear. Cheap fingerings are harsh and do not give the same warmth or comfort in wear as the super-fingering.

Vest wool is about the thickness of Scotch fingering of the same ply, 2, 3, or 4-ply, but it has a softer finish, being specially made for underwear.

Soft knitting is sold in packets and is so labelled. Wheeling or Alloa yarn is a distinctive yarn of 3-ply thickness, usually sold in 2 oz. skeins, 8 of which form a head of 1 lb. When of good quality it is suitable for heavy socks and stockings, as it is much thicker than 4-ply fingering, although one ply less.

Double knitting is a 4-ply wool about twice as thick as 4-ply fingering, and similar in weight and thickness to a good wheeling, although of much better quality and appearance, as well as softer to the touch.

Another wool which is very thick, though made in a two-ply twist, is the "quick-to-knit" type of wool that is intended for speedy knitting on large-sized needles.

Zephyr wool is equivalent to the old Berlin wools, and is sold in the same thicknesses, namely, single

Berlin 4-ply, and double Berlin 8-ply; it is particularly soft and full in the thread, and is more suitable for indoor articles, as its smoothness and softness do not allow for the friction of hard wear.

Shetland Wool is the name of a very fine 2-ply wool, finer than 2-ply fingering, and receives its name from the Shetland Isles where very fine shawls, underwear, and jumpers are made. Andalusian is the standard name for a soft 4-ply wool twisted in a similar manner to soft knitting, but finer in size owing to the twist. Sold in 1 oz. packets, it is chiefly used for children's garments and for socks.

**Knocker.** *See Door.*

**KNOCK KNEE.** In the common deformity known as knock-knee the legs diverge from one another below the knees so that the latter tend to knock against each other in walking. The affection may begin in early childhood, being then almost always due to rickets; or it may come on between the ages of 12 and 18 years. Weak boys or girls who carry heavy weights are very liable to suffer. Pushing a heavy wheelbarrow, for example, may cause the deformity. A child showing signs of knock-knee should not be permitted to crawl or walk. It should lie down as much as possible in the open air and sunshine, and be properly fed.

In many cases these measures alone will remove the deformity, but it is generally desirable to apply pressure. This can be done by putting a soft pad between the knees, so as to separate the lower ends of the thighbones, and bandaging the ankles together.

The legs must be massaged daily, and manipulated in a way the doctor will direct. The boot heel should be made higher on the inner than on the outer side, and, when walking, the feet should be turned in a little.

In the cases which develop later in life, a metal splint from the heel of the boot to the outer prominence of the hip may be used. But the deformity, if pronounced, can be removed by a surgical operation. *See Knee.*

**KNOP.** This term is used for the knobs found at the handle end of old spoons and sometimes for those on the covers of drinking and other vessels. A familiar example is the apostle spoon, while the acorn is often found figured as a knop. Knops are also the rounded protuberances found in the stems of wine glasses. *See Glass Ware; Spoon.*

**KNOT: In Timber.** A knot is a hard part of the wood occasioned by the growth of a small branch, which, by growing out at an angle to the normal grain of the tree, causes one set of fibres to cross the other, thus forming a hard spot, very difficult for the amateur to deal with.

When the worker purchases ordinary prepared timber which has already been machine planed, it will be found preferable to use it in that condition if the material is at all knotty, rather than attempt to plane it up. It is not always possible to do this, as the machined surfaces are not all smooth enough for the purpose for which the timber is required. In such a case, one course

to adopt is, when planing, to set the plane iron very fine, so that it makes a very fine shaving, and to press it firmly upon the surface of the work, especially when planing over the knots.

It may be as well, when a good surface is required, to cut the knot away bodily. In some cases, such as when the wood is thin, it will be found that the knot can be driven down through the wood with the aid of a small punch and hammer. If this is the case, the hole can then be enlarged with a twist drill, and plugged with a circular piece of wood which should be glued and driven in tightly. When the knots are running more or less with the surface of the timber, a recess should be chiselled out with the edges slightly undercut, and a new piece of wood cut and fitted into it with the grain running in the same direction as the rest of the timber. These pieces should be properly glued in and allowed to set hard. The timber can then be easily prepared.

Whenever possible, knots should be avoided by selecting timber that is not prone to this trouble, such as American whitewood, Californian redwood, beech, and similar timber, which can be obtained in sufficiently large pieces to avoid the presence of a knot altogether.

**Knots in Paintwork.** In paintwork, the presence of knots is very objectionable, as they contain a kind of resinous material which may ruin the paint if not specially treated. For this purpose various compositions are prepared, known as knotting. This should be brushed over the surfaces of the knots, prior to the application of the paint, and when the knots are very numerous, two coats or more of knotting will be better than one. The surface may then be prepared in the usual way. *See Wood.*

**KNOT: How to Tie.** (For illustrations of knots see next page. Knots may be divided into the simple ones that are tied every day by ordinary persons, and the more elaborate ones that are used for various purposes by sailors and others who need something much stronger in the course of their work.

The illustrations on next page show how the knots in common use, and also some of the more elaborate ones, are tied. Some of these, e.g. the timber hitch, are only used for certain special purposes, but others are useful in everyday life, and the more difficult among them can usually be tied after a little practice.

Fig. 1 shows a common loop by which most knots are commenced, with its parts lettered for reference. The upper part A to B is called the standing part of the rope, B to C the loop or bight, and C to D the end. When the end is drawn through the loop, the simplest of all knots, a half hitch, is formed.

A figure-of-eight knot, Fig. 2, is made by forming a loop, placing the end behind the standing part and finally over and through the loop and pulling taut. This knot is useful for making a stop on a rope to prevent the end fraying or slipping through a block. A reef-

### **Knot.** Various types of knots useful to the handyman.

Fig. 1. Loop. Fig. 2. Figure-of-eight. Fig. 3. Reef. Fig. 4. Single sheet bend. Fig. 5. Hawser bend. Fig. 6. Two half hitches. Fig. 7. Round turn and two half hitches. Fig. 8. Fisherman's bend. Fig. 9. Bowline and running bowline. Fig. 10. Timber hitch.

Fig. 11. Clove hitch. Fig. 12. Lever hitch. Fig. 13. Draw hitch. Fig. 14. Sheepshank.

Fig. 15. Simple clinch. Fig. 16. Catspaw. Fig. 17. Double hook hitch. See explanation in text.

knot, Fig. 3, is the simplest and best of all knots for tying together two ropes of equal size. A single sheet bend, Fig. 4, is a good method of joining two ropes of unequal sizes, and if the ropes are wet, or likely to be so, the knot can be made still more secure by again passing the end of the thin rope round the loop on the other, as shown by the dotted lines.

A hawser bend, Fig. 5, should be used when two thick ropes or cables require to be joined. A half hitch is formed on one rope and the end tightly lashed with strong cord to the standing part. The end of the second rope is passed through the loop on the first and secured in the same way. Two half hitches, Fig. 6, are made on a rope to fasten it to some object, to finish a lashing or form a noose. This is a good knot for general use.

A round turn and two half hitches, Fig. 7, are employed for tying a rope on which there will be a great strain so that the hitches shall not jam. For fastening ropes to posts, raising heavy beams, weights, etc., it will be found of great service. Two turns of the rope are taken round the post or beam, and then two half hitches are formed on the standing part and drawn taut. If there is an excessive or jerking strain increase the hitches or lash the end down.

The fisherman's bend, Fig. 8, which should be distinguished from the fisherman's knot, will be found useful in making fast where there is a give-and-take motion, or a varying strain on the rope, as in drawing water from a well with a bucket, tethering cattle, attaching anchors, stays, etc. A bowline, Fig. 9, is made on a rope to form a loop or noose which will not slip. It is used when a permanent loop is required at the end of a rope, or to attach to other ropes. A running bowline or slipknot can be formed by drawing the standing part of the rope into the loop.

**The Timber Hitch.** A timber hitch, Fig. 10, is chiefly used for holding timber, etc., where the weight will keep the hitch tight. The knot consists simply of a half hitch made with a rather long end, which is twisted back again round the loop. In cases where there is to be a continuous strain or the timber requires to be kept pointing steadily in one direction, a half hitch should be added as at H. A clove hitch, Fig. 11, makes a good knot for commencing and finishing the lashing together of poles, beams, etc. As it will not slip, it can be attached to another rope or pole and still leave the end free for further use.

A lever hitch, Fig. 12, is a simple way of fastening a rope to a lever worked by a windlass or to piles, stakes, ree-stumps, etc., which are to be drawn out of the ground by horses or power. It is very handy for fixing the rounds of a rope-ladder. The draw hitch shown in Fig. 13 is of great service in securing a rope to a post, ring or other rope, in such a way that it can be instantly released. The diagrams 1, 2, and 3 show its formation. This knot will resist a give-and-take motion and can be released by jerking the end.

A sheepshank, Fig. 14, is used to shorten a rope. To make it, take up the length desired and fold it as in A. Then with parts 1 and 2 form a half hitch round each loop as in B. Wooden toggles can be inserted for further

security, as at T, or the loops can be lashed to the standing parts of the rope as at L. A simple clinch, Fig. 15, is a small loop or ring formed on the rope and held together by tightly lashing with strong cord. For attaching a block, lantern, etc., it will be found very handy.

A catspaw, Fig. 16, makes a temporary loop for hooking on a block or supporting another rope. It is formed by first making two loops as at A and then twisting them up as in B; bring the two eyes together and insert the hook of the block or pass the rope to be suspended through them. To make a double hook hitch, Fig. 17, take the loop of the rope or sling and place it over the upper part of the hook, crossing it behind, then place the under rope over the hook and cross the upper part over it, and draw both taut. This hitch will hold a weight more securely than any other form of hook knot. *See Clove Hitch.*

**KNOTWEED.** This is the popular name of polygonum, a large group of hardy plants, some of which are very decorative. *See Polygonum.*

**KNUCKLEBONES.** This game, also called chuckstones, five stones, dibs, jackstones, and hucklebones, is played with five or six small objects, the aim being to throw them in various ways. The objects, originally the knucklebones of a sheep, are usually of metal; but small stones or pieces of wood will serve almost equally well.

Of the several games, one consists in throwing up one of the pieces, and, while it is in the air, picking up one or more of the others from the table, continuing until all have been picked up. For this six stones are usually employed, the one thrown being called the jack. Another game is to throw up one piece and catch it on the back of the hand, following with two pieces, then with three, and so on until, if possible, the five are thrown and caught together. Special names are given to some of these throws, such as peas in the pot and horses in the stable.

**Knuckle Joint.** *See Rule Joint.*

**KOCHIA.** This half hardy annual, from 18 to 24 in. high, of graceful, bushlike growth, is valued for its light green leaves, which turn reddish purple in autumn. It is known as the summer cypress and is often used in summer bedding, where it contrasts finely with flowering plants. The seedlings are raised in a

heated glasshouse in February or March, are potted singly in small pots, and are planted out of doors in May or early June. Pron. Kō'-ci-a.

*Kochia, or Summer Cypress, valued for its graceful pale green foliage.*

**KODAK.** This name is applied to cameras and other photographic products made and sold by the Eastman Kodak Company. It is generally understood to refer to roll-film cameras. *See* Camera; Developer; Film; Photography; Plate.

**KODOL:** A Developer. This photographic developer, which is made by the Eastman Kodak Co., is a single solution of the paramidophenol type, clean working, non-staining and without liability to fog. It is equally suitable for plates, films, bromide papers and gaslight papers. In ordinary dish development by the visual method, 1 dram of Kodol is used for every 3 oz. of water.

Development should be full, since there is a tendency for a certain amount of density to be lost in the fixing bath. Where the negative is known to be over-exposed, increase the strength of the developer taking 1 dram of Kodol for 2 oz. water, with the addition of 2 or 3 drops of potassium bromide.

If it is certain that the plate is underexposed use a weaker solution, 1 dram of developer to 5 oz. water.

Tables for development by the time and temperature methods have been prepared by the Kodak Co., from whom the preparations may be obtained.

For developing bromide papers the following proportions are required:

Kodol	1 dram
Waterto	4 oz.
Potassium bromide 10 per cent solution	1 drop

Development will be complete at normal temperatures in 2 min., if exposure is correct. If exposure is insufficient it is useless to attempt to obtain detail by prolonging development. For gaslight papers Kodol is used in the following strengths:

	Vigorous paper	Soft paper
Kodol	2 drams	1 dram
Water	3 oz.	3 oz.
Potassium bromide, 10 per cent solution	3 drops	1 drop

With vigorous gaslight papers development should be complete in 30 sec.; with the soft variety it will take perhaps 40 sec. *See* Developer; Developing; Film; Photography.

**KOHL RABI.** This somewhat coarse vegetable proves useful as a substitute for turnips during hot dry weather when it is difficult to provide the latter. It is raised from seed sown out of doors in April or May in rows 18 in. apart, the seedlings being thinned out to about 12 in. from each other. The greenish white variety is to be preferred to the purple one.

*Kohl Rabi, a useful summer substitute for turnip.*

**KOLINSKI.** This is a yellowish-brown and orange-

red fur obtained from the Asiatic mink. Cheap in price, it is usually dyed to represent sable, for which it makes a satisfactory substitute. It is used extensively for trimmings and wraps, and among furriers is known as red sable. The hairs from kolinski tails are widely used for making into artists' sable brushes.

**KOUMISS.** This is the name given to fermented mare's milk, a pleasant acid drink, very digestible and slightly alcoholic. A kind of koumiss can also be made with cow's milk according to the following recipe:

Fresh cow's milk	2 quarts
Water	½ pint
Fresh buttermilk (that obtained from churning whole milk)	½ pint
Loaf sugar	1 ounce

The above should be mixed in a gallon jar. Afterwards cover the vessel with a cloth, and put it in a warm place for 30 to 36 hours, shaking the vessel every four hours; it is then ready for use. Some of this artificial koumiss can be used instead of buttermilk to make a fresh quantity.

Koumiss is a nourishing drink when an irritable stomach will retain no other food. It is useful in fever, albuminuria, disorders of the stomach and intestine, and whenever ordinary milk cannot be well digested. It is slightly laxative and diuretic.

**KROMESKIE.** This term is used to describe a dish made from a mixture of fish or meat enclosed in rashers of bacon, coated with batter and then fried.

**KRONA PEPPER.** Though not so strong as cayenne, this is also a red pepper. It is made from a capsicum pod known as the Hungarian paprika and is sometimes also known as paprika pepper. *See* Pepper.

**KUMMEL.** The Russian and German liqueur which bears the German name of the herb cumin is made with sweetened spirit flavoured with cumin and caraway seeds. Its distinctive flavour is mainly due to the caraway seeds. The Russian variety of Kummel was formerly made at Riga, but is now manufactured in Norway and Sweden.

**LABEL:** Its Uses. Adhesive or gummed labels and tie-on labels or tags are the two kinds most commonly used in the household. They can be obtained from any stationer, and are often sold in packets containing a dozen or more of each.

Tags are made of manilla or other strong, durable paper, cut roughly to 5 in. by 2½ in. and other sizes, with an eyelet through which string is passed. They are used for parcels of all kinds sent by rail or post, and for labelling luggage, being generally tied to the handles of travelling cases, trunks, and bags. Distinctive labels are an advantage when sorting out luggage at a railway station. Large oval tags in a variety of bright colours

are obtainable which can easily be recognized. It is a good plan to choose a particular colour and always keep to it for luggage labels.

Adhesive labels are employed for similar purposes, and are often more convenient, but are more liable to get torn or rubbed off in transit than the tag.

Labels should be addressed in a bold, clear handwriting, so that they can be easily and quickly read by anyone who may have to handle the luggage or parcels. Very often only the town to which the traveller is bound appears on the label, and this no doubt suffices in most cases: but it is safer to give the full address in case of accident. Amongst other varieties is the label used for distinguishing the keys of different rooms, which are made of bone and attached to the key by split rings of metal.

**Gardening Labels.** Garden labels used to indicate the names of each plant are of rolled zinc or plain wood. The former may be purchased with raised letters on a black ground. Garden labels may also be obtained from some automatic machines, which punch out any desired combination of names or letters upon strips of aluminium.

*Label for Plants, consisting of flat glass tube, containing a piece of oiled paper with the written name, attached by a ring to the plant or tree.*

Wooden labels may be made at home from strips of wood about 1 in. wide. The surface of the wood should be well rubbed with a piece of chalk to fill the interstices, and the writing should be done with an indelible pencil.

Always start writing the name of the plant at the top of the label. Wooden labels which it is desired to render as permanent as possible should be given a coat of copal varnish or white paint.

Labels for trees are usually made of tin, painted and tacked on. They should be placed at a height of about 5 ft. from the ground.

A special kind of label consists of a small, flat glass tube which is closed at one end, where there is a ring by which it is attached to the plant. The name of the plant is written clearly on a piece of oiled paper, and this is placed in the tube, being held in position by a small rubber cap which fits tightly over the open end.

**Photographic Labels.** The bottles containing photographic chemicals should always be labelled to avoid mistakes, either in ordinary photographic operations or by confusion with domestic bottles. It is useless to attempt to gum a piece of paper on the side of a bottle containing chemicals, since it will quickly become stained and illegible.

One method is to glue the label, and when dry cover the face of the label with thin glue, finished off with a coat of copal varnish. It will then be impervious to moisture and to the action of any chemicals. Another method is to rub down the front of the bottle with emery-powder until a ground-glass surface is obtained. On this any name can be written or printed in Indian ink or waterproof ink, covered afterwards with a coat of transparent shellac varnish or even with clear wax.

The amateur photographer should make it an inviolable rule to label every bottle, tin or other receptacle that contains chemicals of any kind. *See Lettering; Luggage.*

## LABOUR SAVING IN THE HOME

### Ideas of Value to the Busy Housewife

This article, of necessity general in its scope, is supplemented by the entries on the various domestic fittings and appliances mentioned therein, e.g. Service Hatch; Vacuum Cleaner.

See also Dining Room; Housekeeping; Kitchen; Laundry; Spring Cleaning.

Modern buildings are naturally better fitted for labour saving than older houses designed when economy of work would hardly even have been considered a domestic virtue. Smaller houses built on the square are planned with as few steps as possible. Jointless flooring for kitchens, parquet, linoleum or rubber floorings for other rooms, skirtings with rounded corners so that dust does not collect where it is difficult to remove, shelfless chimney pieces, casement windows that can be cleaned from inside, ample cupboard accommodation in the kitchen and bedrooms and on the landings, gas or electric fires or radiators throughout the house, electric lighting with convenient power plugs for various electric-run devices, fittings such as taps and door handles of chromium plate, porcelain or other material which does not require cleaning, lavatory basins in bedrooms with hot and cold running water: these are all important labour-saving points, many of which architects now incorporate in the home.

Where there is no electric power or gas available, coke, anthracite and oil are all brought into the labour-saving scheme of things with new inventions. Slow combustion fires and the modern grates are aids where coal is used and so also is access to a coal store from the kitchen instead of having to go outside for fuel, especially in bad weather.

Making meal service more efficient can save many footsteps. The trolley wagon is a useful help, and the service hatch and lift are excellent where situation of rooms and circumstances allow. Labour-saving furniture for the kitchen includes specially fitted cabinets, cupboards, sinks, and porcelain metal table surfaces. Modern bathrooms are easy to keep clean. Baths are made with enclosed sides, so that there is no space underneath for dust to collect and the waste

pipes and traps of lavatory basins can be well raised from the floor in order that the space underneath may be easily accessible for mop or duster.

**Cleaning Equipment.** The selection of labour-saving cleaning implements and gadgets is almost bewildering. To be of real utility such devices should be simple in construction, easy to clean, and not liable to get out of order. The cost of any apparatus should be considered along with the amount of service required, e.g. a good electric iron is worth purchasing, as it will be constantly needed; whilst an elaborate tin opener is not necessary, although it may be more convenient and easier to handle than the simple one already in use. Any appliance that will do work better, quicker, and with less labour than the housewife can do it is always worth procuring. A vacuum cleaner comes under this category, provided a reliable one is purchased. The daily use of a suction cleaner rids curtains, carpets and upholstery of dust.

Intelligent and careful housewives get the most value out of all such aids, employing the various attachments to search dirt out of every corner and from hitherto seldom cleaned pelmet or valance. Long-handled scrubbers and floor mops, short-handled mop dusters, a great variety of brushes with labour-saving curves and adjustable heads for particular purposes save much stooping and uncomfortable body angles while working.

A floor polisher such as the one illustrated in Fig. 1 is an excellent electric aid. Owing to the carefully designed brush action no brush marks are left on the surface of the floor. The brushes for polishing and rubbing up are quickly interchangeable and special buffers obviate all possibility of damage to furniture or walls. Quick drying of polish and a highly glazed surface are secured by passing warm air through the motor direct to the floor surface. It can be used on parquet and linoleum.

An electric dish washer is a great convenience for a large family, but is not worth the trouble of cleaning for the washing up of a few plates and dishes. Many housewives have found a clothes washing machine a good investment. Hire purchase system over twelve or eighteen months makes it possible to own one without capital expenditure. A washing machine and a good electric iron form a laundry in miniature, and where much family washing is done at home justify their expense and are a great saving of time and labour. For the small kitchen a combined cookery table and ironing board is obtainable. The latter is stowed away out of sight when not in use. A clothes airer with an adjustable frame and wooden laths which can be fitted to the kitchen ceiling and lowered to any position is also a useful time-saver. The frame projects only 7 inches from the ceiling when pulled up. The efficient disposal of rubbish can be easily effected by a gas in-cinerator where there is no range. There are also good designs in garbage pails with inner containers which can be lifted out to empty. One make has an inner pail that is perforated so that moisture drains away from rubbish, and in this way makes the latter sufficiently dry for

burning.

*Labour Saving. Fig. 1. Electric floor polisher. (Courtesy of Electrolux, Ltd.)*

**The Preparing of Food.** In addition to the implements and machines for cleaning, there are those to do with the preparation of food. A refrigerator lessens labour in the summer by enabling the housewife to turn out very easily prepared and dainty cold dishes or iced sweets for the table. These refrigerators operated by gas, electricity or paraffin are extremely simple to use, and not only render food more wholesome, but save the housewife the labour of constantly bringing in fresh supplies of foods that quickly deteriorate in the ordinary larder.

*Labour Saving. Fig. 2. Bread slicing machine in stainless steel which also cuts bacon.*

A bread slicing machine (Fig. 2) which will also cut bacon and possesses a stainless steel blade is a useful device for the larger household. It is also of great practical help in sandwich making. The fruit or tomato cutter shown in Fig. 3 is inexpensive and ingenious. It is worth possessing, together with a cucumber slicer in the salad season. A potato peeling machine is another exceedingly

useful aid for the housewife who has to prepare large family meals.

*Fig. 3. Fruit and tomato cutter; the serrated edges of the stainless steel blades require no sharpening.*

*Fig. 4. Aluminium cooker which requires no water. A complete meal can be cooked at the same time in separate utensils in one container. (Courtesy of Staines Kitchen Equipment Co.)*

Labour saving low-pressure cookers and steamers are many. The cooker shown in Fig 4 requires no water and a whole meal can be cooked at once in separate utensils placed in the one aluminium container. Obviously a saving not only of labour but also of fuel is effected by employing this simple device. Low-pressure cookers simplify the preparation of meals, and entire dinners can be cooked thus on one gas ring. In such cookers the flavours and vitamins of the food are preserved. A household machine that may be useful in the larger home is one which reverses the ordinary process and turns butter and milk back to cream. The operation is quite simple and enables the housewife to procure rich cream in a few minutes at about one-fifth of dairy cost.

*Labour Saving. Fig. 5. Vegetable strainer for use inside a saucepan.*

The smaller labour saving devices include mincing machines and vegetable strainers. The latter provide excellent substitutes for colanders and save work, heat and time. The strainer illustrated in Fig. 5 fits into the saucepan and can be easily lifted out when the vegetables are cooked.

Work is simplified by using the best cleansing materials available. Excellent polishes, soaps and powders are on the market and many recipes of good cleaning agents are given in our work, from which wide range it should be interesting to test and select the most suitable for the particular work on hand.

Where funds permit it is a good plan to replace all household equipment as it wears out with the best and most modern labour-saving kind on the market. These are not all simple and easy to work at sight, and it is advisable for the housewife to find out exactly how to use even the smallest appliance, or the result may be the reverse of labour saving.

**Easier Ways.** If all the best electrical appliances were installed, the work of running a house would be minimized very considerably. But it is a fact that these ideal conditions exist for a very few only, and that many housewives have to make shift with houses that are badly planned and often poorly equipped. Housekeeping, however, is essentially a business, and as such must be carried on in a methodical way with as many of the labour-saving devices mentioned as are practicable to the particular household, and plenty of ingenuity to make up for lack of expensive equipment where instalment of this is out of the question. In many homes the labour spent in cleaning metal is out of all proportion. The taps and front door brasses admittedly should look as if they receive daily attention, but there are satisfactory ways of minimizing the cleaning. Before coating the taps and door brasses with clear varnish or lacquer they should be well cleaned with ordinary metal polish and rubbed very hard with

a soft cloth, so that all trace of metal polish is removed before the varnish is applied. Metal lacquers are made for this purpose by some of the large paint manufacturers. It is better to apply two coats of lacquer, as it does not then require to be renewed oftener than every six months.

Letter boxes and knockers made in wrought iron to imitate old designs can be bought for a few shillings, and thus do away with brass door furniture. Stainless steel knives for table and culinary purposes abolish the labour of the knife board. Aluminium and enamel kitchen ware are easier to clean than the old-fashioned iron and copper, which require scouring. Aluminium ware is quickly cleaned with a wet cloth dipped in an abrasive powder. Ornamental collections of brass in sitting-rooms should be lacquered. Labour is also saved when patent clips are used for stair carpets instead of metal rods.

Table mats instead of cloths are a saving when laundry is done at home. For the service wagon, or for dressing table in weekend cottage or bungalow, tray cloths and runners in bright-coloured American cloth ornamented with simple designs in raffia save labour, as they merely require wiping over with a clean damp duster. A rubber apron hanging inside a kitchen cupboard that is quickly put on saves changing an afternoon dress to wash up the tea or dinner things.

Labour saving is also intelligently achieved by method in catering and in keeping the contents of the store cupboard adequate for both ordinary and sudden needs. Last, but not least, much less energy is required to do things the right way than the wrong, and if the correct postures are adopted while working. When doing any sedentary work such as mending house linen or darning it is most important to sit well back in the chair so that the spine is properly supported.

When pastry making, ironing or doing other standing jobs, it is important not to stoop continuously over the work, but to take an opportunity to brace the shoulders. While stooping, stand a little away so that the stoop comes from the waist and not from the shoulders. When using a long-handled broom, mop or vacuum cleaner, use the body muscles as well as the arms, swaying from the waist with each movement. Not only is the work better done if you put your back into it, but it is also far less tiring and thus labour saving.

**LABURNUM.** A very beautiful summer-flowering tree, the laburnum is suitable for cultivation in town or country gardens. Trees may be planted at any time from November to March inclusive, given favourable weather and soil.

*Laburnum. Drooping sprays of the beautiful flowering tree.*

The laburnum tree is most effective where the flowers are shown up against a dark background. The Austrian pine, the copper-leaved beech, and the purple nut are instances of trees and shrubs which show the laburnum to advantage. Although there are few species or wild types of laburnum (the Scotch, *Laburnum alpinum*, and the common, *Laburnum vulgare*, are the chief ones) there are many varieties of hybrids, and some of them have much finer flower bunches than others: the best are Vossii, Parksii and Watereri. One named Alschingeri, which blooms later than the others, is also to be recommended. *Laburnum Adami* is a remarkable tree, obtained by grafting the purple broom (*Cytisus purpureus*) on the common laburnum: it bears both yellow and purple flowers. Laburnums flourish in ordinary soil and are increased by seeds, the named varieties by grafting.

**Uses of the Wood.** This wood is dark brown in colour, with a greenish shade towards the heart, and has a broad yellow sapwood. Being very hard, close in the grain, and capable of a good polish, it is used in turnery work and in inlaying. Much of the furniture before and during Queen Anne's reign was beautifully inlaid with laburnum. *See Inlaying; Wood.*

### LACE AND LACE MAKING

#### Beautiful Examples and Practical Directions

In the first part of this article the different types of lace are classified and suggestions given for the care and repair of valuable pieces. The second part deals with simple directions for lace making. *See also the entries on Crochet; Embroidery; Filet; Hairpin Work; Insertion; Linen; Richelieu Work.*

A lace may consist of two distinct parts: the net ground on to which the design is worked, as in Alençon (Fig. 1), or of the pattern only without a ground, but connected by threads, as in guipure (Fig. 2). It may be classified under three headings: needle-point; bobbin; and machine-made.

*Lace. Fig. 1. Part of a border of Alençon lace, an example of 17th cent. French needle-point.*

Where only a single-threaded needle is used in the making, the lace is known as needlepoint; when a number of threads are wound on to bobbins, so that the twistings and plaitings of the threads form the pattern,

the lace is called bobbin. The term point alone should not be taken to mean needle-made, as it is used to express either lace of the finest qualities and also for modern hand-worked laces in which lace braids are used and formed into designs by means of connecting buttonholed bars, and other lace stitches. Bobbin lace is sometimes termed pillow, but this leads to confusion, as needle-point laces are also sometimes worked on pillows.

*Fig. 2. Guipure. Specimen of 17th cent. punto in aria, a type seen in many of Vandyk's pictures.*

**Needle-point Laces.** Italy may claim the introduction of needle-point laces, and certainly their finest workmanship. Venice points inspired the French laces of Argentan and Alençon, which resemble each other, a heavy outlining cord to the pattern being a feature of both, but the Argentan is

considered the finer work. Only the Alençon is made to-day, chiefly at Burano, in Italy. The 19th century Alençon, which is often on sale in old lace shops, has spots or tiny sprigs powdered over the net ground, a floral pattern in running festoons and a conventional bordering pattern. In the modern lace these powderings are occasionally used with real flower patterns. It is an exquisite lace of rare delicacy and charm, and wears well.

The earlier heavy Venice needle-points have no net ground. The pattern is traced on parchment stitched to a linen backing. The lines of the design are sewn on to the foundation in a skeleton pattern, which is buttonholed over, and these outlines are filled in with elaborate lace stitches. When this is complete the lace is cut away from both foundations. In rose or raised Venice point the outlines are heavily padded by threads and then worked over. As the demand for lighter laces grew, the needle-point guipures were evolved (this lace is frequently also made with bobbins), and then the point on net ground which inspired the French laces of Alençon and Argentan, and also the Brussels point de gaze (Fig. 3), an exquisitely fragile needle-lace showing the powdered ground in the 19th century designs. Venetian lace was also copied in Russia and called point de Moscow, while in the varieties of cut work and drawn-thread laces the Russians frequently introduced oriental colourings.

Needle-points chiefly made to-day are Alençon, Burano point, Brussels point de gaze, rose point de Venise, and Greek point. A great quantity is still beautifully worked in the old designs and stitches in Italy, some in Belgium and Ireland, but not much else-

where. Limerick laces are of three types: a beautiful cut-work; a run lace, in which a running design is needleworked on the net, as illustrated in Fig. 4; and tambour, in which a chain-stitch is employed. The last-named was hand-made on a tambourine-shaped holder which held the net flat while being stitched, but is so easily copied by machinery that it is hardly ever now made by hand. The Venice points are largely reproduced in fine Irish crochet.

*Lace. Fig. 3. Specimen of point de gaze, an exquisite needle-lace with powdered ground and raised cord outline to the pattern.*

*Fig. 4. Limerick lace of the type in which a running design is needleworked on the net. (Courtesy of Haywards (Bond Street), Ltd.)*

Carrickmacross lace is of two kinds. One, an example of which is shown in Fig. 5, has a delicate design which is appliqué on net, the other is a cut-work guipure made by tracing the pattern, outlining it with stitches on fine lawn, and cutting out after working in bars to hold the pattern together. Needle-point is sometimes used in conjunction with bobbin lace, as in some

designs of the Honiton sprigs, and needle-point filling stitches have been used with machine-made braid mounted on machine-made net.

*Fig. 5. Carrickmacross. Characteristic design with pattern appliqué upon net.*  
**Bobbin Laces.**

In bobbin laces the pattern is drawn or traced on to parchment and is then pricked with pins on to the cushion, the pins being placed to guide the threads. On the upper part of the pattern the ends of the bobbin threads are fastened, and as the threads are unwound the bobbins are thrown and twisted with regulated movements to plait the threads round the pins and form the ground and pattern of the lace with a variety of combinations. Most of the English laces are worked with bobbins.

*Fig. 6. Honiton. In this beautiful example the design of flowers and butterflies is connected, not by a net foundation, but by bars of twisted thread.*

Copies of Lille, Valenciennes, Maltese laces, guipures and torchons are produced in Bedfordshire, Buckinghamshire and Northamptonshire, while a good deal of Honiton bobbin lace is still made in Devonshire, chiefly in the form of sprays or sprigs to be mounted on machine-made net grounds. The best type is a guipure with a corded outline consisting of a number of motifs joined by bars of twisted thread. An example is shown in Fig. 6. A kind of Honiton lace is known as Devonian, the speciality of which is the raising of flower petals or insect wings so that they stand away from the net ground. The bobbin laces of other countries are well copied by convent workers in Ireland.

A great deal of bobbin lace is made in Belgium, including torchons, Cluny, wire-ground Valenciennes, and the beautiful Malines or Mechlin laces. The first two named are in simple patterns and a somewhat coarse thread is used. Valenciennes made from fine linen thread is a flat lace without any raised design. The machine-made varieties are quickly detected by the even mesh of the ground. Fig. 7 shows the slight variations in the handmade net. Mechlin lace is sometimes confused with Valenciennes, but a magnifying glass reveals the mesh of the ground net to be made by plaiting and not merely by twisted threads.

A bright corded thread outlines the floral motifs and accents the designs of this lace. In the bobbin-made Brussels lace relief is also given to the flowers and leaf veinings by a raised plaited outline Bruges duchesse point resembles the Honiton guipure. Other duchesse lace is on net in fine designs such as the example shown in Fig. 9.

*Lace. Fig. 7. Specimen of Valenciennes, a flat lace hand-made from linen thread.*

In France, a black silk and linen thread lace is made at Chantilly. The net work of the ground is oval in

these laces and the pattern is outlined with a thicker thread. Most of them are now machine-made. In Normandy Valenciennes laces are made, and black silk bobbin guipures at Le Puy. In Spain silk lace is made for mantillas in black and white. Maltese lace is made by hand in Malta in both silk and thread, and the best patterns have portions of the design in high relief.

*Fig. 8. Mechlin. The essential differences in types of bobbin laces are based on variations in the twisting and plaiting of the thread used for the mesh.*

**Machine-made Lace.** Almost every description of lace is now made by machinery, and some is so well turned out that it is difficult at first sight to tell it from hand-made. The weakness is often in the edge—especially where indented—which is liable to ravel in washing. Machine lace never possesses the finish or rich, soft beauty of the hand-made, and its threads have a squeezed look. In net laces the mesh of the ground has a hard even appearance, instead of the soft, slightly irregular charm of hand work. In needlepoint imitations the buttonhole-stitch, which forms a large portion of the work, is not well reproduced, while the plait of bobbin lace can only be satisfactorily imitated at a high cost. Coarse laces are produced for furnishing purposes and curtain laces on bobbinet.

**The Care of Lace.** Old lace should be kept in a dry, warm atmosphere, and if laid away for a time should be taken out of the drawer or box and aired at frequent intervals, as it is liable, especially black lace, to a species of mould. Sometimes lace is handed on which

has been cut or torn; unless the art of lace making be understood, it is worth taking the piece to an expert to be joined or mended.

*Lace. Fig. 9. Duchesse lace. Strip of delicate real lace, showing a characteristic and beautiful floral pattern. (Courtesy of Haywards (Bond Street), Ltd.)*

In the case of laces with torn hand-made net grounds, which are often worn into holes long before the heavier patterns show any signs of wear, the net should be repaired by needle or bobbin, according to the original workmanship, as a machine-made net backing would destroy a good deal of the value of the lace.

Hand-made lace should not be dry-cleaned, as the process is injurious to the delicate fabric. It should be firmly pinned to a linen-covered board with a sufficient number of pins to keep the lace flat, and dabbed gently till quite damp with a sponge. Then, pure Castile soap should be dissolved until it forms a good lather in warm water; the lace is dabbed with this till clean, the soap sponged off with clean water, and as much moisture as possible removed from the lace with a dry sponge. It must not be ironed, but left to dry on the board. If properly pinned it will not be pulled out of shape.

Very thick lace that cannot be sufficiently cleansed by dabbing may be placed in a saucepan in soapy lather which has been allowed to cool, and then brought to boiling point. The lace should be rinsed in clean water, and pinned out flat to dry. Black lace should be pinned in the same manner, but dabbed with vinegar and left to dry. Should a deeper old tint be desired for white lace, after it has been cleansed it may be laid in cold tea.

The sewing on of lace is an important part of its care. The cotton or silk used should match the lace and not the material. For lingerie laces, where a firm and yet delicate method of attachment is desirable, a close satin-stitch is often used, and is suitable for a straight or rounded edge. The lace should first be tacked to the material, and then run with small stitches along the base. This is practically a second tacking, which keeps the line of the lace straight for the closely covering satin-stitch. Without the precaution of this close running, the lace usually has a crooked appearance. After the completion of the satin-stitching, the raw edge of the material behind should be cut away close to the stitches.

For straight edges only, a hemstitched veining may

be used. Sufficient threads having been drawn for the veining, and the lower edge worked in the ordinary hemstitch way, the lace must be tacked to the upper edge of the veining. Between each ordinary hemstitch which connects a group of threads, one or two seam stitches should be put into the edge of the lace. The work is completed by cutting the raw edge at the back, so that only a tiny turning remains. This is overcast from the left, the edge being turned with the needle so that a perfectly neat finish is obtained.

For sewing on a lace with deeply indented edge, when it is wished to keep the points flat and to use the top of the lace for the outer edge of the trimming, as is generally done in lingerie, the extreme edge of the lace points may be firmly tacked to the material. Starting from the right hand on the right side of the garment, a small horizontal back-stitch is made in the material under the lace, and then a perpendicular back-stitch through the lace and material. These stitches are continued at right angles, the perpendicular stitch being worked from the second needle hole of the horizontal, till the lace is completely joined to the garment. On the wrong side cut away the material and overcast. Where shoulder ribbons are used they should be stitched on to the lace, and again on to the material, to save strain on the lace.

**Lace Making.** Whether the hand-made lace is made with a needle or with bobbins, certain French terms are used in describing the details. The pattern is known as the *toile* or *gimp*, the bars or links are called *brides*, the meshed groundwork is the *réseau*; the outlines to the edge of a pattern, made in strong thread or threads, are known as the *cordonnet*. The small loops are *picots*, and ornamental fillings are *modes*. Sometimes the *réseau* is a fine net to which the pattern is stitched down after being made separately. This lace is known as *appliqué*.

The materials required for needle-point laces, besides special lace needles made with rounded points, are lace thread, lace braids in suitable widths, obtainable in white, *écru* and black, and in various designs; also linen, net and muslin. The method of procedure is simple. The pattern is first drawn upon a piece of parchment, and the parchment is tacked to a piece of strong linen. Threads are laid on the leading lines drawn on the parchment, and these are stitched down here and there by threads passing through both linen and parchment. This forms a skeleton outline of the pattern and is closely covered by buttonhole-stitches in thread. Connecting meshes, links, or bars, are made to hold the pattern together with buttonhole stitches. A sharp knife is inserted between the parchment and the linen, and the original stitches, which were passed between the parchment and the linen, are cut. The loose threads are picked off and the lace is complete.

In making the laces known as point lace, lace braids are first tacked carefully on to the pattern, following the design exactly. Patterns are obtainable ready drawn upon the linen. These point lace patterns are all drawn with double parallel lines, between which the braid is tacked on with small running stitches. When the braid

turns a curve it must be whipped on both edges and lightly drawn up to follow the form of the pattern exactly. Having tacked down the braid, the connecting bars must be cast. Secure the thread with a small buttonhole-stitch, pass to the opposite braid, and then return with a twisted thread to the place where the original small buttonhole-stitch was placed.

Other spaces formed by the braid may be filled with various needlepoint-stitches. There are about forty of these, and it is not within the scope of this article to give details of them, or for employing them in the making of modern reticella, Venetian, and renaissance laces. The simplest braid lace is Bruges. This is made by tacking Bruges lace braids of varying widths into the selected design to form the pattern and whipping them into position. The spaces between the braids are then carefully filled. Sometimes a picot bar braid is used, or, if preferred, the connecting bar threads can be plainly buttonholed with equally good effect. Having practised the handling of the braids and making the bars for this lace, it is worth while for the interested worker to purchase a book on needle-made laces.

**Making a Pillow.** The pattern in bobbin lace is made by twisting and plaiting the threads of linen, cotton, or silk. The design is selected first, and is drawn on paper or parchment to form the patterns. It is then pricked with holes by a pattern pricker. This pricked pattern is fastened to a pillow, and serves as a guide in the disposal of the pins used later to guide the threads.

Some workers use a circular-shaped pad attached to a board, which can be rested on a table and moved about easily. Other lace workers use a well-padded pillow, flattened at both ends so that it can be held between the knees. Whilst the lace is being made it is securely pinned down to the pillow, which is covered with a stout but soft piece of cotton for the lace to rest upon during the process of making. The threads from which the bobbins hang are fastened at the top of the pattern, so that the bobbins themselves hang down over the cushion towards the worker and rest above the lace that is being made.

Whatever form of pillow is chosen it must be firmly and evenly stuffed. It is first covered with canvas and then with green linen or sateen. Finally, a piece of white calico, larger than the design, is pinned securely over the pillow and the pattern is pinned to this. The pins are driven right into the pillow to secure the calico cover and the design in such a way that only the heads are visible. Most workers hem covers for their pillows of navy blue linen about 2 ft. square, washing the linen three or four times to be quite sure that all the free dye has been taken out.

In the centre a small circle is marked measuring about 1½ in. in diameter, and the circle is outlined all round by a running of thread. This is then buttonholed around, and finally the small circle of linen is cut out from the centre. Through this small hole the lace is worked so that the rest of the pillow and the lacework

is kept covered and clean.

Ready-made pillows are not very expensive, but the beginner can make her own quite easily. A piece of green linen or sateen measuring 18 in. by 20 in. is folded over, and its longer sides are joined by machine. This is turned inside out, and a half-inch hem is made at each end and a tape is run through each hem. One end is drawn up and tied securely. A circular piece of cardboard with a 6 in. diameter is placed at the end over the drawn-up portion. The pillow is filled up with sawdust or hair, and then a second circular piece of cardboard, exactly the same size as the first piece, is placed over it before the open end is drawn up.

**Marking the Design.** The design is drawn in ink on some strong, smooth blue paper. If the beginner finds it easier, she can have the design pricked on the paper, and even have a dot for every position where a pin must be placed later in manipulating the threads. The pins used by lace makers are smoother and more slender than ordinary pins; but the beginner can use large ordinary pins at first, and will need 4 or 6 dozen. Lace pins must be kept clean and free from rust, and a plentiful supply facilitates the work. Some workers dip the heads of the pins into melted wax, so that a little

globule forms a bead at the head of each pin, and prevents it from slipping through the lace. It is a good plan to have a small pin-cushion with a tab, and to pin it securely to the lace pillow in a position where it can conveniently be reached by the right hand when working.

Fig. 11.

Fig. 12.

Fig. 10. Full bobbin. Lace. Figs. 11 and 12. Showing crossings of the threads to make the half-stitch.

Pricker, bobbins, and bobbin-winder have next to be considered. A pricker can be bought at any art needlework shop. A homemade pricker can be made by taking the wooden portion of an ordinary penholder, melting a drop of sealing-wax, and placing it on the end, and then embedding an ordinary strong but fine sewing needle in the wax while it is still warm and soft. The wax is gently pressed round the eye-end of the needle, and when it cools and sets it holds it firmly in place.

Bobbins of many shapes are available in wood or bone. The number needed depends upon the nature of the design. A beginner would only need about 2 dozen, but elaborate designs may require well over 1,000 bobbins. Each bobbin is like a little spool with a more or less elaborate handle. If the bobbins have any roughness or unevenness on their surfaces, it is advisable to rub them over gently with fine sandpaper,

as the threads used in lace-making are so fine and so easily broken. When the bobbins get dirty, they can be worked in a warm, soapy lather, but they must not be used to hold thread again until thoroughly dry.

A bobbin winder is not necessary for a beginner, but it saves time, especially if it has a skein-holder attached. It is very easy to soil the thread, so all handling must be avoided, and it is a good plan to wear white cotton gloves when winding the bobbins. Many workers wear also a white apron and over-sleeves to protect the lace.

**Making Bobbin Lace.** Amongst the general rules for making bobbin lace, it is important to work in a good light, preferably with the light falling from the left. Directly the eyes feel tired, the work should cease for the time being. It is not necessary to look too closely at the bobbins, but the threads should be watched, as mistakes are then quickly noticed and put right. The bobbins must be kept closely wound and are picked up lightly by the finger-tips, care being taken not to get them accidentally knocked out of place. Both hands must be used.

Lace. Fig. 13. Mesh of Buckinghamshire lace enlarged to show details.

