**Tallis House**

*Printed in Great Britain by The Amalgamated Press, Ltd*

**ABERDEEN TERRIER.** The Aberdeen or Scotch terrier is an excellent housedog, a good ratter, and readily teachable. From 9 in. to 12 in. high, it has a short, hard, wiry coat of iron-grey, brindle, black or sandy, and soft under-fur. A white variety should have no admixture of other tints. The outer coat is of uniform density, about 2 in. long, and without silkiness or curling. The dog is shortbacked and rather flat-sided, with strong hindquarters; short legs and small, short-haired feet.

The head is rather long and domed, with a drop between the eyes to the muzzle, which tapers to the broad, black nose projecting over level jaws. Neck short and muscular, shoulders sloping, chest broad and deep; small, pointed, velvety ears. *See Dog.*

*Aberdeen or Scotch terrier, prize-winning specimen.*

**ABSCESS.** This name is given to a collection of matter or pus, of which there are two distinct kinds, acute and chronic.

**Acute Abscess.** The entry into the body of germs which cause suppuration may give rise to an acute abscess. If an abscess occurs the result is the collection of a thick yellowish fluid surrounded by a thickened layer of tissue which constitutes the wall of the abscess. This may occur anywhere; it may be superficial or it may be deep. The fluid is always under pressure, and this forces it along the path of least resistance, usually to the surface.

An acute abscess produces pain and tenderness. There is also swelling, at first hard and brawny, but later soft, particularly in the centre. The pus is finding its way out, and is said to point at the spot where it will reach the surface, indicated by a deeper redness. The skin becomes very thin, with an increase of pain, and finally the abscess bursts. The patient suffers from fever, not very much, perhaps, in the case of small abscesses, and may have a rigor—that is, feel cold, even to the extent of his teeth chattering. Then he will feel hot, and finally his skin, which has been hot and dry, will be covered with profuse perspiration. There will be several fits of this alternate heat and coldness, but the discomfort will subside as the abscess ceases to discharge.

Treatment is a matter for a surgeon. While the abscess is forming, relief may be afforded by resting the part and also by raising it (e.g. with a sling). Fomentations may also be useful, and these can be wrung out of hot water in which boracic acid has been dissolved (1 oz. to the quart) and covered over with gutta-percha tissue or jaconet. But when pus is definitely present it must be let out.

**Chronic Abscess.** The second kind of abscess, which is generally painless and may dry up without bursting, is a form of tuberculosis (q.v.), caused by the tubercle bacillus.

**ABUTILON.** Evergreen shrub with bell-shaped flowers and handsome leaves, a desirable climber for rafters or pillars, or planting out. The best varieties for growing under glass to flower in April are: Darwinii, orange; fleur d'or, orange and red; canary bird, yellow; boule de neige, white; Princess Marie, rose lake.

*Abutilon. Flower spray, showing drooping blossom and vine-like leaf.*

Propagation is by cuttings of young wood struck in a temperature of 60° in summer. Also from seeds in a propagator or over bottom heat. They are generally sown in spring. Pron. A-bu'-ti-lon.

**ACACIA.** One of the acacias is the wattle or mimosa (q.v.). The acacia tree of suburban gardens is Robinia, or false acacia (q.v.).

**ACANTHOLIMON.** Dwarf evergreen plants, somewhat resembling thrift, but with stiff, spiny leaves, suitable for the rockery. A popular species is glumaceum, which bears a profusion of rose-coloured flowers in summer. Venustum also has a rose flower.

These sea lavenders thrive in warm, gritty, well-drained soil. Take cuttings or layers in the late summer. The slips must be wintered in a cold frame, and make good plants in the second year. Pron. Ak-an-tho-li'-mon.

*Acanthus. Flower spike of a common variety.*

**ACANTHUS.** Of the two species of acanthus, spinosus is so called from its spiny leaves; mollis, or bear's breech, is characterised by large, deeply cut leaves, with soft spines. The plant grows about five feet high, flowering in summer, and is well adapted for herbaceous borders. Latifolius, a form of mollis with heart-shaped leaves and white or pink flowers, is unsuitable for small gardens. To raise a stock, sow seeds in a warm frame or greenhouse in spring. Further increase is effected by division in autumn or spring.

**ACCELERATOR.** The pedal which controls the throttle valve of the carburetter and is operated by the right foot is commonly described as the accelerator.

Widely used types of accelerator pedal are shown at A and B. A form which is comfortable and also smooth in operation is that shown at C, in which a roller on the end of the lever receives the pressure of

the foot. With this pattern the roller allows the pedal to move freely along the sole of the boot. The driver's foot can thus pivot comfortably with the heel on the footboard. This is clearly shown at D.

In a number of modern cars the accelerator pedal doubles the functions of accelerator pedal and starting switch. A coupling through a vacuum-controlled clutch is so arranged that a depression of the accelerator pedal when the engine is stopped engages the starter motor. Directly the engine is running the vacuum-controlled clutch is disengaged and the connexion between accelerator and starter is severed. This may be known as "pedomatic" starting.

*Accelerator. Types of pedal in use. A. hinged plate ; B. rocker and adjustable types ; C. roller pedal, shown in use at D.*

Inventions have also been produced in which the accelerator pedal is combined with the brake pedal. The pedal may be provided with a rocking plate, moved by turning over the ankle, for opening the engine throttle, while direct pressure upon the pedal operates the brakes. Accelerator. Types of pedal in use. A. hinged plate ; B. rocker and adjustable types ; C. roller pedal, shown in use at D. Of this kind is the Smart control pedal. A foot plate at the top of the pedal is hinged so that turning of the ankle rocks it to the right and opens the throttle. Direct pressure closes the throttle and actuates the brakes.

With all types it is advisable to see that the connexions, as well as the pedal bearing, are working freely, so that the return spring brings the pedal easily to the off position ; otherwise an accident may occur through the pedal inadvertently sticking in the open throttle position. Should this happen the engine must be switched off.

**ACCIDENTS.** There are two senses in which the word accident is used in speech and by lawyers :

(1) An occurrence which happens neither by negligence nor design ; and (2) an untoward event which causes injury or damage, even though it may be caused by somebody's negligence or design—thus we speak of a man being injured by an accident if he is knocked down by a motorcar, though it may be the fault of the driver or the fault of the injured man himself. Householders should always insure against liability under the Workmen's Compensation Act, because under it an employer is liable to compensate a servant who meets with an accidental injury arising out of and in the course of the employment. Accidental is here used in the wide, popular sense.

For accidents caused by a person's negligence, he is responsible. For accidents caused by a wife's negligence, the husband is responsible. For accidents caused by a servant in the course of his work, the employer is responsible; for example, if a housemaid, cleaning the windows, negligently drops the bucket on the head of a passer-by, her master is responsible for the accident. A parent is not responsible for accidents caused by the negligence of his child—unless, of course, the child is in the parent's employ and the accident is caused by something done during the employment.

**Motor-Car Accidents.** Whenever an accident takes place that causes damage or injury to any person, vehicle or animal, the driver of any motor vehicle involved must stop without being called to do so, and give his name and address and that of the owner of the vehicle, together with particulars of the car, to anyone, whether a police constable or not, who has reasonable grounds for demanding the information. If any person has been injured, the certificate of insurance must also be produced. When, for any reason, the driver cannot do this, he must report the accident at a police station or to a police constable and (if necessary) produce his certificate of insurance within twenty-four hours, or sooner if he can. Any driver failing to comply with the law in these respects will be liable to a fine not exceeding £20 for a first offence against the Road Traffic Act, and to a fine not exceeding £50 or to three months' imprisonment for subsequent offences.

*It is important to remember that notification of a road accident to the police or to some responsible person is compulsory.*

No one concerned in an accident should accept any blame or make any promises of compensation. The names and addresses of any witnesses should be obtained and the official number of any police-constable present. The final position of the vehicle after the accident and any tracks on the road should be fixed by measuring the distances from the sides of the road, or from a corner or a telegraph pole. If there is any indication on the road of skidding or braking, a record should be made.

For these and other relevant facts the memory should not be relied upon; they should be jotted down at the time. It is a mistake to enter into an argument with any of the other drivers involved or with onlookers, and it is usually preferable not to make any statement—although in actual fact this advice is rarely regarded.

**Accident Insurance.** Insurance of this nature is a wise precaution, and is generally effected through an agent. Owners of motor-vehicles are now compelled to insure against accidents causing bodily injury to third parties. In filling up a proposal form, care should be taken in answering the questions as to age, state of health, and other matters, because if this

is not done correctly the policy will be void. It is not wise to allow the agent to fill up the form. Many cases have occurred in which agents, with an eye to commission, have filled in untrue answers, and in such cases, where the insured has signed without reading the paper carefully, it has been decided that the agent in filling up the form does so as the insured's agent; with the result that the policy is void.

When an accident brings on a disease causing incapacity, the insured is entitled to compensation under an accident policy, because there is one chain of events leading from the accident to the disablement. *See Insurance.*

**Everyday Accidents.** The majority of the accidents that occur in the home are preventable. Fires should never be lighted with paraffin or other inflammable liquid, owing to the risk of serious injury or even death. Gas has its dangers also if jets are not kept clean and in good working order. A blow-out in the gas oven may set a flimsy apron alight, or a lighted match in searching for an escape of gas will cause an explosion and considerable damage and injury.

Everywhere in the home where there is gas, attention should be paid to loose taps that may get turned on by accident. It is also better to leave the gas turned on at the meter all night rather than risk the asphyxiation of someone whose bedroom light has been in use when the meter tap was turned off.

*Accidents in the home: a loose rug may easily cause such a mishap as this.*

To use the proper utensils for the small details of cooking is a sensible way of avoiding accidents.

Severe cuts, for instance, often occur through the careless use of a sharp knife for chopping suet, etc. Splitting kindling wood with a large knife or a heavy axe is not worth the danger it involves when a proper wood chopper costs only a trifling sum. Awkwardly placed pans on the stove are easily upset, with consequent scalding accidents. Similarly the spout of a boiling kettle should be turned sideways instead of towards the front of the stove.

Floor coverings are a cause of accident when insufficiently tacked down, or when slippery with too high a polish. A loose stair rail or a mat in an awkward place may cause a broken neck. Stairs should be lighted at all times.

The use of a step-ladder for putting up draperies, pictures, etc., is safer than the makeshift method of using a chair perched on the top of a table. It should be ascertained that the ladder itself is quite firm before it is mounted.

Low window-sills are a serious danger. Persons who walk in their sleep have been known to step right out of

a low window and fall several storeys. Children playing near such a window are only too likely to venture too far over the sill.

Lastly, there is always the danger of fire. In addition to gas and paraffin the following should be guarded against: failure to damp coal or wood fires when leaving a room; taking candles to look into a cupboard in which clothes are hanging; smoking in bed; placing a candle too near bed draperies; and carelessly dropping glowing cigarette ends on a carpet or in a wastepaper basket.

**ACCORDION.** Suited to the needs of those who wish to play only a simple melody, the accordion or melodeon is so constructed as to furnish an elementary accompaniment of chords. Its drawback is that it stands in one key (C) alone, and that as modulation is impossible, except by implication, the choice of music is restricted. It consists of a small pair of bellows, worked by the left hand, which also controls certain valves, viz. the wind valve (thumb), the accompaniment valve (index finger), and the bass valve (little finger).

At the other end of the bellows is a keyboard having a varying number of keys which are played by the fingers of the right hand. On being depressed these keys admit wind to the reeds, which produce one sound when the bellows are pressed in and another when they are drawn out. The compass varies according to the size of the instrument, that of the accordion with 12 keys being:

Whatever the compass, all have one feature in common: there is a diatonic succession of notes in the middle, with gaps at each end. The accordion with 21 keys has them disposed in two rows, one in G and the other in C, a simple modulation being thus possible.