British-made linen thread is the best for lace-making purposes, but mercerized cotton, silk, tinsel, and plain crochet threads are also employed. If the thread becomes entangled, it must not be handled, but the pricker must be used to free the threads. Any thread not in use should be rolled up in blue paper to preserve its colour, and put in an airtight tin until it is wanted.

If a thread breaks it must be dealt with carefully, and a knot must never be left visible in the lace itself. If the warp thread breaks some distance from the actual plaiting, it may be possible to knot the broken ends and finish the particular section of the lace before the knot is reached. If the break occurs in a traveller thread, it may be brought to the edge and there exchanged by a twist with a stationary bobbin. In this way the knot will not appear in the lace. If the broken end is very short, wind the broken end extending from the bobbin round a pin and tie it. Stick the pin into the pillow near the other broken end of thread. Replace the bobbin and go on weaving. Then cut off the broken end close.

The pattern in bobbin lace is often outlined with stronger thread than that used for the mesh. The varia-

tions in the twisting and plaiting of the mesh constitute an essential difference in the various kinds of lace.

The bobbins should all be wound the same way, i.e. away from the person winding if she is right-handed. When the body of the bobbin is moderately full, cut the thread, wind it twice round the neck, pull the end under the thread when it runs from body to neck, and pull taut (Fig. 10). When all the bobbins are wound and hung on to pins ready to start the pattern, it is advisable to practise lengthening and shortening the threads. To lengthen, hold the bobbin horizontally and revolve it between finger and thumb until it is the length required. To shorten, hold the bobbin in the left hand, insert the right forefinger under the thread which runs from body to neck, and pull upward while the left hand revolves the bobbin until it is short enough.

If the thread gets loose from the neck and the bobbin begins to unwind after the work is started, it is only necessary to wind the bobbin to the length required and finish by winding the thread twice round the neck of the bobbin and pulling taut. There are three elemental stitches used in all bobbin lace. They are known as half stitch, double stitch, and cloth stitch. To make any stitch 4 bobbins are required, and to learn the stitches it is a good plan to knot the threads of 4 bobbins together, fix the knot to a pincushion, and practise the stitches a few times before starting a pattern. Except for outlining with a gimp thread, bobbins are used in pairs.

To make a half stitch, place the two pairs of bobbins to be used in the centre of the pillow hanging from a pin and number them from the left. Cross 2 over 3, cross 4 over 3, cross 2 over 1. The first step should be done singly and the second and third steps simultaneously, using the right hand to lift 4 over 3 and the left hand to lift 2 over 1. Figs. 11 and 12 show the working. Double stitch is half stitch done twice without interruption, while cloth stitch consists of crossing 2 over 3, 4 over 3, 2 over 1, and 2 over 3. Whenever a pin is to be inserted it should be placed between bobbins 2 and 3, i.e. between the pairs.

If the directions say close in, it is intended that a similar stitch should be made with the same two pairs before proceeding. Twist means cross the right-hand bobbin over the left-hand bobbin of any pair mentioned. It is done once or twice or more times according to the pattern. To fix the two bobbins on the pillow, knot them in groups, say 8 bobbins together or less if preferred, and tie the ends of each group to a pin stuck into the pattern about  $\frac{1}{2}$  in. higher up than the work is to be started. The bobbins are counted in pairs, counting from the left.

Lace. Fig. 14 (above). Diagram showing four consecutive stages in the making of Buckinghamshire lace.

Fig. 15 (below). Arrangement of pins for making this lace.

Buckinghamshire Lace. Instructions are given how to make a simple Bucks lace pattern. The two distinctive points about Bucks lace are the mesh or réseau and the gimp, a thicker thread which outlines portions of the pattern. Fig. 13 shows the mesh on an enlarged scale. For the following pattern 26 bobbins are required, two of which should be wound with gimp thread and the remainder with a medium flax lace thread. It is a good plan to have the gimp wound on bobbins which are markedly different from the rest. This pricking can also be worked out on the squared  $\frac{1}{4}$  in. cardboard, and Fig. 14 shows the method in four stages. Tie the bobbins to pins in groups of 6 or 8, and begin the pattern a little further down so as to get clear of the knotted threads. Before beginning arrange that one gimp bobbin is the 3rd from the left, the other the 11th from the right.

Start with the shell edge, which is worked in cloth stitch. Count the bobbins from the left. Use the diagram in Fig. 15, and see also Fig. 16. Make a stitch (cloth) with the 2nd and 3rd pairs, the 3rd and 4th, the 4th and 5th; put a pin in hole 1 and close in. Make a stitch with the 3rd and 4th, 2nd and 3rd, and pass the gimp through the 2nd pair by crossing it over one and under the other bobbin of this pair. Make a stitch with the 1st and 2nd pairs, twist the 1st pair 3 times; put a pin in hole 2 and close in. Pass the gimp back through the 2nd pair. Make a stitch with the 2nd and 3rd pairs, with the 3rd and 4th, the 4th and 5th, the 5th and 6th; put a pin in hole 3 and close in.

Make a stitch with the 4th and 5th pairs, the 3rd and 4th, the 2nd and 3rd. Pass the gimp through the 2nd pair. Make a stitch with the 1st and 2nd pairs, twist the 1st pair 3 times; put a pin in hole 4 and close in. Pass the gimp through the 2nd pair. Make a stitch with the 2nd and 3rd pairs, 3rd and 4th, 4th and 5th, 5th and 6th, 6th and 7th; put a pin in hole 5 and close in. Pass the other gimp through the 7th pair and then twist the 7th pair twice. Make a stitch with the 5th and 6th pairs, the 4th and 5th, the 3rd and 4th, the 2nd and 3rd. Pass the gimp through the 2nd pair. Make a stitch

with the 1st and 2nd pairs, twist the 1st pair 3 times; put a pin in hole 6 and close in. Pass the gimp through the 2nd pair. Make a stitch with the 2nd and 3rd pairs, the 3rd and 4th, the 4th and 5th, and 5th and 6th; put a pin in hole 7 and close in. Pass the right-hand gimp through the 6th pair and twist the 6th pair twice.

Make a stitch with the 4th and 5th pairs, the 3rd and 4th pairs, the 2nd and 3rd pairs. Pass the gimp through the 2nd pair. Make a stitch with the 1st and 2nd pairs, twist the 1st pair 3 times; put a pin in hole 8 and close in. Pass the gimp through the 2nd pair. Make a stitch with the 2nd and 3rd pairs, 3rd and 4th, 4th and 5th; put a pin in hole 9 and close in. Pass the gimp through the 5th pair and twist the 5th pair twice. Make a stitch with the 3rd and 4th pairs, the 2nd and 3rd. Pass the gimp through the 2nd pair. Make a stitch with the 1st and 2nd pairs, twist the 1st pair 3 times; put a pin in hole 10 and close in. The two gimps now change places. Pass the left-hand gimp through the 3rd and 4th pairs, cross the right-hand gimp over it and pass it in turn through the 4th, 3rd, and 2nd pairs. This finishes the shell.

*Lace. Fig. 16. Strip of narrow Bucks lace with shell edge, made by arrangement of pins shown in Fig. 15 above.*

The réseau has next to be worked. The four pairs of bobbins and one gimp on the left hand can be pinned quite aside. Proceed with line A, and count the pairs of bobbins from the right. Make a cloth stitch with the 3rd and 4th pairs, with the 2nd and 3rd; twist the 2nd pair 3 times and put a pin in hole 11. Make a half stitch with the 1st and 2nd pairs and twist them each twice. Make a cloth stitch with the 2nd and 3rd pairs, with the 3rd and 4th pairs; twist the 4th pair 3 times and put a pin in hole 12 between the 3rd and 4th pairs. The selvedge is always worked in this way.

Now begins the réseau proper. The enlarged detail of this is clearly shown in Fig. 13. This characteristic mesh is used in all Bucks lace for few or many holes, according to the pattern. The following stitch is used for it. Make a half stitch and twist once each of the pairs with which the half stitch has been made. If a pin is put in, it should not be closed in. Make a Bucks stitch with the 4th and 5th pairs, and with the 5th and 6th pairs; put a pin in hole 13 between the 5th and 6th pairs. Make a Bucks stitch with the 6th and 7th pairs; put a pin in hole 14. Make a Bucks stitch with the 7th and 8th pairs; put a pin in hole 15. Pass the gimp through the 8th pair and twist the 8th pair twice. Proceed in the same way with line B as far as putting a pin in hole 14, then pass the gimp through the 7th pair and twist the 7th pair twice. In line C (Fig. 15) proceed as before as far as putting a pin in hole 13, then pass the gimp through the 6th pair and finally twist the 6th pair twice.

**LACEWING FLY.** One of the few insects which may be called a friend by the gardener is the lacewing fly, whose larvae devour the aphides. The adult insects have slender, pale-green bodies, about 1½ in. long, pair twice.

*Lacewing or Golden-eyed Fly. One of the few insects which are helpful to the gardener. Left, eggs of the fly.*

They deposit their eggs upon hair-like filaments on leaves and shoots. About a week after tiny larvae hatch out, and these immediately begin to devour the aphides, slaughtering great numbers in a very short time. The larvae measure about ⅜ in., and may be identified by their dirty white bodies, spotted with brown or orange. The parent fly, by reason of its prominent golden eyes, is sometimes called the golden-eyed fly. See Insect.

*Lachenalia or Cape Cowslip, a handsome spring-flowering bulb for the greenhouse.*

**LACHENALIA.** This showy spring-flowering greenhouse plant is popularly called the Cape Cowslip. The narrow tube-shaped flowers are chiefly of yellow, orange, or orange-red colouring. Lachenalias look well in hanging baskets, or may be grown in pots. The bulbs should be potted in August-September in a compost of loam, with some decayed manure and sand added. After having been kept in a cold frame for six or seven weeks they will be well rooted, and should then be placed in the greenhouse. A temperature of 50 to 55 degrees will be found to be suitable. When the leaves begin to turn yellow in spring, watering should be discontinued gradually, and finally, as the leaves fall, the soil must be kept dry until August, when the bulbs may be taken out and repotted. The chief kinds of lachenalias are Nelsoni, pendula and tricolor, but many named varieties of improved colouring are now obtainable. Pron. Lac-e-nā'li-a.

**LACKEY MOTH.** Much damage is done to fruit trees by the lackey moth. Its caterpillars feed on the foliage of many kinds of trees and shrubs, including the apple, cherry, plum, and pear among fruits, and the oak, hawthorn, willow, alder, elm, and rose among trees and shrubs.

In Leaflet 37, issued by the Ministry of Agriculture and Fisheries, the following measures are suggested

for ridding trees of this caterpillar pest: Spraying is effective if carried out early enough, and also at any time if there are not many caterpillars on the tree. When, however, the whole tree is enveloped in webbing it is impossible to get enough poison on to the leaves to do any good. The best time to spray is within three weeks after the dropping of the petals from the flowers. Lead arsenate (1 lb. paste to 20 gal. water) is the best insecticide to use, and the wash should be applied through a fine nozzle, giving a light dressing to every leaf on the fruit tree. In gardens with only a few trees affected the pest can be destroyed by hand. *See Fruit; Insecticide; Spraying; Syringe.*

*Lackey Moth, an insect pest which attacks fruit trees. Left and above, caterpillar; below, right, moth. (By permission of the Ministry of Agriculture and Fisheries and H.M. Stationery Office)*

**LACQUER:** How to Apply. The purpose of lacquering is to protect the surface of the object from the action of the air, and so prevent it from tarnishing. Door knobs, handles, fenders, and other articles can be lacquered, thus obviating the need for constant polishing. They should last at least six months without requiring any further attention.

The materials required are several bottles of lacquer of different colours; good quality soft camel-hair brushes, one or two clean glass bottles with cork stoppers, for the storage of the brushes, a quantity of clean sawdust, preferably boxwood, and some means of heating the objects to be lacquered. The operation must be carried out in a warm room absolutely free from draughts, as they cause the lacquer to bloom, that is, to dry with a milky, bluish appearance.

Suppose, for example, it is intended to lacquer a polished brass or copper object such as a door knocker. The primary stages of polishing are dealt with in the article on polishing (q.v.), or the surface may be finished with a matt effect by dipping in dilute nitric, sulphuric, or hydrochloric acid. The utmost care must be taken when using these chemicals, as all of them are poisonous. Some clean tissue paper will be found useful for handling the lacquered article. The next stage is to

clean the article thoroughly. This may be done by boiling it in clean water, allowing the water to drain off, and then drying it by burying it in a tin of hot sawdust which has previously been heated by baking it in the oven. After the object has been left in the sawdust for a few minutes it can be removed and brushed over with a clean, dry brush to remove any traces of sawdust. On no account must the article be touched with the bare hands after it has been cleansed, but should always be handled by grasping it with a piece of tissue paper, or some other material free from grease.

The lacquer, which is composed of shellac, a colouring material, and methylated spirit, or some similar solvent, is best obtained ready made from the makers, or from any high-class colour shop. One type known as hot lacquer, has to be worked hot; others are known as cold lacquer, which is brushed on like ordinary varnish, and generally sold under proprietary names. The cold lacquers are very simple and easy to use, and very handy for lacquering bath taps and fixtures which have to stand hard wear. For all ordinary purposes the hot lacquer should be employed. All types of lacquers can be obtained in a variety of colours, but, generally speaking, the colourless or crystal lacquer is quite invisible when applied to metal. A pale gold scarcely permits the yellow shade to be noticed. Deep gold imparts a notable increase in the depth of the colour, while the coloured lacquers, green, blue, or red, colour the metal more or less. They are all applied in the same way.

Hot lacquering is performed by first warming the object, e.g. over a flame from a gas burner, or similar heating medium, taking care to keep the object more to the side of the flame so that it does not get soiled from the products of combustion. The exact temperature can only be determined by experience, but a few tests on various articles will show the effects obtained by variation in temperature. Roughly speaking, if the work is too cold, the lacquer dries up lustreless with a dead appearance. If too hot, the lacquer sizzles when applied to the work, and dries off with a streaky, granular effect.

The happy medium is that temperature at which the lacquer can be brushed on comfortably, and will dry quickly with a very bright, lustrous surface. Usually this result is accomplished by using a large brush, dipping it into a clean glass container with some of the lacquer in it. A sufficient quantity, but not an excess, should be held by the brush, as the lacquer evaporates very quickly. Wipe some of the lacquer from the brush on the edge of the glass vessel, but leave the brush so charged that the lacquer will flow freely from it, but without any tendency to drip off the brush.

Apply one coat only, on every part of the work, and never brush the same part twice. In the case of a long, slender object, rotate it with the left hand while brushing on the lacquer with the right. In other cases, a long, firm, sweeping application of the brush is employed. Then bring the work fairly near the heating

stove, and turn and twist it about for a few minutes until it is hard and dry. If any quantity of lacquering is to be done, it will be best to make up a lacquering oven from an old biscuit tin. Fit a door to the tin, and fit up a pair of wire hooks, or a little tray, on which to rest the lacquered objects. The oven should be placed upon the heating stove and warmed up.

Should the work be spoilt for any reason, the best remedy is to clean off lacquer with methylated spirit, repolish and relacquer.

### LACQUER WORK FOR THE AMATEUR

#### Antique and Modern Forms of this Artistic Handicraft

Those interested in similar occupations should turn to the articles Gesso Work; Lampshade; Leather Work; Papier-Mâché; Repoussé Work; Stencilling, etc. See further Bureau; Corner Cupboard; Grandfather Clock; Screen; and other pieces of furniture on which lacquer is sometimes used; also Chinese Style; Chippendale Style; Queen Anne Style.

Lacquer work was introduced into England in the latter half of the 17th century, and Chinese lacquered panels were imported and made up into pieces. In Queen Anne's reign English lacquer work became fashionable and was later popularized by Chippendale. The cabinet in Fig. 1 shows an exquisite example of 17th century workmanship.

Much of the English lacquer was done on papier-mâché trays. The tray illustrated in Fig. 2 is a good specimen of modern lacquer copied from an old piece of English lacquer. The following directions are given for this work. Rub the tray or wood carefully with fine sandpaper, and coat it over with filling, which is paste made of whitening mixed with water to the consistency of thin cream. Add a little plaster of Paris, and a little glue, powdered, if possible. If ordinary glue is used it must be carefully mixed in when warm, and unless the filling is used at once, the mixture must be kept warm. Avoid using thick filling, as this makes an uneven surface. When dry, rub it down again with sandpaper.

*Lacquer Work.*  
*Fig. 1. Cabinet in Chinese style, with brass mounts on silvered stand; English make, c. 1660-85. (By permission of the Director,*

*Victoria & Albert Museum. S. Kensington)*

A filling can be purchased together with a set of Chinese lacquer colours and other requisites in an outfit. They are subject to the Petroleum Act and cannot be sent through the post. Spirit lacquers require careful handling as they are inflammable, and cellulose

lacquers, though yielding a fine finish, possess a pungent odour to which the worker requires to accustom himself.

When the work is filled and rubbed down, a design has to be chosen. Designs may be bought from some firm which specializes in this kind of work. Most oriental designs are built up from several motifs, and can be adapted from illustrations or other Chinese pieces. A willow pattern plate or dish makes a good design for adapting to a small piece of work.

The difference between English lacquer and the Chinese is that the design is usually more crowded in the English. Small borders of flowers, scrolls, etc., tend to alter the character. The scroll shown on the tray is typical of English lacquer.

*Fig. 2. Oval papier-mâché tray, a specimen of modern lacquer copied from an old English piece.*

The next step is to colour the background. For this, dull black lacquer should be employed. Put on one coat with a flat squirrel hair brush and allow it to dry. Then apply a second coat. If it is at all rough, sandpaper it carefully before applying the second coat. Two coats of black are usually sufficient, but should the groundwork look poor, apply a third coat. Draw, or trace from a copy, the main objects of the design on a piece of tracing paper the size of the article, then turn it over and rub the back with whitening. Lay this carefully on the article and go over the design with a pencil, which will apply a clear white tracing to the black surface. The raising paste is next applied. Make all surfaces where it is intended to apply raising paste rough by scratching with a penknife. A paste can be used as directed for the filling, except that it must be much stiffer, or gesso powder may be employed. Choose a hog's hair brush with long hair for this, and apply it by working round the inside of the outline, twisting the brush towards the worker. As it spreads a little, keep inside the outline. Very little raising is used in English lacquer. For the tray the only part raised was the roof, the rocks at the back, the bridge and the figures very slightly. Allow the raising paste to become quite dry, but do not put it near a fire or it will crack. When dry, rub it carefully with sandpaper if at all uneven or rough.

Next gild the raised portions and all main parts of the design, omitting any fine detail. For this gilding first use the special medium obtainable. Paint it over, and when almost dry dust it over with rather heavy bright gold powder, using a chamois leather. Allow it to dry for at least a day. Then wash with soap and water, and dry it carefully, using a soft cloth. If the fine detail cannot be put in freehand, trace, then paint it in with chrome yellow to which a little medium has been added. Dust it over with gold. When it is dry wash it, and put in any foreground, touch it up where necessary and shade it a little with black lining ink and water colour. When dry give it two coats of brown varnish, rubbing down between each coat with *poudre de silice*. After the second coat of varnish is thoroughly dry, give it a good rub with chamois leather. In English lacquer the floral borders are often painted in colours.

Prepare the wood very carefully when lacquering an old piece of furniture. Wash it well with strong soda water, then rub it down or have it scraped, to remove any roughness. Apply the lacquer very evenly. Quick drying spirit lacquers are not easy to use. A modern outfit sold contains a special solvent for thinning these, as the best results are obtainable by using two or three thin coats rather than one thick one. Amateurs should always try black first, as it is much easier to remedy any mistakes, and usually works more evenly. Pale coloured lacquers are the most difficult for them to use as they need careful handling, and cannot be touched up to any extent.

After the surface is ready, transfer the design as explained, then study it well and decide which portions are to be raised. Unless it is a large piece of work, such as a cabinet, do not raise it too much as it looks clumsy. The small table and finger plates shown in Figs. 3 and 4 respectively had the rocks, temple, and roofs of the houses raised; the lamp-stand in Fig. 5 had only the foreground and a bird.

*Fig. 3. Small lacquer table, a good modern example in the Chinese style.*

When dry sand-paper it well and dust it carefully before commencing to work in the foreground. For this the special medium is required. Paint over all the foreground, and when tacky dust it over with coloured bronzes, using gold, red, green, and a little silver. These can be shaded in with the chamois leather. When dry dust off any superfluous powder, and gild all the main objects in the same way. Use fine dull gold for this. When dry wash and dry it. When filling in the detail use a very fine sable brush, and make the strokes as fine as possible. Only do a little piece at a time and dust it over with gold. The medium dries quickly and will not hold the powder if allowed to become too dry.

*Fig. 4. Finger plates in raised Chinese lacquer.*

When the detail is finished and dry, wash it well and dry it carefully. The line work must be done next. Mix the special ink with ivory-black water-colour, and put in the fine lines. Should the gold lines be too thick, this can be remedied by painting a black line at the side.

*Lacquer Work. Fig. 5. Chinese lacquer lamp stand with silk lampshade.*

The work may be shaded by using a little burnt sienna and here and there a touch of red. Poster colours may be used. The advantage of using these is that mistakes can be wiped off with a wet rag and the parts in question put in again. Should the work be too bright when finished, dip a damp rag in a little *poudre de silice* and rub it over the surface, working with the grain of the wood. A final coat of clear varnish may be applied over the whole work where pale ground colours are used. Otherwise brown varnish is used as described for finishing the tray (Fig. 2).

For a silk lampshade, such as that illustrated in Fig. 5, no raising paste must be used, as the effect must be obtained by shading. The shade is painted after it has been made up. If the work is to be transparent, use oil colours and stencilling medium. Broad work is the most effective, and the use of gold should be avoided as much as possible. A vellum lampshade to suit this style of lamp may be coloured with waterproof inks.

**Modern Forms of the Work.** There are other kinds of lacquer work of interest to the amateur. Lacquering on leather will be described under *Leather Work*, and lacquer used in conjunction with raised and modelled gesso and *barbola* paste has been dealt with in the article on *Gesso Work*. Modern methods of decorating over lacquer grounds include Worcester painting, so called from the designs chosen, which resemble those on Worcester China, and Marbling. Examples of the first are shown in Fig. 6, while the candlestick in Fig. 7 has been decorated by means of the second. Stencilling is also employed, being carried out in liquid oil colours over the groundwork of lacquer. When it is desired to mix lacquer colours for

the groundwork this cannot be done from the bottles, and the mixing is done in a saucer convenient to work from while painting the article, as shown in Fig. 8.

*Lacquer Work. Fig. 6. Cigarette box and powder bowls showing Worcester China effect with stippled coloured background and white lacquer.*

Worcester painting is particularly suitable for the decoration of dressing-table sets, cigarette-boxes, and for pieces of pottery. Artistic work is achieved with this type of decoration when applied to a pottery vase suitable for a lamp and using the same designs for the vellum shade. On Worcester and Chelsea china tea services, etc., designs are often set in shaped panels, and birds, small flower sprays and Chinese motifs can be copied. Maroon, canary-yellow and apple-green are all correct colours for the finished groundwork, and show up the panels most effectively. The first stage is to coat the article over with the filler, as already de-scribed, sandpapered to a smooth surface. Then a coat of white brush-lacquer colour is painted evenly over the surface, using a squirrel hair brush. This must be allowed to dry and a second coat applied. The work must now be left for some hours, preferably overnight, to allow the lacquer to harden before proceeding further. The inside of a box or other article should be lacquered without the coating of filler. The surface must first be sandpapered.

*Fig. 7. Candlestick decorated by marbling process in water colour or lacquer.*

The next stage is to wipe the article over with a damp cloth and then to cover it with the desired shade, yellow for instance, using chrome lemon poster colour, and to stipple this over quite firmly afterwards with a dry squirrel hair

brush. The method of holding the brush is shown in Fig. 8.

The coat of stippled poster colour must be allowed to dry before the third and most interesting stage of the work is begun. This is illustrated in Fig. 9, which shows the method of wiping out the panels for the Worcester designs. It is better to use templates for this rather than trust to the unaided hand.

Templates may be cut out of oiled manilla paper, or purchased in packets of a dozen assorted shapes for a few pence, and their usage will ensure the clean shape of the circle, oval or triangle. Through the template the small panel spaces are wiped out with a slightly wetted rag (*see* Fig. 9), removing the yellow poster colour and leaving the originally painted white lacquer groundwork showing.

The rim and base of the article should be treated in the same way. This must be done cleanly, and not a trace of the yellow colour should remain.

After the panels have been thus prepared the designs are drawn and painted. More elaborate designs can be traced by means of tracing paper and a carbon. For this work, however, embroidery transfers can be used of small floral patterns. Poster colours are used to tint these, and their simple delicate nature is shown in the three attractive pieces in Fig. 6. The powder bowl on the left has an apple green stippled ground. The interior handle and rim are of the white lacquer. Crescent-shaped templates were used through which to wipe out the panels on the lid. The design of wild roses is painted in pinks and greens and the panels are outlined with gold. Gold may also be used for the interior of a box or bowl. It must be used over the lacquered groundwork. When completed and quite dry the whole article is varnished with clear white varnish.

Marbling is even a simpler method of decorating a lacquer foundation. This consists in wiping off the poster colour with a damp cloth in a zigzag fashion to imitate graining or the many varied markings of marble. The candlestick which is shown in Fig. 7 has been decorated in malachite green over a cream lacquer groundwork. White or cream lacquer lends itself as admirable for foundations for this work, as for Worcester painting, but other lacquer colours can be used, and except black are suitable for marbling. Blue poster colour cannot be used over red lacquer as it has a tendency to blacken. Designs can be introduced into this marbled work by means of wiping a panel space clean through a template to show the plain lacquer groundwork. Very simple landscape or flower designs of the type used in modern marquetry work look well introduced into articles with slightly marbled surfaces.

**Lacquer Work on Metal.** Examples of a kind of lacquer work which appeals to many people are shown in Fig. 10. For this work four lacquer colours are prepared, red, blue, green and yellow, other shades being obtained by mixture of these. In some cases, as, for example, in the ship designs shown, the colours are used to enhance the pattern already modelled in the metal. In others, as in the brass cigarette box, which is

being painted in Fig. 11, the design for the most part is traced on to the metal. Having cleaned the box with methylated spirit, the selected design is transferred by means of a carbon paper. To prevent the lines being rubbed off they are scratched over with a steel knitting needle. Excellent results can be obtained by the amateur worker skilled in repoussé work, who is able to prepare his own designs in slight relief on pewter, brass or copper, and subsequently to colour them by means of these lacquers.

*Fig. 8. Method of holding dry brush for stippling background.*

*Fig 9. Use of a template when wiping out the panels in Worcester China designs. (Courtesy of Winsor & Newton. Ltd.)*

*Lacquer Work. Fig. 10. Examples of coloured lacquer work on metal.*

Bronze powders can be utilized in this work and

Japan black lacquer. Camel hair brushes are employed for broader effects and fine sable for details. Yellow varnish is used to coat the whole piece when finished and thus render it untarnishable.

In conclusion it may be noted that brushes used for lacquer colours should be washed out in methylated spirit immediately after they are finished with each time. After use with oil colours for stencilling, if this is employed, brushes are cleansed with turpentine, and poster colours are washed off with water.

Bottles must be kept corked when not in use. Best results are obtainable if the work is allowed to dry thoroughly between each process. A coat of varnish should always be given to the finished article. Varnish should be applied evenly with a soft brush and the work set aside to dry where no dust is likely to settle on it. Lacquer colours always require an absolutely smooth surface. Where raising paste is used the opposite rule obtains. The particular portion of surface to be raised has to be roughened to make the paste adhere firmly to the work.

*Fig. 11. Brass cigarette box in process of decoration; the design has been transferred and the coloured lacquer is being applied by means of a camel hair paint brush.*

**LACRYMA CHRISTI.** A famous Italian wine from the vineyards situated on the slopes of Vesuvius is Lacryma Christi. It is a very attractive wine when drunk on its native soil, but comparatively little is imported into Great Britain. An exceedingly luscious wine of refreshing flavour, it is ordinarily of a rich red colour, although white and sparkling varieties are produced. The white variety is noted for its piquant flavour.

**LACTIC ACID.** By the action of the lactic acid bacillus on milk sugar lactic acid is obtained as a colourless, syrupy, sour liquid. It is one of the waste products of muscular contraction and has much to do with inducing muscular fatigue.

Lactic acid is found in the stomach in the earlier stages of digestion, when it is produced, by the action of bacteria on the carbohydrate foods. Metchnikoff thought that the presence of lactic acid bacilli in large numbers in the intestine prevents the growth of other bacteria and thereby prevents auto-intoxication, or

poisoning from the substances manufactured by such bacteria in the bowel. For the purposes of his treatment a large number of preparations containing lactic acid bacilli are sold for the artificial souring of milk, and milk soured in this way can be had from reliable dairies.

Calcium lactate, dose 10 to 30 grains, is used to increase the lime content of the blood, in restraining bleeding, in urticaria, chilblains, and for other purposes. The syrup of calcium lactophosphate, dose  $\frac{1}{2}$  to 1 dram, is a good tonic.

**LACTOMETER.** The specific gravity of milk may be measured by an instrument known as a lactometer, which is floated in the milk, and the figure marked on the stem of the instrument corresponding to the upper surface of the milk is then read off and represents the specific gravity. In good milk this should be 1.028 to 1.034.

The greater the amount of cream the lower the specific gravity; but the increase in the figure which results from skimming off a portion of the cream can be lowered by the addition of water. By itself, therefore, the lactometer is a fallacious guide to the quality of milk, and other tests are therefore necessary. *See Milk.*

**LADDER: How to Use.** Extending ladders, in two or more sections, are very convenient in the home, being light in weight and sufficiently rigid for most household work. These are placed against the wall and extended by pulling upon a rope or by pushing up the extending portion. Iron fittings, varying in type with the different makes, are provided to hold the two parts firmly in contact and prevent the upper part of the ladder from sliding down until released.

When a ladder longer than 10 or 12 rungs is to be raised or lowered, it calls for two or more persons' assistance. To raise the ladder it should be placed on the ground, with the bottom a few feet out from the wall, in the position it will occupy when the ladder is raised. One person places one foot on the bottom rung, grasps the third or fourth rung above it and commences to pull, while the other person lifts the opposite end as high as possible.

The ladder is held with the arms extended above the head, by grasping the rungs and advancing hand over hand, thereby gradually raising the ladder higher and higher. The other person stands on the bottom rung and holds on to the fourth or fifth rung, leaning backward as far as he can, as shown in Fig. 1. This procedure is continued until the ladder is in a perpendicular position; when both persons should stand on the ground, grasping the sides of the ladder, and very cautiously allow it to fall over in the required position on the wall of the house, or wherever it is being placed. For a very long ladder three or four persons may be needed to elevate it.

As a precaution, the amateur may attach a rope to the ladder, leading it through an upper window and stationing someone at the end of the rope to haul on it when the others are lifting the ladder, and to hold on tight when the others pause. Having raised the ladder,

it should be securely lashed to some part of the building, to prevent it from swaying or rocking. The angle a ladder makes to the house is important, and it is better to have it more upright than otherwise; the more vertical a ladder is the less strain is on it, and the less it will sway while anyone is working upon it.

*Ladder. Fig. 1. Correct positions when raising a ladder. Fig. 2. Method of lowering a ladder so that one man acts as a counterbalance to the weight borne by the man who holds it up.*

**Lowering a Ladder.** To lower the ladder, the sequence of operations is to a large extent reversed. The lashings are removed, and if it is proposed to use the check rope from the upper window, this should be attached before the lashings are cast off. The person at the upper window with the check rope should constantly watch, or be advised of the action of those below, so that all concerned may work in unison. The person on the check rope should take the weight chiefly when the persons lowering the ladder are moving the hands from one rung to another.

The usual procedure is first for one to stand on the bottom rung on the inside of the ladder with his back to the wall of the house, while the other stands with arms elevated, reaching up and holding on to the highest available rung. The one behind the ladder pushes, while the one in front pulls, until the ladder is vertical; the one behind then stands on the lowest rung, and holds on to the third or fourth rung, and gradually leans backward, while the other person allows the ladder to incline over his head, walking backward, with arms erect, and grasping the ladder rung by rung until it has been lowered to such a height that it is possible for him to come from beneath it and hold it with one arm, as shown in Fig 2. After this the ladder may be gently lowered.

During the whole of this time the person at the back must keep his weight as far behind the ladder as possible, the object being to act as a counter-balance to the weight of the ladder; by this arrangement it takes on more or less the form of an L-shaped lever. The stronger person should always be the one beneath the ladder, while the heavier individual should generally hold on to the back.

The amateur should, in all cases of doubt, attach a strong rope to the top of the ladder so that it can be controlled. The rope could be twisted round a crowbar or stout iron or wooden bar, which might rest across the window-opening, as by carrying the rope in this way it relieves the slack end of much of the pressure, although it makes it more difficult to pull up the ladder. When placing the ladder, care must be taken that the top does not damage the eaves or gutter, or any part of the house. This is prevented by tying old sacking round the ends of the ladder, but mostly by care in raising it.

*Ladder. Fig. 3. Useful type of ladder giving access to an attic or loft. When not in use it can be drawn up, and is concealed by the trap door. (Courtesy of Loft Ladders. Ltd., Bromley)*

Fig. 3 shows a useful type of ladder for giving access to a loft. When out of use it rises up and is concealed by the trap door. *See Attic; Loft; Step Ladder; Trestle.*

**LADDER FERN.** The genus *Nephrolepis*, known as the ladder fern, includes useful ornamental ferns. The most popular is *exaltata*, which may be grown in greenhouse or room window if potted in a compost of peat, loam, leaf-mould, and sand. As a basket plant the ladder fern is excellent. *See Fern.*

*Ladder Fern. Ornamental pot or basket plant.*

*Punch Ladles of silver with wooden handles, 18th century. The lowest one has a coin inserted in the bowl. (By permission of the Director. Victoria and Albert Museum, S. Kensington)*

**LADLE.** A ladle is a large spoon used for serving soup, sauce, and other liquids. Ladles are made of silver, electro-plate, and various alloys. Others are of china and earthenware, generally being made to match the dinner service and fit the sauce boats. Examples of silver ladles are found dating from the beginning of the 18th century. These include ladles used for filling glasses from the punch bowl, many of which had handles of whalebone or a dark wood. Some were

ornamented by fitting a coin in a hole cut in the bottom of the bowl; but collectors should beware of spurious examples. *See Cutlery; Sauce Boat; Spoon.*

**Lad's Love.** This is a name of the plant also known as *artemisia*, old man, and southernwood. *See Southernwood.*

**LADYBIRD.** There are about 30 species of the scarlet and black spotted beetle known as the ladybird, and all are of assistance to the gardener in destroying green fly. The larvae are known as garden crocodiles. The most common species is the seven-spotted ladybird.

*Ladybird*

The larvae live for about three weeks, hatching out from buff-coloured eggs laid underneath leaves, afterwards turning to pupae, and in another three weeks emerging as mature beetles. The crocodiles are each able to destroy hundreds of aphides in a short time.

**LADY DAY.** This is the name given to March 25, the reason being that it is the feast of the Annunciation of the Virgin Mary. It is a quarter day in England and Ireland, but not in Scotland.

**LADY FERN.** The name is applied to a very beautiful hardy fern belonging to the genus *Athyrium*. The actual lady fern is *A filix-foemina*; there are numerous fine varieties. They thrive in ordinary soil to which leaf-mould has been added, and they like shade. Free watering is necessary in dry weather. The dead fronds should not be cut off until spring. They are

propagated by sowing spores in pans of moist peaty and sandy soil in a cool greenhouse. *See Fern.*

*Lady Fern. Delicate fronds of this beautiful hardy fern, very suitable for indoor decoration.*

**LADY GRASS.** Ribbon grass and gardener's garters are other popular names for *Phalaris arundinacea variegata*, an ornamental grass, 2 ft. high, with green and white leaves. It flourishes in ordinary soil and is increased by division in autumn. An annual, to which the name *Phalaris canariensis* is given, supplies the birdseed which is in demand by those who

keep cage-birds.

**LADY'S FINGER: The Biscuit.** To make these rich biscuits, take 4 eggs,  $\frac{1}{4}$  lb. castor sugar, and  $\frac{1}{4}$  lb. flour, also 1 extra yolk of egg. Work the yolks of the eggs, after separating from the white, with the sugar until of a creamy appearance, and add the flour and any essence desired.

Whip the whites of the eggs to a stiff froth and fold lightly into the mixture. Fold a sheet of kitchen paper to make in it three divisions, lay it open on the board, and pipe the biscuits evenly in rows between the dividing lines. They should be 3 in. long by  $\frac{1}{2}$  in. wide. Cover them with sugar, lay the paper on a thick baking sheet, and bake in a moderate oven to a light fawn colour.

To remove the biscuits from the paper, lay the whole sheet on a board or cloth wetted with hot water; the warm moisture will enable the paper to be peeled off without breaking the biscuits.

**LADY'S FINGER: The Plant.** This is the popular name for anthyllis, a rock-garden trailing plant which bears pea-shaped flowers in early summer. It needs well-drained soil and a sunny place and is increased by seeds sown in late summer; or by division in autumn or spring. The best is *Anthyllis montana*, which has greyish leaves and rose-pink flowers. Another name for the plant is kidney vetch.

**LADY'S MAID.** The duties of a lady's maid vary, but she must be a good needle-woman, able to keep her mistress's clothes in repair, to renovate or alter any garment, and to make from patterns or copy garments when required.

In addition she will be expected to know something about hair-dressing, manicure, and face massage. Her employer's wardrobe is entirely in her charge, and she is responsible for its care and for the setting out of the toilette to be worn. She assists her mistress to dress, and may also be expected to do some of the finer washing, such as lace, gloves or evening handkerchiefs.

In many cases the lady's maid is a kind of travelling companion, whose business it is to look after the luggage, get the tickets, and save her mistress from all the routine work of a journey, either by sea or land. Packing and unpacking are included in her work, whether she accompanies her mistress or not. A competent lady's maid can command high wages. *See* Packing; Servant.

**LADY'S MANTLE.** The name is given to a genus of hardy herbaceous perennials, *Alchemilla*, of which a few species only are grown. *Alpina* is a British native with silky hairs and leaves which are silvery on the under surface. It is about 9 in. high, and suitable for the rockery.

**LADY'S SLIPPER.** The popular name of the *Cypripedium* group of orchids is lady's slipper. Some of them are hardy; others need greenhouse treatment. The name is derived from the shape of the lip or lobe of the

blossom, which resembles that of the toe of a lady's slipper. *See* Orchid.

*Lady's slipper.*  
*Flowers and leaves of*  
*a favourite green-*  
*house orchid*  
*(Cypripedium).*

**LADY'S SMOCK.** The name of *Cardamine pratensis* (cuckoo flower), a familiar wild plant with pale lilac-coloured flowers in spring. The double variety is a pretty plant.

**LAELIA.** One of the most popular forms of hot-house orchids is the laelia. The pseudo-bulbs must be placed in pots, pans, or hanging baskets in a mixture of peat, sphagnum moss, charcoal, and sand. They should be watered freely during the summer months, given plenty of sunshine and air, and kept at a temperature of about 70°. In winter the thermometer may be allowed to drop to 60°.

There are many species and hybrids, with flowers that range in colour from white through pink and lilac to purple, and new sorts are produced every year by orchid growers. Propagation is effected by division of the pseudo-bulbs at potting time, or when new growth is developing. *See* Orchid.

**LAGENARIA.** A hardy annual climbing plant, with bottle-shaped fruit, *lagenaria* (bottle gourd) is an excellent climber for covering fences, trellises, etc., and belongs to the same family as the gourd (q.v.) It is best raised from seeds sown in April in a heated greenhouse and planted out in early June.

**LAGER BEER.** Of a pale amber colour, bright and sparkling, full and pleasant in flavour and entirely free from acidity, lager beer is not so strong as English beer, and contains a smaller quantity of alcohol. In brewing it, not only fewer hops but from 20 to 40 per cent less malt is used than in most English beers.

Most of the Austrian beers have a mild and soft flavour, and it is rarely that any of them are as bitter as English pale ales. Pilsener beer, brewed at Pilsen, in Czecho-Slovakia, is exceedingly pale in colour as well as remarkably light. It is even weaker than Vienna beer, but it has a sharp, almost medicinal, bitter flavour due to Saaz hops. *See* Beer.

**LAI D WORK:** In Embroidery. Laid work is used chiefly in Chinese embroidery, for filling

backgrounds and large spaces in designs, or when copying 17th century Italian work in which gold and silver thread are couched down with tiny stitches. A thread is laid, either following the outline of the design or in straight rows across it, or in some filling pattern when the background is to be decorated with laid work, or following the lines of the ground material.

Laid work is employed for designs when the embroidery is wanted in high relief, and where the working medium cannot be drawn through the ground material in the ordinary way, as in the case of cords, chenille, and heavy silver or gold threads. When embroidering with metal threads this work has the advantage of using less of these expensive materials, as they are not taken through to the wrong side of the fabric, but only caught down on the surface.

Designs are frequently first padded all over by means of stitchery in coarse, soft crochet cotton. Floral designs may have leaves and flowers stiffened or still further raised by means of cardboard shapes. The latter can be prepared by transferring the required portions of pattern on to a sheet of cardboard and cutting out the shapes with a sharp knife. Sometimes such cardboard shapes are pasted on to the fabric to be embroidered; in other work they are stitched over with the raised padding cotton to give a more raised effect. The metal thread is wound double on to a spindle; this facilitates the even laying of the thread. For raised designs in which the effect of satin-stitch is desired the double metal thread is taken backwards and forwards across the padded leaf, or other figure, and secured on the opposite side with a tiny back-stitch. Laid work is employed for designs embroidered on leather, suède and felt, and also in conjunction with appliqué.

*Laid Work. Fig. 1. Simple couching stitch used in this form of laid work.*

**Couching Stitches.** Several forms of laid work are accomplished by means of different ways of placing the laid threads, and variations in the couching stitch used. In its simplest form couching stitch is shown in Fig. 1, holding down the double thread. Such a stitch has been used for the gold laid work on the embroidered cushion shown in Fig. 2. To keep the metal threads in position a little couching stitch has been worked across them at intervals of  $\frac{1}{8}$  in. This design has not been raised by padding, but is laid down directly on to the black satin. In the central leaf ornaments the beauty of the design is made by the variations in laying of the gold thread, with the veined couching in black silk going in a contrary direction.

*Laid Work. Fig. 2. Black satin cushion embroidered in gold thread couched down with small stitches in black silk.*

In Fig. 1 the couching stitch is shown in black, and is left rather loose so that the position of it can be plainly seen; but in the actual work it is drawn down closely, so that it is almost invisible. It is quite permissible to work this stitch obliquely across the laid thread when working an ordinary outline, but when working couched filling, and over very round laid threads, as in the gold embroidery on the cushion illustrated, the stitch should be quite straight and uniform. In couched filling the stitches come exactly midway between two stitches of the first round.

To work, the laid thread can be caught down at the beginning to keep the end in position, then bring the working thread to the right side of material, after fastening it on the wrong side, just above the laid thread, which is on the outline of the design, draw the thread through, and put the needle back under the laid thread in a perpendicular line. Now bring the point of

needle through ground material again about  $\frac{1}{8}$  in. to the left, just above the laid thread, and draw through, when a perpendicular stitch will be seen across the laid thread. The illustration shows the needle in working position, and it will be seen that it is like a hemming-stitch, but set wide apart.

*Fig. 3. Showing laid threads couched down with oriental filling.*

Scaled couching is formed with loops couched down in the centre, and arranged so that the loops of successive rows begin in the centre of a loop of the previous row and finish in the centre of the next loop of the previous row, so making the formation of scales.

In veined couching, when the first threads are laid in the form of leaf outlines, these are often only caught down with a tiny stitch on either side, but the veins are laid in a reverse direction to the foundation threads, and each vein is couched down as it is laid with the stitch used in oriental filling, and thus holds the first

laid threads in place.

**Oriental Filling.** This filling is an important stitch in laid work. Used for a background, it is illustrated in Fig. 3. It is shown, worked in silk, following the lines of the soft canvas groundwork, and it is worked here more open to illustrate the stitch better. The work can be done over the fingers, or in a frame for large pieces. To work, proceed as follows: After joining the silk on the wrong side bring the needle up through the material to the right side at the lower edge of the design and pass it down again exactly opposite on the upper edge of the design. Bring the needle up again a little to the left of this laid thread, about  $\frac{1}{4}$  in. down. Insert the needle exactly opposite to the right of this laid thread and bring it out to the left again about  $\frac{1}{4}$  in. down, as shown.

When it is drawn through, a little stitch will be formed across the laid thread. The needle is again inserted to the right of where it last came out, and brought out again on the left about  $\frac{1}{4}$  in. down. Repeat the process to the bottom of the thread, after which another thread is laid close up to the previous one, and so on in succession until the background is covered closely so that no material is visible.

**Diamond and Diaper Stitch.** Other fillings are of threads laid with diaper stitch, and also with diamond stitch. They are both used as embroideries for covering backgrounds or large spaces such as bold fruit designs and conventional flowers.

In the form of laid work utilizing diamond stitch the foundation threads are first laid in a sloping direction from left to right, the second lot of threads crossing these in the opposite direction. This is best worked in an embroidery frame to make sure that the threads are taut without being drawn too tightly.