In such types of accordion every C, E, and G is a pressed-in note, all the rest being drawn out. They form the tonic or key-note chord, while the others mostly belong to the dominant chord (the fifth degree of the scale). It is possible not only to play with the fingers a melody with or without a simple harmonisation, but by means of the accompaniment valve to add thereto the following chords:

and by the bass valve these notes:

For playing, the instrument rests on the performer's knee. The bellows must first be inflated by means of the wind valve, to what extent depending on the notes required. If there is a long series of push-in notes, they may be fully inflated. The music is written on the treble staff.

The most popular and easiest accordion to play is the piano accordion, in which 5 or more keys are available. Large "multi-coupled" models (costing about £18) give a vast range of tone and modulation, and are quickly learnt by a pianist. Musical novices should use a smaller "club model" (about £5 upwards), soprano, baritone or bass.

After use an accordion should be wiped and kept free from dust and damp.

*Accordion. The 21-note instrument, taken apart.*

*A. bellows.*

*B. melody keyboard.*

*C. valves for accompaniment, etc.*

**ACCOUNTS: How To Keep Them.** The simplest way of keeping accounts is in a cash book ruled with three columns for the £s. d. On one side, the left, or debit, is entered all that is received, and on the other the right, or credit, all that is paid out. The amounts in cash can be added up every week or month as desired, and the balance shown compared with that which actually exists in cash. The items on the right-hand can be examined and put into classes, thus showing clearly what has been spent in a particular direction. In keeping a banking account one method is to enter all receipts and all payments, whether made in cash or by cheque, in the one account. The balance will be that of the two combined, the cash in hand and the cash at the bank. Another method is to keep two accounts, one for cash and the other for items that pass through the banking account. The cash account can then be checked by the amount of cash in hand and the other by the pass book provided by the bank.

Household accounts can be kept in an account book with the pages prepared and ruled, for a quarter or a year, as shown in the form above.

Daily amounts expended should be entered in the places intended for them, and amounts received in the spaces below. At the end of each week the accounts are made up by adding the amounts in each daily column and the amounts in each line, after which the totals of the six daily columns and the totals of the various headings should be added up. If no mistake has been made these two totals will agree. The daily total is transferred to the payment column at the bottom of the page and the amount of cash in hand ascertained and entered.

The last column on the right-hand side of the sample is provided to check expenditure more carefully. In it are entered weekly the amounts spent up to date on

each housekeeping item, and also the total obtained by adding the totals for the week in question to those on the previous page of the account book. Thus at the end of any stated period the housewife can tell whether her housekeeping is costing more than it ought to do or whether any particular item is exceeding the allotted amount.

**ACCOUNT STATED.** When two people have accounts, one against the other, and they agree the account at so much, it is called an account stated. The account may be reopened on showing fraud or mistake, but the importance of an account stated is that it gives rise to a new cause of action, and the statute of limitations runs from the date when the account was stated.

**ACCUMULATOR.** Electric accumulators are employed for providing electric light and to a less extent for traction, as in electric carriages and motor launches. The accumulator is an indispensable adjunct of the small, self-contained electric-lighting plant. On motor-cycles accumulators are used for lighting; and on cars for lighting and for the electric starter, horn, and other devices. As a source of low tension and, to a less extent, of high tension current, the accumulator is also used in wireless sets.

An electric accumulator, known also as a secondary battery and as a storage battery, differs from the primary electric cell in that the accumulator does not generate energy, but is charged by sending an electric current through the cell from an outside source.

*When mixing electrolyte for the accumulator, acid must be added to the water (not water to acid) very slowly and stirred.*

The lead-acid type of accumulator in common use consists of a rectangular container of glass, celluloid, etc., in which are a number of grid-like lead plates, grouped into positive and negative elements. The plates are immersed in an electrolyte consisting of sulphuric acid in distilled water. The interstices of the grids are filled with a preparation of lead, and the plates are kept from touching by spacers of some non-conducting material. The positive and negative plates alternate, all the positive and all the negative grids being coupled.

*Accumulator. The state of the battery should be tested with the hydrometer, and distilled water added if the plates are not well covered.*

When a suitable electric current is sent through such a cell, hydrogen passes from the anode or positive plate, which is said thus to become peroxidised, to the other plate—the cathode or negative—where it combines with some of the oxygen of that plate, which thus becomes reduced. This chemical change is the measure of energy put into the cell and stored. The plates will remain in this charged condition for some time, though they will gradually run down if left alone; but if the terminals of the cell be connected outside, chemical action restarts in the opposite direction, the hydrogen removed from the one plate returns, and an electric current passes through the connexion in the opposite direction to that in which the current entered the cell. The cell is thus discharged. These operations of charging and discharging may be repeated indefinitely. In discharging the electricity put into the accumulator (stored) is utilised.

While essentially simple, accumulators require careful attention. The most serious trouble arises from sulphating. The sulphate is a white scale which forms on the plates and renders them useless. Sulphating may arise from over-discharging, running down the battery below the limit voltage ; by leaving the battery discharged for a time, or from too strong a solution. If not too bad the scale may be scraped off the plates, and by slow and careful charging proper conditions may be restored. If badly scaled the plates may become buckled or the preparations dis-integrated, necessitating renewal of the plates. Any acid which may be spilled from the vents should be wiped off carefully, and the terminals should be coated with petroleum jelly to prevent corrosion.

New accumulators are generally sent out dry, i.e.

without the electrolyte. Follow the maker's instructions carefully as to rate of charging, specific gravity of electrolyte, etc.

*If it is necessary to prepare acid of the required strength, the strong acid should be slowly added to the distilled water, stirring it in a little at a time. Never, in any circumstances, add water to the acid.*

Care must be taken not to spill the acid on the hands, clothes, or on any fabric.