The second process is the making of the little stitch at each crossing of the threads, and this sets the diamond pattern. Fig. 4 shows this stitch in progress. The needle comes through material to the left of the crossing, and is put down again in a straight line to the right of it. With one movement it can be brought up again to the left of the next crossing. When the needle is drawn through a little stitch is formed which holds down the two threads of the foundation.

*Laid Work. Fig. 4. Showing how the small stitch is made at the crossing of laid threads in diamond stitch. Fig. 5. Diaper stitch, showing position needle at the second half of the stitch.*

In diaper stitch the foundation threads are also laid

obliquely, first in one direction, then across the reverse way. The points of the crossings are then couched down with diaper stitch, which resembles cross stitch, but is made and placed differently.

The first half of the stitch is worked across the junction of the two threads, letting it extend at each side of the main threads, so that it is a distinctive stitch in itself and not a little couching stitch only. The first half of the stitch runs parallel with the warp threads of the material, then the work is turned and the second half of the stitch worked in the same way and parallel with the weft threads. Fig. 5 shows the second portion of the stitch in operation. *See Embroidery.*

**LAKELAND TERRIER.** In size the specimens of this breed are similar to the fox terrier, but in colour are fawny brown. The coat should be of a wiry texture and close, as these dogs are used for going to ground to bolt fox or badger. They are active and game, therefore

must have sound and level teeth, strong jaws, and small eyes. The best weight is about 16 lb. *See Dog.*

*Lakeland Terrier.  
Specimen of this tawny-brown wire-haired terrier, bred for fox hunting. (Photo, Thos. Fall)*

**LAMARCKIA.** A hardy, low-growing annual ornamental grass, lamarkia has silky golden foliage, and when dried is useful for the purposes of indoor decoration. Seed may be sown out of doors in springtime. The grass should be cut and dried during August.

**LAMB: In Cooking.** The flesh of the lamb is both delicate and digestible, and is of a lighter tinge than mutton when cooked. It takes longer to cook than beef or mutton, for, whether it is roasted or boiled, every portion of the joint should be thoroughly done and frequently basted. When roasting lamb it is necessary to lower the temperature of the oven after the first 10 or 15 min. to prevent the flesh being scorched or hardened. Allow 20 min. to each pound and 20 min. over. Roast lamb is served with clear gravy and mint sauce. New potatoes and green peas, when in season, are the usual vegetables. English house lamb can be obtained by the end of November or the beginning of December. Grass lamb is fit for the table by April, and lasts all summer and early autumn.

When purchasing, one of the chief points to observe is that the lamb is fresh. To judge the fore-quarter, see that the vein of the neck is either ruddy or bluish in colour; if it has a green or yellowish tinge it is not good. The quality of the hind-quarter can be determined by the feel of the knuckle and the state of the kidney; this latter must be small and perfectly sweet and the knuckle should be quite stiff; the flesh

should be firm to the touch. In foreign lamb, the best quality of Canterbury (New Zealand) meat is excellent if well cooked, but the joints should always be of a clean appearance and the flesh a good colour.

Lamb is cut up first into hind and fore quarters, and these are again divided into legs, shoulders, loins, necks, and breasts. The pluck, known as lamb's fry, is served as a breakfast or supper dish, while the liver, heart, brains, sweetbreads, ears, tail and feet can be used in the preparation of side dishes.

**Lamb Blanquette.** This is an entrée composed of scallops of cold roast lamb heated in a rich white sauce with the addition of mushrooms. Cut some thick scallops of meat from a cold roast leg of lamb, keeping each one as much as possible the same size and giving them a neat rounded appearance. The quantity required is about 1 lb.

For the sauce, melt in a stewpan  $1\frac{1}{2}$  oz. butter, and mix with it 1 oz. flour. Cook these together without browning, and then moisten with  $\frac{3}{4}$  pint clear white stock. Add 6 oz. mushrooms which have been prepared and cut into strips, and a pinch of grated nutmeg. Stir over the fire for a few minutes, then add the meat and heat it in the sauce.

Beat together the yolks of 2 eggs with 2 tablespoonfuls of cream, remove the blanquette from the fire, add the liaison and cook all gently 3 or 4 min. to take the rawness from the eggs and cream. Take care that the sauce does not boil after the mixture is added. Season with salt and cayenne pepper, and squeeze in a little lemon juice. Serve with croûtons of fried bread.

**Chops and Cutlets.** Before they are cooked, lamb chops should be well trimmed and all skin and superfluous fat removed. They must be grilled or boiled, and served with a pat of maître d'hôtel butter on each one. Sometimes the maître d'hôtel butter is omitted and plain butter is spread over, with a seasoning of pepper and salt and a good sprinkling of chopped parsley. Lamb chops are usually small, and it is well to provide sufficient for a second helping.

*Lamb Cutlet. Dish of cutlets fried in egg and bread-crumbs and garnished with peas.*

Lamb cutlets should always be cut and trimmed as described for mutton cutlets, and with all cutlets a good shape should be of the first importance. They are good simply broiled and served with fried potato straws. After broiling they need brushing over well with butter and plentifully seasoning. They may also be egged, crumbed and fried, and served with a garnish of peas, or one cutlet as a casserole dish. For this fry the cutlets for a few minutes in butter, then remove them and cool the butter. When cool mix it with the yolks of 2 well-beaten eggs and add seasoning. The cutlets must be dipped in the egg and then into white breadcrumbs and laid in a casserole. Pour a little good gravy over them,

add seasoning, 4 tomatoes cut in halves, and the juice of half a lemon. Stew gently for  $\frac{1}{2}$  an hour. Serve on a bed of peas and strain the gravy round.

Slices from the centre of a leg of lamb can be made into an excellent dish of cutlets if stewed with good stock to which has been added a bouquet garni and a little spice tied up in muslin. Stew the cutlets 20 min., then take them up, skim the fat off the surface of the gravy and remove the bouquet and the spice. Thicken the gravy with butter and flour made into a roux and add 8 forcemeat balls,  $\frac{1}{4}$  lb. mushrooms, prepared and fried in butter, a pinch of ground mace and the yolks of 2 eggs beaten with 4 tablespoonfuls of cream.

Stir the mixture of eggs and cream into the gravy and cook, but do not let it boil. Heat up the cutlets in the sauce, and serve them with some neatly cut beetroot. One ounce each of butter and flour would be sufficient to thicken 1 pint or more of gravy.

**Lamb Pie.** To make lamb pie, procure a neck of lamb, remove the chine bone, and saw off the breast part, so that the bones of the cutlets remaining will measure only about 3 in. Separate these neatly and pare off any superfluous fat. Put the spine bones and trimmings into a stewpan with an onion stuck with 2 cloves, a grated carrot and turnip, a few peppercorns, and salt. Cover with cold water and boil at least 1 hour to make stock. Place the prepared cutlets in a meat pie-dish, arranging them in circular form round the side, season them, and fill the centre with peeled, uncooked, and rather small new potatoes or old ones pared and shaped in balls. Pour over these and the meat sufficient stock to three parts fill the dish. Cover with a rich crust as for meat pies, and bake  $1\frac{1}{2}$  hours. When the pie is baked add more stock, and serve hot or cold.

**Lamb's Head.** To make a tasty dish of lamb's head, remove the brains, blanch and boil them, then chop them and make them into a forcemeat, adding the same ingredients as for veal stuffing. Soak, blanch, and boil the head with the tongue and the liver, if procurable. Cook gently for an hour, remove the bones, and lay the flesh neatly on a well-greased Yorkshire pudding-tin. Skin the tongue and cut it into dice with half the liver; mix these with the forcemeat. Cover the flesh of the head with the mixture, and grate over a little lemon rind. Bake in a good oven for 20 min., and baste it well with dripping.

With the liquor in which the head was boiled make a rich gravy, thickening it with butter and flour and flavouring well. Dish the head with the stuffing covering it, strain the gravy round, and garnish with fried bacon and the remainder of the liver cut in thin slices. The bacon and liver can be cooked by the side of the head in the baking-tin. *See Carving; Cutlet; Hot Pot; Mutton; Pastry.*

**LAMBETH WARE.** A sharp distinction should

be drawn between the two great classes of decorated pottery for which Lambeth is famed. For about a hundred years after the middle of the 17th century several factories in that vicinity produced glazed faience of the style introduced at Delft, in Holland. This Lambeth delft was painted in blue and other colours and comprised tiles, wine-bottles, oval dishes, candlesticks, and mugs.

Pieces much prized by collectors consist of sets of six plates, each bearing a line of a doggerel verse describing a Merry Man. As this ware seldom has a factory mark, it is often difficult to distinguish from contemporary delft made at Bristol or Liverpool, and even from Dutch ware itself. A rosy tinge, showing up the dark clay body through the thin tin-enamel, sometimes helps to distinguish it.

*Lambeth Ware. Lambeth Delft mug, with the arms of the Leathersellers' Company, and inscribed Bee Merry and Wise, 1660.*

Lambeth faience is a name given at the Doulton works to a form of art pottery consisting of a coloured body painted in decorative designs and fired under the glaze. See Delft; Doulton; Faience.

**LAMBREQUIN.** This word is now used for a drapery, usually of embroidered linen or some rich material, found on bed testers of the time of William and Mary and of Anne. The carved wood is closely covered with the fabric, which is fastened on and elaborated by festoons of drapery and hanging tassels. In some beds made to-day for period rooms this type of drapery falls from a wooden corona. The name lambrequin is also used for the Victorian arrangement of festooned drapery on mantelpieces and over doors. See Tester.

**LAMBSKIN.** Skins of young or pre-maturely born lambs are tanned with the fleece on and treated as furs, which are used in the Near East to make caps, coats, and cloaks, and are also employed by western furriers. Imitations are made in mohair yarn plush in cream colour for babies' wear as well as in dyed shades with curls of different pattern, length, and lustre. The fabrics can be washed like woollens, and the light colours can be re-dyed to darker shades by the use of wool dyes. See Fur.

**LAMB'S LETTUCE.** The leaves of lamb's lettuce or corn salad, a quick-growing salad plant, are valuable in winter and spring. Seed is sown in late summer in drills 6 in. apart, the seedlings being thinned to 5 or 6 in. from each other. The fresh, young leaves are the best to eat.

**LAMENESS.** Many causes may produce lameness,

including corns, bunions, deformities of the feet or other parts of the lower limbs, whether present at birth or acquired subsequently through injury or otherwise, and diseases of the joints or of the nerves or muscles. The symptoms should be investigated at once in any case and treatment will vary with the cause. See Club Foot; Foot; Hip Disease; Infantile Paralysis.

## LAMPS: OIL, GAS AND ELECTRIC Latest Ideas in Practical and Decorative Lighting

This contribution deals with the various forms of portable lamp, and also with gas and electric lamps which are flexibly connected to the mains and may be moved from place to place. Other lighting articles include Acetylene; Air Gas; Burner; Electricity; Gas; Lighting; Oil. See also Bent Iron Work; Lacquer Work; Standard Lamp

The three main kinds of lamp used in domestic lighting are oil, gas, and electric. When oil lamps are used it is generally because neither gas nor electricity is available, though some people prefer them, especially for reading purposes, because of their soft light. Formerly vegetable or animal oils, such as colza and sperm, were burnt in them, but these have now been superseded by mineral oil.

In an ordinary oil lamp the wicks by which the oil is sucked up from the reservoir and supplied to the flame are either flat or circular; in duplex lamps two flat wicks are placed side by side. Whether flat or circular, the wick should be of a size to fit the burner exactly and long enough to allow of about 2 in. being coiled up on the bottom of the reservoir. When so much of it has been burnt away that its lower end only touches the bottom, the wick should be discarded and replaced by a new one. It should be kept trimmed as evenly as possible. For this purpose it is turned down until it is nearly level with the top of the burner, and then the charred portion is gently rubbed away with a rag. This operation should be repeated every time the lamp has been used. Cutting the wick is rarely necessary.

In lighting a lamp, turn the wick down low and wait a little time before turning it up again after putting the glass chimney in place, lest the glass be cracked by the heat. If the wick is turned up too high the flame will smoke and not burn clear. The function of the chimney is to create a draught and supply the flame with sufficient air for proper combustion. By fixing a talc or glass shield, of which various patterns are sold, on the top of the chimney, the current of hot air rising from the flame may be deflected and spread, and blackening of the ceiling above the lamp reduced.

Some lamps are provided with a lever, which when pressed extinguishes the flame. In the ordinary type, when it is desired to extinguish the light, the flame should be turned down low and either allowed to go out by itself or put out by blowing sharply across the top of the chimney, not down it. Sometimes there is an arrangement which automatically extinguishes the

flame should it be overturned or tilted far from the vertical.

Kerosene lamps should be kept scrupulously clean. The oil reservoir should be of metal, not glass, because if the lamp is knocked over, the glass breaks, and there is serious risk of fire. The reservoir should be kept fairly full, the lamp not being burnt continuously for so long a time that the oil is exhausted. The older type has been superseded to a great extent by lamps in which an incandescent mantle is used.

**Incandescent Oil Lamps.** There are several types on the market, some in which a wick conveys the oil to the special burner, and others in which the oil is vaporised under pressure before mixing with air at the burner. In the latter type a pump is incorporated in the reservoir, or an attachment is provided to which a small air pump (e.g. a cycle inflator) can be connected when starting the lamp. Figs. 1 and 2 illustrate pressure lamps and Figs. 3 and 4 the other type. The pressure lamps shown hold enough oil for about 10 burning hours, and the makers state that a gallon of paraffin oil will give a light of 300 c.p. for 64 burning hours. The intensity of the light is governed by the air pressure at which the lamp is worked. The average candle power of the lamps shown in Figs. 3 and 4 is given as 125, and a gallon of oil lasts about 60 hours.

*Lamp. Fig. 1. Left, pressure oil lamp which is easily adapted to an existing fitting. (Tilley Lamp Co.)*

*Fig. 2. Pressure oil lamp with vase in coloured glazed pottery.*

*Fig. 3. Aladdin table lamp, in which a wick conveys the oil to the special burner. (Tilley Lamp Co.; and Aladdin Industries, Ltd.) Fig. 4. Aladdin bracket lamp, showing the incandescent mantle, which produces a pure white light.*

**Gas Lamps.** When gas is spoken of in connexion with the lighting of houses, the coal gas or town's gas supplied from public gasworks is usually understood.

To a limited extent, however, in places where a public supply is not available, other kinds of gas are employed, such as acetylene and air gas. The former can be utilized in portable lamps for indoor use, and a useful type of acetylene table lamp is shown in Fig. 5. Another type, which might be used in a shed or outdoor workshop, is illustrated in Fig. 6.

Those who rely entirely on coal gas for lighting are not debarred from using table lamps, since it is possible to obtain useful and decorative gas lamps which take their supply from a gas plug point on the skirting, through a flexible metallic tube (Fig. 7). Their use calls for a certain amount of care in the disposal of the flexible connexion, so that it is out of the way, and does not pull on the lamp, and the latter must be placed so that its heat cannot cause danger to fabrics or woodwork.

*Lamp. Fig. 5. Acetylene table lamp. Fig. 6. Acetylene lamp useful for a shed or outdoor workshop. (Thorn & Hoddle Acetylene Co. Ltd.)*

*Fig. 7. Gas lamp supplied from a gas plug point through flexible metallic tubing. Fig. 8. Sunray electric lamp which gives out warmth as well as light. (Fig. 8, Modern Electric Homes)*

*Fig. 9. Electric table lamp contrived from a narrow-necked vase.*

**Electric Lamps.** In addition to the many kinds of electric flash lamp or torch, designed only for

intermittent lighting, there are battery operated hand lamps which will give continuous light for a few hours. These are relatively expensive to work, since the dry battery must be often replaced, so that electric hand lamps are hence adapted rather for use in any emergency that arises.

Electric table lamps for flexible connexion to the mains are made in all styles, from a desk lamp to the more ornate and decorative types with suitable lampshades. The Sunray lamp shown in Fig. 8 gives out warmth as well as light.

**Plug Points.** When connecting or disconnecting a lamp at the plug point make sure that the switch at the lamp and the plug are turned off. In a safety type of switch-plug (described in the article on Electricity, page 703) the switch is interlocked so that the plug cannot be withdrawn until the switch has first been turned off.

**Vases for Lamps.** Glass, metal or pottery vases, provided they are narrow at the neck, can be converted into table lamps by means of a cork, a piece of wire, an electric bulb holder, a plug, and a few yards of flex. The cork is shaped to fit the neck of the vase and the piece of stout galvanized or copper wire can be cut to the required length by means of pliers or wire cutters. Failing these, file a notch in the wire and bend it till it parts at the notch. The ends can be sharpened by means of a file so that they will penetrate the cork after the wire has been bent in the middle to form the circular support for the bulb holder shown in Fig. 9, which remains in position by means of its lower ring, when this is screwed up tightly from below the wire circle. The electric bulb is then placed in the holder. The holder, flex and the plug, to fit the existing plug point in the room, can be obtained from any electrician.

The effect is particularly good when these vase table lamps are suitably shaded, and many helpful suggestions will be found in the article on Lampshades. It is often possible to repeat the design or part of the design on a pottery or china vase by tracing it on to a parchment shade and colouring it. Lovely lamps can be made from cut crystal vases of rounded shapes, or even from those of plain glass when these are filled with water dyed to a colour which is repeated in the design of the shade.

**LAMPREY.** Similar to the eel in general appearance, the lamprey is in season during March, April and May. Lampreys are usually stewed in the same way as eels, or they can be made into a pie. *See Eel; Fish.*

## LAMPSHADES: THEIR MATERIALS AND MAKING

An Artistic and Profitable Occupation for Leisure Hours

Among the various articles in our work containing other helpful ideas in connexion with this decorative art are those on Appliqué; Candle Shade;

Embroidery; Lacquer Work; Stencilling; Woodwork. *See also Electric Light; Lamp; Standard Lamp.*

In most homes lampshades are an essential decorative feature. When chosen with due regard to their surroundings they can greatly aid the appearance of a room by day, and are still more important by night, as they can be cleverly employed to make subtle changes in the quality of lighting effects. Even where wall or ceiling fittings are of metal and glass, parchment or vellum shades are probably required for table lamps and standards. Artistic shades for ceiling fittings can also be made in simple pagoda and inverted shapes by the home worker, while many wall brackets are furnished with pendant lampshades or shields for candle lamps.

There is economical and artistic pleasure in producing for a trifling cost something that looks exactly right in the room, and as if especially designed at an expensive shop. To achieve such a result consideration must naturally be given to the particular lamp or fitting and also to the material, colouring and style which will harmonize best with the particular surroundings. When redecorating a room, table lamps or floor standards which have become shabby can be brought into the new scheme of things by restaining and polishing, or into colour relation by being painted with cellulose, enamel or lacquer brush paint. Various ideas for the decoration of lamps and shades to match are given in the articles on Lacquer Work and Lamp.

**Materials Obtainable.** The way of the lampshade creator is now eased by the great variety of practical materials available for her assistance. Ready-made imitation vellum or parchment paper shades are very cheap in the smaller sizes and are also obtainable in a variety of larger sizes suitable for floor standards. Packets of cut-out lamp shades in assorted shapes may be bought, or, for those who prefer to cut out their own, sheets of imitation vellum and coloured parchment papers are sold. Special lampshade paper is also made for pleated shades and there are coloured strip borders. Wire frames are obtainable to suit all sizes and shapes in standard, pendant and gimbal fittings.

For making-up purposes, galons by the yard in black and gold, to be sewn or cemented on the edges of shades, and leather thongings or coloured silk braids for lacing them, are provided. Ornaments such as beads and tassels are out of fashion now, but a large velvet bow to tone with the colour scheme of the room looks very decorative on an otherwise plain shade.

There are also certain fancy materials cut into shapes and perforated for lacing with thonging. These materials have marbled, mother-of-pearl, or opalescent finishes. A large assortment of lampshades with designs already transferred and only needing to be coloured

are obtainable in many sizes. Separate transfers for designs adapted to various styles of decoration, mandarin and other inks, and also lampshade colours, for painting on parchment or, with the correct medium, on silk, brushes for use with these, clear varnish and cement can all be either purchased or ordered in a good art department, or from firms which specialize in materials for this decorative work.

Nowadays all kinds of materials can be used successfully for lampshades. In a nursery or kitchen a checked or striped gingham looks very well, and a dainty muslin, spotted or flowered in a pretty design, can be ruched or frilled for a bedroom lamp. Linen is also used and is particularly suitable for shields to shade electric candle lamps.

*Lampshade. Fig. 1. Pleated shade for mahogany table lamp. It is of peach-coloured paper bordered with chestnut brown ribbon.*

**Pleated Paper Shades.** Simple to make and yet most decorative are shades of pleated paper. They are popular for modern table lamps, either on a plain pottery vase shape, or for the wooden type illustrated in Fig. 1. A charming effect is obtained by employing two colours, one for the lamp, the borders, cord and tassels of the shade, and the other for the pleated paper, which accent colours in the room. The part of the shade through which the light actually shines should be one of the becoming tints ranging from cream to apricot, or from pale pink to deep rose. The exception is green for a reading lamp. On the mahogany lamp stand in Fig. 1, the effect of peach-coloured paper, chestnut borders and silk cord finished with brown and gold bead tassels is dignified and uncommon.

Any good quality of firmly textured and yet finely grained paper will be suitable for pleating. A small-patterned wall paper which answers this description can be used, but most makes are too brittle for successful pleating. The best paper is of the same description as a cream-laid or bond notepaper. The easiest bordering is one of the specially made strips pasted on, or a passe-partout, but a thin silk ribbon can be sewn on, as used for the shade in Fig. 1, with a fine needle and sewing silk to match.

When cutting the paper for a pleated shade, first measure the frame. Two and a half times the circumference of the base will be the length of paper required for pleating, and two inches extra should be allowed for the depth. To get the required length, several widths of paper may have to be joined. They should be decorated and pleated first.

For this style of lampshade, either a plain border may be used for top and bottom, as in Fig. 1, or a good effect is gained by applying two strip borderings in a broad and narrow width, the lower one about 2 in. from the base of the shade; or stripes may be painted in mandarin inks either side of a pasted gold border. Cut-

out motifs can be applied, but these are not really so successful for this style of shade as the plainer borderings.

To pleat the paper, having allowed any paste used to apply decoration ample time to dry, fold in sections of about 1½ in. wide, pressing each fold down firmly with the thumbnail. The folds must be in concertina fashion and afterwards are folded again backwards and forwards to make them each ¾ in. wide. The pleats can, of course, be larger or smaller, according to the size of the shade. Pleating can be practised on a spare piece of paper to be sure that the size of the folds will give the effect desired.

The next process is to punch a row of small holes through which the cord or narrow tinsel ribbon is passed, about 2 in. below the top border of the shade. In some of these shades a lower row of holes is punched for a second cord and tassels. This ensures that the pleats will be held in place, and two rows look well when no other decoration is used. The holes must be cut an equal distance from the edge of each pleat. Before threading them, the lengths of pleated paper must be pasted together and the shade joined. Then the cord or ribbon is threaded through and the shade adjusted on the frame before drawing up, tying and finishing off with ornamental tassels or glass pendants.

**Parchment and Vellum Paper Shades.** The number of other varieties possible in paper shades makes selection quite difficult. Natural coloured vellum paper is attractive when decorated with a border or a painted design. For those who like to do as much of the work themselves as possible, white parchment paper or imitation vellum shades can be made from sheets of prepared paper.

*Fig. 2. Diagram showing method of cutting one strip of paper or parchment used for shade. Fig. 3. Wire frame for pendant lampshade, 9½ in. across base.*

In order that the shade should set properly it is essential that it should be cut out as shown in Fig. 2, so that the paper used for the shade is a segment of a true circle. Whatever the size required, it should be carefully measured out for depth and cut in this way, with the help of a pair of compasses formed of a pencil, a short piece of string, and a drawing-pin, to which one

end of the string is attached, while the other end is fastened to the pencil.

Pin the paper at its four corners down to a flat-topped table, or a drawing-board, and mark out the segment for the shade with the compasses. If an elaborate design is to be painted, it is easier to decorate before cutting out. Ordinary water colours may be employed, or lampshade colours, or inks. The use of special lampshade colours facilitates putting in a smooth background if it is desired to colour the shade all over. Trace or draw in the chosen design. Work the background to a finish before putting in the colours of the design. A little medium is mixed with the lampshade colour selected, and a flat squirrel hair brush is used to wash in the background. A swab of soft white rag is necessary to smooth the colour over the shade, wiping it off with a light, circular movement.

The use of the medium and rubbing with the rag produces a good surface on which to finish the work. When the background is quite dry the design can be painted in. After this work has been completed the shade can be cut out with sharp scissors and stuck together with strong lampshade cement. Weight the join until quite set, afterwards connecting up the design with additional touches of colour. The latter operation is very essential so that the join does not show.

On a ready coloured paper effective designs can be outlined in black waterproof ink, and metallic bronze powders can be employed with the correct medium. Map varnish can be painted over the shade when dry, leaving a border of dull gold paint half an inch wide, top and bottom, which makes a good finish. This method of decoration is especially suitable for a lacquered standard lamp or for small shades in a room with lacquered furniture. Designs for Chinese scenes can be adapted from those employed for lacquer work, or appropriate stencils can be obtained. In the case of an oriental vase lamp the design on the base should be copied by tracing or adapted by freehand drawing on to the shade.

When desiring to copy the same design for a number of shades to be made of natural coloured vellum paper, the original tracing or drawing can be outlined in heavy black waterproof ink, and this pattern can be traced under the vellum paper, which being oiled is semi-transparent and shows the design clearly through. This method, while facilitating the drawing for the amateur, does away with pencilled lines on the surface of the vellum paper, which gives the work an unprofessional look.

Once the shades are coloured, and the edges joined, making up is simple. For a pendant to be used on a bracket the shade is placed over a wire support as shown in Fig. 3. For a table lamp a gimbal fitting is used. Turn the joined shade on its head, paste the wire of the top of the frame, and the lower ring in the same way. Allow time to set, and then lightly stitch the wire rings to the frame. Take a pair of very sharp scissors and cut off any edges of the shade which come beyond the wires, and then bind the wired edges with a fancy galon sewn on with a fine needle and silk by hand.

Fig. 7. Inverted shade of vellum paper for a ceiling fitting.

The rough elegance of design, with the ship in full sail, of the parchment-and-braid lampshade (Fig. 4), is well suited to candles, or imitation "electric candles." There are few colour schemes into which this would not fit. Many coloured geometrical designs lend themselves to painting with waterproof inks, as these are transparent, leaving the natural vellum for a few of the lighter portions of the pattern. To dilute these inks distilled water should be used, or rainwater, or water that has been boiled and allowed to cool. Do not use cold water from a tap. Sable or camel hair brushes are best for painting with in this medium, the former for fine work. The military design (Fig. 5) is a simple and effective notion: other regiments are obtainable. For landscape painting moist tube water colours are best used, as they give a softer effect than any other kind of painting, while waterproof inks are best where brilliancy of tone is required, as in a hard, conventional design. This shade has been varnished with clear map varnish on completion.

An attractive touch is given to a lampshade with a border design if the vellum is treated with lampshade colour on the inside. The colour should be shaded from deep rose or orange at the top to a pale tint, as this forms a delightful background on which the design at the base of the shade stands out well. Applied designs may be used for these shades. Very simple, but effective, is a border of frieze banding, cut out and applied to a tinted parchment shade, which is afterwards varnished. Chintz or cretonne floral sprays can be cut out and pasted on in the same way, but such decoration is apt to look spotty unless kept to borders leaving the light to shine through the softly-tinted parchment. Silhouettes are purchasable in black and

gold or can easily be cut out from black, silver or gold paper to make a good decoration. In the same way coloured scraps may be used for nursery shades to form amusing borders. Charming colour effect is obtained by staining the electric bulb amber or orange with transparent glass painting colours. Fig. 6 shows a most unusual effect: different motifs on base and shade in unexpected harmony.

**Many-sided Shades.** Lampshades with many sides are cut to fit special frames. Having selected the frame, pieces of vellum paper are cut exactly to fit the sections, holes are punched about  $\frac{1}{2}$  in. from the edge of each separate panel, and the thonging is threaded on to a coarse needle and passed through the shade and round the divisional wires. Such a shade would look particularly well in a study or library, and designs can be copied from bookplates. Fig 7 shows the same method of thonging utilized for an inverted shade. The decoration in this case is a geometrical design on the base carried out in cobalt blue, orange and black inks. The inside of the shade is painted orange.

*Lampshade. Fig. 8. Quickly decorated shade; the parchment panels are bought ready for colouring.*

*Fig. 9. Shaped panels with a marbled effect laced together with leather thonging.*

*Fig. 10. Shade with painted Jacobean design laced with fancy gold braid.*

Very quickly decorated are parchment shades cut out in panels, perforated for thonging and traced for painting with waterproof inks, as illustrated in Fig. 8. The correct placing and size of perforations is clearly seen here as a guide to those who wish to punch the panels for themselves. With the ready prepared panels the frame to fit must be purchased at the same time.

Other materials made up with thonging are obtainable in these shaped panels. The marbled effect seen in the lampshade in Fig. 9 looks well on a pottery lamp, and also on a wooden standard, lacquered in the way described as marbling in the article on Lacquer Work. The mother-of-pearl and jade imitations are also particularly decorative in these fancy lampshade materials, and require little or no further ornament than the thonging, except in the case of a handsome

shade like the one in Fig. 10, which is of fancy vellum with a watered surface, the panels being laced to the frame with a narrow gold braid instead of leather thonging. The design, which is painted in inks to resemble Jacobean embroidery, is particularly effective.

The cut glass lamp in Fig. 11 has a beautifully accordant shade in a fancy material which resembles ground glass. The background is softly-tinted for a sunset sky, leaving a border of grey-green water at the base from which the reeds spring. The birds are painted in blue and brown, and the shade is thonged with silvered leather.

*Fig. 11. Shade in a special fancy material suitable for a cut glass lamp. (Courtesy of Webb & Corbett)*

Many-sided and dome-shaped shades can also be made up by sewing the various panels or sections to the divisional wires of the frame, and covering the joins with a fancy braid or gimp. This method is also used for making up silk or linen shades. The frame must first be covered with nainsook or similar cotton material cut on the cross in strips 1 in. wide. All downward lines of the frame are covered first. In Fig. 12 a frame ready prepared is seen, and also a shade stitched on to it cut to fit the various sections. When the painting has been completed, the stitched joins will be covered with a light gold gimp.

*Fig. 12. Painting a shade after the sections have been stitched together to fit the cambric-bound frame.*

The vellum or silk is first cut out a little larger than the divisional sections of the frame. Taking one piece at a time, cut it neatly to fit the curved top of the frame. Sew this piece on with blanket stitch, holding the thread with the left hand while each stitch is being taken, to prevent any knotting. Having stitched round the top curve, adjust the sections of material neatly against the frame and cut round the base so that it exactly fits, and sew this also to the cotton binding. Make these stitches about  $\frac{1}{2}$  in. apart. Having trimmed the sides to the shape of the wire, leave this panel until the next one has been attached top and bottom, and

then stitch the two panels together on to the frame.

These must not overlay, but just meet on the frame. Continue in this way until all the sections of the frame are covered, and then if a design is to be painted this may be done before stitching the braid or gimp on to hide all joins and to edge the shade. Cover the downward seams first and then the top and back. Panels may have the designs traced on them before stitching to the frame, but in case of tearing a section during the process of sewing together it is better to do the actual painting after stitching has been done.

Some prefer also to sew on the gimp first, but there is little likelihood of tearing the paper while doing this if reasonable care is taken.

In Fig. 13, prints of birds have been used to make the decorations of central panels for a set of shades bound with ribbon, which would look most attractive in a man's room.

**Silk and Linen Shades.** When making a silk shade in the manner just described, the binding on the frame must be very tightly wound round the wire, so that it is impossible for it to turn or slip when the silk is sewn on. The silk should be cut to fit with the lines of the grain going horizontally. The panel section must be pinned to the cambric bound frame, stretching the silk so that there are no wrinkles. Sew the two sides down with fine tight stitches and keep the material very taut. Then sew top and bottom with rather less tension or the silk will sag in the middle of the panel. Trim closely when the sewing is done and then begin the next panel. When the frame is covered bind it with gimp, taking care to sew this through to the cambric covering the frame. When a coloured material is used for the covering the binding on the frame should match in colour.

*Lampshade.

of shades with  
colour prints  
of birds used  
as decorative  
panels.*

*Silk shades*

look their best when left as plain as possible, unless designs are exceptionally attractive. Fringes are now definitely out of date. Pleated silk shades look most attractive made on the same lines as those in parchment or vellum. It is always best to choose silk in a warm shade such as amber, yellow, cream, or tones of pink.

Plain shades covered correctly so that there is not a single wrinkle to spoil the surface are easily decorated with lampshade colours, using the special medium for painting on silk. Inks can be also used in flat washes and the shading and details of the design finished off with tube water colours. The dome-shaped shade in Fig. 14 has a charming conventionalized design on a mottled background. The panels, top and base are

ribbon bound. Such a shade would look well on a table standard in a drawing room.

*Lampshade. Fig. 14.  
Shade made of silk stretched  
on a wire frame and hand  
painted.*

Shields for electric candle lamps or wall brackets are made on small semicircular wire frames, which are first bound in the manner described, so that no part of the frame is visible, except the wire for fastening it to the electric light socket. Such shields can be of vellum, silk or linen. The last-named is particularly attractive with a bordering design in brightly coloured wools. A medium coarse linen should be used. The stitches must be very neat on the wrong side, or they will not look well when the light shines through the shade. The embroidered linen is well pressed, interlined with thin buckram and lined with pink or orange silk. The edges may be left unfinished and neaten after the work has been stretched and fitted to the frame. The shade must not sag in any way. Having pinned it on to the frame as described in the making of a silk shade, the edges are trimmed and oversewn with ornamental blanket stitch or turned in and sewn down with invisible stitches.

**LANCASHIRE CHEESE.** The toasting properties of Lancashire cheese form one of its most popular attractions. This good quality is thought by some makers to be due to the fact that it is moulded when in a colder and more pasty condition than are other cheeses. The great difference in the method of making Lancashire and other varieties of cheese is that it is made from curds of different ages, usually of three different days. Thus the acidity is developed more slowly than with other hard-pressed cheese, and the mixing of curds at different stages of acidity causes the loose, friable curd in the resulting cheese.

Lancashire cheese is usually made in two shapes, one of which is large and rather flat, and the other like a small Stilton. The former usually weighs from 44 to 50 lb., and has a diameter of from 13 to 15 in. The smaller size usually weighs about 12 lb., has a diameter of about 7 in., and is about 9 in. high. *See Cheese; Welsh Rarebit.*

**LANCERS:** The Dance. The lancers, a set or square dance, is an adaptation of the quadrilles, and of English origin. For it at least four couples are needed, though occasionally six dance. Each couple faces inwards, the first (nearest the band) opposite the second, the third on the right of the first and opposite the fourth couple. The women stand on the right of their partners. There are five figures in the lancers, and the correct way of dancing these is at walking

pace; but usually people one-step, or fox-trot, or waltz. The first four figures open with an introduction of 16 bars of music, during which there is no dancing.

**First Figure.** The first woman and second man advance to the centre, turn, and return to their places. The first and second couple advance and exchange places, the first leading through the second couple. They then return to their places, the second couple in this case passing through the first. This occupies eight bars. Set to corners and turn. Here all the partners separate and the men turn with the nearest women to the left. The movement is then repeated from the beginning three times, the second woman and first man leading off, then the third woman and fourth man, then the fourth woman and third man.

**Second Figure.** The first couple advance and valse round the centre for 16 bars and return to their places. The side couples divide and join hands with the first and second couples to form two lines, top and bottom. The lines advance and retire. All turn their partners in their places. The figure is repeated with the second couple leading off, then the third couple, and then the fourth. In the case of the side couples the lines are formed at the sides, the first and second couples separating.

**Third Figure.** The four women advance to the centre and wait. The men advance and join hands in a circle behind the women, while the latter curtsy and pass under their raised arms. The women place their hands on the men's wrists and all dance round in a circle, finishing in their places—16 bars. The four men then advance to the centre, turn back to back, and bow to partners, who curtsy. The four men give their left hands across, put their right arms round their partners, and all chassé round, finishing in their places. The women repeat their lead, and the men follow.

**Fourth Figure.** The first and second couples valse or one-step up and down the centre for 8 bars. They stop and are joined by the third and fourth couples respectively. In two groups of four they give the right hand across, woman to woman, man to man, then the left hand—8 bars. They cross hands and swing round to the left—8 bars; or half-way left and half-way right. This is repeated, the first and second couples finishing with a different side couple. Third and fourth times side couples lead.

**Fifth Figure.** In this figure there is no introduction except a prolonged chord when all face partners, present right hands and bow. All then lead off with the grand chain, which occupies 16 bars. Women walk round in a circle to the left, men to right, giving first one hand and then the other, going in and out until own partner is met half-way round, pause and bow, continue the circle until meeting own partner in own place. The first couple or top then lead off with a waltz or one-step down the centre and return to places—8 bars—finishing in own place but facing outward. Side couples

fall in behind—third couple, fourth and then second, or bottom couples.

All chassé, cross over, women passing in front, men behind. They return to the other side in the same way, women following the leading woman, and men the same—8 bars. The leading woman turns off to the right, men to the left, leaders up the centre, others following—8 bars. All fall back, form lines and advance and retire, turn partners—8 bars. Grand chain is formed again, after which the other couples in turn lead round. The grand chain occurs between each lead round. The figure finishes with grand chain or a general chassé round. *See Dancing.*

**LAND: How to Buy.** When purchasing an estate or a piece of land there are several matters that require careful attention. There must be a writing, signed by the other party, to evidence the contract; i.e. the purchaser requires a writing signed by the vendor before he can sue him; and the vendor requires one signed by the purchaser. The writing need not be formal; it may be contained in a letter. The signature may be by initials, or even a printed bill-heading.

On an open contract, i.e. one not containing any express stipulations to the contrary, the vendor must be prepared to show a good title for 30 years back in himself or his predecessors. He must also show a title unencumbered by restrictions. The vendor must next submit to the purchaser an abstract, or epitome of the deeds and documents of title, for investigation, and allow the originals to be inspected. If, on looking at the abstract or the deeds, the purchaser finds that the vendor has only a defective title, he can refuse to carry out the contract and claim damages. For this reason, contracts are generally drawn up by solicitors, in which the purchaser bars himself in advance from taking certain technical objections; and binds himself not to claim damages if the contract goes off. The conveyance must be by deed. In all these matters a solicitor should be employed.

The purchaser of land should always be careful to see if there are any easements or public right over it—such things as rights of way. If he is buying a farm, but without the minerals underneath, he ought to be cautious how far he gives the mineral owner the right to let the surface down. A man who buys a farm must remember that if it is in the occupation of a tenant he will, if the tenant leaves, have to settle for tenant-right; but if the owner is in possession there is no tenant-right. Therefore a farmer or market-gardener who sells a farm which he both owns and occupies must make a special bargain with the purchaser if the latter is to pay for unexpired manorial values, standing crops, and the like.

The purchaser of land who intends to build a factory, workshop, or other business premises there will be wise to examine the title to see that it contains no restrictive covenants by a former owner which would prevent him from carrying on the business he wishes to start. Unless minerals are expressly reserved

by the seller, the sale of a piece of land carries with it everything underneath. As our ancestors used to say, the owner of land owns down to the centre of the earth and up to the sky. If land is bounded by a river or stream, in the absence of evidence to the contrary the stream belongs to the owners of the bank, each taking to the middle of the bed of the stream. It should be borne in mind that in law a river or a pond is simply so much land covered with water. *See Building; Contract; House.*

**LANDAU.** This is a four-wheeled carriage. It has a divided top, so that the whole can be either open or closed. The word landalette is sometimes used for a small landau, but these carriages are not often seen to-day. The diminutive landalet, or landalette, was sometimes used of a small landau or coupé. *See Carriage; Driving; Horse.*

### LANDINGS: DECORATION AND ARRANGEMENT

#### How to Solve a Difficult Furnishing Problem

This article connects those on Hall and Staircase, to which the reader is referred, and also to such headings as Carpet; Linoleum; Wallpaper.

It is probably due to the difficulty of making landings and passages attractive that so little attention is given to their furnishing, except to hang pictures and ornaments that are considered out of date and unsuitable for the living-rooms. This is quite disastrous from the decorative point of view, which requires hall, staircase and landings to form harmonious parts of an important section of the house which must be properly related to the whole.

Landings in terrace houses often present particular difficulty in furnishing and decoration, owing to the narrow floor space and comparatively high walls. If added to these drawbacks darkness has also to be contended with, well placed lighting fittings, a large mirror which will reflect any natural light from windows, and a pale colour chosen for wallpaper, or painted panelling of hall, staircase and landing will help. In some cases it is impossible to have any pieces of furniture on a landing except one piece that will fit into an angle. Corner cupboards are most useful in this connexion. Very long mirrors are better raised from the ground, and a chest, narrow table or some low stand with plants placed in front of them. In this way they give the same sense of space, but no one is likely to try to walk through them.

**Treatment of Walls.** High walls require careful treatment to make them interesting. In selecting the decoration for the hall, which may be quite well lighted by a good staircase window, such as the one shown in the first illustration, thought must be given to the landings above, which may be merely dark passages. In this instance the temptation to choose a heavy patterned tapestry paper or brown panelling effect which would not be suitable throughout has been

resisted. Light artificial silk for curtains, plain tinted paper, deep cream paintwork and ceiling, the polished surfaces of floorboards, stair rails and chest, patterns confined to the oriental design of the stair carpet and the well placed pictures: all give a feeling of light and space. The landing appears furnished, though actually there is only room for the grandfather clock in the stair angle and the oak chest.

The halls illustrated previously may be studied for suitable ideas of wall decoration. The applied landscape motif shown with a light marbled paper is especially suitable for repetition on narrow passage landings. When panelling, either real or simulated, is used for the hall it is possible to reduce it to a dado height for the staircase and landings. It is a good plan to fix a rail similar to a chair rail and to cover the lower part of the wall with the panelling. The upper part of the wall above the chair rail should remain light in colour. This is a suitable method of decoration where there is much traffic on staircase and landings. Where lincrusta panelling is used, when this becomes shabby a coat of paint quickly freshens it. When also used in the hall, more attractive for the lower part of the wall is wood panelling, which can be fixed and stained at home. Ready-made sections of panelling can be bought in several different kinds of wood.

*Landing. Fig 1 Small landing, rendered individual by the curved stair-head, polished oak chest, and grandfather clock set in an angle of the stairs.*

*Below.*  
*Fig. 2. Wider landing into which extra light penetrates through the glass-panelled doors of the sitting rooms which open off it. (Fig. 2, Humphrey & Vera Joel)*

**Floor Coverings.** If the traffic on landings is heavy, the floor covering should be substantial. A favourite method is to continue the stair carpet along the passage. If the landing runs at right angles to the staircase, the carpet is cut and laid separately; or, if preferred, body carpet can be used. It must be cut to cover the whole of the floor and must match the stair carpet. This method has a neat appearance when carried out in natural hair carpet.

An alternative method, which has the undoubted advantage of facilitating cleaning, is to cover the entire landing floor with self-coloured linoleum, or one of the new composition or rubber floorings, or parquet flooring, and to place a rug where it is most required. Labour in cleaning is thus saved, as the rug only requires shaking, and the flooring is kept free from dirt by mopping and polishing.

A more economical treatment for the floor, provided the boards are in good condition, is to stain and wax polish it. Before staining, any cracks should be stopped with some suitable wood-filler, and the boards well rubbed down with medium and fine glasspaper. A varnish stain can be used, but where traffic is heavy this kind of stain is not so serviceable, as it quickly wears.

Care is necessary, when dealing with landing floors that are polished, to see that no loose mats are placed near the top of the stairs. This difficulty can be overcome by sewing special press-stud fasteners to each corner of the mat; these clip into fasteners that are screwed into the floor. The landing floors of old cottages are often very worn and irregular. Fibre matting and dyed string carpeting are both suitable coverings in such cases.

For upper landings in a small house a piece of oak, which furnishes a passage without overcrowding it, consists of four drawers on a raised stand, surmounted by a large but shallow cupboard. Where space is limited, a corner of the landing may be fitted with a hanging wardrobe. Houses not provided with hot linen cupboards will need some good store for linen, and where there is sufficient room the upper landing is a most convenient place for either a large chest of drawers or a cupboard, in which to keep linen, provided it is placed against a dry inside wall.

**Larger Landings.** Roomy entresol landings give more opportunity for the effective placing of a few pieces of furniture, more particularly if there is a good wide window across the recess. A window seat upholstered with cushions covered in cretonne, printed linen, or artificial silk, and matching the curtain fabric, gives a restful appearance, while a book table is both useful and attractive. Such a space may often be converted into a small extra lounge if a radiator is placed behind a grill under the window seat for winter use. Either side of the recess bookcases may be fitted, stepped in modern fashion, with the addition of one or two small easy chairs, a brightly coloured rug, which tones with the curtains and stair-carpet, such a landing can look most inviting from the entrance hall.

For a squarer type of first floor landing the second

illustration shows the possibility of achieving brightness and a spacious feeling by means of glass panelled doors through which the sitting rooms on either side are visible. The glossy light-reflecting textures chosen for the upholstery of the cleverly designed divan, for the floor coverings and painted walls, together with the well placed angled glass lighting fixtures, decorate and furnish this landing space without any crowding or superfluous ornament.

Country house landings are usually easier of treatment. They are either definitely light and spacious or intended to be somewhat cramped, full of the nooks and corners made by the inequalities of floor boards, odd steps, and cross passages. In the latter case, as much light should be admitted as possible from the casement windows, and heavy curtains or jutting out of pieces of furniture should be avoided. Niches are nearly always effective on landings and provide a safe place for a flower base, well coloured piece of pottery, or lamps. Any niche or recess lined with mirror glass in oblong sections will reflect the light decoratively.

**LANDLORD.** Neither the landlord nor the tenant (except in the case noted below) is bound to repair a house unless he has contracted to do so. A tenant is liable for waste, that is, for damage done by him or his family to the house.

If a landlord has agreed to repair, he cannot be sued on his agreement unless the tenant has given him notice of the want of repair, and he has failed within a reasonable time to put it right. But a tenant is liable without notice from the landlord, because he is on the spot and can see when repair is needed.

**Rent Restriction.** A landlord can always sue for his rent, and can distrain at common law, but under the Rent Restriction Act he must first get leave from the county court. The same act limits the rent which a landlord may charge for houses within the Act to the standard rent, that is, the rent at which the premises were let on August 3, 1914, or the first let thereafter, plus certain increases up to a maximum of 40 per cent, of the standard rent. Notices of these increases must be given.

The Housing Act, 1936, imposes on the landlord of working-class property a liability for repairs, and he cannot rid himself of this liability by making any special arrangement with his tenant. The act applies to houses in London let at £40 a year or under, and houses elsewhere let at £26 or under. There is an implied condition that such houses are in all respects reasonably fit for human habitation when let. There is also an implied condition that the landlord shall keep them so fit during the tenancy.

If the house is let for a term of three years or more on the terms that the lessee will put it in repair, these conditions do not apply, unless the lease is determinable, at the option of either party, before three years.

In the case of such houses as above, the local authority, if satisfied that repairs are needed to make a house fit for human habitation, may serve a notice on the landlord requiring him within a certain time specified in the notice to execute all necessary works. The time named must be a reasonable one, and not less than 21 days. The landlord has an appeal to the County Court. If he fails to do the work required, the local authority may do it and sue the landlord for the expense incurred. The name and address of the local medical officer of health and of the landlord must be written in the rent book or given in writing to the tenant of a house that comes within the Act. When premises are dangerous or injurious to health, the local authority may make an order for the demolition of the house and may themselves demolish if the owner does not obey. *See House; Lease; Rent.*

**LANDRAIL.** A plump delicate small bird, the landrail, commonly called the corncrake, is in season from August 12 to the middle of September. It is usually roasted. When trussing, draw the head under the wing and skewer the thighs close to the sides. The bird should be plucked, drawn, and wiped inside with a cloth dipped in hot water, and before trussing lay inside a good lump of butter with a little chopped shallot and parsley. The time varies for roasting from 15 to 20 min., but the bird must be well basted. Serve with rich brown gravy, on fried crumbs.

### LANDSCAPE PHOTOGRAPHY

#### A Fascinating Branch of a Popular Hobby

In addition to a general article on Photography our work has articles on various kinds of photography, e.g.

Colour Photography, and on the choice and use of photographic apparatus, e.g. Camera. See also Developing; Focus; also Light Filter; Panchromatic, etc.

For satisfactory landscape photography it is almost essential to have a camera which has a focussing screen or a direct vision finder, and one that can be set upon a tripod for time exposures. The camera that possesses only the small so-called brilliant view-finder is almost useless, for the picture which can be seen in it is not only misleadingly bright, but it is far too small, and rarely shows accurately what will be found on the plate. The best help in composing a photographic picture is given by a focussing screen with a hood.

Composing a picture photographically means nothing more than selecting the best view point. To do this it is necessary not only to see how it looks to the eyes, but what the camera sees—which is a very different thing. The eye will miss objects in the foreground which, on the focussing screen, will be found to be too prominent, or to be out of focus because they are too near the camera. An insignificant bush, or even tall, waving grass may cover part of the plate with an out-of-focus blur. With a brilliant view-finder they would not be noticed, and the photograph would be spoilt. If the camera has no focussing screen, a direct vision finder, through which is seen the actual

portion of the view which will appear on the plate, provides a fairly satisfactory alternative, particularly if the photograph is to be taken with the camera held at the level of the eye.

*Landscape Photography. Fig. 1. Woodland view showing distance and interest gained by sharp focussing of foreground detail.*

The size of the camera is largely a matter of convenience. Such good lenses can be obtained with the modern small camera that satisfactory enlargements can be made from 3½ in. by 2½ in. negatives up to 12 in. by 10 in. A good tripod is essential in order that lengthy exposures may be given when occasion requires. A light aluminium one is best if much tramping about the country is to be done. It should be fitted with a ball and socket head so that the position of the camera itself may be adjusted without having to move the tripod legs with every change of position.

The amateur will find it best to use ortho-chromatic plates or films if he does not use panchromatic, which are generally preferred. Whichever he uses he should have one or two light filters to render the different tones. If he uses panchromatic plates or films, light filters are essential. The advantages of panchromatic plates or films are explained under the heading Panchromatic.

Only flat, white, toneless skies can be obtained with ordinary plates or films. Even if brilliantly lighted clouds are not present the tone value of the sky will be better represented on orthochromatic or panchromatic plates. No sky is completely toneless, whatever the weather conditions, and a photograph which represents it as a blank white space is false and inartistic.

For photographic purposes all landscapes should be viewed as series of different tones. The beginner is very apt to be taken with the beauty of the colour in the view before him, forgetting that the camera can only record the colours by monochrome tones of varying depths.

**Some Useful Hints.** The following hints will be of use to the amateur in landscape, but he should remember that the best results are only to be obtained by practice, by cultivating an eye for the composition or making of a picture, by severe criticism of his own photographs, and by the study of the work of others.

A common failing is a lack of sharpness of detail in the foreground of a photograph. The eye insists that objects near at hand should be sharp and clear to be convincing or satisfying. Fuzziness or woolliness of foreground objects betrays carelessness in the photographing, or failure to observe that some objects are too near the camera and out of focus. This does not mean that every object from the foreground to the farthest distance should necessarily be sharp and hard. An all-over sharpness destroys the atmosphere of the picture and brings its distant parts forward in an unpleasing fashion. Do not therefore stop down the lens too much in an effort to get sharpness.

Do not attempt to get too much on the plate at once. Conflicting interests particularly should be avoided. A primary rule in composition of any kind is to concentrate the interest. Everything in the view chosen should therefore be in harmony with, or subordinate to, some main feature. The view point should be shifted until the best possible composition is obtained.

The eye should be led on from the foreground through more or less clear middle distance to the more distant part of the scene, which should be comparatively soft. The best method is often that known as differential focussing, which, with moderately good lenses, gives very pleasing results. This means that while the foreground is moderately sharp, the focussing is so arranged that the more distant parts are progressively, though perhaps slightly, out of focus, thus the planes of a picture can be separated and a feeling of distance gained.

The amateur should not be misled by the grandeur of a great open space or of towering hills. Their small size in the resulting photograph is inevitably disappointing unless something is contained within the photograph to suggest distance or height.

The foreground of a landscape photograph should always have something to concentrate the interest and lead the eye onward. An example of this is seen in Fig. 1, where the cart tracks and sun on the beeches are the principal points of interest in the foreground. This is also a case of differential focussing. Had the trees in the farthest distance been as clear as those in the foreground all sense of depth in the wood would have been lost. Another method frequently adopted in building up a landscape photograph is to get the foreground interest and to make the distance recede by using trees as a frame. An example is seen in Fig. 3. This framing effect is the secret of much of the charm which photographs of scenes through archways often possess.

Finally, the amateur landscape photographer will be well advised to attempt no photographs unless the sun is shining. Grey weather inevitably gives grey and flat photographs; the best times are perhaps early morning and late afternoon, when the shadows are long and the

light contrasts are great. At these times a suggestion of mist softens distances.

*Fig. 2. Above, open landscape view from a hill-top in which the eye is led from the foreground by the chalk road. Distance is given by differential focussing. The three subjects reproduced are from panchromatic plates.*

*Fig. 3. Tree used as a frame for a view from a hillside, giving both foreground effect and throwing distance into proper perspective.*

**LANGSHAN.** This is one of the best all-round breeds of fowl, noted for combining good laying with excellent table qualities. Though principally bred in black, there are white and blue varieties, the plumage of the first-named being of a beautiful metallic green sheen.

It is conspicuous by its stately carriage, and the legs are slightly feathered, the feather line running down the outside of the legs to the toes. The hens are quiet and docile, making reliable sitters, and they lay a good-sized dark brown egg. The hardiness of the breed adapts it to all climates, positions and soils, and it also

does excellently in confinement. *See* Fowl; Poultry.

**LANOLIN.** Lanolin or hydrous wool-fat, which is obtained from sheep's wool, is a commonly used basis for ointments. As it is readily absorbed through the unbroken skin, drugs to be absorbed through the skin, especially mercury, are frequently incorporated with it. Lanolin is softer than ordinary woolfat, and as it penetrates into the skin it is a favourite basis for wrinkle-removing creams, skin foods, etc.

**LANTANA.** A shrubby plant, with verberna-like flowers of various colours, lantana is suitable for the greenhouse and for planting out of doors for the summer months. In autumn the plants must be lifted, potted and kept in a heated greenhouse. A compost of loam, leaf-mould and sand is suitable. Propagation is by cuttings in August; if repotted in spring they will be ready for use in summer flower beds early in June. The tops must be cut off to induce the development of side shoots. If the plants are kept for several years they should be pruned and repotted in spring.

**LANTERN.** A lantern is a transparent case enclosing a lamp or source of light, and it is found in numberless designs and types. The Chinese lantern, made with decorated paper and provided with a candle or nightlight, lends itself also to illumination by electric lamps. The hall lantern lighting fitting is commonly made with inserted panels of glass, suitable for gas or electric light, as well as oil lamps or candles.

The bull's-eye lantern has a small lens that throws a concentrated beam of light to a considerable distance. These are usually made with a device to cut off the light by turning the top, which turns an inner piece shaped like a tube and pierced with a hole for the passage of the light; thus when the tube is turned the light is obstructed.

Various types of folding lantern are suitable for campers and for holiday purposes, as they can be packed into small compass; they are available for oil or for candle illumination. Magic lanterns are optical projectors.

The first attention required with lanterns is to keep them clean. This applies to all types, but more particularly to those in which paraffin oil is the illuminant. Paraffin has a natural tendency to creep and cover everything with a film of oil, and unless this is removed with a dry cloth the lamp will smell in an objectionable manner, and the light will also suffer. The wicks should be kept well trimmed by smoothing them with a piece of flat wood wiped over the top of the wick when it is just above the level of the wick tube. To get the best illuminating results, the glasses must be kept in a perfectly clean condition.

**LANTERN SLIDE.** A lantern slide is a photograph on glass intended for showing on an enlarged scale on a screen by means of an optical or magic lantern. The standard English size of a slide is  $3\frac{1}{4}$  by  $3\frac{1}{4}$  in. Plates of this size are sold coated with

lantern or transparency emulsion. They may be obtained of either gaslight or bromide emulsion.

Lantern slides are made from photographic negatives. If the negative is a small one, or if only a portion of a large negative is to be utilized for the lantern slide, the latter is made by contact. The negative is placed in an ordinary printing frame, a sensitive lantern plate laid film to film with it, and, after the two have been pressed firmly into contact by springing in the back of the frame, the negative is exposed to the light of an electric bulb or incandescent gas for a time ranging from a second or so to several minutes, according to the density of the negative and speed of the lantern plate.

If the whole subject of a larger negative is to be included in the lantern slide, the reduction process is used, the large negative being photographed on to a lantern plate, using any convenient camera. A usual plan is to fix the negative in a frame attached to one end of a board; at the other end the camera is secured by means of a screw passing through a slot in the board, so that the position can be adjusted for focussing. The plate is then developed, fixed, washed, and dried.

Formulae for the solutions are given in the instructions for every commercial lantern plate.

To complete a lantern slide, a black paper mask is attached to it so as to cut off some of the margins, and give an exact shape to the picture. Two white paper disks, about  $\frac{1}{4}$  in. diameter, are stuck on the part of this mask above the picture. They are required as a guide to the lanternist when showing the slides. A clean cover glass is bound to the lantern slide with a gummed strip of paper. *See* Gaslight Paper; Optical Lantern; Photography.

**LAPAGERIA.** This is a Chilean evergreen climbing plant with slender stems and bearing large rose-red or white drooping lily-like flowers in spring and early summer. It likes cool conditions and thrives in a greenhouse facing north or east. A winter temperature of 40-45 degrees is high enough. In mild districts it can be grown out of doors on a partially shady wall. If trained on wires beneath the greenhouse roof it is very beautiful when in bloom.

**LAPDOG.** Among the small pet dogs favoured especially by women and often termed lapdogs is the King Charles spaniel (q.v.), the pug, the toy black and tan terrier and the Yorkshire terrier. The first-named is the black and tan variety of the old English toy spaniel, the others being the tri-colour, ruby, and Blenheim, which has rich chestnut red markings on a white ground.

In later times the Pomeranian came into fashion, at first too big to justify the appellation lapdog, as well as the Brussels griffon, which is quite small. The little Japanese at one time looked like becoming very popular, but was ousted by the Pekingese. Attempts

have been made to acclimatize the papillon, or butterfly dog of the Belgians, so called from the characteristic shape of his ears. *See Dog.*

**LAPEL.** The lapel is that part of the breast of a coat or overcoat that is turned back. The exact size and shape of the lapel, both on men's and women's coats, varies with the fashion, but their correct set is one of the marks of good tailoring.

**LAPIS LAZULI.** This is a mineral which has a very beautiful azure or ultramarine blue colour. Sometimes the stone is necked with white spots and bands. It takes a good polish, and is used for ornaments and for chains of beads. In jewelry it is best suited for daytime wear, as it appears almost black by artificial light.

**LAPPED JOINT.** In the simple form of joint known as lapped joints, one part overlaps the other, and the two are glued or nailed together. The lapped joint has been developed in many directions, as, for example, the lapping dovetail, in which the overlapping portion is dovetailed to the other portion. A lapped halving joint is one in which the one piece overlaps the other, and half of the substance of each is cut away so that their surfaces are flush.

Assuming that an ordinary lapped joint is to be made at right angles, the angle may be attained by the use of a square, as shown in the illustration. The upper piece of wood is set in place by the edge of the square, which is applied to it as a guide. The first nail is then driven and the accuracy again tested with the square, and if all is in order the jointing is completed by driving the remaining nails.

*Lapped Joint. Showing how to set the two parts of the framework square and true before hammering in the nails.*

Screws are put in on the same system, but in this case the gimlet is used to make the hole for the screw, and the work tested as before. In either case the parts can be adjusted by tapping them with a hammer or mallet to set them square after the first fixing has been made, as the two parts of the joint will then hold together by the friction between their faces.

When a square-cornered frame is to be made, as for a packing case, it is preferable to make the joint between two ends first, thus making two L-shaped parts, and then to join up these two, rather than to attempt to join up all the corners and then to expect them to come square. If the former method is followed it is known that the two opposite corners are square,

and it is then an easy matter to adjust the remaining two corners. *See Amateur Carpentry; Dovetail Joint; Joint, etc.*

**LAPPET.** The name denotes the process by which the goods are woven on the lappet loom, fitted with a special attachment. Lappets are cotton muslin with white or coloured dots, sprigs, or other simple designs formed by one continuous thread, and looking as though they had been embroidered on the cloth. They are considerably cheaper than muslins embroidered by a separate machine. Loose ends of thread are left at the end of each pattern. They are used chiefly for summer wear and are suitable for window curtains.

**LARCH.** The common larch (*Larix europea*) is a hardy non-evergreen tree which is ornamental in spring, when the young growth contrasts with the brown trunks and red cones; it reaches a height of 70 feet or more. It is good as a plantation tree, apart from the value of its clean, straight stems. In damp sites and on stiff soil it is particularly liable to the attacks of a fungus.

A closely related tree is the golden larch (*Pseudolarix kaempferi*), so called because of the autumn leaf colouring.

**Uses of the Wood.** The heart-wood of the European larch varies from a yellowish white to a reddish brown, and is usually straight grained. Its lightness and durability have brought it into use for sleepers, pit props, scaffold poles and ladders, while in carpentry it has the merit of being comparatively free from large loose knots. Its straight stems are welcome to the flower gardener for pergolas and arches or rustic bridges. Old pieces of larch with the base charred, creosoted or otherwise treated with a preservative, last many years. *See Arch; Wood.*

**LARD.** To be genuine, lard should be clear and colourless, but firm to the touch. It is obtained by melting in a pan over boiling water the inner fat lining of the pig, and also the fat surrounding the kidneys. As it melts it should be poured off, leaving the sediment. It is used for making cakes and pastry, either alone or mixed with butter. For all kinds of light frying, lard can be employed with advantage.

It is frequently adulterated by the admixture of the fat of other portions of the pig, also with veal and mutton fat. Lard should be kept in a cool place in a covered dish. *See Dripping; Frying.*

**LARDER.** In country and the larger types of town houses larders are often allotted a good floor space. In some of the modern houses they are replaced by a ventilated food store, which is practically a big, well arranged cupboard, augmented by a refrigerator. In very small flats perishable food is kept in a meat safe, and storage room is often merely supplemented by a

kitchen cabinet and vegetable rack. Wherever possible, a baby refrigerator should also be installed.

When the larder is separated from the kitchen it should be placed conveniently near. A northern aspect is always desirable, as it is essentially a cool room. If the larder has two windows, one may have glazed glass panes and the other be covered with a fine gauze wire or perforated zinc to exclude flies and dust, and allow free access of fresh air. If there is only one window, it should be kept open with a piece of white muslin fastened over it, which can be secured with drawing pins. The window sills may be lined with tiles or have fitted porcelain enamel covers. The ceiling should be whitewashed, and the floor of concrete, red tiles, or flags. The walls should be tiled, or, failing this, they can be either distempered or painted with sanitary paint or plainly whitewashed. If there is not sufficient ventilation by means of windows, it is a good plan to have a few perforated bricks let into the wall, and the panels of the door replaced by sheets of perforated zinc or wire gauze.

**Suitable Equipment.** The larder must be well equipped with shelves. Many modern larders have shelves of slate, marble or stone. Fixtures should include strong iron hooks fixed from the ceiling or hanging from iron rods running from wall to wall. Small hooks should also be fixed to the shelves.

In a good sized larder there may be accommodation for vegetables, which may take the form of either special wooden rack shelves or a wire rack hanging from the wall. Some wire covers of different sizes for covering cold meat are necessary, and a few hanging meat safes consisting of muslin stretched over wooden hoops will be useful, also plates, dishes and basins and, a large earthenware vessel for milk. A piece of muslin weighted by beads at the corners should be provided for covering the milk. Butter should be kept in a butter cooler, or in a bowl of salted water.

In a small house or flat where there is no special larder, and a cupboard has to do duty, it is best to set aside certain shelves for fresh foods and to cover such shelves with American cloth, or, better still, with slabs of slate. Meat must be placed in a special small safe. The table safe described in the article on Kitchen is the most suitable for a larder substitute.

Perfect cleanliness is essential in the larder, and the floors and shelves should be wiped daily with a damp cloth. When thoroughly cleaning, all food should be taken out and the woodwork or floor scrubbed with hot, soapy water to which some disinfectant has been added. *See Kitchen; Refrigerator; Store Room, etc.*

**LARDING.** The process of larding consists of running strips of fat bacon through meat by means of a larding needle. Dry portions of meat, such as the breast of poultry, beef fillet, liver, etc., are those most usually larded. A special kind of bacon can be bought for the purpose, but if preferred the fat of ordinary bacon may be used. The strips, which are usually about 2 in. long, should be threaded through the needle and the latter put in rather deeply across the grain of the meat. A

small stitch only should be made and an equal length of fat left at each end. About  $\frac{3}{4}$  in. should be left between each stitch.

**The Larding Needle.** This is a length of hollow, graduated steel. The thin end is pointed and the thick end is slit into four for the purpose of holding the strips of larding bacon called lardoons. These needles vary both in size and length and are from about 5 in. to 9 in. long.

**LARDIZABALA.** An evergreen climbing shrub, *Lardizabala bitermata* is familiar chiefly to dwellers in the south and west of England, as it is not hardy in cold districts. It should be planted in spring or autumn in well drained loam, peat and sand. Its purple flowers are borne in early winter, and it may be propagated by shoots struck under glass in autumn. It is chiefly suitable for the greenhouse.

**LARKSPUR.** This is the name popularly used for the annual delphiniums, of which there are some beautiful varieties. The pink larkspur is particularly attractive. Seeds are sown out of doors in April when the plants are to bloom in summer. *See Delphinium.*

**LARVA.** The term larva is applied to an insect emerging from its egg-stage in the form of a caterpillar, which may devour the foliage, stems, or roots of plants. Although most of the damage to crops results from the activities of larvae, the prudent gardener will not fail to wage war against the adult insects, be they beetles, moths, or butterflies, because it is during this stage that they deposit their eggs upon growing crops. *See Insect; Insecticide.*

**LARYNGITIS.** Inflammation of the larynx is caused mainly by cold or excessive use of the voice, the chief symptoms being hoarseness and cough, with difficulty in swallowing food in severe cases, and in breathing, especially in children. The patient should be kept in bed and the temperature of the room should be about 65°. Wring out a piece of flannel in hot water and apply it to the neck, keeping in the heat by covering with a piece of oiled silk. Warm drinks such as barley water or weak tea may be given.

Inhalations of steam give relief; to each pint of water add 1 or 2 teaspoonfuls of compound tincture of benzoin or 10 drops of carbolic acid or creosote. A spray may be used consisting of equal parts of sodium bicarbonate, borax, common salt and white sugar. A saltspoonful is dissolved in 2 tablespoonfuls of warm water.

The chronic form of laryngitis is common amongst singers, clergymen and others. The voice requires complete rest, and the patient must not breathe through the mouth. The use of tobacco and alcohol is forbidden; theatres and crowded places should be avoided. A month at the seaside often works wonders.

Beneficial results are mainly to be looked for by the employment of sprays or inhalations. *See Inhalation.*

**LARYNX.** The vocal cords of the larynx produce the voice, which is modified by the agency of lips, teeth, tongue, and throat. The larynx is a box formed of cartilage extending from behind the tongue to the top of the windpipe, and projecting in the front of the neck to form the Adam's apple. The epiglottis forms a sort of lid to the larynx.

The vocal cords are two pairs of bands one above the other, which stretch across the larynx a little below the most prominent part of the Adam's apple. The upper pair of these ligaments are known as the false and the lower as the true vocal cords. When stretched they produce a high-pitched sound, when relaxed a sound of low pitch. During inspiration the cords move apart, during expiration they approach one another, and when a sound is produced they come very close together.

**LASSAR'S PASTE.** For eczema and other skin diseases a favourite remedy is Lassar's paste, which is made up as follows: zinc oxide, 48 parts; salicylic acid, 4; starch, 48; vaseline, 100.

**LAST:** For Boot-making. The last used by bootmakers is a piece of wood, preferably beech, or iron, in the shape of the foot, usually made in two pieces and hinged, and on this the boot is fashioned. The leather inner sole is placed upon the bottom of the last, and the boot upper, all ready and sewn together, is tacked to the inner sole, thus fashioning the upper to the shape of the last and forming the base for the middle and for the outer sole.

Lasts are made in all sizes, with as many as eight different fittings or sub-sizes to each size. Regular customers of a bootmaker frequently prefer to have their own last, in order to ensure a perfect fit. The foot is measured with a tape or a pedometer, which gives such exact measurements to the last-maker that he can produce a perfectly anatomical model of the customer's foot in wood. Plaster casts are often used for a crippled or otherwise abnormal foot. *See Boots.*

**LASTING.** Exceptionally firm, strong and heavy cloths resembling linings are known as lastings. They are generally black, but can be made in other colours. House boots and slippers are sometimes made with lasting, instead of leather, uppers. Hard, smooth and unstretching, lasting is useful for the binding of account books.

**LASTREA.** The shield, male, and buckler ferns belong to Lastrea (nephrodium). Most of them need greenhouse culture, but a few are hardy. The indoor species need a peaty soil and a shaded corner of the greenhouse. Hardy kinds are best when grown in a shady corner in soil to which leaf-mould has been added. The common male fern, of which there are many beautiful varieties, is Lastrea (nephrodium) filix-mas. Propagation is by spores sown under glass.

**LATAKIA.** One of the most costly items in the tobacco blender's store is the dark, almost black, aromatic leaf which is grown in the neighbourhood of Latakia in N. Syria. It imparts a distinctive flavour to the more expensive mixtures sold in Great Britain, and also makes for cool smoking, but it is not liked by all smokers, and consequently retailers generally supply mixtures without latakia as well as with it. It is treated by fumigation before it is ready for the market. *See Tobacco.* Pron. Lat-a-kee-a.

**Latania.** This is a greenhouse palm with bright green, fan-shaped leaves. It needs the same treatment as kentia (q.v.).

**LATCH.** The latch is a device to keep a door, window, or other movable part closed, and does not as a rule require a special key, as in the case of a lock. Simple latches are made in the form of a pivoted bar that drops into a slot, other forms being actuated by a handle or a spring. Some varieties combine the functions of a latch and a bolt; several types of spring lock are known as latches, such as the night latch, which is closed by shutting the door, but can only be opened from the outside by a latch-key.

*Latch. Fig. 1. Mechanism of the secret latch.*

*Fig. 2. Gate latch with part of woodwork cut away to show structure of latch.*

**The Norfolk Latch.** One of the best known types for the home is the Norfolk latch. This comprises a handle, and a plate that is screwed to the door; above the handle is a thumb latch which when depressed raises the other end of the lever of which it forms a part, and this in turn raises the catch which is screwed to the other side of the door, and drops into a striker or notched plate attached to the door frame. Variations are the Suffolk and the Canadian latches, both of which are in substance the same as the Norfolk, though

the Canadian has a somewhat shorter catch.

Fig. 3. Gothic latch for an entrance door.

Fig. 4. Thumb latch combined with door-handle.

**A Secret Latch.** The secret latch is a pattern that is useful on cabinets and other furniture, shop fittings and the like. It is a simple spring latch, and is released by pressing on a circular plate let in flush with the surface, so as to be inconspicuous. Fig. 1 is an example of this type of latch.

**Other Types.** The gate latch which is illustrated in Fig. 2 is made in cast iron, and screws to the surface of the gate. The striker is made, as indicated, to fix to the edge of a frame, or with a flat plate to fix to the face of the gate post. Patterns are also made to build into brickwork, and for stone or concrete gate posts.

A pattern of latch that has developed from the same style is illustrated in Fig. 3, which shows a typical Gothic gate latch. It is made of malleable iron, finished in Berlin black, and varieties have ring and other shaped handles. There is a square hole in the boss or hub to which a short shaft is fitted. This shaft passes through the door and connects with the boss of the handle on the other side.

The thumb latch seen in Fig. 4 is of the Norfolk type; it is used with the Gothic gate latch, and takes the place of the drop or ring handle and cross shaft. The bow latch shown in Fig. 5, still used in old houses, is a link between the earlier varieties and the modern type of night latch. It has a pivoted lever actuated by a handle, which is shown separately, and the latch is pressed down by a spring. The handles are fixed to a square shaft that passes through a hole in the end of the lever; when the handle is turned the lever is raised and the door released. There is also a bolt which can only be actuated from the inside of the room. When shot, it slides behind the round-headed knob that projects from the striking plate. The lever drops behind the top of the same knob, which thus does duty as a fastening for both lever and bolt.

The rim latch, shown in Fig. 6, is a development of the bow latch, but is enclosed in a case; it has a spring-pressed latch which can be drawn back by the handle

and is controlled by a separate bolt and a slider. The night latch is made in many forms; for example, the pin tumbler type, Fig. 7, and the mortise night latch, which fits into a recess or mortise cut into the edge of a door. A handle is fitted on either side of the door, and these are attached to a squared shaft by means of a set-screw or a fixing pin; thus, when the handle is turned the latch is drawn back. In some varieties there is only one handle, on the inside of the door, and a key is needed to shoot back the latch from the outside; in others the outside handle is not attached to the shaft, but directly to the door. See Door; Gate; Lock.

Latch. Fig. 5. Mechanism of the bow latch.

Fig. 6. Rim latch which is enclosed in a case.

Fig. 7. Constituent parts of pin tumbler type of night latch.

**LATH: In Building.** The principal use of the lath, which is a thin, narrow slat of wood or other material, is to construct a lath and plaster partition in a building. Laths are required for the repair of ceilings, and are

useful in the home for such purposes as making packing crates and chicken coops, and also for trellis-work. Laths are usually 1 in. wide, and are made in lengths up to 4 ft. 6 in. The sizes are: lath 3/16 in. thick, lath and a half 1/4 in. thick, and strong or double lath 5/16 in. thick.

In making a lath and plaster partition a framework of timber is provided to which the laths are nailed. The frames should be so positioned that there is a support for the laths at a distance of not more than 12 to 14 in. apart, when they are at right angles to the studding or framework. The laths should always break joint; that is, the ends should not all come over each other. This may be done by fixing, say, 8 or 10 laths, with their joints on the middle stud; the next set should come on another stud, as in the illustration. If this were not done the vibration would be likely to cause the plaster to crack along the joint, since all the lathing would then bend along the same line. The laths are fixed about 1/4 in. to 3/8 in. apart, and the best nails to use are ordinary 1 in. French or lath nails. When it is necessary to fix lathing to a wide piece of wood, as, for example, to a boarded part of the work, the laths must not be nailed directly to it, but to a set of underlying laths or battens at right angles to the face laths. This is done to provide room for the plaster at the back of the laths, as the plaster has to be pressed through the gaps between the lathing to form the key that prevents the plaster breaking away.

*Lath. Showing how the laths are nailed to the wooden studs or uprights in the construction of a lath and plaster partition.*

Metal lathing is used for the same purposes in the form of a sheet of perforated or expanded metal, the interstices providing the key for the plaster. This lathing is fireproof, and valuable for many building purposes.

**Lath Nail.** This is a wire nail with a fairly large, round, flat head, used principally for nailing laths to studding, in the early stages of making a lath and plaster partition or other structure. Common sizes are 1 in. and 1 1/4 in. in length and No. 16 gauge in thickness. *See Building; Ceiling; Eaves; Furring; Nail; Plaster; Roof.*

## LATHES FOR AMATEUR WORK

### Describing the Different Types and their Uses

This article is complementary to those on Metal Turning and Wood Turning. *See also Amateur Carpentry; Centre; Chuck; Drilling; Mandrel; Milling, etc.*

A lathe is an indispensable tool to the amateur

craftsman, as by its aid all manner of circular objects can be produced within the capacity of the tool. Essentially, the lathe consists of five parts. The head stock comprises a spindle, called a mandrel, which turns in bearings formed in the body of the head stock. The spindle is provided with a flat or V-shaped pulley, generally with several steps of different diameter. The end of the mandrel is screwed for the attachment of various devices for holding the work.

The head stock is fixed at the left-hand end to a bar known as the bed. A movable part, called the tail stock, is usually provided with a spindle, which can be pushed in and out of the tail stock body by means of a lever or hand wheel and screw. The tool rest is also movably attached to the bed, and is used as a support for hand tools. Most lathes for metal turning have a mechanical tool-handling device, known as a slide rest. The next feature is a stand or support of some kind, and may take the form of short feet projecting from the bed and raising it about 6 in. above the surface of the table or bench to which they are screwed; or preferably strong legs well braced together and extending from the floor to the bed itself. Means of driving or rotating the mandrel have to be provided. This usually takes the form of a heavy fly-wheel with steps or grooves turned upon its rim, varying in diameter, and corresponding with the proportions of the steps on the mandrel pulley. In the case of a bench lathe, that is, one which is screwed to the top of the work bench, the fly-wheel is mounted upon a light stand complete with a treadle, forming a foot motor. On other types the fly-wheel is mounted on a spindle attached to the left-hand standard. A flat or round belt transmits the motion from the fly-wheel to the mandrel. Motion is imparted to the fly-wheel by pressing upon the treadle with the foot, working always with a regular, steady motion, so that the lathe revolves at a uniform rate.

**Types of Lathes.** These range from simple wood-turning machines to elaborate screw-cutting lathes, which have a set of gear-wheels and a long threaded steel shaft known as a lead screw. This is connected to the slide rest, which is free to slide along the bed, and has an independent part known as a top slide, which also has a little lead screw of its own and propels the tool holder. The tool is clamped into the tool post on the top of the tool holder, and it is possible to traverse the tool along the length of the bed, an operation known as sliding. By turning the top slide lead screw, the tool is traversed across the bed. Twisting the top slide at an angle to the bed causes the work to be turned to a taper, and is known as angular turning. Turning at right angles or across the bed is known as surfacing.

Screw cutting is effected by connecting the lead screw to the mandrel by a train of spur gears, and arranging their ratio so that the lead screw makes a certain predetermined number of turns per minute, while the mandrel makes another number of turns. Consequently, if the tool is mounted in the tool post

and brought into cut, so that when the point of the tool touches the work it will remove shavings, a long, continuous groove or screw thread is formed upon the work held between the centres of the lathe.

Modern small lathes, of which three are illustrated, include a variety of mechanical devices. In all lathe work, whether turning wood or metal, the work has to be held in one of two ways. It may be bolted or otherwise attached to a disk of metal screwed on to the mandrel nose, and called a face plate, or held in some form of chuck, in which case the turning operation is generally known as face-plate or chuck work. The other method, especially applicable to the case of relatively long spindles or rods, is to mount them between centres. This means that one end of the rod is supported by a point centre placed in the end of the mandrel, the opposite end of the work being supported by a similar centre in the tail stock spindle. The ends of the rod have to be drilled and countersunk to form a bearing for the ends of the point centres. The next step is to fix a clamp called a carrier to one end of the bar, and to screw on to the mandrel nose a small, flat plate with a peg projecting from it and called a driver plate. The peg engages with the back of the carrier, and when the mandrel is rotated thereby rotates the work. The tool is either a hand tool, or a slide rest tool mechanically held in the slide rest.

Generally speaking, all wood turning, as far as the amateur worker is concerned, can be carried out with hand turning tools. Metal turning is usually effected by the use of the slide rest, even quite inexpensive lathes being now provided with a slide rest.

Figs. 1 and 2 show a Drummond lathe with  $3\frac{1}{2}$  in. centres. The leading features are indicated in the diagram, Fig. 1, which shows the lathe arranged as a bench machine. A lathe of another type, especially adapted for the model maker, is shown in Fig. 3. This has a bed of hollow, circular form, enclosing the lead screw. The height of centres is 4 in.

Fig. 4 shows a representative small lathe of American design which is on sale in Britain. This is the "South Bend" Workshop Lathe, with  $4\frac{1}{2}$  in. centres. Provision is made for direct electric drive, the motor being bolted adjustably to the stand carrying the countershaft. The drive is thus horizontal, forming a compact assembly. The principal features are indicated by reference letters in the caption to the picture.

**Essential Points.** Points that should be looked for in any lathe include the following. The mandrel should be made of highest class steel, and rotate easily but without the least trace of shake in adjustable bearings. The moving parts should operate smoothly, easily, and without shake. The centre of the mandrel and the centre of the tail stock should always be in the same line, no matter into what position the tail stock is moved. For wood turning, the fly-wheel should be large in diameter and the mandrel pulley small, as high speed is essential. For metal turning, the fly-wheel should be smaller and the mandrel pulley larger. There should be a difference in the stepping ratios, that is, one large diameter step on the fly-wheel and a small diameter on

the mandrel pulley for wood turning. The intermediate position should be provided, and in addition a small step on the fly-wheel, in conjunction with as large a diameter on the mandrel pulley as possible, for turning cast iron. Metal-turning lathes, intended for turning cast iron, are preferably fitted with a mechanical speed-reducing arrangement known as a back gear (*see* Fig. 1). The treadle should be so arranged that if the foot is accidentally placed beneath it the connecting rod will automatically be thrown off the crank pin, otherwise the foot may be severely injured.

The lathe as a whole should be stiff, rigid, and strong, so that when in use it does not vibrate or shake about, as this is fatal to good work. Chucks, tools, and accessories can be added to it from time to time as occasion demands. The bearings must be kept free from dirt and frequently oiled.

*See next page for images of lathes.*

**LATHER.** Soap and hot water stirred together form a thick froth or lather. It is used in laundering certain fragile materials which would suffer if rubbed with soap, the garments being squeezed in the froth until they are clean. A lather is also necessary for shaving, special soaps being prepared for the purpose. A quick method of producing a lather for washing is to shread some soap into a bowl, pour boiling water over it and stir with a stick. This will be found satisfactory for most purposes. *See* Water Softener; Laundry; Shampoo; Shaving.

**LATTICE.** A lattice is an openwork structure of wood, metal, or other material, formed by crossing or interlacing strips of material. Such a structure is often used to cover a window, to form a screen, or to protect a doorway. In lattice work all that is necessary is to cut strips of material to requisite lengths and, if working in metal, to drill them at regular intervals for the rivets. When wood is used it will suffice to nail the strips together. To ensure uniformity, the strips may be guided in position by means of a simple space jig, made from a batten having notches cut in its edge at regular distances corresponding to the desired spacing.

In use, one set of strips is laid on the bench or other support, and spaced by placing the notched batten upon them, so that a strip is held in each notch. The first of the next series, which run in the opposite direction, is laid up against the batten, and nailed to the first set of strips. The batten is then removed and turned at right angles, and one of the notches placed over the strip just nailed on. The other strips are put into position into the notches and similarly nailed and fixed. The batten is then removed towards the end of the strip and the joints nailed together.

(R. Melhuish, Ltd., London)*

This article will be helpful to the housewife who wishes to economize by doing the laundry work at home. See further the entries on Clothes Line; Clothes Peg; Copper; Dolly; Mangle; Soap; Starch, and those on the materials washed, e.g. Cretonne; Lace; Linen; Silk. See also Bleaching; Ironing; Labour Saving; Stain.

The laundry work for a large family can only be satisfactorily done with space and equipment and a place set apart for its performance. The floor should be of concrete, tiles or brick, with a fall to one corner where there is a drain or outlet, so that the floor can be washed down at any time. There should be good light and ventilation, together with sufficient space for the various appliances. It is sometimes possible to arrange a small laundry in the scullery by converting the kitchen into a combined kitchen and scullery, fitting a new sink and connecting the waste-pipe to the nearest trapped gully. Due regard must be paid to the by-laws of the local authorities. Scrupulous cleanliness is essential in any laundry and the walls should be finished with tiles or washable paint.

The first requirements for this task are an ample supply of hot water and a convenient means for boiling. These requirements can be met in most cases by a portable copper, which is placed in a corner, and the smoke-pipe taken to the nearest flue, or carried out through the roof or walls. The hot water can be drawn off from a tap fixed in the lower part of the copper, while the cold supply is provided by a separate pipe terminating in a tap over the top of the copper. Many varieties of copper are available for heating with solid fuel or gas; it is best to choose one with a galvanized case and tinned copper pan.

A strong bench should be fixed along one side of the laundry for the washing-tubs, if hand-washing is to be undertaken. If a washing machine is used, less space will be required. There is a large variety of these appliances both electrically and gas driven and also non-gas. The task of washing is lightened by these machines. Compact machines can be purchased from about three to ten pounds by means of which rubbing the clothes by hand is eliminated, the hot soapy water being forced through the fabric automatically. Afterwards the garments are removed for rinsing.

A mangle or wringer is also an asset, and small compact mangles can be used even when laundry work has to be done in the kitchen. One variety of mangle fits on to the kitchen table. A wringer is obtainable which is fitted with a table top. Another useful type is combined with a washing machine. Four castors enable this machine to be easily moved about. It has rubber rollers, and pressure is secured for wringing or mangling by screws which operate through powerful double springs.

Probably the chief difficulty for the housewife is the drying of the clothes after they have been washed, especially in bad weather. The most economical plan is to fix cords, or smooth wooden slats, across the ceiling and as near to it as possible, supporting the ends of the slats by ropes which run over pulleys fixed to the walls. By means of the pulleys the slats can be raised or lowered without difficulty. With such an arrangement,

if a small amount of ventilation is provided near the top, a heating stove can be lighted overnight and the laundry closed, the clothes being generally dry by the morning without further trouble. Ready-made ceiling drier fixtures are obtainable.

Another plan is to make a cupboard-like structure, preferably with asbestos cement sheets, and hang the wet clothes in it. Hot-air pipes should be led around the interior of this cupboard, and may be heated by means of a small oil stove, gas ring, or other convenient means, much on the lines of the heated linen cupboard. The apparatus may follow the general principle of construction adopted for greenhouse heating, and hot-water pipes can be used instead of hot air.

**Other Simpler Appliances.** For laundry on a big scale wicker baskets are required for storage of the clothes. Where sufficient space is available a good solid table should be provided, and if possible should be of such a size that one or more of the laundry baskets can be stored beneath it. The irons, soap, scrubbing brushes, etc., should be housed in a cupboard. The use of electric or gas irons not only saves the cost of a heating stove, but keeps down the temperature. Besides the more important furnishing equipment the home laundry requires one or two galvanized tubs, an ironing table or board, sleeve board (essential when ironing sleeves), enamelled basins for washing smaller articles and for starch, a wooden spoon, clothes line, clothes rack or horse and clothes pegs. A wooden dolly and tub may be useful where there is no washing machine. A small washer is obtainable which has a strap that fits over the hand and a surface that squeezes out the dirt without damaging the material, but thus saving the knuckles. The indoor clothes line illustrated is a convenience to the housewife who only has a small kitchen in which to do the washing. The required length of line is drawn out of the container and fastened temporarily by the ring on to a hook on wall or dresser. By a device the handle fixes the line tautly. An attachment with arms is procurable for the clothes horse.

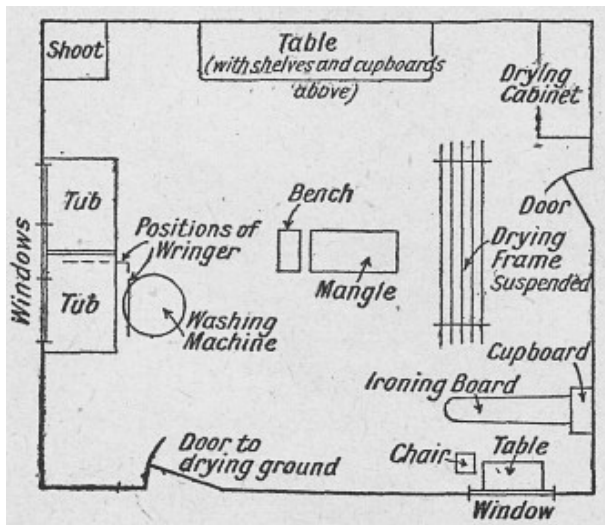

*Laundry. Indoor clothes line; the handle can be fixed so that any length of line is made taut.*

**Practical Suggestions.** Unnecessary stooping must be avoided by taking care that washing and rinsing tubs are not placed either too high or too low. Washing machine, rinsing tubs, mangle or wringer should be placed near together to avoid unnecessary steps to and fro.

Select one day a week or fortnight for laundry work and avoid doing any other unnecessary housework on that day. Either a Monday or Tuesday is the best day to choose, as when the weather is bad for drying it

leaves several days in which the drying, ironing, and airing can be completed before the week-end.

*Laundry. Arrangement of a laundry, for which a basement room or an outbuilding could be used.*

Mend all clothes before they are washed; this prevents rents and holes from becoming further torn during the washing process.

Make soap solution and starch the previous day, if possible. Ecu starch is obtainable which tints and starches curtains, etc., at the same time. Keep in stock hard soap, borax, and washing powder. Soda turns white materials yellow.

Soak any badly soiled clothes overnight in cold water. Remove any stains that may be on the clothes. Prepare the copper and light the fire early. While the water is getting hot, sort the clothes in the following heaps: white and coloured woollens; silks; fine things and table linen, handkerchiefs, bed linen, and upstairs towels; coarse things; coloured articles.

If the entire wash is to be done on one day, the silks and woollens should be washed first, so that they may be dried quickly, followed by the coloured things. Entirely fresh water must be used for the white wash, or the clothes will not be a good colour.

**Softening the Water.** The softening of the water is a problem which must be solved by every laundress before dirt can be removed from the clothes. Where a water-softening apparatus is not installed, some housewives prefer to use borax, others rely on one of the prepared soap powders.

Whichever method of softening is selected, it must be remembered that no cleansing can take place whilst the water is hard and soap curd is visible. All the soap that is rubbed on to the clothes or added to the water, as dissolved soap or jelly, combines with the dissolved minerals in the water and forms soap curd. More soap must be added until there are no minerals left with which it can combine; the surplus soap forms a lather. A lather is merely a sign that free soap is present in the water. When washing new garments that contain dressing soap curd may appear in water which previously was very soapy. Should this occur additional soap

must be added to the water.

Always wash the cleanest things first. Any new clothes and handkerchiefs should be rubbed out separately in a little soapy water. This economizes washing waters, as they do not get dirty so readily. Where no washing aids are available, prepare two baths of soapy water. Rub the garment all over in the first bath; when clean, wring out, turn garments and pillowcases on to the wrong side, and wash again in the second bath of clean water. Any very soiled parts, such as collars, cuffs, and neckbands, need special hard rubbing. Wring the things from the second water and rub on a little hard soap before rinsing.