*If acid touches the fabric it will be definitely marked, and will be completely destroyed unless the acid is washed off immediately.*

Ammonia water will neutralise the acid, and should be available, particularly where strong sulphuric acid is being used.

Accumulators are made up of two-volt units, usually separate, although two or more cells may be housed in a single outer container. The voltage of lead-acid cells is about 2, but increases to 2.2 when fully charged. A six-volt lead accumulator thus contains 3 cells and a twelve-volt 6 cells.

The number and size of the plates in the cell does not affect the voltage, but governs the output or amperage. The effective capacity of an accumulator thus depends upon the plate area exposed to the electrolyte.

The electrolyte in the cell should cover the plates. Any loss caused by evaporation must be made good by adding distilled (not tap) water until the electrolyte is at least half an inch above the top of the plates. The best time to do this is just before charging, as the charging process facilitates the mixing of the water and acid. Vent holes should always be clear so as to allow gas to escape.

The specific gravity of the cells can be tested with a hydrometer. A handy type of apparatus comprises an outer tube into which a small quantity of the liquid may be withdrawn by compressing a rubber bulb at the top of the tube. Inside the tube is the hydrometer proper, which floats in the liquid. After testing, the electrolyte is returned to the accumulator. The table in the next page gives average readings for an accumulator in different states of charge or discharge. The hydrometer should be used in conjunction with a voltmeter.

Condition of Cell.	Sp. Gravity.
Fully charged .. .. .	1.285
Half discharged .. .. .	1.245
Fully discharged .. .. .	1.190

The voltage of a cell should not be allowed to fall below 1.85. On charging, the voltage rises to about 2.2. It is useful to remember, in connecting cells together, that joining them in series adds voltage, and that connecting them in parallel adds amperage.

**ACETIC ACID.** The acid principle of vinegar is acetic acid, of which vinegar contains six to twelve per cent. The kinds and strengths of acetic acid are:

**Pyroligneous Acid.** A crude form sold as Essence of Smoke to flavour bacon and dried fish. It is applied with a brush on the meat or fish and adds colour as well as flavour.

**Glacial Acetic Acid.** So-called because in cold weather it solidifies and becomes like ice. It consists of pure acetic acid, burns the skin if applied freely, and has a pungent smell. When perfumed it forms aromatic vinegar, used to wet the sponge with which vinaigrette bottles are filled. The formula is as follows:

Lavender oil	40 drops
Clove oil	40 drops
Lemon oil	40 drops
Bergamot oil	20 drops
Cinnamon oil	10 drops
Neroli oil	5 drops
Glacial acetic acid	1 fluid oz.

Another preparation containing glacial acetic acid is toilet vinegar (q.v.).

Glacial acetic acid is used for warts, applied once a day with a small camel-hair brush. The skin round the wart is smeared with vaseline to prevent burning the sound skin.

**Ordinary Acetic Acid.** This contains a third of its weight of acetic acid and is used as a pickling vinegar where the colour of ordinary malt vinegar is an objection. One part of acetic acid mixed with four parts of water forms white vinegar, which is suitable for pickling vegetables.

To make spiced vinegar, boil for 10 min. the following bruised spices in a gallon of white vinegar:

Jamaica ginger	1 oz.
Pimento (allspice)	1 oz.
Long pepper	3 oz.
Black pepper	3 oz.
Mustard seed	1 lb.

Two tablespoonfuls of dilute acetic acid in a pint of water makes a useful lotion for dabbing on an itching skin, provided there is no inflammation or broken skin. It is also useful as a cold application to the forehead for headache or for sponging fevered patients.

Acetic acid is used for making raspberry vinegar (q.v.). See Vinegar.

**ACETYLENE.** Carbide of calcium when excess brought into contact with water produces acetylene gas, which is used by motor cyclists for lighting when their machines are without electrical equipment. Under normal conditions one pound of carbide generates 180 litres, or 6 cubic feet, of gas. This quantity will supply gas for about 8 hours to a burner passing from 20 to 24 litres per hour.

Acetylene is a colourless gas, and when pure has a rather agreeable odour, but it usually contains

impurities which give it a distinctive disagreeable smell. The gas will explode with great violence when mixed with oxygen or even air in any proportion from 3 p.c. to 83 p.c. It is not poisonous in small quantities, and burns with a white flame.

Acetylene lighting is obsolete on cars and has been almost entirely superseded by electricity on commercial vehicles and motor cycles.

Burners for acetylene gas are illustrated in the diagram. They utilise the Bunsen principle, the aim being to get as much air as possible to the gas at the point of issue from the burner; *a, a*, are air passages, and *b* the gas outlet. When burning properly, acetylene light is exceedingly white and brilliant; colours and shades appear the same as by daylight.

At one time acetylene gas was fairly widely used for country-house lighting, a water fed automatic gas-making plant being installed in an outhouse specially built for the purpose. The disadvantages associated with control of water supply, the smell of the gas if leakage or burner failure occurred, and other difficulties have caused it to be displaced by air gas (petrol gas) and other systems. See Air Gas; Gas; Electric Lighting, etc.

**ACHILLEA.** Both for borders and the rockery the achillea or milfoil (q.v.) is useful, *Millefolium*, *ptarmica* and *tournefortii* are three good species for borders. The most popular is the double Pearl, producing white flowers in summer and much esteemed for cutting. For rockeries the best are the white-flowering *clavennae* and *tomentosa*. The achilleas can be raised from seed, and thrive in plain soil. Pron. Ak-i-lee'-a.

**ACID.** Acids are of two classes: organic, and inorganic or mineral acids. Instances of organic acids are acetic, carbolic, citric, gallic, lactic, salicylic, tannic, and tartaric; and of mineral acids, boracic (or boric), hydrochloric, sulphuric, and sulphurous. See Acetic Acid; Boracic Acid; Fertiliser; Prussic Acid, etc.