When washing woollens, fine work or coloured articles, soap flakes are usually the best cleansing agent. Coloured things can be kept without fading if the soapy lather is allowed to cool before use. The garments should be washed quickly, never wrung out if of fine materials, but wrapped separately in clean cloths and the water gently squeezed out by a kneading process.

### How to Wash Delicate Fabrics

Small lace handkerchiefs, georgette collars and cuffs, can be put into a preserving jar with a screw top, filled with a warm, soapy lather and shaken vigorously. When clean they may be rinsed in the same way. This method obviates any damage by rubbing the delicate fabrics. Chiffon or net can be washed in a clean muslin bag by placing it in warm, soapy lather and gently squeezing out the dirt. Afterwards the articles are rinsed in the bag by placing it in clean, warm water. Rinse again, in fresh water, until no soapy moisture comes from the bag when it is kneaded.

Only handkerchiefs, kitchen cloths and the heavier white cotton and linen articles should be boiled to keep them a good colour. Underclothing or table linen should not be boiled in the same water as soiled kitchen cloths or towels, etc. Arrange for two boilings. The water in the copper should contain plenty of soap, and it should not be boiling when the clothes are first put in, but should be allowed to reach boiling point moderately slowly. Boil for 20-30 minutes.

The next process is the rinsing and blueing. Take the clothes from the boiler, and rinse them thoroughly in plenty of clean, warm water to remove the soap. If a large wash is in progress it is better to rinse first in warm water, then in cold. Prepare a bath of blue water, and blue one or two things only at a time, as if garments are left in the blue water the colour settles in streaks and is difficult to remove. The same thing results if the blue water is made and left to settle before used.

After blueing, wring and hang those things out to dry that do not need starching. Whilst these are drying, starch table linen, collars, aprons, etc. Things that do not actually require starching, such as pillow-slips, sheets, and lace-trimmed mats, etc., may yet be improved in appearance by passing through starch water, which gives them just a slight firmness. Exactly

which things should be starched depends on individual taste.

Damping and folding are the final stages. Take in the clothes when nearly dry. Those things requiring careful ironing will need further damping with cold water, but woven underwear, towels, etc.. can be folded ready for ironing. These will naturally require a little damping if they have been allowed to get bone dry. Roll up all fancy things tightly and leave for several hours before ironing, preferably overnight. The labour of ironing is minimized if large things that can be folded flat are mangled after damping; this removes a large proportion of the creases in the garments. The clothes are then ready for ironing.

**LAUREL.** The laurel is grouped by botanists as a section of the group or genus *Prunus* which includes the almond, apricot, plum and cherry. The common laurel (*Prunus laurocerasus*) is a vigorous shrub with large evergreen leaves, often used to form a hedge; it impoverishes the surrounding soil and is not suitable for small gardens. Old overgrown hedges may be cut hard back in April. Cuttings form roots if inserted in sandy soil in a frame in August. The Portugal laurel (*Prunus lusitanica*) and its myrtle-leaved variety are handsome evergreens. The best time to transplant laurels is in May or September, and it is advisable to put in small specimens, because they become established more quickly than large ones.

**LAURUS.** *Laurus nobilis*, the sweet bay, a favourite evergreen shrub with fragrant leaves, is not very hardy. It is usually grown in large pots or tubs, and if placed out of doors for the summer must be brought under cover before winter and kept safe from frost. In mild districts it may be planted out of doors. Propagation is by cuttings in sandy soil in a frame in August.

**LAURUSTINUS.** This hardy evergreen shrub (*Viburnum tinus*) grows 5 to 6 ft. high and bears pink buds which open to white flowers in autumn, winter and early spring. It flourishes in ordinary soil.

*Laurustinus.*  
Clustered blossoms of the beautiful winter flowering evergreen.

#### LAVATERA.

The rose mallow (*Lavatera trimestris*) is one of the most beautiful hardy annuals. There are several improved varieties, e.g. Loveliness, which has large, rose-pink flowers on plants 2 to 3 ft. high. Seeds are sown out of doors in spring for summer flowers. The

tree mallow (*Lavatera olbia*) is of vigorous shrubby growth, forming a bush 4 to 5 ft. high and bearing carmine rose flowers for many summer weeks. It may not survive the winter in heavy soil, but is raised from seeds sown under glass in spring.

*Lavatera.* Beautiful rose-pink flowers of the annual lavatera or rose mallow

#### LAVATORY.

A lavatory is a place for washing. The word is sometimes used in the home, but more usually cloakroom is the term employed for it.

**The Lavatory Brush.** Although chemical salts and acids are available for dealing with the closet pan when it becomes discoloured or furred, the use of the lavatory brush will keep the pan in sanitary condition. The two standard designs are a long, round handle with a dome-shaped brush at the end, and a flat brush similar to a long-handled bath brush. If preferred a flat brush is obtainable with a half-round dome end. Stiff bass, bassine, fibre, or cocoa-fibre are the materials used, a serviceable quality being a mixture of bassine and fibre known as union. *See Basin; Brush; Water Closet.*

**LAVENDER: The Plant.** The sweet-scented garden lavender is a half-shrubby plant, with greyish leaves and purple flowers. Its thick, ragged-barked stem, 2 ft. high, branches above into a broad bushy head. The flowers are produced in long, erect spikes. It makes an admirable hedge. For the purposes of perfume manufacture it is grown by the acre in Essex and Kent, and to a lesser extent in Surrey.

*Lavender.* Purple heads of the sweet-scented garden plant.

As a garden plant lavender thrives best on warm light soils, and may be planted either in spring or autumn. The plants should be about 18 in. apart every way. Lavender is propagated by cuttings inserted outdoors or in a frame in September. The proper time for gathering lavender for distilling or drying is when the flowers are fully expanded and fresh. The Munstead lavender blooms very freely and blossoms earlier than the common kind.

**Domestic Uses.** Lavender should be cut when it is in full bloom and spread out to dry on a newspaper,

either in the sun, on the rack of the kitchen range, or in a hot linen cupboard. When quite dry it may be made up into bags, sachets, or whatever form of scent-container is required.

Lavender bags may be made from organdie or butter muslin. This is cut to the size required, and the sides run up in the ordinary way. A bunch of lavender is inserted, heads downward, and the opening made fast with cotton firmly stitched, or tied with narrow mauve ribbon. The stalks are then cut neatly until only a few inches remain. This method has the advantage of retaining the perfume longer than if the stalks were removed.

**Lavender Vinegar.** A refreshing toilet preparation with mild astringent property is made by mixing 6 parts of rosewater, 1 part of spirits of lavender, and 2 parts of Orleans vinegar. It can also be prepared from freshly-gathered lavender flower tops. These are dried, placed in a stopped bottle and steeped for a week in Orleans vinegar. Every day the bottle must be shaken, and at the end of the week the liquid is drained off and filtered through white blotting paper or through a filter paper bought from a chemist.

**Lavender Water.** This toilet preparation is easily prepared at home. Into a quart bottle are put 1 oz. essential oil of lavender, 1 drop musk and 1½ pints spirit of wine. These three ingredients are well mixed together by shaking. The mixture is left to settle, shaken again in a few days, then poured into perfume bottles with airtight stoppers. *See Scent.*

### THE LAWN: ITS MAKING & MAINTAINING How to Get the Best Results with this Desirable Garden Feature

The amateur gardener who is interested in this subject should consult also the articles Garden; Grass; Soil and others of that kind, while, when the lawn is made, those on Croquet; Lawn Tennis will be found useful. *See also Drainage; Edging; Spirit Level.*

The lawn is an expanse of turf in the garden, generally adjacent to the dwelling-house. If it is to look well and wear well, the laying-out and maintenance are matters requiring careful attention, especially in regard to soil and drainage. Heavy soil in which clay preponderates will speedily stagnate if water does not drain off easily, therefore road grit and leaf-mould should be added while digging proceeds. Light sandy soil requires manure, so that moisture may be conserved and parching prevented during a season of drought.

Large lawns which become sodden should be drained by pipes, laid in the way shown in the diagram. The pipes should be laid about 12 in. deep and slope gradually to a sump or outlet. Where branch pipes meet the main drain they need packing above the junction with slats, tiles, or stones. Open ends of drains must not be near the roots of trees or strong-growing creepers, as these eventually choke the inlets.

**Levelling.** Levelling a site is not such a difficult task as it appears to be. The implements necessary, with the exception of a true spirit level, are a number of wooden pegs; a, straight-edge board, 6 ft. or more in length; and a strong garden-line. First ascertain the centre level by stretching the line from top to bottom of the plot. Then drive one of the wooden pegs into the highest end of the site to just above the surface of the soil, following this with another peg down the line at a distance something less than the length of the straight-edge. Do not drive it far in at first, but gauge the relative depth by placing the straight-edge on the two pegs, with the spirit level on top, and sinking it further until exact level between the two is secured, carrying on in the same manner the whole length of the line, when a true centre level will result. Cross level must next be ascertained, working on the same principle across the garden, and securing the level from those pegs already in the ground. The whole procedure is made clear in the next page.

**Grassing.** The two best methods of grassing a plot are by laying turves or by sowing seed, the former possessing the advantage of forming a sward almost at once. It is essential, however, that turf should be of good heart, and free from such weeds as daisy, crowfoot, dandelion, and plantain. Turves are usually obtainable in lengths of 3 ft. by 1 ft., and it is easy to estimate the number required, allowing for spoilage.

If a lawn is not immediately required, seed-sowing has much to recommend it. Any seed, however, will not suit every kind of soil; a mixture that is excellent for dry, light land may fail on moist loam. Consequently it is advisable to order the seed from one of the reliable seedsmen who specialize in grass mixtures, mentioning the particular class of soil for which it is required. Provided there has been thorough preparation of the plot, and a suitable mixture of grasses obtained, excellent lawns may be secured economically from seed, 3lb. being sufficient for about 30 sq. yd.

The best time for sowing is April or August-September. The soil must be dug over, levelled and made "fine" on the surface. Choose a calm day for sowing, scattering the seed with a swinging motion, first down the plot and then across.

Strands of black cotton should be tied on sticks a few feet apart, as well as with rag flutterers and rattles of tin and glass, to scare away the birds. Cutting should not be attempted until growth has reached a height of 5 in., and then only light topping with a scythe until the roots are strong enough to stand cutting with a mowing-machine.

The most suitable time for laying turves is between autumn and spring, laying them evenly down so that they join lightly together. Fit them in position so that open seams will not occur, and dump them firmly with a wooden beater as pictured in the diagram. This

useful implement can be made at home. To keep the lawn at its best, watering must be done freely in dry weather and always in the evening. When a lawn is established and growing vigorously, the mower without its collecting-box may be run lightly over the grass, leaving the slight trimmings as they fall to act as a mulch, and as a protection during hot days. As a rule mowing should be performed when the grass is dry.

**Lawn Sand.** A preparation of sand and chemicals, known as lawn sand, acts as a destroyer of certain lawn weeds, and as a fertilizer to stimulate the growth of lawn grass itself. Lawn sand may be purchased prepared, but may be made, if desired, by thoroughly mixing  $\frac{1}{2}$  lb. of finely pulverized sulphate of iron,  $1\frac{1}{2}$  lb. of sulphate of ammonia, and 15 lb. of ordinary sand. It should be applied in spring at 2 oz. per sq. yd. The grass may be discoloured but will recover.

**LAWN: The Material.** The materials known as lawns are predominantly made in cotton. Sheer lawns are plain white linens with no lint on the surface, bleached in the cloth and made with fine or very fine yarns, in this way resembling handkerchiefs. White lawn is the traditional material for bishops' sleeves. Boiled linen lawns are not so free from fibre on the face of the fabrics. Linen lawn costs considerably more than cotton, wears better and does not soil so quickly. It feels cooler, and is preferred upon that ground for summer underwear.

Cotton lawn is a superior calico about the same fineness as good longcloth. A good quality of raw cotton is taken to make lawn cloths. Cotton lawn is almost always worn white, and it makes up well into underwear and summer frocks.

### LAWN MOWERS AND THEIR CARE Machines Suitable for Large and Small Gardens

The various implements needed by the Gardener are dealt with in this work, among them being Dibber; Fork; Garden Roller; Spade. See further Gardening; Gear.

Lawn mowing machines act on the scissors principle, by means of a fixed knife across which blades, set at an angle, revolve as the machine is propelled. The moving blades are fixed together so as to form a cylindrical cutter, which is caused to revolve on its axis by gearing connecting it to the wheels on which the machine runs. The knife is fixed to the frame of the machine, and the height of the knife above the ground is determined by an adjustment which has the effect of tilting the machine bodily. A gear case is fitted on most types of machine to prevent the teeth of the spur wheels from becoming clogged with grass cuttings, and a detachable box is fixed in front of the machine to catch the cut grass as it flies off the cutter blades.

**Back Drum Mowers.** There are two main types of lawn mower, one working on the back drum principle,

and the other by means of side wheels. The former has a drum of large diameter, extending the full width of the machine, which drives the rotating cutters by toothed wheel gearing, though a chain drive is used in some designs. The cutters and the knife across which they pass are disposed forward of the drum, and a roller is placed in front of all; twin handles are generally fitted. The axle of the cutter is carried in journal bearings at the ends, and these are capable of being raised or lowered by means of screws.

The position of the cutters must be adjusted with these screws, so that as they revolve they just scrape the knife or bottom blade equally all along; if the cutters are slightly too high they will only tear the grass instead of cutting it cleanly, and if too low they will hammer on the knife and blunt both themselves and it. Should the axle be at all slack in its bearings, the half bearings must be taken out and filed carefully on their small flat abutting faces till the slack is just eliminated.

The double spur wheel, which is driven by the drum and drives the cutters, is mounted with its axle in a slot and has a nut to lock it in position. After the cutters have been adjusted into correct relation with the knife, this nut should be slacked off and the axle of the intermediate spur wheel moved in its slot and secured by tightening the nut when it is so placed that it is in mesh with the pinion on the cutter shaft.

Gear wheels must not be engaged so deeply that the tops of the teeth of one wheel reach down to the bottoms of the gaps in the other. The bearings of the drum are designed so that they can be moved a little and re-secured; this adjustment is provided to enable the depth of meshing of the main spur wheel and the intermediate pair to be corrected, but this is seldom necessary. The brackets carrying the roller are arranged to slide up and down in the frame of the machine. This is the means provided for regulating the length to which the grass is cut; the effect of raising the rollers is to tilt the front of the machine down and bring the knife nearer to the ground, so that the grass is cut shorter than if the rollers were lowered.

*Lawn Mower.  
Fig. 1. Side  
wheel mower  
with roller  
behind.*

**Side Wheel Mowers.** The other type of mower is operated by side wheels provided with internal gear teeth meshing with pinions on the cutter shaft; no adjustment of depth of meshing is provided, as none is required. In this class of machine the roller is behind, and its height is adjusted to regulate the length of grass cut as in the back drum design. The

adjustment of the blades to scrape the knife, however, is reversed, the knife being the movable member in this case. The knife is mounted so that it can be rocked by slacking one pair of screws and tightening another

pair, the edge being thus brought closer to or farther from the cylinder blades.

*Fig. 2. Machine designed on the back drum principle.*

(Courtesy of Ransomes, Sims & Jefferies, Ltd.)

Each of the two main types has its special advantages. The side wheel pattern, owing to the arrangement of its design, is considerably cheaper than the back drum machine and is

commonly used for small lawns. The former has the roller placed behind the cutters, which is an advantage for cutting long grass, as it avoids flattening the crop before the blades can reach it. This advantage is, however, considerably discounted by the fact that it is only at the beginning of the season that lawn grass is long, and the ground is then very moist after the winter, under which conditions the wheels give a lot of trouble by skidding and consequently cutting up the ground.

*Lawn Mower. Fig. 3. Motor mower with 4½ h.p. four stroke petrol engine. By de-clutching cutting cylinder the machine may be used as a roller. (Courtesy of Dennis Bros., Ltd., Guildford)*

The back drum machine, though the more costly and heavier, is free from the skidding trouble, and has the advantage that it will work without any trouble with part of the cutter blades overhanging the edge of the lawn. When cutting at the edge with the side wheel type, on the other hand, a strong twist has to be maintained by the hands so as to prevent tilting sideways, and force the machine to run firmly on the roller and the one wheel that is on the turf. Both patterns are perfectly capable of doing their work and lasting, with fair treatment, for many years.

**Sharpening the Knives.** Mowing machines are designed to be sharpened by removing the knife and blades and grinding each on appropriate machinery. A less expensive process is to sharpen the cutting parts at home with emery powder without removing them. The machine is turned upside down so that it rests with the handles on the ground and the knife on top, the knife blade being on a slope with its cutting edge lowest. The cutters are adjusted up to scrape the knife, but not so hard as to prevent the mechanism being turned by the palms of the hands pressing on the drum. The cutting

edge of the knife is then smeared with a thin paste of fine emery powder moistened with a mixture of oil and paraffin, and the drum is turned by hand to grind the blades.

The grinding paste on the knife must be frequently added to, as it soon gets dull and loses its abrasive power; this can easily be done by putting the new supply on the inclined face of the knife, when it will flow down to the edge. When the grinding process has proceeded so far that the drum becomes easy to turn, the blades should be raised up a trifle so that the action may continue. The sharpening must go on till all the blades rub equally throughout their length on the knife; the sound, as the mechanism is turned very slowly, will be found to be a sufficient guide.

Some machines are arranged so that a handle can be screwed on to the first spur wheel, and this makes the operation less laborious, but it is not essential. Emery powder of suitable grade is on sale as knife polish. Care is needed that a finger does not get caught among the rotating blades. The above refers particularly to the back drum type; side wheel machines are sharpened in an exactly similar manner, except that when turned over the machine must rest on the cross-bar of the handle and on a block placed under the front frame cross-bar, so as to leave the side wheels off the ground and free to revolve.

**Useful Hints.** Mowing machines require attention to keep them in order. The edges of the blades and knife should be wiped clean after use. The bearings require oiling occasionally. If the mower runs heavy, the meshing of the gears probably needs adjusting. If the blades sometimes fail to revolve when the machine is wheeled forward, the ratchet action must be taken out, scraped clean and oiled.

In the case of back drum machines the ratchet gear, usually fitted in duplicate, is located inside the drum; in the side wheel type the ratchets will be found inside the pinions on the cutter shaft, and can be got at by taking off the side wheels. If the grass is not cut cleanly, or if the blades clog, the cutters must be readjusted to scrape the knife correctly; if this fails, sharpening must be resorted to.

When the machine is put away at the end of the mowing season the bearings and gear teeth should be given a good oiling, and the blades and knife must be wiped clean and dry and well greased; neglect of these precautions will cause rusting serious enough to involve heavy grinding to get the blades sharp in the spring. Stones on a lawn are apt to blunt the blades, or even chip them; the only safeguard is to keep a sharp lookout, especially where the grass is alongside a path.

## LAWN TENNIS ON GRASS AND HARD COURTS Hints on Playing this Popular Outdoor Game

This work contains articles on the outdoor games that are played in and about the home, such including Badminton; Bowls; Croquet. See also Lawn.

There are two forms of lawn tennis, singles and doubles. In singles two players are pitted against each other; in doubles four take part, two against two. It is also possible for one person to play two others. The game is as suitable for women as it is for men, and mixed doubles, as they are called, are very popular.

The game is played on a court, usually of grass, but often of gravel, asphalt, sand, cement or some other hard substance. The former kind is the most popular, but the latter, which is coming more and more into favour, has the advantage that it can be used in winter and almost at once after a spell of wet weather; in such conditions grass courts are unsuitable for play. In general the game is faster when played on a hard court.

**Balls, Racquets and Net.** The implements required are a net to divide the court, a racquet for each player and a number of balls. Each player provides his own racquet, choosing one that suits him or her. The main considerations in making this choice are weight, balance, the size and feel of the handle, and the thickness and tautness of the gut. As regards weight, a man's racquet will weigh about 14 or 15 oz. For most men a light one, say 14 oz., will be quite heavy enough, but others will prefer a heavier one. Women should not use a racquet weighing more than  $13\frac{1}{2}$  oz., while one of 13 oz. is probably heavy enough for the majority. The rules of the game place no restrictions upon the size and weight of the racquet.

To test the balance of the racquet the following method is suggested. Place the racquet on the first finger just about where the screw passes through its neck. The racquet will then either sink at the handle or the head end, or will remain balanced. One that will remain balanced is the most suitable for an ordinary player.

If, however, a player wishes to concentrate on driving from the back of the court, a racquet that sinks at the head should be chosen. If, on the other hand, a player wishes to devote himself to volleying, one that sinks at the handle is advised. As regards the handle, a fairly thin one is usually preferred. For a woman this should not exceed  $4\frac{3}{4}$  in. when measured below the leather, and it need be no more than  $4\frac{5}{8}$  in. For a man it must be somewhat thicker. The handle should be fairly rough; if it gets smooth and slippery it is a good plan to rough it with a file.

Some players like a rubber covering for the handle, and in some cases this certainly prevents slipping. Persons with moist hands should, however, avoid these grips. Other grips which they may use are made of adhesive surgical wrapping. If a grip is used it should on no account be more than 6 in. long.

Gut for racquets is either thick, medium, or thin, the medium being best. It is important that a racquet should be tightly strung. This can be tested by nicking the nails across it, when a good one will give forth a musical sound. In addition to these points the buyer of a racquet should take it firmly in the hands and see how it feels in the grip when swung. If it is not absolutely comfortable and easy, it should not be bought, however good a racquet it may be. A racquet

should be kept in a press when not in use.

After the Great War a new kind of racquet was introduced, aluminium wire taking the place of gut. For a time this was popular, but after a trial many players abandoned it and reverted to those made of gut.

The balls are of rubber, covered with flannel or cloth. The rules of the game order that a tennis ball shall not be less than  $2\frac{1}{2}$  in., nor more than  $2\frac{5}{8}$  in. in diameter, and shall weigh between 2 and  $2\frac{1}{16}$  oz. The court, whether hard or grass, shall be a rectangle 78 ft. long. For the singles game it shall be 27 ft. wide, and for the doubles game 36. These measurements are shown by white lines marked on the grass or gravel. It is customary to mark out a court for the double game, and if a single is played to regard the  $4\frac{1}{2}$  ft., which is marked on either side, as outside the area of play.

By the rules, the court must be divided across the middle by a net suspended from a cord, the ends of which shall be attached to, or pass over, the tops of two posts,  $3\frac{1}{2}$  ft. high, that shall stand 3 ft. outside the court on either side. The height of the net shall be 3 ft. at the

centre, where it shall be held down taut by a strap not more than 2 in. wide. There shall be a band covering the cord and the top of the net, not less than 2 in., nor more than  $2\frac{1}{2}$  in. in depth on each side.

*Lawn Tennis.*  
Diagram of the court marked for both singles and doubles. For the former its width is only 27 ft., the side boundaries being the inner of the two lines shown.

**How to Play the Game.** The aim of a tennis player is to drive or place the ball over the net into the opponent's court, in such a way that the opponent, or opponents, cannot return it, or, if they can, they return it wildly, and therefore send it out of play. Each game is opened by a service, the player serving, each through-out a game, in turn. Serving consists in landing the ball in what is known as the service court, behind which one of the server's opponents stands ready to take it. The server himself stands just behind the back line. If he fails to land it correctly at the first attempt he is allowed a second; but if he fails in this service also, his opponent scores a point.

As soon as a correct service has been delivered the ball is in play and any player can hit it. A hit is correct if the ball is either volleyed or taken on the first bounce, provided that it lands across the net and within the court. The players return it from one to another as often as they can, this being known as a rally. When one side fails to return it correctly, the other side scores a point. The score is called at the end of each point, that of the serving side being put first. Thus 40-15 means that the serving side has scored 40 and the opponents 15, while 15-40 means the reverse. If the two sides are equal, the score is called with the word all added.

**Method of Scoring.** The score is reckoned thus: 15, 30, 40, and game. A game can, therefore, be ended after four rallies, or even by four strokes. If, however, both sides reach 40—deuce, as it is called—one side must win two points in succession before a game is secured. This is done by a system of advantages, or vantages.

The score that immediately follows deuce is either vantage-in or vantage-out, the former if the server wins it, the latter if his opponent does so. If the side that won the vantage wins the next point, the game is theirs; but if the other side wins, the score reverts to deuce and play goes on. As, therefore, a game can theoretically go on for ever, and as in actual fact games do last for a considerable time, the players in friendly games sometimes agree to decide a game by the issue of a single point.

A set, which is the unit generally played in lawn tennis, consists of six games. Here, again, there is an arrangement similar to that for the advantages in a game. If the combatants reach five all, a set must continue until one side is two games in front of its opponents. Thus a set may go to 6 all, 7 all, 8 all, and only end when 10 or perhaps more games have been played, with a score of 10-8 or 11-9. Players usually toss as to which side of the court they shall play. The one who wins, chooses, and the other side takes the first serve. It is customary to change from one side to the other at the end of each odd game, i.e. 1, 3, 5, etc. This applies to both singles and doubles.

Such is the game in brief outline, but fuller particulars can be obtained by reference to the laws drawn up by the Lawn Tennis Association and accepted by lawn tennis players everywhere.

**Advice on the Game.** To be proficient in the game a lawn tennis player needs the quickness of eye, hand and foot that is essential to success in most ball games, a knowledge of the various strokes and constant practice. Primary rules are that he should keep his eye fixed on the ball, and by correct footwork should make the best use of the weight of the body. He should remember that the amount of pace imparted to a stroke depends upon the speed of the racquet when it meets the ball.

One authority lays it down that every stroke in lawn tennis can be divided into three separate and distinct actions, which should, however, in practice be blended harmoniously into one movement. The first is the swing back of the racquet; the second is its swing forward and its hitting of the ball; and the third is the end of the

swing after the ball has been hit, the follow-through, as it is called. The third, far from being unnecessary, controls the balance of the player's body. To some extent the play of men differs from that of women, but this distinction does not affect the main principles of the game.

The lawn tennis player must first of all learn how to serve. The service most favoured today, largely as the result of the example of American and Australian players, is the high overarm one, delivered at a very rapid pace and usually made additionally difficult to take by the spin that is put on the ball. The first service is usually delivered at the utmost possible speed; the second, if such is necessary, only a little less fast.

*Lawn Tennis.*

*Overarm service. Fig. 3. Beginning the serve, racquet being shown at its lowest point.*

*Fig. 4. Raising racquet and tightening grip.*

*Fig. 5. Position of racquet after ball has been hit, showing full extent of reach.*

This high overarm service is used by most men players and by the best women players. Figs. 3, 4, and 5 show a great player in the act of delivering it, which he does by hitting the ball with the racquet at the full stretch of his arm, thus getting the greatest possible power on to it, and then letting his racquet follow the ball right through the stroke until it comes to rest near the right leg. The ball should be thrown up over the right ear and struck the second it comes within reach of the centre of the racquet.

When beginning the serve, the weight of the body will be on the right foot, but when the ball is hit, it should be transferred to the left. To impart the necessary spin, he draws his racquet across the ball at the moment of impact. This service can usually be acquired by men of ordinary agility and strength, provided they practise. They should not hesitate to throw the ball up to a good height when serving; many serves are quite spoiled because this is not done, and

therefore the ball cannot be hit with the racquet at the player's utmost reach and power.

To receive a service of this kind the player should stand well behind the back line, diagonally to the server. He should watch carefully for the break of the ball, and, if it has this quality, should meet it so that it breaks towards his hitting arm, not across his body. It should be hit hard, preferably with a little top spin, as this will kill the spin the ball already possesses. The return strokes generally used are the drive across the court and the one down the side line. If these strokes are made with the forehand drive and a spin is put on the ball they are very difficult to return.

**The Chief Strokes.** It is fairly generally agreed that there are five strokes, apart from the service, that are of major importance, the others being variations of one or other of these. The five are the forehand and backhand drive, the smash, the volley and the lob.

*Fig. 1. Correct method of gripping the racquet for forehand drive. Fig. 2. Grip of the racquet at finish of back hand stroke, showing position of thumb during whole of stroke.*

The way in which the racquet should be held for the forehand drive, perhaps the most used of all the tennis strokes by good players, is shown in Fig. 1. The handle should be grasped so that it lies diagonally along the hand, not straight across the palm, and rather in a straight line with the forearm than at right angles to it. The head of the racquet, as a general rule, should be parallel with the ground. It is well for the player to separate the forefinger from the other fingers, as he will get a firmer and more comfortable grip. The thumb should lie across the handle, not tightly round it.

There are several varieties of the forehand drive, the names, such as the chop drive, the cut drive, and others, given to them suggesting slight variations in the way the ball is hit. One that is most practised is the horizontal drive. In this the ball is hit either with the racquet at right angles to the ground, i.e. without spin or cut, or hit with a racquet that moves upwards a little and turns over after the ball has been hit, thus giving

what is called top spin to the ball.

*Fig. 6. Forehand drive. Beginning the stroke, the player being sideways to the ball.*

To make this drive successfully it is necessary to have the body in a correct position. The player should stand sideways to the net with the left foot in front of the right, the feet being parallel to the base line and about 15 or 18 in. apart, according to his height. The reason for this position is that without it the player cannot swing his racquet freely, cannot use his weight properly, and cannot keep his eyes so easily on the ball.

The drive should be made with the arm straight or almost so and the ball taken as high as possible consistent with the horizontal position of the racquet and when it is at a point about the middle of the player's body. In this way racquet and arm, moving together in one long, straight sweep, put the greatest possible power into the stroke, the analogy being that of a straight stick, by which a harder blow can be struck than with a crooked one. A common fault is to get too near the ball, which cannot then be hit as strongly or as accurately.

Equally important is the correct use of the weight of the body. This should remain, as far as possible, on the right foot until the stroke is half completed, when the player should begin to transfer it to the left one. It should be entirely on the left or front foot as the stroke is finished and the player swings the racquet round for the follow through. The right or back foot should never be lifted from the ground before the ball has been hit. It is understood that these instructions refer to persons who hold the racquet with the right hand; for left-handed players the position of the feet must be reversed.

For the backhand stroke the racquet should be gripped in a somewhat different manner, the correct method of doing this being shown in Fig. 2. It should be grasped so that the handle lies diagonally across the hand. It is held in position by the thumb, which presses it against the fingers and the palm of the hand. Greater flexibility of wrist is secured by allowing the forefinger to be separated slightly from the others. The thumb may be placed across the handle or may lie along it. The wrist is more flexible if the thumb lies along the handle, but the alternative way of holding it makes for a stronger grip.

When making the backhand stroke the player should be in the same position as for the forehand stroke, i.e. the body in a position sideways to the net with the feet parallel to it and apart. He should remember that, more even than other strokes, the backhand drive depends for its success upon correct footwork, i.e. the use of the feet and transferring the weight while the

stroke is being made. The racquet should be swung both backwards and forwards parallel with the ground, and the ball should be hit as far away as possible from the body, provided that there is no loss of balance. The ideal place to hit it is at a point a little below the line of the waist, that is, lower than that taken for the forehand stroke.

When he begins this stroke the player should have his weight upon the back foot, from which it should be transferred to the front one as the racquet comes forward and makes the hit, and it should be wholly upon the front foot as the drive is completed. It will be of assistance to the follow through if he lifts his left foot from the ground as soon as the stroke is made. The wrist should be quite rigid when the ball is struck.

In playing this stroke good players make use of the left shoulder. By means of this the body is turned as the stroke is made, and the rotary movement thus given helps the swing and power of the drive. If a player is unable to play this stroke with a horizontal racquet at right angles to the ground, or wants a variation from it, he can play it with the racquet slanted back somewhat. This will then pass under the ball, and so give back spin to it, thus causing it to hang a little after pitching.

### The Smash Stroke

The smash stroke is played with very much the same action as the serve, and players who are good at the latter are usually good at the former. As this stroke depends for its success very largely on power, the harder the ball is hit the better. In some cases a ball hit in this way can hardly fail to score.

To play the smash well a player must get into the correct position, and with the arm stretched to its fullest extent must bring the racquet down with its utmost force just as the ball is on the middle of it. The stroke must not be hurried, and the weight should be transferred from the back to the front as it is finished. If the right position has been taken up, this movement enables the full weight of the body to be put into the hit. If this cannot be done the player has probably misjudged his position.

In addition to this, the usual form of the smash stroke, there is a backhand smash that can sometimes be used to good purpose. To make it the racquet should be held with the backhand grip, with the thumb along the handle to give control. It should be made with the forearm, the ball being taken above the left side of the head and hit with a sweeping action round it. As with the ordinary backhand stroke, the player should have his body sideways to the net and his feet parallel to it and apart. The wrist should be rigid as racquet and ball meet.

**Volleying.** Volleying, which means hitting the ball before it has touched the ground, is one of the most effective of lawn tennis strokes. It should only be attempted when the player is quite near the net and in position to dash the ball down at great speed. In this stroke the wrist plays the dominating part, little or nothing depending upon the weight or swing of the body and the sweep of the racquet. The wrist must be

as firm as possible and the racquet held in a strong grip. If this is not done the racquet will turn in the hand and the stroke will consequently be a failure. The volley derives its power from the pushing action of forearm and wrist and its speed from the pace of the ball when it meets the racquet. Accuracy of aim is secured by keeping the head of the racquet supported above the wrist.

To make a volley it is not necessary for the player to put himself into a position sideways to the net, as he should do for a drive, although this position is recommended by some authorities, who assert that a harder return is thus secured. Most players volley facing the net with the feet more or less parallel to the side lines. One reason for this is that there is less time to prepare for the volley than for the drive.

There are several forms of the volley. A forehand volley is made with the racquet held in the forehand position. The ball should be hit about the height of the shoulder, and the head of the racquet kept a little above the horizontal, with the wrist pressed down. A variety of this stroke is necessary when the ball drops below the height of the net. The danger of driving it into the net can be avoided by stooping down and keeping the head of the racquet up, so that the ball is hit slightly upwards and clears the net.

Volleys, like other strokes, must be placed if they are to score. This is done by turning the wrist one way or the other. For instance, if a player is near the net in the centre of the court, and he wishes to volley to the left of his opponent, who is almost facing him, he must turn his wrist out, i.e. away from the body, and slant his racquet in that same direction. The ball will then be volleyed to the right, which is the opponent's left.

The volley is sometimes made with a backhand stroke. For this the grip should be shortened and the thumb placed down the back of the handle. The player should take up a position sideways to the net, and should stoop down so that the head of the racquet is about the height of the waist. As for all other volley shots, the racquet must be held tightly and the feet planted firmly on the ground. It is not necessary, however, to swing the racquet for this stroke.

### Use of the Stop Volley

Very useful on certain occasions is the stroke known as the stop volley. If properly delivered it makes the ball drop just over the net, and, is, therefore, often played when an opponent is at the back of the court. It can be made in two ways. One is to hold the racquet loosely at the moment of hitting the ball, and the other and better way is to slant it, thus giving the ball the necessary spin.

The same purpose, i.e. placing the ball just over the net when the opponent is well away from it, is fulfilled by the drop shot. To play it the ball must be hit crossways, the racquet being almost parallel with the ground. It hits the ball underneath from right to left in order to put on it the spin which will prevent it from bouncing far when it drops over the net. This stroke is

made with the wrist and arm. The player does not put any of his weight into it, neither does he swing the racquet for it nor follow it through, as he does with most other lawn tennis strokes.

The stroke known as the half-volley is worthy of attention, although it should only be played in an emergency. It is something between a volley and a ground shot, and is useful when the ball comes in such a way that the player can neither volley it nor drive it. It should be played with the racquet quite firmly held and in as horizontal a position as possible, the ball being hit as soon as can be after pitching. It differs from volley shots inasmuch as the racquet should be swung to the ball and should follow it through as far as possible.

**The Lob.** The last of the five main strokes is the lob. In this the player lifts the ball over the head of an opponent so that it pitches just inside the base lines, or at least in the back part of the court. It is a very easy stroke to play, though it cannot be played with the necessary accuracy without a good deal of practice.

In order to play a lob properly the player must be in a sideways position, just as for the forehand drive. The racquet should be slanted back and be swung from underneath in a firm grip. Care must be taken to lift the ball high over the opponent's head otherwise it will be smashed back. The lob can also be delivered with a backhand stroke, and it can be made with spin on the ball. Its prime essential, however, is accuracy, as inaccuracy cannot in this case be compensated for by pace, as it can with the drive.

These and other lawn tennis strokes are played in the same way for singles as for doubles. In singles the player's task is quite simple; he must himself return every stroke to the utmost of his power, but in doubles the two players must have an understanding on the subject; otherwise confusion and loss of points will be the result.

**Tactics for Doubles.** In men's doubles the tactics of the best players are as follows. The server, having delivered his service, dashes up to the net, where his partner is already stationed. Each in his own half of the court, they will then be in a position to smash or volley a large proportion of the returns. They must be prepared to run back if a lob is threatened, each watching his own side of the court; but otherwise the nearer the net the better is quite a good rule. Players in this position should always be moving, or appearing to move, towards the centre of the court, in order to cut off an opponent's return and also to keep him in a state of uncertainty.

When it is the turn of a player to receive a service, he and his partner should both be on or behind the base line, the best players having abandoned the idea of having the one not receiving the service at the net. When a return justifies it they should go forward together, keeping in line and the same distance from each other, so that they will cover as much of the court as possible. One authority suggests that the striker-out should occasionally send a drive straight at his

opponent at the net, as a stroke of this kind, if delivered about waist-high, is usually very difficult to return, either forehand or backhand.

In mixed doubles different tactics are desirable. The accepted formation is for the man, when not serving, to be at the net and his partner on or near the base line, the best position for most women players being a little outside the line and not far from the corner of the court. In this position the woman player can make two effective shots, the drive across the court and the drive down the side line. When the man is serving, he dashes up to the net as soon as he has delivered his service.

In most cases this formation is doubtless the best, but there are exceptions. For instance, if the lady is a good volleyer it may be advisable for her to play the same game as a man would do; but if she is not, her partner, being at the net, should hit on the volley everything that comes within his reach.

**Handicapping.** In lawn tennis tournaments, and sometimes in friendly games, players are handicapped. This is carried out by giving strokes to the weaker players, and making the stronger ones owe strokes. For instance, a player may receive 15 points, or 30 or 40. This means that he has one, two or three strokes in hand when the game begins. If, on the other hand, a player owes 15, 30, or 40 points it means that he must win one, two, or three strokes before he can begin to count, 15, 30, and so forth. Thus, if a player owing 30 plays one who receives 15, the latter only requires three strokes to win, unless deuce is reached; the former requires six.

The more usual way, however, of handicapping is to give, or receive strokes represented by sixths of 15. These odds are received in each group of six games of a set; in the first place in the earliest possible even games. That is to say, a player who receives one-sixth of 15 receives a stroke in the second game of each group of six; a player who receives two-sixths receives a stroke in each of the second and fourth games, and a player who receives three-sixths receives a stroke in the second, fourth and sixth games.

**LAX: Of Smoked Salmon.** A special preparation of smoked salmon, lax may be served as hors d'oeuvres, being cut into thin slices, covered with dressing and garnished with parsley or chopped pickle. Lax is also served as a savoury on small buttered biscuits. It should be freed from the oil in which it is preserved, moistened with salad oil and lemon juice and then seasoned with pepper. It should be allowed to stand for some little time so that the oil, etc., may soak in. Parsley may be used as a garnish. *See* Hors d' Oeuvres; Salmon.

**LAXATIVE.** The mildest cathartic or opening medicines are known as laxatives or aperients. The principal laxatives are cascara sagrada, sulphur, euonymin, manna, magnesia (magnesium oxide), castor oil, olive oil, and liquid paraffin. Many fruits have a

laxative effect, particularly stewed prunes, figs and tamarinds. *See* Aperient.

**LAXTONBERRY.** This is a new berried fruit raised by cross-breeding between the raspberry and the loganberry; it needs the same treatment as the latter. As the flowers are partly self-sterile the laxtonberry should be planted near other berried fruits.

**LAYERING.** This is a method of increasing stock of carnations, roses, and other shrubs and plants. The idea is to prevent the return of the sap from the extremities of the leaves and branches to the roots by means of a cut in the stem. The sap bleeds, the wound hardens, throws out roots, and eventually the branch becomes a separate plant.

To take a layer, a suitable low-lying branch or shoot must be chosen, and all the leaves stripped off below a selected joint. The joint is sliced half-way through with a sharp knife, at a very acute angle. The partially severed branch is bent upward and pegged firmly down into the ground in a patch of very sandy soil.

Pegs, in the shape of inverted V's, are pressed down, with one leg on either side of the layer, in order to keep it in position. Hairpins may be used for layering carnations. Summer is the best time for layering. *See* Carnation; Rose.

*Layering Methods.* 1. Layering stolons of *St. Bernard's Lily*. 2. Multiple layering of *Lapagerias*: a, soil; b, fibre; c, staging. 3. Strawberries layered into (a) plunged pot and (b) box. 4. Stem-layering: a, pebble in tongue; b, halved flower pot. 5. Carnation cut and pegged (a). 6. Carnation cut wrongly (b). 7. Method of layering certain fern plantlets. 8. Layering loganberry shoots: a stones. 9. *Clematis* layered: a, slit stem behind joint.

**LAYIA.** The only species of layia generally offered is *elegans*, an annual with downy leaves and yellow flowers in summer, growing about 12 in. high. It is sown outdoors in April. There is a white-flowering variety.

*Layia.* Yellow blooms of the annual variety *elegans*.

**LEAD: Its Uses.** Lead, which is one of the heaviest and softest of metals, has many uses in the home. In the

form of pipes it is extensively used in sanitary systems, for waste pipes, and occasionally for hot and cold water services. In sheets, lead is used in the construction of gutters and for covering flat roof surfaces, the lining of sinks, and in numerous other directions. It is not much affected by the weather, and does not rust or corrode under the action of water.

Lead can be soldered, or joints formed by burning, this process consisting in melting the lead at the joints so that it fuses or burns together. Lead is often used for decorative purposes in the form of garden ornaments, rain-water heads and pipes, and in some forms of ornamental statues, generally those used as a centre ornament for a fountain.

In the home lead is used for keeping carpets in place at the edges, or for weighting the bottom of a table-lamp stand or other structure. It has the advantage of occupying less space for its weight than any other convenient metal.

**Poisoning by Lead.** The presence of lead in water or food may lead to poisoning, but it is most commonly found amongst persons whose work involves the use of lead, such as, for example, plumbers, painters, and potters. The symptoms are sickness, acute pains and diarrhoea. While awaiting the doctor induce vomiting by tickling the back of the throat or by an emetic. If it is at hand a dessertspoonful of Epsom salts should then be given, followed by milk and white of eggs. A hot poultice on the abdomen will help to relieve the pain.

In chronic lead poisoning the first symptoms may not appear for months, the most prominent being colic, with agonizing pains in the region of the navel. There is a blue line along the gums at the junction of the teeth, also anaemia and muscular weakness. Thorough medical treatment is required. *See* Casting; Flashing; Gutter; Plumbing; Sink.

**LEAD ARSENATE.** This is a poisonous and dangerous compound, which may be purchased in paste form in jars for mixing with water in the proportion of  $\frac{1}{2}$  lb. of paste to 10 gallons of water. It consists of a combination of acetate of lead and arsenate of soda, and special precautions must be taken in its use, the maker's instructions being strictly followed.

The wash is valuable for clearing fruit trees from the larvae of such pests as the codlin, vapourer, winter, lackey, and currant moths, gooseberry slugworm and sawfly, and also caterpillars and biting beetles. *See* Fruit; Lackey Moth; Spraying, etc.

#### LEAD ART CRAFT FOR HOME DECORATION How to Make Inexpensive Leaded Windows and Mirror Frames

This article deals with the various forms of ornamentation possible by means of prepared lead

strips. The entry on Leaded Lights and that on Stained Glass should be consulted. See also Name Plate.

Many people like the appearance of leaded lights for their homes, but are deterred from installing them owing to their cost. By the use of prepared lead, obtainable in coils, a special cement, brush and sponge, the amateur can for a trifling sum convert a plain window into one with leaded panes.

This lead is manufactured in thin strip form and in various widths. It is extremely pliable, easy to use, and is coiled to facilitate handling and for convenient packing. A particular feature of the lead is that it adheres to tiled surfaces, metal, wood, or glass. It can be used for framing pictures or mirrors, and is one of the easiest materials for applying with cement as a moulding. It can be painted with cellulose quick-drying paint when employed to outline tiled surfaces in a bathroom or kitchen.

Designs for decorating glass screens, glazed doors for wall cupboards, bookcases or overmantels, can all be carried out by the amateur, while the lead can also be employed for name plates on front doors and gates. The cement to be used with the coils of lead is specially prepared to withstand all weathers. Various outfits are obtainable for this craft, including one which contains glass colour stains for use on windows, etc., in ruby, amber, blue, and green.

**Simple Leaded Windows.** A small window on the staircase or landing may be selected on which to experiment. It will be found that after applying this form of decoration the window is quite easy to clean. The strips do not work up, however much they are rubbed, if the special cement is used for fixing them on to the single panes of the ordinary window.

The first task will be to measure off the correct length of lead. Hold an end of the lead in one hand at the top of the window and allow the coil to unwind and fall perpendicularly (Fig. 1). Then nick the lead at the desired point with the thumb nail and, taking it from the window, snip it off at that mark.

Measure off and cut all the lengths for one window before proceeding any farther; then take the brush and the tin of liquid cement and paint each strip of lead on one side only with a thin but even coating of cement (Fig. 2). Treat two or three strips of lead in this way before attempting to affix any to the window, as the cement must be on the lead for fifteen minutes before applying. This will ensure that the cement has partially dried and is slightly "tacky," and therefore more adhesive. Pencil-mark the window frame to ensure the strips being laid on straight. Now take the strip of lead which was cemented first and lay it against the glass in the position required.

Having made sure that it is exactly straight, press it firmly and evenly with the ball of the thumb (Fig. 3), and with a linen rag dampened with petrol or turpentine gently sponge away any cement which has been pressed out from under the lead on to the glass. It has been found better to start with the horizontal strips, but leaving the top and bottom horizontals until last. They

will serve to frame the others and keep them in position. Many people leave the spare cement on the edges of the lead, preferring the appearance of age which the resulting irregularity affords. The strips may be applied to both sides of the window, as the cement stands all weathers.

Similarly, opinion is divided upon the question of overlapping. Some prefer to overlap the strips of lead, for this method is easier and quite attractive. Others prefer to cut each section flush with the next, giving a soldered-joint effect (Fig. 4). Mistakes are easily rectified. If a strip of lead is applied incorrectly turn up the edge with the point of a knife and the whole strip can then be pulled off quite easily. After experimenting with a squared pane effect, diamond panes (Fig. 7) will be found equally easy to simulate.

To imitate the Gothic or Norman arch, as seen in Fig. 8, or to insert panels of heraldic designs, etc., the amateur must learn how to bend the lead. Hold the strip so that the side which is to become the outer-edge of the curve is uppermost, and gently pull the lead round to the desired curve, doing a little piece at a time (Fig. 5). The lead is now neatly curved on the outer edge, but the inner edge is buckled. Proceed, therefore, as follows: Lay the curved strip on a flat surface. Hold firmly in position with finger and thumb of one hand and gently press the buckled surface with the ball of the finger (Fig. 6). Practically all the buckling will then disappear, and by gentle rubbing with the finger, which should be protected by the corner of a linen rag, a completely flat appearance will be ensured.

For making a number of curves of the same size it is easier to work with a template. This is a thin piece of cardboard which is cut to the exact curve required. Tack this template on to a smooth piece of wood. Next tack the metal strip to be curved just above the top of the template; then gradually ease the lead round the edge of the template with the fingers by means of a gentle pulling and pressing movement.

Glazed bookcases can be treated in the same way as windows. Books appear attractive behind leaded panes, and so do china and glass. Recessed cupboards on landings or in halls often look well if the upper portion is glazed and decorated in this way. Fig. 9 shows a simple design for a bookcase or cupboard. Coloured glass effects may be introduced by means of the specially prepared stains, but requires discreet usage.

The possibilities of lead strips for framing pictures and mirrors are well worth noting. By this means a permanent frame is procured with little more trouble than the temporary one made with passe-partout paper. A groove in the particular form of strip sold for framing purposes allows the lead to be bent on to the back of the picture or mirror mount. Figs. 10, 11 show this simple process, while in Fig. 12 may be seen the artistic effect of a perfectly plain mirror framed in lead.

Designs may be heavily drawn in pencil and placed under glass to be outlined in lead for ornamenting

*(Continued in page 1264)*

panels for screens or other articles. A special form of very narrow lead strip is sold for the purpose of outlining such designs.

**House Name Plate.** One of the most effective uses to which lead strips can be put is to make the lettering and framing for house name plates. Under a rectangular piece of glass of the size required for the plate, the name, having been written or printed in one of the various types of lettering suitable for this purpose, is placed and the letters are double outlined with the narrowest width of lead strip obtainable. The lead must be slowly eased along, the forms of the letters showing through the glass, and one end must be steadied with the left hand so that the forms already made will not be pulled out of shape. The worker must not proceed too fast if the letters run on, or the first letters of the name will not have a chance to adhere properly.

Metallic paint may be applied on the back of the glass, so that the letters appear golden in the centre and outlined with lead. Another piece of glass of the same size and shape as the first piece is then laid over the leaded letters, so that they are protected on either side by glass. To provide for safe suspension of the plate two thin pieces of brass are each eyeleted at one end and slit at the other, so that the slit ends can be bent up, one to the front and the other to the back, to form resting places for the two pieces of glass. Having placed these on the upturned ends of both pieces of brass, bind together with strips of the passe-partout width of the lead, thus binding in the brass with the bottom of the plate and leaving the two eyeleted ends projecting at the top, where this is in turn bound with the passe-partout. In order to avoid the danger of moisture condensing between the two pieces of glass, the under edge of the passe-partout framing should be pierced in several places to provide ventilation. The lead strips are obtainable in widths of from  $\frac{1}{4}$  in. to  $\frac{3}{4}$  in. Stranded leads are used for fine out-lining.

## LEADED LIGHTS FOR THE HOME

### All Old-World Attraction for the Modern Home

Other articles that deal with the decoration of the home are Enamel; Paint; Panelling; Parquet. See also such entries as Casement; Glass; Stained Glass; Window and those on the materials and processes, e.g. Cement; Soldering

The old form of decoration known as leaded light work consists in the use of pieces of glass to form a pattern, in which they are held together by cames, or strips of lead. These are soldered together at the joints, and the whole fixed in a framework. Leaded lights form a pleasing feature of some styles of decoration, particularly in houses furnished on the Tudor or Jacobean models. In many cases it is possible for the amateur to take out existing casement windows and replace them with leaded light panels, or add lead panels to the framework.

The amateur worker is recommended to study the

article on Glass and Glazing. The tools required for making leaded lights are one or two good glass-cutters, either a diamond or one of the newer types of wheel cutter. On a rippled or variegated surface it is probable that a better result will be obtained from the use of the wheel, but in large sheets the diamond is less likely to cause a breakage, as it requires less pressure to effect the cut. A board upon which to cut the glass, a T-square and set-square, and straightedge are required, as well as one or two knives for cutting the lead, a pair of pliers, and soldering iron.

*Leaded Lights. Fig. 1. Diagrams showing three varieties of lead cames employed in this decorative work.*

*Leaded Lights. Fig. 2. Above, cutting board, T-square and soldering iron; below, other special tools required.*

One or two special implements are needed, including the lathykins, made from a piece of hardwood or bone about 7 in. long, and shaped as shown in Fig. 2, which shows a group of the tools required. The point is used for opening up the flanges of the lead before inserting the glass, while the prepared flat end is used for pressing them down again when the glass is in position. Machine-drawn lead cames can be obtained ready for use from various firms specializing in this material. The smaller sizes are generally solid lead, while the larger are often reinforced with a steel core.

The types of glass in common use are the ordinary sheet glass, such as is used in windows, and which may be obtained in various colours, and obscured glass, which is made in different grains or surfaces. One of the cheapest kinds that can be used for tints is rolled cathedral glass; it is made in a variety of colours, is non-transparent, and is very useful where some obscurity is required, as for the panels in a screen or a hall lantern.

A number of glasses are graded under the heading antique, and include pot, flashed, streaky, Venetian, and opal. In the pot metal glass the colouring medium is introduced in the process of manufacture, and

consequently the glass is coloured right through. Flashed glass is only coloured on the surface. Streaky glass exhibits a variety of streaks of different colour. Venetian has a strongly marked pattern, and is a very brilliant glass; opal glass has an opaque white surface.

**Preparing the Design.** When preparing a design it is necessary to bear in mind the nature of the material and the restrictions it imposes. For example, it is impracticable to introduce very thin lines, except those which are formed by the lead, as obviously there is a limit to the breadth of the glass in the sense that it is extremely difficult to cut a very narrow strip. The desired effect should be obtained therefore from breadth of treatment rather than detail. This only applies to self-colour glass, for when stained glass forms part of the composition the design may be treated in a more decorative and detailed manner. For example, the body of a window made with plain glass of various colours could have a central panel introduced in stained glass which may have some particular feature, such as a heraldic shield or emblem. The best models of such windows should be studied, as it is easy, when dealing with stained glass, to introduce a garish or cheap effect into a window by the use of poor design and colouring.

*Leaded Lights. Fig. 3. First stage in the work.*

Taking as an example the light for a window composed of pieces of clear glass, the first procedure is to make full size drawings showing the exact arrangement of the separate pieces. The lines upon the drawing should represent the heart or centre of the lead. The size to which the glass is cut must then be smaller by the thickness of the heart (i.e. half the thickness for each side). Sometimes the drawing shows also the thickness of the came itself.

When it is necessary to cut up a number of squares or lozenges of the same size, the glass is first cut into strips of the desired width, and then cut across to form the squares, etc. Test the first strip by placing it between odd pieces or came and observing that the centre of came registers with the centre line on the full-size drawing.

When the glass has been prepared and the requisite quantity of lead is at hand, the framing is placed flat upon a level table or board, and laths are nailed down on two sides of it in register with the line of the rebate, of the window frame, as shown in Fig. 3. The outside lead is then arranged so that half of it will protrude from the rebate and show inside the sight lines.

**Inserting the Glass.** Before using the lead it should be slightly stretched to straighten it. The lead is laid upon the bench and the grooves slightly opened with

the lathykin on both sides. The requisite number of pieces of lead are cut to the length and breadth of the light and laid on one side ready to hand. Sufficient pieces of glass are then inserted into the lead and built up in the vertical direction of the light. The glass is inserted into the grooves in the lead and tapped tightly in position with the handle of the lead knife. As each piece of glass is inserted, it is temporarily fixed by driving a nail lightly a little way into the bench with the side of the nail against the edge of the glass. Short pieces of lead must be inserted between each piece of glass and cut to such a length that their ends will butt against the vertical strips, as in Fig. 4.

*Fig. 4. Three pieces of glass in place, the comes held by pins.*

When the first set of glasses has been inserted a long strip of lead the requisite length for the vertical strip is slipped over the edge of the glasses. To do this will necessitate lifting each glass separately from the bench, for which purpose the bent knife is required. This is pushed under the glass and raises it just enough to allow the flange of the vertical lead to be held between the glass and the bench. The temporary nails are removed while the lead is inserted, but fixed behind the lead to prevent it slipping off again. Each nail and separate piece of glass is treated in the same way until the whole length is complete. The light is continued until all the glasses are in position. The remaining two outer leads are placed in position and temporarily secured by nails to the bench. The whole is then pressed tightly against the laths, and afterwards secured by two additional laths.

Before driving the nails into the bench to secure these laths test all the dimensions. Should the panel be oversize this may be corrected by tapping the edge of the lath and driving the pieces of glass more closely together. Corner angles should be tested with a set-square, and when all is in order the second set of laths may be fixed and the joints carefully soldered.

**Soldering the Joints.** The soldering tool must be tinned before using. The surfaces to be soldered are rubbed over with a composition candle and the solder flowed on to the joint. Neat joints are best obtained when the soldering iron is at the right heat. The face of the iron should be placed only on the joints and held firmly until the solder runs into place, as shown in Fig. 5.

*Fig. 5. Soldering the joints.*

When all the joints are soldered the panel should be turned over very carefully. Two of the laths can be removed and the panel drawn forward on the surface of the table until it projects sufficiently to allow the hands to be inserted beneath it. It should be grasped between both hands and the projecting portion laid on a strip of wood, while that part of the light resting on the bench is raised with the left hand until the panel is vertical, as in Fig. 6, when it should be turned round and rested against boards which are slanting backwards. The bench is then cleared and the panel lifted by means of boards, laid in a vertical position, tilted over and pushed on to the table. The second side is then soldered as before.

*Fig. 6. Turning panel over to solder other side.*

For cementing, a small quantity of white lead may be used. Another cement is composed of whiting, plaster of Paris, boiled oil and turpentine, coloured with lamp-black, and with the addition of red lead and patent driers.

The object of cementing is to fill up the grooves and crevices between the glass and the lead so that the panel becomes one solid structure. A good way of doing this is to apply the cement with an ordinary paint brush which has been much worn and has got strong in the bristles, and to brush the cement well in under the flanges of the lead, as indicated in Fig. 7.

*Fig. 7. Brushing cement into joints with an old paint brush.*

The corners should receive extra careful attention; proper cementing is evidenced by the cement working right through from the top to the underside of the work. Lift the light from the bench occasionally and see if the cement has worked through. Surplus cement should be wiped off with cotton waste or clean rag, the light turned over and the cement brushed in on the other side. The whole surface of both sides should then be wiped over to remove surplus cement, and the surfaces dusted with whiting. The panel should be set against a sloping board to harden, and allowed to stand for 12 to 24 hours, when it may be cleaned by dusting it over with clean, dry sawdust and the use of a scrubbing brush. Any cement adhering in the corners should be cleaned out with a pointed piece of hardwood. The panel is then set aside to dry and harden for several days.

**Fixing the Panels.** Leaded light panels are fitted in different ways according to the nature of the frame. A simple method is to fix the panel into a rebate in a wooden frame secured with little battens of wood screwed or bradded. In the case of large panels,

strengthening bars of iron or copper have to be fitted, soldering a little hook of copper wire to the leads and twisting it round the iron bars. On outside work the rebate should be loaded with putty or cement prior to inserting the panel. If the light is to be fitted into a window with a stone mullion or framework having a rebate, the holes for the supporting bars will have to be chipped out with a mason's chisel and the light bedded in mastic cement, which may be composed of lime, sand, and a little litharge.

**Repairing Lights.** Repairs to leaded lights are effected by a process known as stopping in, and presuming only one or two small pieces of glass are broken, these are removed by levering up the flange of the lead with the aid of a lead or putty knife, until the pieces can be removed easily. The new piece is cut to shape, inserted in place, and the lead pressed down smooth again. If this necessitates cutting the soldered joints at the corners, they will have to be resoldered. If several pieces of glass are broken, the best plan is to cut away the whole of the damaged part and replace it with new lead and new glass, soldering and cementing as if the whole were new work.

**LEAD SALTS.** When applied to ulcers or broken skin surfaces lead salts act as an astringent and help to arrest bleeding. They are common ingredients in douches and lotions, and are sometimes of value for itching. Preparations commonly employed are strong solution of subacetate of lead (Goulard's extract); dilute solution of subacetate of lead (Goulard's water), the most convenient liquid preparation for external use; glycerin of subacetate of lead; ointment of sub-acetate of lead; lead or diachylon plaster.

**LEAF.** Leaves perform important functions in the life of a plant, but cannot be called absolutely essential organs, branches sometimes performing similar offices, as in the case of cacti and other plants. Nevertheless, if leaves are denuded from plants, the plants will quickly die or else have their vitality greatly injured. The function of a leaf appears to be a combination of lungs and digestive apparatus, which enable a plant to absorb air and nourishment from the atmosphere. In the case of evergreen plants these functions are performed for years, but in deciduous trees and plants leaves cease to function after a short period, and the withered leaves fall.

Transpiration with plants varies according to temperature and growth, and this explains why they do not require so much water in cold weather or during the period that blossoms ripen into seed. Free transpiration is essential to the health of plants, and consequently it is important to keep the leaves clean so that they can function properly.

Directions for drying the leaves of herbs for culinary purposes is explained in the article on herb.

**Leaf-Mould.** Leaf mould is one of the constituents of nearly all potting composts, and in conjunction with loam and sand it forms an ideal rooting material for plants. It also helps to lighten the soil.

The decayed leaves of oak, elm, and beech make excellent leaf-mould, especially oak leaves. Evergreen leaves, such as those of the holly and laurel, are not good for the purpose. All leaves of the right sort should be preserved by the gardener rather than burnt. Decayed leaves are the origin of the bulk of the humus which is found in the soil. They should be swept into a heap, or heaps, in corners as sheltered from the wind as possible. As a precautionary measure it is well to cover them with a thin layer of coarse soil, in order to prevent them from being blown. *See* Begonia; Compost; Loam; Mould; Potting.

**LEAK: How to Stop.** A leak is recognized by the escape of the contents through failure of some part of the container. In the home, a leak is most common when water pipes burst owing to the action of the frost, and, if neglected, may result in the flooding of the premises.

The pipe should be blocked at some point above the fracture, so that the water cannot flow through the pipe and the leak is stopped. Repairs are effected according to the nature of the material of which the pipe is made. In the case of a lead pipe, this is done by making a plumber's wiped joint, and in the case of an iron pipe, by fixing a new section in place of that which is damaged.

When rain finds its way through a roof or guttering, the leak usually is caused by a broken or misplaced tile or slate, a small hole through the gutter, or through the roof covering if of some material such as bituminous sheeting. The remedies are to replace the damaged tiles or slates with new ones, and close up the fracture in the sheeting. There are several patent compositions which are often effective in curing a leaky roof.

The remedy for a leaking water tap is generally to fit a new washer in place of the old one. Directions for this will be found in this work in the article Tap (q.v.) *See* Frost; Water Supply.

**Lean-to Building.** This is a simple form of erection which leans against another building. *See* Greenhouse; Shed.

**LEASE.** A lease is a grant of property either at will or for a period determinable on notice, or for a fixed period by a person who has a greater interest in the property. The person who grants the lease is called the lessor, and the other who receives it the lessee. That which is left to the lessor after he has granted the lease is called the reversion. The lessor need not be the freeholder. He may be himself a lessee from another lessor, and in such a case the lease which he grants to his own lessee is called a sub-lease, and he is usually spoken of as a sub-lessor, and his lessee as a sub-lessee. A lease is usually given in consideration either of a sum of money paid down or an annual rent in money, or both, but it is not necessary that there should be any

monetary consideration.

A lease for three years or over must be by deed under seal, but if anyone has an agreement for a lease in writing, and goes into possession of the house or other property on the strength of it, he will be considered a lessee, and cannot be turned out so long as he is prepared to execute a lease if required, and to observe the terms of the lease which was to have been made. The ordinary lease taken by a householder is for a fixed term, varying from 3 to 21 years. Sometimes it contains an option to terminate the lease at certain fixed periods by giving a certain notice, or to renew the lease on notice. The person taking advantage of the option should be careful to give the notice strictly in accordance with the terms agreed upon.

**Rates and Taxes.** In leases of houses and other buildings, especially in towns, the landlord very often insists upon certain covenants and conditions being inserted in the lease. The most common of these are that the tenant shall pay all rates and taxes, except landlord's property tax, which the tenant cannot agree to pay; a covenant to repair the premises; a covenant to pay the rent, and very often covenants not to use the building for certain purposes. A covenant to pay rates and taxes is simple enough, but sometimes it is put in the form that the tenant shall pay not only rates and taxes, but "all impositions whatsoever," and this sometimes results in a tenant being obliged to pay unexpected burdens which may be placed upon the property by the local authority.

**Restriction of Use.** It is quite common for leases to contain covenants restricting the use of the premises. Thus, when a landlord owns a row of shops, he sometimes desires to keep the shopkeepers from cut-throat competition; so he decides to let one shop to a butcher, another to a baker, a third to a tailor, and so on, and he inserts a clause in the lease that the butcher shall use his shop as a butcher's shop and for no other purposes without his consent.

Another form which this covenant may often take is that the tenant shall not use the premises for businesses which the landlord considers to be objectionable, or which might be a nuisance to the neighbourhood; e.g. it is common to find a stipulation that the premises shall not be used for a fried-fish shop, or as a soap boiler's, or as a public-house. This is, of course, partly to preserve the value of the property and partly to protect the neighbourhood against nuisances. A third form is to be found in the case of houses on a residential estate.

In some neighbourhoods the residents object to lodging houses and boarding houses and schools and the like occupations which can be carried on in a private house. To protect himself against depreciation the owner of the estate inserts in his leases a clause to the effect that the house shall not be used as anything but a private residence. The courts interpret this clause very strictly; and have even held that a person who established a home for girls out of work, to whom she

made no charge at all, was carrying on a trade or business within the meaning of such a covenant.

At common law every lessee is entitled to assign his lease or to underlet the premises or any part thereof to suit his own convenience. The tenant sometimes agrees not to assign or underlet without consent.

An express covenant is always put in a lease that the tenant shall pay the rent, and this is done to make the tenant take or send the rent to the landlord. If there is no express covenant by the tenant to pay the rent the landlord cannot distrain upon the premises or sue for the rent unless and until he has made a legal demand for it. A legal demand must be made after the rent has become due, and upon the premises themselves between the hours of sunrise and sunset.

**Breaches of the Covenant.** Where a tenant is guilty of a continuing breach of some covenant which is not immediately remediable by the payment of a sum of money, the court will injunct him from continuing to do it. In the case of a breach of a covenant to repair, the landlord can always get as damages the reasonable cost of doing the repairs. But nearly every lease in these days contains what is called a condition of forfeiture and re-entry, whereby it is stipulated that if the tenant shall fail to pay the rent or to perform and observe the covenants contained in the lease, then the lease shall be forfeited and the landlord shall have the right to enter upon the premises and take possession of them again.

Before taking the step of trying to eject the tenant the lessor must, however, give the lessee notice of the breach of covenant complained of, requiring him to remedy the breach, to pay compensation for it, also to pay the costs of the landlord's solicitor and surveyor in connexion with the matter. After the notice is given, the lessee must be allowed a reasonable time within which to comply with it, and if he does not do so the lessor may then take action.

It should be observed that the forfeiture of the lease does not exonerate the lessee from paying damages. Even after the lessee has failed to comply with the notice and the landlord has brought his action in the court, if the lessee comes forward and expresses his willingness to comply with the covenants and pay reasonable compensation, the court will not allow his lease to be forfeited, but will suspend the action to give him time to do what he ought to have done at first. The lessee will also have to pay all the costs of the lessor.

An exception to the rule about giving notice is when the tenant has failed to pay his rent. In this case the lessor can bring his action for forfeiture without giving any previous notice or requiring the lessee to remedy the breaches of which complaint was made.

If a lessee of premises continues in occupation of them after his lease has expired he is said to hold over. The tenant who holds over and pays to his lessor rent on a yearly basis becomes a yearly tenant upon the same terms as the lease, and his tenancy will be only determinable by six months' notice on either side, which notice must expire at the end of a current year of the tenancy.

The Rent Restriction Acts, so long as they continue in

operation, entitle a tenant under a lease to hold over after the expiration of his lease, but if he pays rent to the landlord no presumption arises that the landlord has accepted him as a yearly tenant. He is what is called a statutory tenant. The landlord can raise his rent to the amount which the statute allows by giving a month's notice of his intention. *See* Agreements; Building, House.

**LEASEHOLD.** This is the name given in England, Wales and Ireland to land that is let on a long lease for building purposes, not sold as is freehold. It is usually leased for 99 or 999 years for an annual payment known as the ground rent. At the end of that time the land, and also any buildings that have been erected thereon, revert to the successor of the one who granted the lease. Such buildings must be handed over in good condition. It should be noted that leasehold property is regarded as personal, not as real estate.

**LEASH: For Dogs.** Some form of leash is desirable for dogs when they are taken out for a walk. The various leather leads that can be purchased are undoubtedly the most satisfactory, and they can be had, either round or flat, suitable for almost any breed. See that the swivel at the end has a strong spring; otherwise it will continually be coming off the collar. The leather may be preserved by rubbing occasionally with Mar's or castor oil. For very powerful animals a chain may be preferred, but it is much heavier and less comfortable for the hands. *See* Dog.

#### **LEATHER & ORNAMENTAL LEATHER WORK** The Necessary Tools and Simple Methods Described

The following article contains many useful hints on materials and accessories required for this decorative craft, together with practical directions for modelling and colouring leather.  
See also the entries on Boot; Glove; Lacquer Work.

When choosing leather for an important piece of work such as a fire screen, large bag or blotter, it is advisable to purchase a quarter skin of medium growth. Older skins are coarser and young ones cut to waste. Merchants charge more in proportion for supplying panels of flawless pieces, and if there is a surplus of material after cutting out the required amount for the work in hand, the extra pieces can be made up into smaller articles. Skins are usually sold by the square foot.

English calf skin is the best leather for plain or modelling purposes. It can be prepared so that embossed work retains its shape without padding. Kip calf, or East India kip, is a less expensive leather with a coarser grain, but is also good for modelling work. Cowhide is a useful leather for large pieces of work such as a screen or a shopping bag. It models, stains and wears excellently. As the skins are very large

these leathers are obtainable at the lower rate in eighths as well as in quarters and halves. A cheaper underhide is obtainable in narrower widths. Russian leather has a beautiful surface for bookbinding work. Morocco is made from the finest selected and hand-dressed goat skins. Pigskin is light, but very tough and durable. The reptile skins, crocodile, alligator, lizard and snake, make ornamental but expensive leathers.

**Lining and Imitation Leathers.** Persians are hardwearing and made from foreign sheepskins. They are obtainable in browns and several other colours. Velvet persians are a fancy form of this leather with a suede finish. Persians are used extensively for lining first-class work. Degrained persians are a superior form of suede, finished leather used for golf coats and other dress wear. Velvet sheepskin is similar in appearance to velvet persian, but coarser, and is used for making bags and blotters, etc., required with a suede finish. Less expensive for smaller articles is a strong leather made from hide splits and known as velvet splits. Plain skivers are cheap and useful lining leathers. These are the upper grain of split sheepskins. The under or flesh split is called chamois, though only an imitation of the skin of that almost extinct animal. Skivers should be strengthened by pasting to leather, linen or board. They are not suitable for pockets or gussets, as they tear easily. They are obtainable in plain colours, in fancy shadings and in nappa finish. White kid is used for glove making and linings, and lacing calf for thongs and gussetting for pockets.

Imitation morocco is made from sheepskin with a grained instead of a velvet surface. Polished crocodile, in large or small grainings, and velvet crocodile are copied well in hide. These are strong and effective leathers for shopping bags, pochettes and undecorated blotters. Lizard-grained sheepskin is also an excellent imitation of another reptile skin which can be most successfully made up into handbags.

**Tools and Accessories.** Simple outfits are best for the beginner. There are many excellent ones on the market which vary slightly in their contents. A useful set of tools comprises: a transparent set square for correcting angles and cutting the various parts of the work to fit; being marked with inches and quarter inches it takes the place of a rule; sharp knife for cutting leather and turning edges (Fig. 1, D); double-edged ball tool for embossing, i.e. pushing up the design to raise it from the back; combination tracer-modelling tool, used for tracing and modelling the finer parts of a design (B); pliers punch for punching holes in the leather before thonging (A); boxwood mallet for flattening out corners and pressing the edges of finished work (K). A large-eyed blunt needle is required for use with leather thongs (G). A rug needle will do.

A Dresden tool is often used for backgrounds and completing delicate detail. One end is shaped like an inverted V and the other forms a semi circle. Both these working ends are thin and smoothly finished. A purse crease is a useful tool for finishing the edges of leather work. It is heated over a gas jet and held vertically. The

groove in the creaser fits over the edge of the leather. To round corners it is important to move the article round to meet the creaser. A well finished smoothly indented crease is thus easily made. A brass holing gauge (Fig. 1, F) is a detachable device for the punch pliers which enables the worker to punch holes accurately at equal distance both from the edge of the article and from hole to hole.

*Leather Work. Fig. 1. A simple outfit. C, paring scissors. D, cutting knife. E, stitch tool, J, press button punch and die set.*

*A, six-hole punch pliers. B, combined modelling and tracing tool. F, holing gauge for pliers.*

*G, needle for thonging.*

*H, awl.*

*K, boxwood mallet.*

A brass die outfit (J) for fixing press studs and eyelets to bags and other articles can also be obtained, and press buttons can be bought in various sizes and colours. Each press button consists of four parts: two upper pieces, cap and cap eyelet; and two under pieces, spring and spring eyelet. Directions for the use of these outfits are sold with them, but if the amateur wishes it is possible

to get press studs put in work by a leather merchant or sadler. Matting punches for ornamental work are used for simple forms of decoration instead of modelling the leather and are sold with a number of fittings.

Many other helpful accessories are obtainable. Metal corners can be bought ready for fixing in wallets. Zip fasteners, bag mirrors, frames and locks for bags and metal edges and tabs. Made-up bag linings are also supplied with patterns showing the exact sizes of the outside covers required to fit the inners. Inners for

wallets, blotters, pochettes and other articles can be fitted to the panels embossed or decorated by the home worker. Frames are obtainable for fire-screens in oak, mahogany or walnut. Rubber linings are made for leather tobacco pouches. Thongs are prepared for use in various widths and lengths of persian and calf.

Aniline spirit dyes are chiefly used for colouring leather work. A special polish is sold to give a brilliant finish; manilla board is used for stiffening purposes and pattern making, and a cement or flour and water paste for fixing linings, etc. Bronze powders and silver and gold leaf are suitable for decorating leathers, and may be supplemented with transparent lacquer colours. Designs and patterns are obtainable in great variety for decoration and articles in leather.

**Modelling or Embossing.** Having cut out a piece of leather to the required size, damp it with a clean sponge and water, place it on a drawing board and fix the selected design over it by means of drawing pins, beyond the edges of the leather to obviate marking this. Having traced over the whole design with the tracing tool, remove the paper and trace the design again firmly with the tracing tool on the leather itself.

*Leather Work. Fig. 2. Useful book or shopping bag in hide decorated, with a modelled conventional design.*

To raise into relief portions of the work from the back, if the panel is a large one, the leather is held in position by the left arm, the first finger and thumb of the left hand limiting the particular portion of the design being raised, while the right hand underneath the panel pushes up the leather, between the left finger and thumb, with a ball modelling tool, working it to and fro. Care must be taken not to stretch the leather too much. High relief does not look well in leather except in rare instances, when it is usually filled with a padding of cotton wool pasted to the back of the leather and covered over with paper, pasted on before affixing the lining. Medium and low relief should require no filling out if a good quality of calf or hide is used for this work. All the raising work required is done from the back before any modelling is begun on the front of the leather.

Having completed the raising, lay the panel flat on a piece of plate glass; or, if a soft surface is required, pin several sheets of blotting paper on to the drawing board. Then holding the modelling tool at an angle of about 45°, press the whole design down into position along the traced lines. Use the tool in one direction only and with sweeping strokes, to produce a distinct groove, without creasing the background. The heavier the

leather the more frequent will be the damping required to keep it soft. Having thus completed the raising and depressing of the principal portions of the relief, work is now done with a Dresden tool on the detail and background. Using the same long, sweeping strokes, the whole design is thrown up by this means into varying shades of relief. In really good leather craft, designs are not overworked, but accomplished with a minimum of strokes and curves. Matting punches are often used for backgrounds to give them variety of texture. The whole of the ground must be covered and the punch is held upright, the same force being given to each blow of the boxwood mallet on to the punch. Where very low relief is required the background is merely pressed down without raising the design from the back.

**Staining.** In all decorated leather work it is essential that the surface should be absolutely clean before using any stain. When the design is completed the whole piece of leather should be damped over with a clean sponge moistened in water, and then oxalic acid solution is applied with a pad of cotton wool. When this is dry, colouring may be proceeded with. An antique effect is obtained by applying a coat of bichromate of potash to the leather after it has been cleaned. Choose spirit stains of the required colours and mix them with methylated spirit to the tint suitable for the particular work. In some cases the entire surface of the leather is stained one colour, in others several shades are used to bring out the designs. The leather must first be damped before applying stains.

After the article has been coloured (excluding the design if that is to be multi-coloured) and the stain allowed to dry, begin to paint in the design with a camel-hair brush, working quickly to avoid hard lines, as these stains dry rapidly. Several coatings of a stain may be required for dark colours. For large surfaces stains are applied with flat wash brushes or with pads of cotton wool. Shading and tinting require practice. Several colours may be merged into one another by painting them on with small, rather dry brushes. If the effect is crude when finished, a softer one can be produced by a quick wash of very thin background colour over the whole design. Staining may be used to colour designs without embossing, and embossing without staining, as forms of decoration in leather work. The natural colour of calf is beautiful in some modelled work. Small pieces of leather may be utilized to make artificial flowers. Once modelling and colouring have been grasped these can be effectively copied from real or imitation flowers. Skivers and suède are mostly used for this work, and flower centres and other accessories can be bought for it. (See Artificial Flowers.)

**Thonging.** Lacing leather by means of narrow thongs threaded through a rug needle is a simple method for fastening, and is also used for ornamental edging as seen in Fig. 7. If thonging is to present a

workmanlike appearance it is essential that the spacing between the holes is accurately gauged. Using a lacing of  $\frac{1}{8}$  in. wide, the holes should be  $\frac{3}{16}$  in. from each other and from the edge of the article. By means of the holing gauge device already mentioned, marking and measuring are rendered superfluous.

In use it has been found that shorter lengths of thonging are the most practical. Dragging more than 30 in. of lacing through a large number of holes merely to avoid joining is not only waste of time and energy, but also is apt to spoil the look of the work and to twist the thong. To start, fix the end of the thong between the lining and the leather with paste, and sew as if over stitching. To join thonging, pass the old and new piece through the same hole at the actual join, the old one from the back and the new one from the front, and paste about  $\frac{3}{4}$  in. of each under the lining, cutting off the superfluous length of the old piece. Another method is to shave off each end and paste them together, but this is not so durable.

**Hide Book Bag.** A most useful bag for books or for holding oddments when travelling is illustrated in Fig. 2. It can be made from two pieces of cowhide each 14 in. by 11 in.; two pieces of brown persian or of skiver for lining of the same size; two pieces of persian calf 14 in. by  $1\frac{1}{2}$  in.; one piece of hide for the gusset 36 in. by 3 in. (the gusset is without joins); one piece of lining for same; four pieces of hide for handles, 11 in. by  $\frac{3}{4}$  in.; brown stain, paste and thongs.

A conventional design is traced on the upper portion of the bag. Any good oblong formation which comes to within about 2 in. of either side and  $1\frac{1}{2}$  in. from the top will be suitable. The background of the design is pressed down, but the latter is not raised from the back for this piece of work; it is lightly modelled with a modelling tool from the front. Both sides of the bag are stained dark brown.

When cutting the 36-in. strip of persian for lining the gusset, allow 1 in. for turning at either end to neaten and strengthen. Turn down firmly and then paste the lining to the gusset. Paste the lining to the back and front pieces of the bag. Lay two pieces of leather together for each handle, and thong them all round on both sides. Fix the handles on to the back and front pieces of the bag temporarily with paste, and paste over them the two strips of persian calf,  $1\frac{1}{2}$  in. wide, to neaten and strengthen the top of the bag. Thong along the top of the bag through leather and lining and through the handle pieces and strips, to fix them firmly to the bag. Trim the sides of the bag pieces quite evenly and see that they are of exactly the same size. Now thong the sides and the gusset strip together, working from the top corner all round the front pieces, and then do the back piece in the same way. Stain the thonged edges brown to match the rest of the bag.

**Fire Screen.** The panel for the fire screen illustrated in Fig. 3 relies on colouring and not on modelling for its decoration. A variety of designs are obtainable which would be suitable for such a screen. Having traced the

design in the manner already described and gone over it lightly with the modelling tool, the spirit stains are applied, using dark brown for the gull's wings and tail, tipping them with black or with white to bring out the feather markings. The top of the body and head are also white, the eye is black, and the beak and legs scarlet. The curves of the sea are in white and gradations of blues and greens, while the fish are in browns and white. The sky is left the natural fawn colour of the leather.

*Leather Work. Fig. 3. Fire screen of painted leather, mounted on a 3-ply wooden backing and framed in oak.*

The leather panel when painted is covered with a thin layer of paste and affixed to a 3-ply wooden backing. This is allowed to dry thoroughly before framing. It is kept in position by hammering gimp pins through the beading to the sides of the screen. The panel is polished with a special leather polish to give it a glossy surface. Screen panels are also sometimes thonged to frames which are furnished with screw eyes.

**Embossed and Coloured Blotter.** To make the blotter illustrated in Fig. 4, cut out the panel in calf skin or hide,  $22\frac{1}{2}$  in. by 14 in., this being the size when opened out. Choose a bold, conventional design, and after damping the whole surface that is to take the design, trace this as directed in the general instructions for leather work tracing. Now proceed to carry out the instructions given for modelling leather and for punching the background; then to stain the embossing in different colours, proceed as directed for staining.

When the design has been completed and the skin is ready to be made up, cut out a piece of skiver  $\frac{1}{4}$  in. smaller than the calf-skin and place this over the inner side. The skiver can be obtained to match the background colour of the blotter. A better article results from using a plain persian lining. The finished cover can be sent to a leather merchant to have an inner fitted to it if desired.

Fold the calf-skin over the skiver and paste down securely. Cut out two triangular pieces, 2 in. by  $2\frac{1}{2}$  in., and paste these across each of the right-hand corners. Now cut out a piece of skiver 10 in. by 16 in. and fold over one edge of the wider side  $\frac{1}{4}$  in., pasting securely. Cut out another piece 14 in. by 7 in. These pieces make the inside flaps. Turn the edge of the smaller piece to make a  $\frac{1}{4}$  in. hem and paste down. Now place the smaller flap over the larger, bringing the bottom edges together, and machine them together through the centre, thus making two pockets. Machine the sides of

the smaller pocket on to the larger. Place the bottom edges to the edge of the blotter and the sides of the larger flap to the sides of the blotter. The extra inch on each side of the larger flap must be folded in, gusset-wise, and flattened down.

*Fig. 4. Front cover of a blotter in calf skin or hide, embossed in a bold conventional design. The inner fittings are shown in Fig. 5.*

*Leather Work. Fig. 5. Interior of blotter of embossed leather, the front cover of which is shown in Fig. 4.*

Now open the blotter out flat and machine all the way round, joining the edges of the skiver to the outer skin and joining the two flap pockets on also. Care should be taken that all the parts are exactly in position before being machined, as the work will probably be spoiled if the machine stitching has to be undone. A  $\frac{1}{4}$  in. strip of calf, stained to match the lining, cut the length of the blotter must be sewn securely at the top and bottom edges at the exact centre, inside the blotter. This forms a strap for the blotting paper to be slipped through. This strap should be glued in position before the machining is begun, as it can then be machined in with the lining and pockets. These are shown in Fig. 5.

The blotting paper sheets should be cut  $\frac{1}{4}$  in. smaller than the blotter and slipped under the narrow strap the whole width of the blotter. Turn all the blotting paper sheets over on to the right side and slip the corners into the triangular pockets. The whole blotter can be finished off by wax polishing. To do this, put a small quantity of polish on a piece of flannel and

rub it carefully into the whole surface, using a circular motion. Continue this until an even polish has been applied. Leave for a short time and then rub over with a soft flannel.

**Decoration with Silver and Gold.** When the methods of modelling and staining have been successfully practised there are several forms of decoration which give beautiful and antique finishes to leatherwork. Lanellé is a form little known in England. It derives its name from the silver thongs used in the decorating. These are often interlaced to form a kind of mesh. Lanellé is used in conjunction with modelling. To carry out this work, thin strips of silver are cut  $\frac{1}{8}$  in. wide. The leather is placed on a board and holes punched with a single thonging punch at the points where it is desired to thread the silver.

The silver is threaded from back to front, and is tapped with a tiny hammer so that it shall lie flat. It is threaded through the next hole from front to back, and so on, until the design is completed. The silver is cut off and pressed flat. When the silver thonging is finished it must be tapped at the ends and at the back with the hammer to ensure that it will lie flat. Most of this class of work is thonged round the 4 edges when finished, but the example shown in Fig. 6 is finished with a crease made by the purse creaser already described.

The design for the loose cover for an A.B.C. or telephone book illustrated in Fig. 6 has been thonged, after the modelling has been completed, with silver in the central motive and at the bottom, also on the outer edge. The background has been gilded with gold bronze powder. To make the cover, the calf to be decorated is cut out in one piece to fit the book, allowing  $\frac{1}{2}$  in. over for the edges to project. For a telephone book cover the panel of calf required would be  $20\frac{1}{2}$  in. by 12 in., and the skiver for lining would be cut 21 in. by  $12\frac{1}{2}$  in. to allow for turnings when pasted inside the cover. For an A.B.C. cover the calf would measure  $12\frac{1}{2}$  in. by  $8\frac{1}{2}$  in., and the skiver for lining 13 in. by 9 in. When making up, eyelet holes are punched into the back of the cover top and bottom for a thong, or cord, to be passed through which holds the book in place.

A fascinating form of leather work is Venetian lacquer on leather. This may be worked with gold or silver leaf, but it is simpler to employ bronze powders. These are obtainable in small tins, the upper part of which holds the silver or gold powder, and the lower contains the special medium for using with it. The diary or address book cover in Fig. 7 has a raised and modelled design which has been ornamented in this method. Flat brushwork is also possible, and very beautiful effects are carried out on leather with a flat design painted in bronze powders and transparent lacquer colours.

The modelling of a raised design is first completed with the exception of punching—if it is desired to work up the background in this manner—which is done after the gold has been applied. Mix a little gold powder to the consistency of cream with the medium in a small

container or tinting saucer. Pass this mixture evenly over the surface of the leather, using a flat-topped Japanese stencil brush. Work in circles to avoid streaks. Cover over all the leather, and if necessary give it a second coat after allowing 15 minutes for the first to dry. No sizing is required. Now leave the work for half an hour to dry, then coat over the parts to be left plain gold—in the case of the cover illustrated the back and the border—with a thin coat of spirit varnish. Then on the central unvarnished portion of the front where the design has been raised the colouring is applied with transparent lacquers. Yellow is applied first for the background, and then blue is put quickly over it to make it a green colour, while the raised design is worked up with yellow first and then red for shading, so that it has an orange effect.

Fig. 6. Design for a telephone or reference book cover in silver thonged or lanellé work.

Fig. 7. Diary or address book cover in Venetian lacquer on leather.

When the painting is completed the diary cover is ready for mounting, and the thonging must be painted with gold powder. When the making up is finished the thongs are painted over again with gold. To make such a cover the worker will need 1 piece of calf  $8\frac{1}{2}$  in. by  $6\frac{1}{2}$  in., 1 piece of persian for lining 9 in. by 7 in., 2 pieces of calf-finished persian 3 in. by  $6\frac{1}{2}$  in. The two last pieces are used to make the pockets into which the diary covers are slipped to keep the book in place. Stick the lining to the finished calf panel, turning in the edges of the former to match. Turn in the edges of the neatly

pared pieces of persian calf for the pockets and stick them down with paste. Lay these pieces to the edges of the cover and thong all round.

**LEATHER CLOTH.** This cloth, as its name implies, is a substitute for leather, and is used mainly for upholstering. Manufactured by a patent process, it is obtainable in almost every colour with a variety of grains, morocco, antique leather, and pig and buffalo skins being among the leathers simulated. The cloth is dampproof and fadeless, and requires no special cleaning. Dust or stains may be removed with a damp cloth without destroying its lustre. Leather cloth may also be used for panelling walls. *See* Panelling; Upholstery.

**LEATHERJACKET.** The larva of the daddy long legs or crane fly is popularly termed a leatherjacket. The grubs of this fly are about 1 in. long, two or three times as thick as the wire worm, brownish-grey or black, and exceedingly tough. They have hard black heads and jaws. They are very difficult to reach underground. Watering with a very strong solution of nitrate of soda has been found harmful to them. Special preparations are sold by seedsmen for the destruction of leather jackets. *See* Crane Fly; Insecticide.

**Leaven.** In its household application leaven is used as a synonym for yeast (q.v.).

**LECLANCHÉ CELL.** This is a primary cell used for converting chemical into electrical energy. It is largely employed in electric bell work. A single fluid cell, it consists of an outer glass vessel containing the electrolyte or chemical fluid, which is a saturated solution of sal-ammoniac.

Standing in the solution is a porous pot, made of a kind of earthenware, and filled with a mixture of black oxide of manganese, or manganese dioxide, in the form of a coarse powder. In the centre of the pot and surrounded on all sides by the oxide of manganese is a plate of carbon. The top of the porous pot is closed with a layer of pitch, or similar material. The carbon plate comes up above this pitch, and has attached to it a brass terminal for connecting to the conductor, or wiring system.

In the space between the outer vessel and the porous pot is placed a zinc rod, usually circular in section, and terminating at its upper end either with a terminal or with a short length of insulated copper wire soldered to it. This class of cell has an electromotive force of  $1\frac{1}{2}$  volts, and is suitable for supplying an intermittent current. It can be left on open circuit for a long time without deteriorating, and has the property of recuperating when not used for a time.

The chemical action results in the zinc rod being consumed, and at the same time the sal-ammoniac is used up. For each oz. of zinc consumed, 2 oz. of sal-

ammoniac will be used up, so that whenever the zinc rod has to be replaced the electrolyte should be renewed. After about four zinc rods have been eaten away it will be necessary to replace the porous pot and its contents.

Leclanché cells should be recharged by thoroughly cleaning all the parts, putting in fresh zinc and refilling with fresh sal-ammoniac solution. The solution is made by putting into clean, preferably distilled, water as much sal-ammoniac as can be dissolved, but no more. The proportions are about 3 oz. of sal-ammoniac to 1 pint of water.