**ACID DROPS.** Boil 1½ lb. loaf sugar, ½ pint water and ½ teaspoonfull of cream of tartar together until mixture turns a pale yellow, then add essence of lemon to taste and turn out on to oiled slab. Sprinkle preparation with one dessert-spoonful tartaric acid, work thoroughly in, and when sufficiently cool to touch form into thin rolls. Cut off small pieces with scissors and roll to shape by hand. Sift with sugar and dry before placing in tin.

**ACIDITY.** Term for excess of acid, usually organic acid, in the stomach, in certain kinds of

dyspepsia (q.v.). Where this exists, with occasional risings of sour, bitter material in the back of the throat, the following mixture often gives relief:

Bismuth oxycarbonate	2 drains
Sodium bicarbonate	1 ½ „
Mucilage of tragacanth	1 ounce
Peppermint water enough to make	8 ounces

Take two tablespoonfuls half an hour to one hour after a meal. *See* Diet; Indigestion.

**ACID STAINS:** Their Removal. Stains, as from sulphuric or hydrochloric acid, can usually be removed by washing the stained part with a solution of ammonia. Strong acids burn all fabric and must be washed off with ammonia or other alkaline solution (such as washing soda) at once if destruction of the surface is to be avoided. Some marking is almost unavoidable. Spots of acid on serge or blue cloth will cause red marks, which disappear if neutralized by ammonia while still wet. A strong solution of ammonia may remove many old acid stains as well, though not generally effective, as the material and dye are oxidised, especially by nitric acid. *See* Ammonia; Stain.

**ACNE.** This is a chronic skin disease characterised by pimples, blotches, blackheads, and a greasy skin, on the chin, forehead, shoulders and back. In another form of it, acne rosacea, a prominent symptom is a chronically inflamed, reddened nose. *See* Blackhead; Nose; Pimple.

**ACONITE.** There are numerous species of aconite, which belongs to the buttercup family. They are all poisonous, the roots bearing some resemblance to horseradish. The common monkshood is *Aconitum Napellus*, a British native which favours shade near water. Besides the blues, there are several varieties bearing pale yellow flowers, like *lycoctonum* which is the wolfsbane, *anthora* and *pyrenaicum*, all summer bloomers. The winter aconite (*Eranthis*) does well in shade, and is often grown under trees, its clear yellow cups on their green Toby frills appearing in January.

*Right. Aconite. Seed pods and blue flowers of monkshood, a variety of Aconite. (Photo, Malby).*

*Left. Aconite. This root yields a deadly drug.*

*fatal consequences.*

Horseradish is a pale yellowish colour outside, whitish inside; aconite root is a dark brown colour outside, whitish inside. Horseradish is cylindrical in shape, aconite conical.

In medicine aconite is a powerful poison, sometimes prescribed to slow the action of the heart. The symptoms of poisoning are severe vomiting, an icy wet skin, complete prostration, accompanied by a very slow, often irregular, pulse. *See* Monkshood; Poisoning.

**ACRE.** A land measure containing 4,840 sq. yards, divided into four roods each of 1,210 sq. yards. In addition to this imperial acre, acres of other sizes are occasionally used in various parts of the United Kingdom, among such being the Scottish and Westmorland acres.

**ADAM STYLE:** In Furniture. The brothers Robert and James Adam were architects, famous as designers of buildings in London and the country during the latter half of the 18th century. They designed furniture and decorations to harmonise with these.

Their style was based upon the lighter details of the classic orders (Doric, Ionic, Corinthian, etc.). Swags, festoons, flowers, lutes, paterae (round and oval ornaments), festoons of drapery, mythical figures, husks, the vase and urn, key borders, and rams' heads, honeysuckle and acanthus, dentil and egg-and-tongue are the prominent features found in all Adam work. Much of the furniture was painted, though made of mahogany, and Wedgwood plaques were often inserted as panels. Many of the original Adam drawings are in the Soane Museum, Lincoln's Inn Fields (London), and specimens of the furniture at South Kensington. Fig. 1 shows the urn motif, Fig. 2 the honeysuckle ornament, both frequent in Adam decoration. Figs. 3, 4, 5 and 6 show the characteristic table legs, round, tapered or square, carved and fluted. Fig. 7 is a chair-back with rams' heads, key pattern and honeysuckle on the splat and husks in low relief carved all round the frame.

*Adam Style. Fireplace with an Adam grate and mantelpiece taken from an old house and readily adapted to a new one.*

The photograph of the grate above has an almost familiar present-day look owing to the extent to which Adam designs have influenced modern decoration in this direction. From about 1775 Robert Adam did much to develop painted and inlaid satinwood

*Aconite root has been mistaken for horse radish, with*

typical of this  
style. See  
Text.*

furniture, which then became the fashion. He also designed some pieces in lacquer. The typical Adam ceiling has complicated mouldings of festoons, ovals and medallions.

R. and J. Adam were really the last designers to create a characteristic British style which has lived.

*See* Anaglypta; Antique Furniture; Chair; Chimney Piece, etc.

Adam patterns on splat and frame*

**ADDER BITES:** How to Treat. The bites of the variety of adder found in Great Britain are rarely fatal except in children and debilitated persons. There may be a burning pain at the site of the puncture, but the accident may not be noticed, and the first warning may be the onset of the general symptoms, which are prostration, with perhaps vomiting and diarrhoea, the skin being covered with a clammy sweat ; and the person may possibly become unconscious. The doctor should be sent for and told the nature of the accident at the time of summoning, so that he may bring with him such remedies as he may require.

A ligature (q.v.) should be applied round the limb above the wound to prevent the poison entering the system, or any more of it if general symptoms have actually manifested themselves.

The bite should be thoroughly sucked, and no fear need be entertained of evil consequences, as there is no danger in sucking if there are no broken surfaces on the lips or mouth. The mouth should be rinsed out with

water or spirits, if any are available. Any bleeding should be encouraged.