Too much of the sal-ammoniac must not be used, or a deposit will form around the bottom of the cell and impede its action. Local chemical action may be set up, resulting in the rapid deterioration of the zinc. Since the deterioration takes place more at the top of the zinc than at the bottom, there is little difficulty in finding out whether the cell is too heavily charged with sal-ammoniac. Leclanché cells are used for batteries, several cells being connected in series to increase their voltage, or in parallel to increase their amperage. In the former case, the wire from the zinc rod of one cell is connected with the carbon on the next. In the latter, all the zincs are connected together and all the carbons together. *See Battery; Bell; Sal-ammoniac.*

**LEECH.** Though now rarely employed, the leech was formerly much used for removing blood to relieve local congestion, e.g. in certain eye diseases, etc. As a rule, they drop off when surfeited; but when they remain too long, the application of a little salt will make them quit their hold. Bleeding from the bites is usually easily arrested by pressure. Care should be taken not to apply a leech over a vein, too close to an eye, or not in any case to persons prone to bleeding.

**LEEDS WARE.** As the Leeds pottery was active for 120 years after its establishment about 1760, there is no scarcity of examples of this beautiful ware. The principal body was a fine cream-ware with a rich arsenic glaze, inclined to a greenish tinge.

*Leeds Ware. Girl with birdcage, small figure dating from about 1780.*

Many of the best pieces, except in the blueprinted ware, are unmarked. Among the marks used are Leeds Pottery, sometimes crosswise; Hartley, Greens & Co., for the best period; L.P.; and after 1863, B.B. & S. The pieces to look for are those decorated with quiet enamel colours, together with the large class of perforated or basket ware.

**LEEK.** This is a valuable hardy winter vegetable; the edible part is provided by the blanched stems. For ordinary purposes seeds are sown out of doors in March or April in shallow drills on a seed bed. If the seedlings are not overcrowded they may remain undisturbed until July, when they are planted finally.

Deeply dug and manured soil is necessary. Holes 8 in. deep should be made with a dibber, one seedling being placed at the bottom of each hole, and the roots covered with a sprinkling of soil. As the plants develop they will become blanched, and more soil may be moulded up to produce a greater length of blanched stem. The holes ought to be 6 to 8 in. apart and the rows 15 to 18 in. from each other.

*Leek. Roots, blanched leaf-bases, and leaves.*

To obtain the finest leeks with a good length of blanched stem, the seedlings should be raised under glass in February and planted in early summer in trenches dug on rich ground. As the plants progress the trenches are filled in with soil to blanch the stems. Another method is to plant the seedlings on the ground level and to blanch the stems by means of stiff paper bands. Two excellent varieties of leek are the Musselburgh and the Lyon.

**How to Cook.** The leek is used either as a vegetable, as a garnish or as a flavouring for soups etc.

To stew leeks, trim and wash them, cut them in half lengthwise, and then leave them to soak for about half-hour in a bowl of cold water to which a little vinegar has been added. They should then be drained, cut up again if necessary, and put into a pan containing enough stock or salted water to cover them. Stew them slowly with the lid on the pan for about half-hour, or until they are tender, then season, and before serving add a small lump of butter. White sauce is often served with leeks, or they are excellent if, when cooked, they are covered with a good cheese sauce and browned in a fireproof dish in the oven before serving au gratin as a vegetable entree.

**LEG:** The Limb. The whole lower limb is often referred to as the leg, but the term is more appropriately applied to the portion between the knee and the ankle. In this sense the leg has two bones: the tibia or shin bone on the inner side, and the long, slender fibula on the outer side. The latter takes no part in forming the knee joint, but its lower extremity is an important part of the ankle joint, being that bone which forms the prominence on the outer side of the ankle.

The inner surface of the tibia lies just beneath the skin without a covering of muscle, and is thus much exposed to injury from knocks. At the back of the leg the calf is formed by the muscles which are inserted by the strong achilles tendon into the back of the heel bone. This tendon may be ruptured by sudden strain. Large superficial veins travel up the leg, carrying off

the blood from the foot and leg. These may become varicose and dilated. The veins then stand out prominently when the person stands up, but collapse more or less when he lies down.

In a fracture of the leg both bones are usually broken. *See* Ankle; Bandage; Foot; Fracture; Knee; Thigh; Varicose Vein.

*Legs for Furniture: stock patterns which the home worker can procure. 1, cabriole cabinet. 2, cabinet. 3, 4, dining table. 5, kitchen table. 6, table. 7, tapered. 8, cabriole stool. 9, Jacobean table. 10, 11, swinger and leg for gate-leg table. 12, dining table. 13, sideboard.*

**LEG:** Of Furniture. A leg is a slender support to anything, something that in purpose resembles the human leg. Stands for flowers and stands of other kinds have legs, while the word is used for the supports to certain kinds of dishes and other table utensils. Certain forms of furniture leg have special names, an example being the cabriole leg.

**Turned Legs.** Table or cabinet legs often present some little difficulty to the amateur worker, who is generally obliged to get the work done by a turner. It is possible to obtain turned or shaped legs of certain stock patterns in sets from timber merchants, and their use saves the home worker a lot of trouble. We illustrate a group of designs photographed from the stock of one of the many suppliers of wood turnery. It will be noted that tapered, turned, twist, and cabriole legs are included, and in the case of those for gate-leg tables the necessary swingers for the gates are available en suite. *See* Cabriole Leg; Chair; Furniture; Stretcher; Table; Turning; Woodcarving.

**LEGACY.** A legacy is a gift of personal property by will. A gift of real property is called a devise. Legacies are of three kinds: specific, demonstrative, and general.

A specific legacy is a legacy of a specific thing, e.g. "my gold watch" or "my £200 London County Council Stock." A demonstrative legacy is a legacy, not of a specific thing, but where the testator points out or demonstrates the fund or property out of which the legacy is to be made, e.g. "I give to my son John £1,000 out of my Great Western Railway Stock."

A general legacy is the legacy of a sum of money in general terms without indicating any particular fund or source from which it is paid, e.g. "I give to my daughter Mary the sum of £500." The advantage of a specific

legacy is that if the testator's property is not sufficient both to pay his debts and to pay the legacies, the executor must resort to specific legacies last or, as it is sometimes said, specific legacies do not abate.

Demonstrative legacies share in the advantages of specific legacies in that they do not abate, but if the fund pointed out for payment of a demonstrative legacy is not in existence when the testator dies, the legacy is payable out of the general funds of the estate. A specific legacy, on the other hand, goes altogether if the thing bequeathed is not in existence when the testator dies.

**Two Examples.** For example, "I give to my son John my gold watch." If I sell my gold watch before I die, John gets nothing in lieu thereof. But if I say "I give to my son John £500 out of my money standing to my credit in Barclays Bank," and when I die I have no money in Barclays Bank, John gets his money out of the general fund if there is any; in other words, it is just as if I said "I leave to my son John £500". On the other hand, if I do leave money in Barclays Bank when I die, my executors must pay my debts out of other funds before resorting to the Barclays Bank money.

To give a complete example, a testator bequeathed £1,000 to John, £1,000 to Mary, £1,000 out of his money at Barclays Bank to Susan, and his gold watch to Isaac. The watch is worth £100. The debts and funeral expenses amount to £2,500 and the testator's total assets are only £4,000, including the above legacies. The debts must be paid, so the executor, who has £1,000 besides the legacy money, requires another £1,500 to satisfy the debts and expenses, and this he will take out of the general legacies left to John and Mary, viz.: £750 from each. He will not touch either the demonstrative legacy left to Susan, or the watch left to Isaac.

**The Legacy Duty.** This is a tax paid in Great Britain and many other countries by persons who inherit money either under a will or on intestacy.

In Great Britain the duty varies according to the relationship of the legatee to the deceased. Husband or wife and relatives in direct line, i.e. parents, children, and grandchildren, pay 1 per cent.; brothers, sisters, nephews, and nieces pay 5 per cent.; while other relatives and strangers in blood pay 10 per cent. Relatives of the husband or wife of the deceased are regarded as strangers in blood. Legacy duty is not payable by a widow or child under 21 who inherits a sum of £2,000 or less, or by a husband or any relative in the direct line who inherits £1,000 or less. Moreover if the whole estate does not exceed £15,000 in value, legacy duties are not charged on money inherited by a husband or wife or by relatives in the direct line whatever the amount they receive.

It is the executor's duty to pay the legacy duty out of each legacy before handing over anything to the legatees. If the legacy is payable "free of legacy duty,"

the executor must pay the legacy duty out of the general funds of the estate, and not out of the legacy itself. *See* Estate Duty; Executor; Probate; Will.

**LEGAL TENDER.** This phrase is used in English law for the coinage which a creditor is bound to accept when payment of a debt is offered to him. A creditor is not bound to accept a cheque unless that method of payment has been customary between the parties, or a large sum of money in shillings or other silver coins; he can legally refuse to take it, and the debt will remain unpaid until the debtor returns with the money in legal tender.

Legal tender consists of Bank of England notes and gold to any amount. Silver coins are legal tender up to 40s. and bronze coins up to 1s., provided they are those issued by the royal mint. Bank of England notes, it should be said, are not legal tender in payments made by the Bank itself. In Canada, Australia, and other parts of the British Empire the same principle prevails. Gold is legal tender to any amount and other coins up to a certain figure. In Canada the gold coins of the U.S.A. are legal tender.

**LEGGINGS.** Leggings, usually of leather or canvas, are sometimes worn in bad weather and by those who work in the open air, by sportsmen, chauffeurs, and others. Leather leggings are usually either black or tan in colour, and are fastened either with buttons or with straps, the former being the more general. Canvas leggings are usually light in colour, drab being a common shade for them.

Leggings are sold in sizes, the lengths usually stocked for men being 11½, 12, 12½, and 13 in. Their calf measurements vary also. If leggings are ordered by post it is well to give the measurement round the centre of the calf, and to state whether this is bare or over the breeches. Leggings and boots in one piece are known as Wellingtons. Leather leggings should be cared for in very much the same way as boots. Canvas leggings can also be kept clean by brushing. *See* Boots; Gaiters.

**LEGHORN: The Straw.** Leghorn is a fine, soft straw used chiefly for children's summer hats in its natural colour. It wears almost indefinitely and requires very simple trimming. *See* Hat; Straw.

**LEGHORN: The Fowl.** This breed undoubtedly stands first as an egg producer. It lays a large, white-shelled egg, is a non-sitter, and possesses no merit as a table bird. From an economic point of view it is cheaper to keep than most breeds, as it consumes a smaller quantity of hand-fed food in comparison with its output of eggs.

Apart from this, it is one of the most attractive denizens of the poultry yard, its plumage, be it white, black, brown, or cuckoo, contrasting vividly with its yellow shanks and bright red comb and wattles. *See* Fowl; Poultry.

**LEMON.** The Plant. The lemon is a greenhouse

evergreen shrub which will flower and mature its fruits in a glasshouse having a minimum temperature of 50°. The plants should be placed in pots in a mixture of loam, enriched with manure, crushed bones, and charcoal. They should be watered freely all the summer. The temperature during these months should range from 60° to 65°, but may be dropped 10 points during the autumn and winter.

The flowers, which are white, appear in early summer, and are followed by the fruit. Lemons which are formed in one season, however, will not ripen until the following year.

Lemons belong to the Citrus family, which include the orange, lime, and citron.

**LEMON: In Cookery.** A squeeze of lemon juice is an improvement to fried fish, to a dish of mince, or meat rissoles. It is preferred to vinegar by many for salad dressings. The juice is used to whiten various dishes as well as for flavouring, e.g. for ices or when mixed with icing, for cakes. It is also useful for softening the fibres of tough substances, thus making them more easily digested. Lemon is often substituted for milk or cream in tea. It is cut into thin slices, one being put into each cup of weak tea, sugar to taste being added. This is known as Russian tea. The juice of a lemon in a tumbler filled up with soda water and sweetened to taste is known as lemon squash.

From the rind, lemon essence, candied peel, and oil of lemons are prepared. The last-named is used both in cookery and scent making. The white pith below the rind is avoided in cooking, as it is very bitter. The rind should be pared very thinly or grated. In making custards and creams flavoured with lemon, the thinly pared rind should be added to the milk or cream preparation and brought to the boil. The rind is removed when the preparation is taken from the pan. In making lemon cakes or puddings the rind is usually grated. Slices of lemon cut across diagonally are used for garnishing cutlets, fried or boiled fish, veal, pancakes, and several made-up dishes.

To preserve lemons, smear them all over with the white or yolk of an egg and place them on a shelf to dry, or keep them in a jar of water, renewing the water daily. Another method is to put them under clean dry salt in a box, which must be kept in a cool, dry place. Lemon peel may be preserved if grated, put into bottles and covered with salt.

Many afternoon tea cakes, puddings and sweets are flavoured with lemon. This flavouring is also a favourite one for an icing (q.v.) for cakes and sponge sandwiches with various fillings.

**Lemon Bun.** To make lemon buns, allow ½ lb. flour to 3 oz. butter or margarine, 2 oz. castor sugar, 2 eggs, a teaspoonful of grated lemon rind, and a teaspoonful of baking-powder. Add the baking-powder and lemon rind to the flour, stirring them in lightly. Beat the butter and sugar to a smooth cream, gradually whisk into them 2 beaten eggs, and then fold in the flour, etc.

*Lemon Buns, an acceptable addition to the afternoon tea-table.*

If the eggs are small and the mixture seems too stiff, add a little milk to obtain the right consistency of a smooth batter. Grease some patty-tins and drop the mixture in, about two-thirds filling the tins. Bake them in a hot oven for about ten minutes. If liked, the buns can be covered with lemon icing when cold.

**Lemon Cake.** Lemon cake is made in the following way. Take 6 oz. flour, 4 oz. butter or margarine, 3 oz. castor sugar, 1 teaspoonful baking-powder, and 1 lemon. Beat the butter and sugar to a cream. Grate the lemon rind on to the butter and sugar, and stir in. Beat up the eggs very lightly. Add a little of the beaten egg to the butter and sugar, then a little of the flour, and whisk lightly with a fork. Continue beating in the eggs and flour alternately, and at the last add the juice of the lemon and then the baking-powder, which must be lightly stirred in but not beaten. Pour the mixture at once into a greased cake-tin and bake in a moderate oven for about one hour. Let the cake cool on a wire cake stand, and then ice it with lemon icing.

A lemon sandwich cake is made by preparing 2 thin rounds or quares of sponge, as described under jam sandwich (q.v.), and spreading them, while hot, with lemon cheese.

**Lemon Cheese.** This is made by beating well together in front of the fire 3 oz. fresh butter and  $\frac{3}{4}$  lb. white sugar. When this is soft and melted, add the grated rind and strained juice of 2 lemons, and 4 or 5 new-laid eggs, well beaten, and mix them thoroughly. Stir the cheese over a slow fire until it is thick and creamy, but do not let it boil, then put it into small jars and tie down when cold. Keep it in a cool, dry place until needed. It is used as a preserve for sandwich filling or for open tarts and cheese cakes (q.v.).

**Lemon Cordial.** For this boil 1 lb. sugar and 1 pt. water together for 15 min. and leave to cool. Then mix 1 oz. citric acid with  $\frac{1}{2}$  dr. essence of lemon and add these to the syrup, which must be bottled for use. To a tumbler of hot or cold water add 1 or 2 tablespoonfuls.

**Lemon Drops.** See Acid Drops.

**Lemon Pudding.** An economical pudding that can

be baked or steamed is made from  $\frac{1}{2}$  lb. flour, 6 oz. suet, 2 oz. breadcrumbs, 8 oz. castor sugar, 2 teaspoonfuls. baking-powder, 2 lemons, water to mix. Chop the suet and mix it with the breadcrumbs, flour and baking-powder. Add the juice of the lemons to a cupful of water for mixing. Mix the sugar with the grated rind of the lemons and add these to the dry ingredients. Mix all to a loose, moist consistency. Put into a greased pie-dish and bake for about an hour, or put into a greased pudding basin and steam for about two hours. Serve with a plain sweet sauce or a sauce flavoured with lemon if the pudding is steamed. If baked, sprinkle it with castor sugar.

A different kind of lemon pudding is made in the following way. Line a pie-dish with puff paste. Mix 6 oz. bread or cake crumbs with 4 oz. castor sugar and a tablespoonful of grated lemon rind. Add 4 oz. butter or margarine and simmer all together for about 10 min. Put the mixture aside until it cools. Add the juice of 2 lemons and the beaten yolks of 2 eggs. Whisk the egg whites and add these at the last. Pour this mixture into the prepared pie-dish and bake for about 40 min. It should be served with cream and sugar or, as an alternative, a sweet sauce.

A very dainty lemon pudding is made by boiling the thinly pared rind of 2 lemons in  $1\frac{1}{2}$  pints milk until the peel is soft. Pound the peel with 4 oz. butter and pour the milk over  $\frac{1}{4}$  lb. Savoy biscuits. Stir the butter into the mixture and add  $\frac{1}{4}$  lb. castor sugar, the juice of 1 lemon and the yolks of 3 eggs well whisked. Pour the mixture into a buttered pie-dish and bake for about 40 min. Whisk the whites of the eggs to a stiff froth and pile roughly over the top of the pudding, sifting castor sugar, over the froth. Turn the oven to a slower heat and leave the pudding in for about 10 min., or until the froth is crisp and pale fawn in colour.

**Lemon Sponge.** This is made from 1 pint of water, 2 oz. castor sugar, 1 oz. gelatine, 2 lemons and 3 eggs. Pare the lemon rind very thinly, and mix it with the sugar and the strained juice of the lemons. Dissolve the gelatine in the water over gentle heat. When dissolved, strain the gelatine into another saucepan and add to it the sugar, grated lemon rind and lemon juice. Simmer for about 10 min., then place on one side to get quite cool. Separate the whites of the eggs and whisk them up very stiffly with a pinch of salt. Add these to the gelatine, etc., and whisk all together lightly. Pile in rough heaps on a dish or set in a mould rinsed out in cold water. Turn out when firm. The sponge should be kept in a cool place until required. If the sponge is served in a dish it should be garnished with crystallized cherries or violets and pieces of angelica.

A lemon cream sponge is made thus. Add to a pint of cream the grated rind of a lemon and a little castor sugar and set it on the stove to heat slowly, but not to boil. Dissolve rather more than  $\frac{1}{2}$  oz. of gelatine in a little milk, stir it into the flavoured cream and set it aside to cool. Then add the juice of  $1\frac{1}{2}$  or 2 lemons,

and the beaten white of an egg, and whisk the whole until it is stiff.

*Lemon Squeezer which screws on the edge of the table. The handle rotates the centre piece and the juice drains into a basin.*

**Lemon Squeezer.** This is designed for the purpose of expressing the juice of lemons without the admixture of pips or pulp. The simplest squeezer is of glass, formed like a pyramid with a channel round the base and a spout on one side. The half of the lemon should be pressed, cut side down, on the point of the pyramid, and as the pressure takes place the juice flows down the sides into the channel. These are obtainable in aluminium and glass. An improved kind has a glass cup beneath the squeezer, the base of which is perforated so that the expressed juice is collected in the cup, and several lemons can be squeezed in rotation and the juice is strained at the same time. A juice extractor which clamps on to the side of a table is the most convenient form of squeezer and strainer combined.

*Lemon Squeezer in coloured pottery suitable for making lemonade at table. The top has holes through which the juice runs into the cup.*

*Lemon Squeezer which is useful when only a few drops of the juice are required. A perforated aluminium tube is first pushed through the lemon, and withdrawn. The wooden pusher shown in the foreground is then used for removing the centre pith, and the perforated tube is again inserted, the juice straining through a few drops at a time. ( Courtesy of Staines Equipment Co.)*

**LEMONADE.** When making lemonade allow two good-sized lemons to a pint of water. The juice should be squeezed into a jug with a lemon squeezer, and about  $\frac{1}{4}$  lb. of loaf sugar added. Pour on a pint of boiling water and stir until the sugar is dissolved. A little thinly pared lemon rind may be added, to be removed before the lemonade is served.

When the lemonade has cooled it should be strained and then more sugar can be added, if desired, and more water if it should be too strong. It should be put aside to get quite cold before being served. A stronger solution can be made by using double the quantity of lemons and sugar. The lemonade can then be diluted with water as required. For an effervescing drink  $\frac{1}{4}$  teaspoonful of bicarbonate of soda should be added to a tumblerful of the beverage and stirred quickly in. *See Glass.*

**LEMON GRASS.** This is the common name of a hothouse grass, *Andropogon schoenanthus*. The leaves give off fragrance when pressed with the fingers. It thrives in a compost of loam, leaf-mould and sand, and is propagated by division of the tufts.

**LEMON-SCENTED VERBENA.** This favourite small shrub (*Lippia citriodora*) is valued for its fragrant leaves. It is not very hardy and needs the shelter of a greenhouse in most localities in winter. In mild districts it may be planted at the foot of a sunny wall where it will reach a height of 3 or 4 feet. It is propagated by cuttings in summer. Moderate pruning is necessary in spring.

**LEMON SOLE.** This is a kind of plaice somewhat resembling a Dover sole and occasionally called the sand sole. The flesh is not so plump, neither is it as firm as the true sole.

It is better not to attempt to broil or grill this fish, and it is not well adapted for being fried whole, but if skinned both sides and filleted it can then be egged and crumbed and fried in boiling fat.

Fillets of lemon sole are also very good cooked with a stuffing and baked in a deep fireproof dish in the oven. The dish should be greased with butter, and the fillets, after being filled with stuffing, should be laid in it, seasoned and covered over with a buttered paper. About 15 min. will cook them and they will look white and creamy. Serve with a well-flavoured sauce poured over them.

**Stuffing the Fish.** The stuffing may consist of a plain veal forcemeat or it may be made with 6 mushrooms, chopped fine, 2 oz. butter or margarine beaten to a cream, 1 oz. fine breadcrumbs, a pinch of nutmeg, a teaspoonful of grated lemon rind, seasoning of pepper and salt, and 1 large egg to bind it. Heat this mixture until the egg is set, then cool it and lay a portion of it on one half of the fillet, fold the other half over and proceed in the same manner until all the fillets are stuffed.

Lemon sole fillets, stuffed or unstuffed, may also be baked with tomatoes, to which should be added 2 chopped shallots. They must be laid in a deep dish with 1 oz. butter, and with the tomatoes round them. Baste them while cooking with the liquor which runs from them, and keep them well covered with thick greased paper. When cooked, coat the fillets with fried crumbs and sprinkle over them grated cheese. Return to the oven for 2 or 3 min. to brown the cheese. Serve very hot. *See Sole.*

**LEMON THYME.** This is an attractive variety of the common thyme (*Thymus serpyllum*) named *citriodorus*. It has fragrant leaves and purplish pink flowers in early summer, but grows only 5 or 6 in., high. Propagation is by cuttings in summer; if set in sandy soil and covered with a handlight they will soon form roots. The golden-leaved (*aureus*) and silver-

leaved (argenteus) varieties colour well if they are planted in full sunshine in poor sandy soil.

*Lemon Thyme, a fragrant garden plant.*

## LENSES AND HOW TO CHOOSE THEM

### An Important Consideration in Amateur Photography

A reference to the article on Camera is suggested by this contribution, which is another step in making our work an Encyclopedia of Photography. The reader is referred also to Developing; enlarging; F/Number; Focus; Photography; Stop, and other articles dealing with the subject.

The amateur photographer thinks when he sees a photograph which is sharp in detail all over and bright in appearance that it must have been taken with a very good and, therefore, expensive lens. This is quite a mistaken idea, for cheap lenses, used within their limitations, can give a picture which is sharp in every detail. The outstanding difference between a cheap and an expensive lens is its speed, that is, the length of exposure it requires. This factor is expressed in a figure representing the aperture of the lens, or its f/number. Thus a lens working at f/8 requires twice the length of exposure of a lens working at f/5.6 to give the same properly exposed negative.

Cheap cameras necessarily mean cheap lenses with comparatively small apertures f/8 or f/11, which can only be used for snapshots or so-called instantaneous photographs in the bright light of a summer day. All good types of cameras are supplied with various lenses, according to the desire of the purchaser, so that the price of a particular camera may vary with the lens with which it is fitted. The idea that special lenses are required for different kinds of photographic work may be dismissed entirely, with the partial exception of portraiture; any good modern lens will meet all the requirements of the amateur photographer.

*Lens. Fig. 1 (left). Diagram of simple achromatic lens. Fig. 2 (right). Rapid rectilinear for symmetrical lens, which gives better definition.*

*Fig. 3. Sectional diagram of modern fast anastigmatic lens (Zeiss).*

There are three main types of lenses used in photographic work. The

simple colour-corrected or achromatic meniscus lens, the rapid rectilinear lens, and the varieties of anastigmatic lenses. The simple achromatic meniscus lens type is seen in section in Fig. 1, in which two meniscus lenses, one of ground glass and one of flint glass, are cemented together. This type gives good definition if it is stopped down to about f/16 or f/11. The whole of the lens cannot be used, because definition is lost towards the edges. The rapid rectilinear, sometimes called symmetrical, shown in diagram Fig. 2, is a great improvement and gives good definition without distortion at f/8, though its definition at this aperture is not equal to that of an anastigmatic lens of equal aperture.

The chief points about an anastigmatic, one type of which is seen in diagrammatic form in Fig 3, are that without being stopped down definition is perfect over the whole of the plate which they are designed to cover, and also that they are much faster than meniscus or R.R. Lenses.

Having obtained a good lens, the amateur may be disappointed to find at first that he does not get as good results, from the point of view of definition, as he did with his cheap, probably fixed-focus lens. The reason is that the modern lens is an instrument of precision, and accordingly needs knowledge for handling it to the best advantage. With his fixed-focus lens in a box-form camera all objects from 2 or 3 ft. away up to the farthest possible distance, called infinity, were automatically in focus, and no question of focussing arose. With the anastigmatic lens, on the other hand, the greater the aperture and the focal length the shallower is the field of focus.

From one point of view this may be regarded as a disadvantage attaching to the speed of a lens, but in practice it will be found that at least with a moderately large aperture, say f/6 or f/5.6, more artistic and pleasing results will be obtained. So long as objects in the foreground of a picture are not blurred or fuzzy, those in the distance may be softened by being slightly out of focus.

It is largely a question of understanding the capacities and limitations of a particular lens in use and practice in its accurate focussing; the wider the aperture and the shallower the field of focus the greater the necessity for care in focussing.

Two other questions which arise in the choice and use of a lens are its focal length and its angle of vision.

In the average lens short focus means a wide angle giving a large field of vision on the plate, while a long focus means a narrow-angle lens giving a smaller field of vision on the plate with detail on a larger scale. A lens of short focal length and wide angle throws a larger amount of the object on to the plate than one of long focus; that is, it covers a wider field and reproduces it in smaller detail. On the other hand, a lens of long focus and narrow angle (as in telephoto work), covers a smaller part of the field, does not focus the object until it is farther away from the plate than the short focus lens, and gives detail on a larger scale.

Not only has this the advantage of getting objects in comparatively large scale, although the camera is at some distance from the object being photographed, but it has the very valuable property of giving much truer perspective than the wide-angle lens. The familiar case of the amateur portrait in which the hands are larger than the rest of the sitter's body is an exposition of the disadvantages of the wide-angle lens. Again, the wideangle lens sees more than the human eyes at one glance, and consequently the photograph given by it seems to lack actuality.

On the other hand, it will sometimes happen that a building or other object is to be photographed in a street or confined quarters where it is impossible to get far enough away to focus a narrow-angle long-focus lens. In such a case a wide-angle short-focus lens must be used. In earlier days photographers carried a complete selection of lenses of different angles and types to meet such circumstances. With the modern lens, however, this is overcome, either by adding temporarily an extra lens to shorten the focus, or, more satisfactorily, by making the lens convertible.

This means that the lens is so designed that either of the two principal components seen in Fig. 3 may be used as a separate lens. Thus the complete lens may have a focal length of  $5\frac{1}{2}$  in. for a quarter-plate camera. If the back portion alone is used the focal length will be, say, 8 in., while if the front portion alone is used the focal length may be 11 in. We have thus three lenses in one, each of which is a good anastigmat. Of course, if the complete lens works at  $f/6$  the back and front components will probably only be equal to  $f/11$  and  $f/16$  when used separately.

To use a convertible lens it is essential that the camera front should be capable of being racked out twice the distance normally required.

If a convertible lens cannot be acquired a sound rule in choosing a lens for general photographic work is to select one whose focal lengths equals the diagonal of the plate it is to be used with. For colour and speed work an extra large aperture is desirable. In the modern miniature camera the very small lens has a considerable depth of field even at large apertures. Thus, the miniature lens will be  $f/3.5$  as against  $f/6$  in the ordinary camera.

For the best results in portrait work, specially large lenses are designed with considerable focal length, so that the camera may be a good distance away from the sitter. The aperture in some cases is as large as  $f/1.5$ ,  $f/2$  or  $f/3$ , with a focal length of 16 or 17 in. for a whole-

plate camera.

Camera lenses should be kept free from dirt and damp, and when not in use they should always be covered up. Under no circumstances should they be cleaned with anything but a camel-hair brush, special lens paper, or a piece of old, well-washed, soft linen. Lenses are easily scratched, and while a scratch will not be visible in a photograph, yet several scratches will reduce the amount of light which passes through the lens, and in bad cases will impair the definition. Of course no polishing substance of any kind whatever should be used. In the special kind of glass used in making modern anastigmatic lenses small bubbles will sometimes be observed; these are unavoidable in the manufacture of the glass and have no effect on the brilliancy or definition of the lens.

**The Lens Hood.** In the modern folding hand camera it is rarely possible to provide any shade or hood of considerable size for the lens, owing to the lack of space. The result is that on bright days a certain amount of light from the sky enters the lens beyond that which comes from the object or scene being photographed. This light tends to be scattered over the negative and reduces the brilliancy of the picture, the negative being, in fact, more or less fogged.

Much more brilliant photographs will be obtained by the use of a sky shade or hood for the lens. The simplest form is a piece of thin card about  $2\frac{1}{2}$  in. long by  $1\frac{1}{4}$  in. wide, coated with a dead black varnish. It is held in place on the top of the lens by means of an elastic band. A black card is not sufficient, as its slightly shiny surface reflects back the light.

*Lens Hood, consisting of clip and hinged shade.*

Another form consists of a stiff wire frame fixed to the lens mount at an angle and arranged to fold down when the camera is folded up. Over the frame is draped a small piece of black cloth. A third form consists of

a clip which fits the lens flange with a metal shade hinged as shown in the diagram. It should be treated with dead black.

When a shade is fitted it is essential to test it to see that no direct light is cut off from the lens. This can be effected by focussing on a near object and examining the image on the focussing screen. See that there are no dark shadows at the bottom of the focussing screen. If no focussing screen is fitted to the camera, a test exposure should be made.

**LENTEN ROSE.** There are some beautiful flowers among the varieties of Lenten rose (*Helleborus orientalis*), a hardy herbaceous perennial, 12 to 18 inches high, which blooms in spring. The plants like

partial shade and loamy soil with which decayed manure has been mixed. A few of the finest varieties are Isolde, rose; Queen of the North, blush-white; and Robert Froebel, reddish crimson. It is unwise to disturb the plants unnecessarily, but propagation may be effected by lifting and dividing the clumps when the flowers are over.

**LENTIL.** The lentil is a hardy annual bean, the seeds of which may be sown in sunny borders in April in rows about 1 ft. or 18 in. apart. They should be put in about 2 in. deep and the same distance apart. The flowers appear in June and July. After flowering the tiny seed pods, about 1 in. in length by  $\frac{1}{2}$  in. wide, are formed. Each of these contains two seeds. The plants should be left in the ground until they are yellow. They should then be pulled up, thoroughly dried in the sun, and the pods stripped off and stored in a dry place.

**How to Cook.** Largely used in vegetarian cookery because they possess all the strengthening qualities of meat, lentils sometimes take the place of a second vegetable, and are also made into soup or used as the foundation of side dishes. Lentils should not, however, be served as a vegetable in the case of a heavy meat dinner, but rather when the meat course is scanty.

The Egyptian red lentil is used most commonly; it requires soaking overnight, and must be thoroughly washed and picked over in the morning, all pieces of black being removed. If to be served as a vegetable, boil it in plenty of salted water with an onion peeled and cut in strips. Add a little dripping or some other fat and boil for  $1\frac{1}{2}$  hours. It is better to cook lentils a little too long than not enough. When done, drain the water away and add another 2 oz. of dripping. Season well and mix in the fat thoroughly by stirring over the fire. Serve with chopped parsley sprinkled over.

Lentils may also be served with bacon, and in this way make a good supper dish. To prepare this, cook the lentils according to the directions given in the previous recipe, and, just before they are ready to be drained and dished, fry 3 oz. streaky bacon and cut it into dice. Dish the lentils and bacon together, and serve with them  $\frac{1}{2}$  pint of any good brown sauce and a few sippets of toast or fried bread.

**Lentil Soup.** One pint of red lentils, soaked overnight, are required to make lentil soup. Prepare it by melting 2 oz. butter in a saucepan, adding the lentils, a sliced onion, 2 sticks of celery cut into small lengths, and a bunch of herbs, stirring the whole over the fire for 5 min. Pour in 2 quarts of stock and boil the soup until the lentils are soft; then take out the herbs and rub the soup through a fine sieve. Reboil it, season it carefully, and then add 1 gill of cooked peas and 2 oz. cooked ham cut into dice, if liked. Serve the soup in a hot tureen, shaking in some powdered mint. This quantity is sufficient for about 8 persons. *See* Soup; Vegetarian Cookery.

**Lent Lily.** This is the popular name of the wild

daffodil(q.v.)(*narcissus pseudo-narcissus*)

**LEOPARD MOTH.** Also known as the wood leopard moth, this is a long-bodied insect bearing white wings with black spots. Its larvae penetrate the interior of the branches and trunks of apple, pear, and plum trees, besides several other ornamental trees.

The presence of larvae in trees may be detected by holes, but owing to the extensive turnings and galleries bored it is difficult to get at the pests. The only remedies are to push a hot wire in the burrow with the hope of killing the caterpillar, or to squirt carbolic acid or paraffin emulsion into the holes. Where the injury is confined to a single branch this should at once be removed, if the above remedies fail.

**LEOPARD'S BANE.** This is the common name of *doronicum*, a hardy herbaceous plant 12 to 24 in. high. It bears large, yellow, daisy-like flowers in spring and will flourish on a shady border. It thrives in ordinary soil and is easily increased by division in September. The finest of all is *Doronicum plantagineum excelsum* (Harpur Crewe), with long-stemmed blooms which are most useful for cutting.

*Leopard's Bane. Long-stemmed yellow flowers of doronicum.*

**LEPTOSIPHON.** This pretty, hardy annual, 6 to 8 in. high, is useful as a flower border edging or in the rock garden. A mixed packet of seeds will yield flowers in rose, yellow and other colours. Seeds are sown out of doors in April where the plants will bloom in summer.

**LESCHENAULTIA.** This family of Australian evergreen greenhouse shrubs is in bloom from June till September. They thrive best in peat and sand in a sunny glasshouse, and like plenty of ventilation in fine weather.

**LESPEDEZA.** This is a Japanese shrub, 4-5 ft. high, which has attractive pinnate leaves and bears purplish pea-shaped flowers in early autumn. It is suitable only for planting in mild districts. The branches should be hard pruned in spring. Propagation is by sowing seeds or by division of the root-stock in spring.

*Lespedeza. Leaves and clusters of pea-like purple flowers of this hardy shrub for a sunny border.*

'K' AND 'L' RECIPES: A SELECTION SHOWN IN COLOUR

**King Edward Pudding.** Take 2 eggs, and their weight in flour, margarine and sugar. Cream margarine and sugar together, add beaten yolks and beat for a few minutes. Stir in flour, a level teaspoonful of baking powder, 1 tablespoonful milk, and flavour with vanilla. Add whites of eggs, turn mixture into greased pie-dish and bake in moderately hot oven for 1 hr. Serve with hot jam or golden syrup. **Lobster à l'Ostende.** Remove flesh from shell and cut into fairly large squares, except that from claws, which should be kept unbroken. Melt 1 oz. butter, stir in smoothly  $\frac{1}{2}$  oz. flour; add  $\frac{1}{2}$  pt. Fish stock or milk, and stir until it boils. Put in 3 tablespoonfuls boiled rice, then the lobster, 6 shelled prawns. 1 teaspoonful anchovy essence, 2 tablespoonfuls tomato sauce. Heat mixture thoroughly, season and arrange on dish, garnishing with meat from claws and a few prawns. **Lemon Meringue.** Boil together 1 pt. hot water, 2 heaped tablespoonfuls castor sugar, and grated rind and juice of two lemons. When boiling, stir in 3 tablespoonfuls cornflour previously blended with a little cold water. Cook all gently for 5 min. When slightly cooled add well-beaten yolks of 2 eggs. Continue cooking without boiling for a few minutes. Turn into greased pie-dish. Heap the stiffly-whipped whites on top, sweetened and vanilla-flavoured, and bake in slow oven until a pale biscuit tint.

**LETTER: How to Write.** There are a number of formal matters which those who wish to write a good letter should know. The writer should see, first of all, that his own correct address and also the correct date are stated at the top of the letter. If there has been a change in the address, whether temporary or permanent, and the existing paper is still used, the new address should replace the old one; if it is a temporary one it would be well to add the date at which it will cease.

**Methods of Address.** The method of addressing the person written to varies according to the degree of intimacy. For persons of rank there are recognized forms of address, but relatives and intimate friends will discard these. For letters on business matters the usual opening is Dear Sir if to an individual, or Gentlemen or Dear Sirs if to a firm. As regards others, there can be no hard and fast rule, as so much depends upon the personal element. It is well, however, not to take a familiar tone with persons who are only acquaintances or with those, not intimate friends, who are of high social position. The phrase, My dear, suggests an intimacy not present in the ceremonial Dear.

The subscription to a letter also takes many forms. Persons use yours truly and yours faithfully indifferently; yours affectionately implies a close personal relationship, while yours respectfully and yours obediently suggest a request or a formal letter to a superior. Yours sincerely or yours very sincerely is the subscription most commonly used to acquaintances or friends.

If a letter is an answer to one received, the correct date of the latter should always be given when replying to it. If to-day or to-morrow is mentioned, the day of the week should be added; otherwise a person may be in doubt whether it refers to the day on which the letter was written or the one on which it was received. If a day is mentioned it is well to add the date again in order to avoid a possible confusion. It is a good plan to read a letter over carefully after it has been written; this will prevent mistakes due to hasty writing, such as, for example, the omission of the important little word not.

**Formal and Ceremonial Letters.** Convention or etiquette decrees that letters shall be written to friends, and in some cases to acquaintances, on certain special occasions. Letters of condolence are written to the relatives—generally to the nearest—of a dead person. Letters of congratulation are written to persons who have received some honour or appointment; to persons whose engagement is announced, and on other occasions of rejoicing, such as the celebration of a silver wedding or a birthday. It is also customary to write a letter of thanks to one's hostess after a stay in her house.

When writing to a stranger, perhaps one who has asked for the character of a maid, some persons write in the third person. This kind of letter has the advantage that it need not contain expressions of friendship, which seem incongruous in the case of a

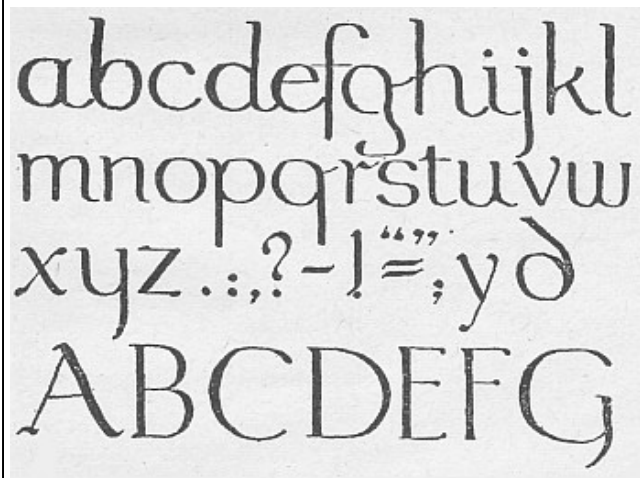

stranger, nor be signed. Care should be taken, the third person is maintained throughout the letter. *See Ink; Notepaper.*

**The Letter Case.** This is a case for holding envelopes, writing paper, blotting paper, pens, and all the necessities for writing letters. The covers are usually of leather, or one of its imitations, and can be fastened by a flap, made safe by a lock or snap, or both. *See Leather.*

**LETTERING.** There are so many uses for lettering in the home that a knowledge of the various styles will be useful. Good letters must be readable, simple, and distinct. They must be proportionate and pleasing in form, and suited to the purpose for which they are employed.

*Lettering. Figs. 1 and 2. Line and block letters. Figs. 3 and 4. Capitals in Gothic and Old English styles.*

*Lettering. Fig. 5. Small letters, some capitals and punctuation marks of a simple but decorative form of lettering.*

The Roman alphabet is the basis of all lettering. The simplest form is the line letter illustrated at Fig. 1; the proportions are the same as in Roman, but it is drawn with fine strokes of the pen or pencil. A development of this style is the block letter shown at Fig. 2; this may be done with a wide pen-nib or outlined and filled in with ink or colour. Decorative letters suitable for various purposes are the Gothic and the Old English, shown at Figs. 3 and 4. For letters over ½ in. high, a reed or cane pen is most suitable, but smaller work can be done with a quill or one of the steel pen-nibs sold for the purpose.

Preliminary practice will soon enable the writer to

form the simple strokes. He should commence with glazed paper, and with a pencil rule faint guiding lines. The paper should be supported on a board at about an angle of 45°, and the ink should be applied to the pen by a brush rather than the pen dipped into it. The pen should be held lightly and horizontally to the paper, with the nib always in contact with the paper. Thick strokes are vertical, thin strokes are horizontal.

The correct spacing of half-uncials, as the small letters are called, is important; as a general rule two curved letters should be close together and two straight strokes spaced well apart. The space between words should be exactly equal to the height of the letter. In massed writing the usual distance apart of the writing lines is three times the height of the letter o, and the up and down strokes of the small letters are, with the exception of t, twice the height of the o. The uncials, or capital letters, should not be coupled together when forming words, and while their height should be twice that of the o, the spacing may be wider apart. To acquire proficiency, it is advisable to commence with letters about  $\frac{3}{8}$  in. high and gradually reduce to about  $\frac{3}{16}$  in., and always work to ruled lines. Indian ink should be used in preference to any other.

The Roman capital is distinguishable from the line and block letters by the endings of the strokes, known as serifs; the thin stroke should, as a rule, be  $\frac{1}{4}$  the width of the thick stroke, and the latter about  $\frac{1}{8}$  of the height. It is equally as effective drawn in outline as filled in. The letters A, C, D, G, H, N, O, Q, R, and T are about the same width as height.

E, F, K, P, U, V, X, Y, and Z are slightly narrower; B, L, and S are much narrower, and M and W wider. The same proportion applies to line letters, but block letters have, as a general rule, more or less the same width as they have height.

Dealing with the suitability of letters for various purposes, the line letter should be used for marking ink on household linen and clothes, but if the name is stitched the block letter is more effective. Small notices, menu cards, and programmes look well if uncials and half-uncials are used. The use of margins should be considered in spacing out lettering in this connexion.

**Preparing Labels.** Labels used for boxes, bottles, canisters, and other purposes should be in block lettering. A special pen is made to enable a thick line of ink to be drawn on labels and parcels, but a good substitute will be found in a camel-hair brush with the pointed end cut off or one of the flat bristle brushes used in oil painting. Large notices may be done in the same way, but it is advisable to use thick ink or water-colour paint. Trunks and other travelling cases should be painted in block lettering with Brunswick black or paint mixed with varnish. Roman letters are suitable, but look better when painted on attaché cases, and lend themselves to brushwork better than any other form.

**Cutting Stencils.** For cutting stencils it is customary to use block letters with properly situated ties to hold the metal together. Incised letters in wood and stone are

usually executed in Roman type; it is not a difficult matter to cut capitals in hardwood with a veining tool. The letters should be drawn in pencil or ink direct, or they may be traced on with carbon paper and then cut as far as possible against the grain. It is essential that the veiner employed in making the V cut is kept perfectly sharp in order to leave clean edges; the correct depth and width should be tooled in one cut, not worked out bit by bit. *See Drawing; Stencilling.*

**LETTER PLATE.** A metal framework with a hinged flap is used for closing an aperture in a door through which letters can be delivered, and is known as a letter plate. A usual variety is made of cast iron and painted with Berlin black, or coloured. Better qualities are made in polished and lacquered brass either plain or ornamental.

The letter plate should be chosen with regard to the appearance of the front door or to the entrance of the house, and the design should harmonize with the metal fittings of the door. Usually the flap is hung on two pivot bearings, and it is shut by means of a small coil spring. To ensure the flap working smoothly the bearings should be oiled occasionally, and if necessary the tension of the spring increased by unfastening one end, giving it another turn, and then refixing it. *See Door.*

**LETTERS: Games With.** Collections of letters with which a variety of games are played can be bought or made at home. Bristol board, or any thin cardboard with a smooth surface, may be used. Squares are cut to any size required, the most usual being about  $\frac{3}{4}$  in. square, but the actual size is immaterial if all the letters are uniform. They should be Roman capitals, done either in ordinary black ink or in Indian ink, and though the number required for each letter varies with the size of the set, the following may be taken as a useful proportion for a small set. There should be at least 25 of each vowel, and preferably 30 for A and E; most of the consonants need 20, but Q and Z can be cut down to 5, and X and Y to 10. D, N, P, R and S may very well have 25. A set made round about these figures should keep four players amused for a considerable time.