Meanwhile the patient is kept warm, and the limbs may be chafed for this purpose. Stimulants should be given, spirits, sal volatile in teaspoonful doses in water, or hot tea. It is necessary to keep the patient cheerful. The wound will subsequently need to be kept covered with an antiseptic dressing.

### ADDER'S TONGUE.

This dwarf-growing fern is grown at its best in the partially shaded section of the rock garden, and likes a moist, loamy soil. It may be planted or transplanted at any time during the spring or summer months, and may be propagated by putting spore-laden fronds in a cold frame towards the end of summer. It was once largely used in window fern boxes.

*Adder's Tongue. Dwarf fern.*

### ADENOIDS: CURE AND AFTER TREATMENT

How these Troublesome Growths may be Detected and their Consequences Prevented.

*See further under Breathing; Nose; Throat; Tonsils, etc.*

*Adenoids. Section of the mouth and nasal cavities  
showing the common site of the growths*

An overgrowth of lymphoid tissue called an adenoid is often to be found in children at the back of the nose on the vault of the nasopharynx. This lymphoid tissue is similar to that of which the tonsils are largely composed and is present in every body. It is the overgrowth of this tissue in the shape of small bosses or finger-like processes which constitutes adenoids. These processes may be soft and friable, or may be tough and firmly attached. Adenoids are usually associated with enlarged tonsils.

From their position they more or less block up the air

passage between the nose and throat, making it difficult or impossible to breathe through the nose. They may obstruct the opening of the Eustachian tubes, which lead from the throat to the ears, and thus cause deafness and perhaps earache.

Adenoids may be noticed shortly after birth, but are most common between the ages of 3 and 10. In infancy, because the blocking up of the nostrils causes difficulty in breathing, suckling may be seriously interfered with, and the nutrition of the child suffer in consequence. When the child is somewhat older say, perhaps 3 or 4, it may suffer from a constant "wet nose," and the discharge may contain pus or be tinged with blood; the mouth is always open, and it will be found that the child always breathes through the mouth.

The cavity of the nose is so constructed that it warms, moistens and cleanses the air, but when the air passes through a large cavity like the mouth, which is always swarming with microbes, it is neither cleansed nor warmed. The result is that the child with adenoids is liable to suffer from catarrh of the throat and air tubes, and an irritating cough is frequently present. The voice tends to become thick and nasal in quality, and snoring at night is usual. Deafness is very common, and infection may extend into the ear.

If the condition is not relieved, the face assumes a characteristic appearance, with a compressed nose and prominent upper teeth, like a rabbit. Owing to the difficulty in taking sufficient air into the lungs the chest may become deformed, flattened from before backward, or from side to side, with a prominent breastbone—the so-called pigeon breast. The liability of such a person to contract tuberculosis of the lungs is notorious. Sleep is apt to be disturbed, and while awake the child may be peevish and irritable. The expression is often dull and stupid, and the child may be inattentive at school, so that the mental development is retarded.

Treatment of adenoids is a matter of controversy. If they are small and recent, if they are only swollen because of inflammation, it is possible that the procedures which we shall mention in connexion with the treatment necessary after operation may do good. They should not, however, be persisted in too long. But when the adenoids are actual overgrowths, and perhaps tough growths, operation is the only treatment, and it should be performed without delay. It is usually also necessary to remove the whole or part of the tonsils at the same time. The operation is simple.

It must be remembered that failure to carry out the after treatment is responsible for any incompleteness in cure.

The child should be supervised in (1) clearing out the nose by blowing it twice a day; and (2) in performing simple exercises with the mouth shut. This treatment should be commenced a week or ten days after the operation. In clearing the nose the child should stand erect and grasp the nose with the right hand across the bridge, not on the compressible part. It should then take a deep breath through the nose and finally blow down forcibly into a piece of soft paper held in the left hand. This is repeated several times. In blowing the

nose only one nostril at a time should be compressed. Compressing both at once may result in forcing infectious material into the ears.

With regard to the exercises, a simple one is to make the child stand erect and stoop about 10 or 12 times a minute. The mouth must be shut, and the child breathes out in descending and in when raising the body. The exercises should be performed, if possible, in the open air, and should be continued for at least four or five months. The tendency to sleep with the mouth open may persist, and it may be necessary to bandage up the lower jaw to prevent this.

After complete recovery from the operation the patient's health should be built up in every way possible by plenty of outdoor exercise, plain, nourishing food, long hours of sleep and freedom from school if necessary. A month at the seaside or in the country will often work wonders in these cases.

*Adenoids. Left boy showing typical symptoms of adenoids; right, seven months after their removal*

#### ADHESIVE PLASTER.

A mixture of resin, lead plaster, and hard soap, melted together and spread on strips of linen, are the components of an adhesive plaster. Another form, which has a rubber basis, Mead's plaster, is obtainable in various widths, and does not require warming before application. These plasters are useful for bringing the edges of a wound together, and for strapping on dressings. They are sometimes used round boils to protect the surrounding skin from infection. A hole is cut in the centre to permit of the discharge escaping.

#### ADMINISTRATION, LETTERS OF.

When a man dies without a will, before his money or property can be dealt with someone must take out letters of administration. England is divided into districts, and the proper thing to do is to apply at the registry of the district where the deceased resided. The following is a list of the towns where the district registries are situated:

Group 1. Newcastle, Durham, Carlisle. Group 2. Leeds, Sheffield, York. Group 3. Manchester. Group 4. Liverpool, Lancaster. Group 5. Chester, with sub-registries at Bangor and Shrewsbury. Group 6. Lincoln, Nottingham, Leicester, with a sub-registry at Derby. Group 7. Peterborough, Norwich, Ipswich. Group 8. Birmingham and Oxford, with a sub-registry at Northampton. Group 9. Cardiff, with sub-registries at Hereford, Gloucester, and Carmarthen. Group 10. Bristol and Exeter, with a sub-registry at Bodmin. Group 11. Southampton and Lewes, with a sub-registry at Salisbury.