The games played with these letters are very numerous. Word making and word taking may be mentioned first. Rules and directions are sold with every box of letters purchased. Another game is for each player to draw a given number of letters, say 30, and with those to make as many words as possible in a fixed time. The letters must be well shaken up before drawing.

The players may be given letters forming one polysyllabic word, such as incomprehensible, and be told to form as many other words as possible using only those letters. It is usual to stipulate that no word must contain less than three letters. Another variant is to have the letters piled up in a heap in the middle of the

table, while the players turn them over at their will, making as many words as possible in a given time. The rule mentioned above holds good in this game also, and plural and singular are not allowed as separate words.

Another form of letter game is the adjective letter, in which a letter is written with all the adjectives omitted. Only the writer knows its contents, but the players are then asked to suggest adjectives in turn, each of which is filled in by the writer in the order chosen. As the adjectives are chosen haphazard by a number of players, the result, when the letter is read aloud at the end, is always amusing by its incongruity. If possible the letter should be written before the guests arrive.

**LETTUCE.** This favourite salad plant is grown chiefly for summer supplies in the average garden, but it can be obtained in spring, summer and autumn by making successional sowings out of doors and under glass. Lettuce must be grown on rich soil and during dry weather needs watering very freely. There are two types, the tall upright cos, and the flattish cabbage lettuce, and numerous varieties of each type. The cabbage lettuces are grown largely for late and early supplies and the cos lettuces for summer: the latter are more difficult to grow really well than the cabbage lettuces and should not be attempted on poor soil.

The first sowing out of doors should be made in March or early April as soon as weather and soil conditions allow of the seed being sown. The drills should be 12 in. apart. It is most necessary to thin out the seedlings before they become crowded; if necessary some of them may be transplanted to form fresh rows which will be ready later.

*Lettuce. How to grow them successfully. 1. Correct soil preparation: a, fine soil; b, soil; c, manure; d, vegetable refuse. 2. When thinning, a, shows correct distance apart; b, too crowded. 3. Result of good thinning. 4. Growing cos lettuces: a, neglected plant; b, plant with leaves tied round to blanch the heart. 5. Catch crops on celery ridges. 6. Forcing under cloches on hotbeds. 7. How to grow for spring supplies: a, fine soil; b, soil.*

Successional sowings are made in May and June to meet requirements. As lettuces are only palatable when fresh it is preferable to sow a short row every fortnight than to make several large sowings. Lettuce is often

grown as a catch crop between rows of peas, on the ridges of celery trenches, or in parts of the kitchen garden where room can be found among other crops.

Seeds sown out of doors in July will provide lettuces in autumn, and for winter and spring supplies seeds are sown in August and September, the plants being lifted and set in a bed of soil in a frame in the autumn. Some of them may be planted on a warm sheltered border in March if protection can be given in cold weather. A further sowing in a heated glasshouse in early spring will provide seedlings for planting out in March.

A few of the best cabbage lettuces are Hercules, Wonderful, Continuity, Commodore Nutt, Standwell and Ideal. Favourite cos lettuces are Superb White, Exhibition Cos and Jumbo. Varieties most suitable for sowing in August and September are (of cos lettuce) Black Seeded Bath, Winter White, Hick's Hardy White, and Brown Cos. Of cabbage lettuces for autumn sowing Hammersmith and All the Year Round are favourites.

**Pests of the Plant.** One of the chief pests to guard against is the lettuce fly, a brownish-black insect with black wings, which lays its eggs in the blossoms and interstices of the lettuce in early summer. The effective remedy is to uproot infested plants and burn them. The lettuce-root aphid cannot be discovered until the plant begins to fade and droop. Usually a lot of cottony looking insects will be found to be clustered about the roots. The bad plants should be at once destroyed, and the lettuce patch treated to a dressing of lime. The other chief pest is caterpillars.

The cabbage lettuce is in season earlier than the cos, and is more delicate in texture and flavour. It is, therefore, more suitable for salads; for other purposes of cookery the cos lettuce is the kind preferred.

**Preparing for the Table.** Lettuce is valued by cooks as a foundation for salads. It must be thoroughly cleansed before use, and all leaves carefully looked over, in case insects should be lurking in them. When preparing a salad lay the lettuce in water to freshen, then sprinkle it with salt and leave it for an hour or two; wash it in two or three waters, shake well, and lay it on a hair sieve or a piece of clean cloth to drain.

Lettuce may be made into a stew. Tie together a large cos lettuce after preparing it, and boil it for 5 min., cool it, part it in the centre and fill with a good forcemeat. Tie it together again and braise it gently on a bed of vegetables with good stock for 20 min. Dish the lettuce, strain the gravy, reduce it by boiling, skim and pour over the lettuce. The stuffing may be omitted, but the gravy must then be thickened and flavoured with Worcester sauce and lemon juice. *See Salad.*

**LEUCOJUM.** This is the name of a group of spring and early summer-flowering bulbs. The best known are the spring snowflake (*vernum*), 6-7 in., which bears white, greentipped flowers in April, and

the summer snowflake (*aestivum*), 18 in., which has white flowers in May. The bulbs should be planted in autumn and left undisturbed; they thrive in ordinary well-drained soil. An increased stock can be raised by means of offsets taken off the bulbs when the leaves have died down or in autumn.

*Leucojum.* Drooping white and green flowers of the spring snowflake.

**LEUCORRHOEA.** A discharge from the vagina commonly called whites is termed in medicine leucorrhoea. It occurs most frequently in women who have borne children, but is also found in children and unmarried women.

Infection by microbes is the most common cause amongst children, aggravated often by want of cleanliness. Threadworms sometimes produce a discharge both in very young and older girls. The parts should be washed four or five times a day with warm water and an antiseptic lotion applied, such as a weak solution of permanganate of potash.

Leucorrhoea may occur in young women who work in close, badly ventilated rooms or stand a great deal. It is very common in anaemia and chronic constipation. Married women often make the mistake of not consulting their doctor early enough. The cause may be inflammation following childbirth. Attention must be directed to the general health, and the doctor may order an astringent or antiseptic douche. The patient should take no alcohol, and tea only in moderation. Sufficient rest is often of importance.

**LEVER: In the Home.** In the domestic sense a lever may be considered as a rod or bar which can be inserted under or behind an object in such a manner that it is possible to prize it along, or to force it from its position. In most cases the word lever is employed in order to indicate some rodlike part of a machine which is provided in order to obtain a mechanical advantage.

Supposing that the fulcrum, or that part about which the lever turns, is so placed that one part of the lever is four times as long as the other. Four times the pressure exerted at the long end is imparted by the short end, but the long end will travel four times the distance of the short end. When a bent lever has one arm which is jointed to another portion of the mechanism by means of a pin somewhere near a right-angle corner, it is known as a bell-crank and will then transmit motion from one point to another at right angles to it. *See Handspike.*

**LEWISIA.** This describes a group of rockery plants having fleshy leaves and summer flowers of various colours. They need rather special treatment and should be planted in full sunshine in well drained soil of peat, loam and sand. They must be protected from wet in winter by glass fixed a few inches above them on wires. *Howellii*, *rose pink*, and *Tweedyi*,

*salmon rose*, are two of the best varieties of the plant.

*Lewisia in bloom, with rosette-like cluster of leaves.*

**LEYCESTERIA.** This is an attractive hardy flowering shrub, also called the pheasant berry. It thrives in ordinary soil, grows 3-4 ft. high and in summer bears red bracts and cream coloured flowers, which are followed by black fruits. It is not recommended for planting in cold districts. Propagation of the leycesteria is by cuttings in autumn. Pruning takes the form of thinning out weak or crowded branches in spring.

**LHASA TERRIER.** Some specimens of this small, rough-haired dog, found in Bhutan, and other hill countries adjacent to Tibet, have been imported into England. They have engaging manners which make them pleasing pets. The body is covered with a profusion of soft, shaggy hair, and the plumed tail is carried over the back, as with the Pekingese. The legs should be straight and short, and the colour white and black, silver, grey, or coffee-coloured. *See Dog.*

**LIBEL.** Libel is both a civil wrong, giving rise to an action for damages by the person libelled, and a criminal offence. Seditious libel and blasphemous libel are criminal only. The one consists of publishing words calculated to bring about discontent against the king's government or the king; and the other of writing against religion in an irreverent and indecent manner.

**LIBERTIA.** In gardens only three species of the hardy evergreen perennial libertia are generally found. *L. formosa*, with its slender, grass-like leaves, height about 18 in., bears some resemblance to the iris. It retains its freshness throughout the winter if grown in a sheltered, sunny place, and in light, sandy loam, peat and loam, or other friable soil. The white flowers appear in May. *Grandiflora* and *ixioides* are taller plants and flower rather later; both are white. They reach a height of from 2 to 3 ft. The plants may be separated into pieces and replanted in spring, or seeds can be sown in the autumn in a frame.

**LIBOCEDRUS.** Name given to certain evergreen conifers. The most generally useful is *Libocedrus decurrens*, a magnificent tree of narrow, upright,

columnar growth which will reach a height of 40 to 50 ft. in time. It likes deep, moist, loamy soil and makes a splendid lawn tree.

**LIBRARY: How to Furnish.** There is no room more conventional in its furnishing than the library. Its model comes down from the 18th century as preserved in many country and town houses. Decorative schemes are simple and dignified. The books in themselves form ample variations in colour. In a small room the shelves may reach to the ceiling, but in a more spacious library panelled walls are in keeping with the period of the original model and look particularly well in natural coloured wood, wax polished. The same wood is used for the bookcases and parquet for the floor.

It is important in a library to prevent the accumulation of dust; for this reason there should be either rugs on the floor or the carpet must not come to the edge of the room. The surround should allow a space of at least 1½ ft. from the bookcases.

The conventional desk or bureau is a necessity, but it is useful to have in addition a substantial table placed in a good light on which work can be spread out. This table is all the more useful if it is provided with drawers. Large makes of book tables are also appropriate, since they are composed of several tiers divided into sections which hold journals, magazines and reference works, besides books in use taken from the wall shelves.

*Library. Corner of room modelled on the conventional form of the 18th century, with recessed bookshelves and walls in panelled wood stripped and wax polished. The girandole lighting fixtures, graceful settee and oriental rug enhance the period decoration. (Humphrey & Vera Joel)*

Any bureau or writing table must be placed so that the light falls from the left-hand side. A good reading lamp is essential; several should be provided if the room is to be used by more than one person habitually. Convenient wall lighting fixtures, and, for a large room, a central ceiling fitting are also advisable. Velvet in a rich yet quiet shade is particularly suitable for the curtains and upholstery of a library, with a comfortable leather armchair or two. Heating arrangements must

also be well thought out in order to maintain a pleasantly equable temperature, which is important not only for the occupants of the room, but also for the preservation of the books. A tapestry panel, one or two bronzes or good pieces of pottery, a handsome writing desk set, are suitable in a library, but anything superfluous or merely pretty seems out of place.

**Care of Books.** Built-in bookshelves are usually open. Sectional bookcases sometimes line one wall, for such volumes as are better kept behind glass. If the shelves reach to the ceiling library steps will be necessary. Dummy backs of books on simulated shelves are sometimes used to cover the doors of the cupboards or of the room so that the line of the bookshelves may be unbroken. This is an old form of interior decoration which has been revived in present day libraries.

Books require careful handling, especially under modern conditions, when bindings are less robust than formerly. A feather brush thoroughly used once a week will keep them reasonably clean, if pamphlets and other unbound books are placed in folders properly labelled, a supply of which can easily be made at home. Once a month a methodically arranged cleaning is necessary. A vacuum cleaner is best for the purpose, but if this is not available the books must be taken out and the books and shelves thoroughly dusted. At spring and autumn cleaning a real overhauling must be undertaken, when books which are no longer useful can be weeded out, and those which are in need of rebinding can receive attention. *See Bookcase; Bureau; Writing Table.*

**LICE: How to Remove.** There are three forms of lice, the head louse, the body louse, and the crab louse. They lay many eggs per week, and these nits mature in about ten days. Applications which destroy the lice may have no effect on the eggs. There is itching, sometimes intense, of the parts affected, which may be the seat of eczema. Treatment of infestation with head lice is dealt with in the article *Hair* (q.v.).

Body lice live in the folds and creases of the clothing. A warm bath, followed by rubbing in sulphur ointment for several days, will cleanse the body of any eggs that may adhere. The underclothing and bed linen should be boiled. The outer clothes are to be ironed on the inside with a hot iron.

Crab lice most commonly infest the hair in the pubic region, but sometimes they attack the armpits and chest, and may reach even to the beard and eyebrows. For this variety rub into the hair and the neighbouring parts equal parts of white precipitate ointment and vaseline. Or use the following application:

Beta-naphthol	1 dram
Cologne water	6 oz.

Make into a lotion. Sop on to the affected parts twice daily. *See Disinfection.*

**LICENCE.** In Great Britain the owners of firearms, motor cars, motor cycles, dogs and guns, and users of armorial bearings, are taxed on them, the tax taking the form of a yearly payment for a licence. Licences are usually taken out at a post office, and fines are inflicted if the articles in question are owned or used without a licence, which must be shown to the police if required.

In England, one of the ways of getting married is by licence.

A licence must also be obtained before a wireless receiving set can be used. This costs 10s. a year. In addition to the receiving set, at the home of the licensee, it allows the use of a portable set. *See* Carriage; Chauffeur; Dog; Gun; Marriage; Motor Car; Wireless.

**LICHEN: A Skin Disease.** Lichen is the name applied to a group of skin diseases characterized by the formation of papules. There is itching, which may be severe. The cause is considered to be a generally run-down and exhausted state of the nervous system. If the general health is below par a course of Easton's syrup, or some other tonic, sometimes does good. Arsenic is often prescribed.

For the itching a 1 in 40 solution of carbolic acid in water may be sopped on the spots. As a local application to the papules, the following prescription may be made into an ointment and applied locally twice a day:

Carbolic acid	10 gr.
Bichloride of mercury	2 „
Zinc oxide ointment	1 oz.

**LIFE INSURANCE.** Persons can insure their lives for almost any sum of money from £5 upwards. This is done through insurance companies or friendly societies that transact business of this kind. The premiums, usually paid half-yearly, vary according to the age and condition of the person insured. Full information on this point can be obtained from any insurance office.

In addition to the policies that provide for the payment of a sum of money at death, all offices issue policies payable at a certain age, say 60 or 65. A certain measure of relief from income tax is allowed on money paid as premiums on life insurance policies. *See* Annuity; Friendly Society; Income Tax; Insurance.

Lift. *See* Service Lift.

**LIGATURE.** Ligatures are cords of silk, catgut, or some other material used for tying arteries cut accidentally or in the course of an operation, to stop bleeding. *See* Bandage; Bleeding.

**LIGHT: In Therapeutics.** Light, which is a form of electrical energy, travels from its source in straight lines. The lines of transmission only maintain their direction, however, so long as the waves are passing through the same medium, say air. When they strike another medium the direction is changed, and the line

is then said to be refracted. If a beam of sunlight is made to pass through a glass prism, a bar consisting of a succession of colours is produced, the order of the colours always being the same, namely, red, orange, yellow, green, blue, indigo, and violet.

This bar is called the solar spectrum, and represents the disintegration of visible light into its constituent parts, or colours, this disintegration taking place because these different rays of which white light is composed have different wave-lengths the longer having greater difficulty in passing through the prism, and therefore being more refracted. The longest waves are at the red end of the spectrum, and they become progressively shorter towards the violet end.

Beyond each end of the spectrum rays are passing, although they are not visible, simply because the eye is adjusted for the range of the ordinary spectrum only. Beyond the red end they have a longer wave-length than red rays, and are the invisible heat rays, whilst beyond the violet end they have a shorter wave-length than those of the latter rays. They are called the ultra-violet or invisible actinic rays, and are the most powerful as regards chemical action.

The ultra-violet rays have important functions in the processes of life, and their effect on human health is far-reaching. Those coming to us from the sun, however, are largely prevented from passing through the atmosphere by dust and moisture, and the supply is therefore very restricted in towns. Moreover, they are absorbed by ordinary window glass, so that they are not available in a room so protected. Arc lamps of various kinds are used to produce ultra-violet rays artificially, so that this method of therapy is readily available. The light from such lamps is sometimes described as artificial sunlight.

Exposure to ultra-violet rays will kill micro-organisms, and this explains the long-known disinfecting properties of sunlight. It also largely explains the success of ultraviolet rays in the treatment of skin disorders. The rays are absorbed by the blood, increasing its content of calcium, phosphorus and iron, and increasing its germicidal power.

Exposure to ultra-violet rays also increases the vitamin activity of foods. In consequence of this the rays afford a powerful means of preventing and curing rickets. They have, in addition, a general tonic effect on the whole body and a tranquillising effect in states of irritability. Applications of the rays have cured sciatica and lumbago, headaches and neuralgia, and have been beneficial in a large number of other disorders.

Treatment by natural sunlight, or heliotherapy, is carried out at Alton and Hayling Island in connexion with the Treloar Homes, and elsewhere in Great Britain, and at Leysin in Switzerland and other places abroad. The value of light in the treatment of surgical tuberculosis was well established at some of those places a long time before its other possibilities were grasped. As ultra-violet rays form such a powerful weapon, however, their indiscriminate use, or,

particularly when they are artificially produced, their overdosage, is capable of doing harm. Even moderate doses are capable of causing quiescent tuberculosis of the lung to flare up into activity, and of doing other harm, so that this form of therapy is unsafe except under medical supervision.

**LIGHT FILTER.** All objects which contain colour will be more accurately rendered in a photograph by the use of a light filter, which is known also as a colour filter, colour screen, or orthomatic screen. A light filter is a piece of gelatine, dyed yellow, placed in front of the lens of a camera to filter out more or less of the blue light to which the ordinary plate is unduly sensitive.

This undue sensitiveness is very marked in outdoor photographs which include a portion of the sky. Although the sky may be full of clouds, nothing of them will be seen in the print made from an ordinary plate which is anything like sufficiently exposed. The blue rays in the light coming from the sky have so much more effect on the plate than the mixed rays coming from the objects in the landscape that the sky portion of the plate is seriously over-exposed and without detail. This is the cause of the harsh and unreal white skies seen in many photographs. A pale yellow filter overcomes this defect by absorbing a part of the blue from the white light passing through the lens.

*Light Filter.*  
**Fig. 1.** Photograph of a shelf of books made on an ordinary plate, without a light filter.

**Fig. 2.** Same books taken with a filter on a panchromatic plate. The difference in results is obvious.

A light filter has other advantages. Used in conjunction with orthochromatic or panchromatic plates, it permits the production of photographs in which colours are represented by differing tones in a scale of accuracy rising with the depth of colour of the filter used and the colour sensitiveness of the plate. For instance, an ordinary plate without a filter will represent a bright yellow as an almost black tone in print. The eye sees a yellow tulip as a bright colour and therefore a light tone, but the unaided plate is so much more sensitive to blue than yellow that the yellow of the tulip has little effect and is dark in the print. Again, the green varies in different trees, and when rendered into monochrome, or one colour, in a photograph they should appear as differing tones; this cannot be effected

without a colour-sensitive plate, aided by a light filter.

An example of the difference in result obtained by the use of a medium light filter is seen in the two illustrations. Fig. 1 was made on an ordinary plate without a filter; Fig. 2 was made on a panchromatic plate with a K 1½ filter. It will be noticed how incorrectly the red and blue look as represented in Fig. 1; also the darkness of the yellows.

**LIGHTING: In the Home.** Building by-laws lay down minimum requirements as to the area of the windows in every room, which is generally taken as 10 per cent of the floor area in sq. ft.; but this rule is only a guide and the allowance should be exceeded when-ever possible.

The regulations tend to develop a tall window, which may be satisfactory on north, east, or west, but is not so good as a long, low window on a southern wall, as in the summertime, when the sun is high, the long window restricts the amount of sunshine that can enter the room, as the wall above the window casts a shadow into the room; but in winter, when the sun is not so high in the sky, the rays of light pass more directly into the room. The result is that full advantage is obtained of the winter sunshine, while the intense light of the midday sun in the summer is moderated without detriment to the occupants.

In planning a house, windows should be placed so that early morning sunshine can have access to all working rooms. When it is not possible to place the windows in this way it is often feasible to provide a reflector or to whiten an adjacent wall, and so gain the advantages of increased lighting. Another aspect of natural lighting is the effect of colour, especially that cast by the window hangings. This is noticeable on the north side of the house even more than on the south, as the north light is always cold and cheerless. The use of brightly coloured curtains will correct this, as is easily proved by hanging flame-coloured curtains in place of white ones. Colours such as blue and grey on the south windows have a cooling effect, softening the glare of the sun.

**Artificial Light.** Artificial illuminants are numerous, the simplest being the candle, which still has its uses. Modern developments of oil as an illuminant have produced highly efficient lamps with an incandescent mantle. Various types are used in the home, from the ornamental floor standard or table lamp to the small hand-lamp.

Coal gas has many advantages, not the least being that one installation is available for lighting and heating. The wide choice of artistic fittings, the use of inverted incandescent burners, together with the by-pass system of control of the burners from a distance are factors which have greatly contributed to the value of gas as an illuminant. Gas lamps can be made movable by the aid of flexible metallic tubes, just as electric lamps can by the aid of wires. The article on Gas should be referred to for further information.

The great advantages of electricity as an illuminant are safety and convenience; there are no exposed flames, and the light is obtained or turned out with a simple switch. Moreover, electric lighting permits of decorative schemes which would not be practicable with an illuminant having an exposed flame. Useful information on this subject is given in the article *Electric Light Fittings* (q.v.).

Other kinds of artificial lighting are provided, by acetylene gas and air gas, but as a rule these are only used where persons are unable to get gas or electric light. Acetylene is sometimes used as an illuminant in farmhouses and detached country residences, as it can be produced by a small plant. It has, however, certain disadvantages. The producing apparatus must be housed in a building outside the house that is to be lighted, and great care must be taken that naked lights are not brought into this room. Smoking, too, is dangerous there.

Air gas or petrol gas is another illuminant often seen in country districts. It can easily be made by means of a small apparatus, and for it incandescent mantles are suitable. It is, however, dangerous if the proportion of petrol in it is between 2 and 5 per cent. On the other hand it is claimed that it vitiates the atmosphere of a room less than any other artificial light except electricity.

**Theory of Illumination.** Scientific experiment has shown that the human eye cannot sustain a brilliancy greater than about 5 candle-power per sq. in. of lighting surface, equal to the old-fashioned single-wick oil-lamp. The modern gas-burner and electric lamp have an intensity very many times greater, the high efficiency types of the latter reaching 3,000 candle-power and over per sq. in. For this reason the employment of proper shades and diffusing globes becomes a matter of the greatest importance.

Three ways of dealing with the problem are in general use. They are known as the direct, that is, when the lamps are protected by shades; the semi-indirect, where they are protected by translucent bowls through which the light is filtered and diffused; and the indirect, where the lights are concealed behind cornices, mouldings and ornamental screens.

With all these systems the bulk of the light in the room is reflected from the walls and the ceiling. It is therefore very important that the light sources be placed in proper positions to give the most advantageous results. It may be assumed that indirect lighting takes twice the amount, and semi-indirect half as much again, as direct lighting, to produce equivalent lighting effect.

But the diffusion will not be similar, as the direct light is more concentrated, the indirect most diffused, and the semi-indirect the most pleasant for all-round lighting, apart from the beauty of the fittings that are available on this system. Therefore when a strong light is needed in any particular part of a room, the direct system is best, but for all general purposes the semi-indirect is preferable.

The colour of the wallpaper has an important

bearing on the matter, as a dull or dark-coloured paper will take twice as much light for efficient illumination as will be necessary when the walls are papered with a light-reflecting colour. See *Acetylene*; *Air Gas*; *Electricity*; *Gas*.

**LIGHTNING: Injuries From.** Injuries due to lightning may be slight and temporary, or may consist of severe wounds and permanent damage to the brain and other organs.

When insensibility results, it may last only for about 5 or 10 minutes, or may endure for an hour or two. In this condition the pupils of the eyes are dilated, the victim breathes very slowly, and the pulse can scarcely be felt. Except in immediately fatal cases the patient usually recovers in a short time.

A doctor should be sent for, and in the meantime rub the limbs and pile coats on the patient, if necessary, to keep him warm. If he is unconscious, put smelling-salts to the nose, and as soon as he can swallow a stimulant should be given, either a little spirit, a teaspoonful of sal volatile in water, or hot coffee. When the patient gets to bed hot-water bottles should be put to the feet, and if there is collapse the foot of the bed should be raised. In case of almost imperceptible breathing artificial respiration (q.v.) should be practised.

**Lightning Arrester.** This is a device used in conjunction with the aerial of a wireless apparatus. It is intended to protect the building from the effects of lightning, which might be attracted by the aerial and directed into the building.

*Lightning Arrester. Device used as a safety precaution, with hooded insulator and enclosed gap which breaks down at a comparatively low voltage.*

The device generally comprises a small gap between two conductors, which are joined to aerial and earth respectively. In the event of an atmospheric or lightning discharge, the current goes to earth by way of the gap, in preference to the path of greater impedance through the aerial circuit of the receiver.

Common types of arrester employed in broadcast reception consist of a hooded insulator and an enclosed gap which breaks down at a comparatively low voltage. A bracket is provided by means of which the device can be fixed to the window frame or wall outside the house. One terminal of the arrester is connected to the aerial lead-in, and the other terminal is joined to earth. An arrester may be employed in conjunction with, or instead of, an earth switch.

**Lightning Conductor.** The functions of a lightning conductor are first to cause rapid leakage of electricity

between a thundercloud and the earth, so that the charge contained in the cloud is reduced to such an extent as to be harmless; and secondly, if the leakage action has only been partially successful, to provide a safe path to earth for the lightning flash, so that it does little damage, if any, and that only to the lightning conductor and not to the house it protects.

A charge of electricity leaks readily off a sharp point, and therefore the first requirement is met by providing three or four such points round the top of the main vertical lightning rod whose lower end is efficiently earthed. The second requirement is met nine times out of ten by the same vertical rod, but practically certain protection is afforded if the building is enclosed in an earthed metallic network. This result is readily achieved by electrically connecting all such external metal work as rain-pipes, gutters, metal roof-sheeting or lining, metal casement frames, etc., to the main conductor. These connexions are known as subsidiary conductors.

The need for protecting a house is perhaps less if the adjacent house is protected, but is certainly greater if the house is higher than its neighbours or stands alone.

**LIGHTS.** The lungs of animals used for food are known as lights, and were formerly included in the fry, but are now only employed as food for cats and dogs. They should be well washed, soaked, if possible, boiled for about  $\frac{3}{4}$  hour, and then cut in pieces. *See Cat.*

**LIGNUM VITAE.** The hard, heavy wood known as lignum vitae comes from S. and Central America. It is used in furniture making. In the 17th century it was employed for marquetry, and was much used later for inlaid furniture by Sheraton and others. *See Wood.*

**Ligustrum.** This is the botanical name for privet (q.v.).

**LILAC.** The botanical name of lilac is *syringa*, a word commonly and wrongly used to denote the mock orange or philadelphus. This hardy flowering shrub (*Syringa vulgaris*) is represented by numerous single and double varieties of various colours. It thrives in ordinary well-tilled soil, but is liable to be disappointing if not pruned correctly. When the flowers are over, old weak branches should be cut out to prevent overcrowding, and some disbudding or the removal of superfluous young shoots is necessary. Suckers, shoots which grow through the soil from the stock on which the named variety of lilac is grafted, must be pulled up. It is beneficial to topdress the soil with manure in early summer. The best method of propagation is by layering in summer. The common lilac attains a height of about 20ft., and has smooth, heart-shaped, opposite leaves.

Some of the best single varieties are Marie Legraye, white; Charles X, rose purple; Souvenir de L. Spath, reddish crimson. Good double ones are M. Buchner, lilac; Charles Joly, reddish; Mme. Lemoine, white. The Persian lilac (*persica*) is an attractive shrub, 3-4 ft.

high, bearing fragrant lilac-coloured blooms very freely.

For forcing, the lilacs should be potted up in autumn in the usual potting mixture and kept out of doors until they are needed. They should then be taken indoors and kept in a temperature of from 50° to 55°, and syringed daily. Increase the temperature when the buds burst. Prune back flowering shoots after blooming, and place the plants out of doors. They will be of no more use for forcing, but may very well be used in the open. Fine grained in character, the wood of the common lilac is employed in inlaying and turning. *See Flowers; Pruning.*

**LILY.** The true lilies (*lilium*) are delightful flowering bulbs, some of which must be regarded as indispensable in every garden. While a few need special conditions to ensure success, most of them are hardy and easily managed if given correct cultivation. The most popular of all is the Madonna lily (*Lilium candidum*), which bears white, fragrant flowers on stems 3-4 ft. high in June. The bulbs should be planted in August-September, 3 in. deep, in ordinary well-cultivated soil. As this lily is liable to the attacks of a troublesome disease the bulbs should be shaken in a bag of sulphur before being planted, and it is wise to mix sulphur freely with the soil.

Other showy hardy lilies to plant in late summer or early autumn are croceum (orange lily), 3 ft., orange red, July; elegans, 12 to 30 in.; yellow, red, June and July; Hansoni, 3 ft., yellow, June; Henryi, 5-6 ft., apricot, August-September; Martagon, 2-3 ft., reddish purple, June-July; pardalinum (Panther lily), 5-7 ft., yellow and red, July; pyrenaicum, 2-3 ft., greenish-yellow, May-June; testaceum, 4-5 ft., light yellow, June-July; tigrinum (tiger lily), orange red, 3-5 ft., August-September; umbellatum, 2-3 ft., orange red, July.

Bulbs of *Lilium auratum*, white flushed with yellow, and speciosum, rose and white, arrive in Great Britain in the New Year, and are planted in February and March. There are several fine varieties of these lilies; *auratum rubro-vittatum* and *speciosum melpomene* are richly coloured.

All the lilies mentioned above (with the exception of *auratum*, which often deteriorates after the first year) will flourish out of doors if planted in deeply dug soil with which leaf-mould and sand have been mixed freely. In heavy land the bulbs should be set on sand. It is necessary to set the bulbs at the correct depth, and this varies according to whether the lily belongs to the stem-rooting class or not. The following produce roots at the base of the stem as well as below the bulbs, and should be covered with 5-6 in. of soil: *auratum*, *croceum*, *elegans*, *Hansoni*, *Henryi*, *regale*, *speciosum*, *tigrinum*. The others named need a covering of only about 3 in. of soil.

Of numerous other lilies which are available for cultivation in gardens the most remarkable is *Lilium*

(Continued in page 1294)

## LILY

Suitable examples for garden and greenhouse.

*giganteum*, which, when established, throws up a giant, leafy stem 8 to 10 ft. high and bears large, fragrant white flowers. It likes partial shade and moist, leafy soil. The bulbs die after flowering, but are perpetuated by offsets.

The favourite lilies for cultivation in pots are *auratum* and *speciosum* and their varieties, *tigrinum* and *longiflorum* (white trumpet lily). The bulbs should be obtained in autumn, winter and early spring as they are available, and set singly in well drained pots 6 to 8 in. wide, using a compost of two-thirds loam, one-third peat or leaf-mould (or both), with a free addition of sand. The bulbs must be set low down in the pots to leave room for top dressing with fresh soil later on: they are partly covered with soil, and the remaining space is filled with fibre, which will be replaced with soil when the bulbs begin to grow. They should be placed in a frame from which frost is excluded. In summer the lilies may be grown out of doors or in the greenhouse. Lilies can be raised from seeds, but the seedlings of most of them grow slowly. *Lilium regale* will bloom in two years from seed sowing. *See African Lily; Arum Lily; Belladonna Lily; Guernsey Lily, etc.*

**LILY OF THE VALLEY.** This favourite spring-flowering hardy plant flourishes in shady places in soil with which leaf-mould and decayed manure have been mixed freely. It is not a true lily, its botanical name is *Convallaria majalis*. The roots of lily of the valley, which are known technically as crowns, should be planted in October, 3 or 4 in. apart, the tops just below the surface of the ground. An annual top-dressing of leaf-mould in October should be given. In the course of years the plants will become overcrowded and fail to

bloom freely; they should then be lifted and replanted in early autumn. The finest variety is *Fontin's*, which has unusually large blooms, in one named *rosea* the flowers are tinged with pink.

*Lily of the Valley. Beautiful clump of this fragrant flower, grown in a pot.*

There are many methods of forcing to provide early blooms under glass. One of the simplest is to put a bundle of crowns into damp moss and put them on hot-water pipes. Another is to place as many crowns as will go comfortably into a 6 in. pot in a compost of sandy loam and leaf-mould, and introduce into bottom heat. Good crowns will produce flowers in two to three weeks if plenty of tepid water is used.

Crowns alone need not be used in the culture of lily of the valley under glass. Imported clumps may be potted in autumn, kept in a frame for a few weeks, and then put in the greenhouse. They will bloom in spring. Large-flowered varieties are now available. Excellent lilies of the valley for all purposes are available at any time of the year, by obtaining what are known as

retarded crowns, and forcing them on. *See Flowers.*  
(*See also page 1296*)

**LILY POOL:** How to Make. Even in small gardens which possess no such facilities as running water, the cultivation of the water lily is not difficult, if a satisfactory pool can be provided. Tubs, barrels, tanks, or old cisterns will serve the purpose if placed in an open, sunny aspect, with periodical changing of water. All that is required is a drain-off plug and bottom foundation of brickbats, as illustrated. A more permanent structure may be made in the form of a round, oval, or square pool with a good foundation of cement. April and early May are the best months for constructing a pool, as the hardiest water lilies are then ripe for planting.

The two sectional diagrams 4 and 5 give the details for a pool of moderate size. Materials and implements required consist of cement and shingle, straight-edge, spirit level, spade, and a bricklayer's trowel. The bases of constructional work are excavation and lining of concrete, faced with cement mortar, trowel-finished and smoothed; and a draining pipe with wooden plug as shown.

**Draining the Pool.** The concrete basin or pool should have a thickness of about 8 in.; its water depth may be something under 3 ft. On sloping ground it is quite practicable to associate two or more pools, with pipes connected to the basin possessing an outlet pipe of sufficient size to permit quick drainage. This is important, as the plants will suffer if time is lost between emptying and refilling. A more ambitious design is shown in Fig. 6, which contains a centre pool with flag-stone margin, rose beds, and grass. Such pools generally draw their water from a stand-pipe or tap, and therefore a convenient and suitable spot must be selected for their construction.

After construction of the pool, when its components appear to be well set, fill it with water to be the desired level, take careful register of depth, and leave it for a week or 10 days. If no rain has fallen, measure the depth again, and if there should be any appreciable drop from the original depth, drain off the pool and give the whole another facing of cement mortar. The cause of the leakage may be a crack or fissure, and in that case the necessary filling may be done and the pool tested as before. It is essential that any leakage should be stopped immediately.

**The Contents.** It must be remembered that the plants are gross feeders, and an excellent compost for their needs is made of two parts mud from the bottom of a ditch or pond, two parts loam, one part coarse sand, and one part of rich manure free from straw. A layer of crocks should be placed on the cement floor, then a good layer of the above mixture, followed by mounds of the same compost for each plant with its

apex 1 to 2 ft. below water level.

The roots must not be planted too deeply, but simply covered sufficiently to allow the crown of the plant to peep through the soil. If preferred, the lilies may be planted in wicker baskets holding a few bushels of compost, and sinking each in any desired position. Such baskets sometimes rot away, but generally the plant roots form a network which holds the soil together. Planting operations are shown in the diagrams.

There are numerous varieties of Water-lily suitable for various depths of water. The most vigorous flourish in ponds, others grow in water only 8-10 in. deep. *See* Water Lily.

**Lima Bean.** This is an alternative name for the butter bean (q.v.).

**LIMB.** The upper extremities or limbs are attached to the trunk by the shoulder blades and the collar bones, and the lower ones by the innominate bones. The shoulder blades are bound to the chest wall by muscles simply, and this allows of very free movement, while the innominate bones take part in the formation of the pelvis, move little, if at all, and thus promote stability in standing and walking. *See* Bandage; Fracture.

**LIME: The Tree.** The lime tree or linden (*Tilia vulgaris*) is much favoured for town planting, and is met with in numerous suburban gardens. It bears yellow flowers in July, with a rich and rather cloying odour. The leafy, half-winged bracts which fall so abundantly with the accompaniment of moisture after the flowering are also a feature. The tree loses its freshness rather early in autumn. *Tilia petiolaris* and *dasystyla* are to be preferred to the common lime because the leaves do not fall so early.

The lime thrives best in substantial loam or friable clay, but it may be planted in most soils and in most situations that are not distinctly bleak or dry. Propagation is by layers in autumn. *See* Lime Juice.

**LIME: For Building.** Lime is a natural cement, and there are various qualities and grades, of which those used for building are the blue lias, and the grey or chalk. Lime requires dry storage. Quick lime, before it can be used, is slaked with water.

Lime is best slaked by spreading it out upon a board, covering it with a small proportion of sand, and sprinkling the whole with water from time to time, turning the lime over until it is thoroughly slaked. It should be allowed to stand for at least a month before use. For plaster work lime should be slaked by providing a tub, or by digging a hole in the earth and lining it with boards, two-thirds filling it with lump lime, covering it with water, and allowing it to remain for several weeks until it is a thick creamy mass. It is then known as lime putty, and is used in conjunction with sand or other ingredients.

Lime is purchased from builders' merchants, and when ordering it is well to state the purpose for which it

is required. For instance, lime for mortar will be blue lias, and lime for plaster-work pure or fat lime, these expressions referring to the setting properties. Rich limes are those which only contain about 6 per cent of insoluble impurities, and are used for plastering because of their readiness to slack, and their consequent non-liability to blister as compared with hydraulic limes.

The rapidity of setting of lime depends on the quantity of other substances it contains which render it independent of external agents for its setting properties. The limes containing about 15 per cent of such substances are termed feebly hydraulic. Those containing about 25 per cent are moderately hydraulic, and those containing from 25 to 35 per cent are eminently hydraulic. The last named grades are most suitable for constructional work.

**Lime in the Eye.** If lime gets into the eye the consequences may be serious unless medical treatment is promptly obtained. Therefore, no matter how trifling the injury may appear to be, the doctor should be sent for at once. In the meantime the eye should be washed thoroughly with tepid water and vinegar, a teaspoon-ful of vinegar in half a tumbler of water; or with large quantities of tepid water alone. Afterwards drop a little olive oil into the injured eye. *See* Ceiling; Mortar; Plastering.

**LIME: For the Garden.** Lime is most valuable for application to new gardens and to old gardens which have been heavily manured for a long time. Heavy soils are rendered more workable by its aid, and it also sets free various plant foods. In addition, it acts as a soil insecticide. To light soils lime is best applied in the form of chalk. A stone (14 lb. ) of lime per pole is a good average quantity to use.

Chalk may be applied to the extent of double this amount. The dressing may be repeated every three or four years. Gas lime, i.e. burnt lime, is an excellent thing to apply in autumn to vacant land which is pest ridden.

**Lime Sulphur.** This is a useful spraying mixture for apples and pears in spring and early summer. The Ministry of Agriculture (Bulletin 5) describes its preparation and use.

It may be purchased ready made in large or small drums, so that it is only necessary to dilute it to the proper strength. For spraying against apple and pear scab summer strength lime sulphur, namely 1 gallon of concentrated solution mixed with 29 gallons of water, should be used. The lime sulphur should be poured slowly into the water, stirred well, and used at once. Spraying machines with copper parts should not be used for lime-sulphur spraying. It should be noted that Cox's orange pippin and James Grieve are particularly sensitive, and for these varieties, and also for Wellington and Newton Wonder, half summer strength

is necessary, namely 1 gallon to 59 gallons of water. *See* Apple; Bordeaux Mixture; Garden; Manure; Pear; Spraying.

**LIME:** In Medicine. Salts of lime form a most important constituent of our food. They are required to provide the earthy matter, or calcium phosphate, which imparts hardness to the bones. Calcium salts are necessary for the coagulation of blood, and in other ways they perform an important part in the body chemistry. Some foods are poor in lime; for instance, fish, meat, fruits, and potatoes. Others contain it in abundance, among them being milk, eggs, oatmeal, wholemeal bread, and some varieties of green vegetables.

The calcium compounds are of great use in medicine. Calcium chloride, 5 to 15 grains, and calcium lactate, 10 to 30 grains, are remedies against bleeding. These are also good remedies to take for chilblains, and in some cases of urticaria, or nettle-rash. Calcium hypophosphite, 3 to 10 grains, calcium phosphate, 5 to 15 grains, and syrup of lactophosphate of lime,  $\frac{1}{2}$  to 1 dram, are good general and nerve tonics. The carbonate of calcium or chalk has the same action and uses.

**Lime Water.** Lime water acts as an antacid and a mild astringent, and is often taken in milk for dyspepsia and diarrhoea. The lime water is added in the proportion of 1 to 3 of milk. It is often added to a baby's milk mixture to make it more digestible. It enters into skin lotions for weeping eczemas, burns, and other conditions. For a burn in which the skin is not broken it may be mixed with an equal quantity of olive oil or of linseed oil (Carron oil).

**Poisoning by Lime.** Chalk is a good antidote in poisoning by acids. In any case of lime poisoning give draughts of weak vinegar and water, or lemon juice and water. Follow these with warm milk, cream, olive or cod liver oil, or barley water. Apply hot poultices or fomentations to the abdomen for the pain. The physician should be called in at once.

**LIME JUICE.** The fruit of the lime tree common in tropical countries closely resembles the lemon, but is smaller and more sour. The juice has medicinal qualities of an antiscorbutic character. It has a cooling effect, and when added to water or soda water makes a refreshing drink. Several preparations of lime juice are on the market. *See* Lemon.

**LIME PUTTY.** Also known as plasterer's putty, this is made by slaking chalk lime, allowing it to stand in a tub with water for some weeks. It ultimately becomes of a thick, creamy consistency, and is then used for making plaster. Other relevant entries are: Coarse Stuff; Gauged Stuff; Lime; Plastering.

**LIME WASH.** Lime washing, or lime whitening, is the process of treating exterior or interior surfaces with

a mixture of pure lime and water, which is applied hot with a stiff brush of substantial proportions. In preparing the lime wash, a sufficient quantity of quick-lime should be put into a tub or old box that is reasonably water-tight, and the lime covered with boiling water. After it has dissolved, sufficient hot water is added to make an easily workable mixture, a quantity of which may be put into a bucket and stirred as required.

*Lime-washing the interior of a shed.*

Before applying the lime wash, the surface to be coated should be washed down with soda water, and in the case of outbuildings, such as poultry houses and the like, a little soft soap can be added to the washing water.

The walls should be sprayed with a strong solution of disinfectant, such as carbolic acid, diluted with water in the proportion of 35 parts of water to 1 part of carbolic acid, and sprayed on by means of a garden syringe fitted with a fine rose head.

As soon as the carbolic is dry, the whole surface is coated with lime wash, and, to assist it to harden and adhere to the woodwork, a little common salt and sulphate of zinc may be mixed with the slaked lime. The proportions are 2 lb. of salt, and about twice the quantity (i.e. 4 lb.) of zinc sulphate to a bushel of lime. The best brush to use is a well-worn whitewash brush, and the wash should be applied vigorously, so that it is driven well into the surface. If necessary, two or more coats may be given, according to the nature of the work to be done.

After walls or ceilings have been repeatedly coated with lime wash, the surface will show a tendency to flake and chip off, and in such cases the old lime wash should be thoroughly well washed and scraped off. Lime wash should not be confused with whitening, which is made up with powdered chalk. *See* Distemper; Whitening.

**LIMIT GAUGE.** This is a measuring device used as a standard of comparison. The term limit means that the permissible error is limited, or in other words that a piece of work to be measured with it must be within a certain predetermined degree of accuracy. The one shown in the illustration is seen gauging the diameter of a disk of steel. The gauge has two sets of jaws, one a little larger than the other, and known as the go gauge, because the article must go into the jaws, and the other as the not-go gauge, because the

article must not go into it. Thus the actual size of the article must lay between the two, and its absolute dimensions are limited. *See Gauge.*

**LIMNANTHES.** A pretty, low-growing hardy annual with yellow and white saucershaped flowers.

*Limnanthes Douglasii*, 6 in., is the only one grown. Seeds are sown out-of-doors in April where the plants are to bloom in summer, or they may be sown early in September for spring flowering. Self-sown seedlings are usually numerous.

**LIMOGES: The Ware.** The hard-paste porcelain which was produced at this ancient town in central France for about 70 years after 1780 was decorated on a highly glazed translucent body. An early mark is C.D. If combined with the Sèvres mark it means that the body was made at Limoges, which had the advantage of its own china-clay beds, and was decorated at Sèvres, whose own ware was soft-paste. Biscuit figures and medallions were marked Limoges. The very large range of pigments introduced by Limoges chemists has been adopted by other French potteries, and gives to these products their characteristic variety of colour.

Still another special development was the artistic treatment of the chromo transfer and the gold transfer, thereby imparting to decorated Limoges the effect of hand-painted wares. In the middle of the 19th century American enterprise took the local industry in hand, and there is now a large output, by a score of factories, of modern Limoges ware. Among these the name of Pillivuyt survives from the early period.

That which bears the mark Haviland & Cie is a strong ware, deco-rated in styles sometimes suggestive

of Moorish art. There are also inexpensive dinner services and other useful pieces with floral and scenic designs.