In any other part of the country, or when the deceased lived abroad, application should be made to the Principal Probate Registry at Somerset House, Strand, London.

The widow or widower is the first person entitled to take out letters of administration, and then the children. Failing children, a grandchild; failing descendants, a parent, brother, sister, nephew, niece, grand parent, uncle, aunt, cousin, the Crown, and creditors—in that order. The registry supplies forms to fill in, and explains where to swear the necessary affidavit; but unless the estate is a very small one indeed it is generally advisable to entrust the business to a solicitor. *See* Executor; Will.

**ADOPTION: The Legal Aspect.** Not until 1926 in England and 1930 in Scotland was it made legally possible for an adult to adopt a child under 21 so as to exclude the rights of the natural parents.

An adoption order must be obtained from the court and the case will be heard in camera. The adopting person must not be under 25 nor, except where the parties are related, less than 21 years older than the child to be adopted. No male person can adopt a female child as sole adopter except in special circumstances. The consent of the parent or guardian of the child must be obtained to any adoption before an order will be made. A husband and wife may adopt jointly or one of them may adopt alone, but in that case the consent of the other must be obtained unless they are living apart. Money may be given for the adoption, but this must be sanctioned by the court.

The adopting parent has the same rights over the adopted child as over his own children as to custody, maintenance, and education. The adopted child does not lose any rights it may have of succeeding to property through its natural parents, nor does it acquire any right to succeed to property as the child of its adopting parent. A special register is kept of adopted children at Somerset House, London, W.C.

**ADULTERATION OF FOOD.** The different kinds of adulteration may be classed under the following headings:

The mixing of a cheaper substance with a more expensive one, the mixture being sold under the title of the latter constituent. Examples of this are glucose and sugar, sold as sugar, or chicory and coffee as coffee.

The addition of worthless substances fraudulently to increase the bulk, such as the addition of coarsely ground shells of fruit stones to pepper and spices, dilution of milk with water.

The addition of preservatives to delay putrefaction and conceal the use of stale food. This, however, is allowed by law in particular cases, and under certain conditions.

The addition of artificial colouring matters, allowed in some cases.

Anyone who suspects that food or drink supplied has been adulterated should interview the medical officer of health of the district. Any private purchaser

may submit a sample to the public analyst, who must analyse it and report on payment of 10s. 6d.

Any medical officer, sanitary inspector, inspector of markets, inspector of weights and measures, or police constable acting on the instruction of the local authority can compel any retail trader to sell him a sample of food exposed for sale. Samples may also be taken in the course of delivery, with the consent or at the request of the purchaser. In the case of milk no consent or request is required. *See* Food; Preservatives.

**ADZE.** This is an edged tool having a curved blade set at right angles to the handle, so that the cutting stroke is always towards the worker. It is used principally for rough planing timber. The tool is extremely dangerous for an amateur to use.

*Adze used for smoothing a plank. It is a very dangerous tool*

### **AERATED WATERS.**

Certain kinds of mineral waters which have had carbonic acid gas dissolved in them under pressure. Small quantities can be made with the aid of a gasogene or seltzogene, and the steel capsules sold at chemists' containing carbonic acid gas under pressure. If pure water is used in the gasogene the product is simply mineral water. For soda water dissolve 80 grains of sodium bicarbonate to the gallon; for lithia water 80 grains of lithium carbonate; for potash water 32 to 64 grains of potassium bicarbonate; and for seltzer water 80 to 160 grains of a mixture of chloride, bicarbonate, sulphate and phosphate of sodium, all to the gallon. Lemonade and similar aerated waters merely require the necessary flavouring agents to be added. *See* Mineral Waters; Soda Water.

**AERIAL: How to Erect.** In erecting a broadcast receiving aerial it is necessary to bear in mind the limitations imposed by the P.M.G. The combined height and length must not exceed 100 feet. Thus an "L" aerial with a 75 feet horizontal span and a downlead of 25 feet would be permissible. An aerial which crosses above or is liable to fall upon or to be blown on to any overhead power wire (including electric lighting and tramway wires) must be guarded to the reasonable satisfaction of the owner of the power wire concerned. With present-day broadcasting conditions it is not always necessary to use an aerial of the full length allowed, and greater selectivity may be obtained in many cases with a shorter one.

The inverted "L" aerial gives good results and is in the main the easiest to erect. It will be assumed that the aerial is to be attached at one end to the house, e.g. to a chimney stack, and supported at the other by means of a mast.

A straight, sound, scaffold pole 30 feet long may be

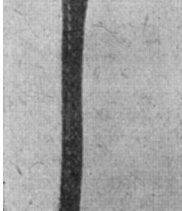

used; it can be painted and the lower end tarred. For foundation place it on a square of York stone, let 2 to 3 feet into the ground. The side of the hole on which the pull of the aerial will come should be vertical. To the pole must be fixed 8 guy wires for holding it in an upright position. This wire should be about 7-32 S.W.G. galvanised steel wire. Cut suitable lengths and seize four of them round the pole about a foot from the top and four more half way up its length. Anchor the guy wires by fastening them to stout stakes driven into the ground. A good anchorage may be made of a stout iron bar formed into an eye at the top end and bent over at an angle at the lower end. This is embedded in a mass of wet concrete in a hole. Before proceeding to erect a pole, fasten a pulley-block to the top threaded with the halliard or rope for running the aerial up and down. The halliard must be made endless by joining up the ends. Help will be necessary for erection of the pole.

The next thing is to erect the house-end fixture. If there is a convenient chimney a galvanised iron strap may be fixed round it to take the aerial; a pulley-block should be attached to the strap, and the halliard or

A close-up photograph showing a horizontal wire being twisted around a vertical rod. The wire is being manipulated to form a loop or knot around the rod.

***Aerial. Method of joining lead-in.***

The aerial wire should be stranded hard drawn copper wire 7-22 to 7-25 S.W.G. Run it out on the ground, taking care to avoid kinks, loops, etc. Fix a shell insulator to the mast end of the wire, and, judging the amount required for loading in, fix an insulator into the wire at the point where the aerial will leave off, and the leading-in wire or down-lead commence. Where the aerial lead is to enter the house a proper lead-in tube should be fixed. The lead-in should be kept at least 4 ft. away from walls or trees. Hoist up the aerial, but do not draw it too taut, as wind and wet may cause too great a strain. Every three months the stay wires must be examined, and, if necessary, adjusted. Insulators should be cleaned and dried periodically. Nothing is gained in broadcast reception by using aerials with more than one wire, except of course, in the cage type, which is useful in confined spaces.

**AEROPLANE: Making a Model.** The actual making of model aeroplanes is simple. The main consideration is lightness, and strength of construction has to be sacrificed to achieve this. An illustration is given of a popular and simple type of model. The fuselage consists of a single spar of balsa wood, with wings and tail unit of the same ultra-light material. Motive power is provided by a couple of strands of aeroplane elastic.

*Details of the inner wing attachment, showing the wing clips and the dimensions recommended.*

The shaping of the propeller is the most difficult piece of work. The wood has to be soaked in boiling water and twisted carefully at each end to the required pitch. When fashioning the wings, care must be taken that they are of exactly the same dimensions and thickness. Generally speaking, the thinner and smoother the wing surface, the better the model will fly. The rudder and each half of the tailplane are

of identical size and shape. The wings should be soaked like the propeller and twisted from front to rear to give a cambered surface.

While the wings are drying, take the spar to which wings, tail and elastic are to be attached. Sandpaper this all over and taper the extreme tail. Then make a shallow cut along the tapered portion, sandpaper the base of the rudder and insert the latter in the cut, using special cement to fix it firmly. The two halves of the tailplane can then be cemented together and fixed on the spar at right angles to the rudder.

*Aeroplane Model. The lower photograph shows the completed model, directions for the construction of which are included in the article on this page.*

A two-foot length of piano wire provides all that is necessary to make the wire parts of the models. These include the spindle for the propeller bearing, the two under-carriage legs (bent out at the foot to form axles), a clip to hold the elastic down over the centre of the fuselage, a swivelling bracket-cum-skid as rear attachment for the elastic and the wing clips, of which more is said later.

The wheels are made from a piece of stiff card. A paper tube through the centre of each wheel will act as a bearing, and a piece of thread wound round it and cemented will prevent the wheels falling off.

The propeller should now be cut exactly in half, and the two halves cemented into a notch on a central wooden hub. Insert the propeller spindle in the notch, with two brass washers between the wire loop and the blades.

The wire wing clips are bent into shape and cemented into position about 1 in. from each edge of the wings (*see Fig.*). When these have completely dried, bend the clips again very carefully to give the entire wing unit a slight dihedral angle, so that the wing-tips are higher than the centre section. The wings are then clipped to the spar, the elastic is attached to the brackets at the nose and tail, and the model is complete.

**AFFILIATION ORDER.** Any single woman, or married woman living apart from her husband, who has an illegitimate child may obtain an order at the police court against the father for the payment of a sum not exceeding 20s. a week until the child is 13 or in

special cases 16, and of a further sum for the expenses of her confinement. Application may be made before the child is born and must be made within 12 months after the birth, unless it can be proved that the alleged father paid money for the maintenance of the child within 12 months of the birth, in which case the application may be made at any time. Where the alleged father went abroad within 12 months of the birth, the application may be made within 12 months of his return.

The evidence of the mother as to the paternity must be corroborated by some other evidence, such, for example, as some statement or the behaviour of the alleged father.

**AFRICAN LILY.** A native of South Africa, the African Lily, or *Agapanthus*, has long, sword-shaped leaves and beautiful blue flowers, the latter being borne on a stem about 3 ft. in height. There is a single species, *umbellatus*, also several varieties including whites, and a double form. It is usually grown in small tubs or large pots, which may be placed outside in the summer, and is propagated by suckers. A fairly rich compost is necessary, preferably three parts of old turf, one part of decayed cow manure, one of leaf-mould and a fair proportion of sand.

*African Lily. Blue flowers of this large pot plant.*

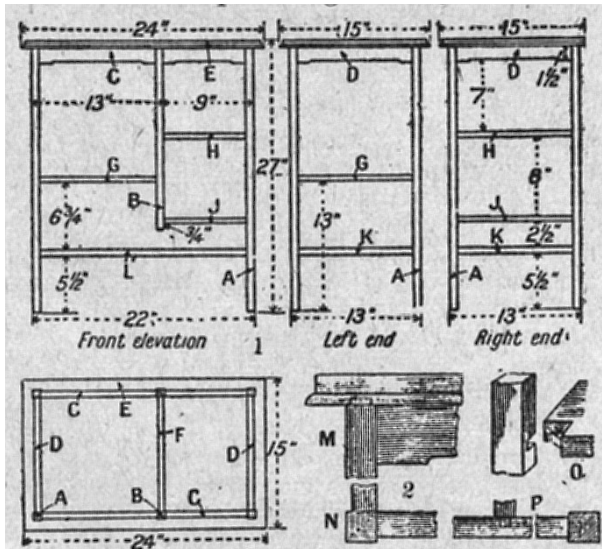

**AFTERNOON TEA TABLE.** This light tea table is designed on Japanese lines. The framework is of the slightest consistent with strength.

The legs are  $\frac{3}{4}$  in. square throughout their length. They are cut with stub tenons to enter the top, mortised for the rails as they occur, and notched for the shelves, two at the right-hand side and one at the left. The sizes are given in Fig. 1. The top rails are tenoned to the legs, and the two longer ones (C) may be bridle-jointed to the intermediate uprights (B), which are  $\frac{3}{4}$  in. square.

The table top may be in one piece finishing  $\frac{5}{8}$  in. thick. It overhangs an inch at each side, and is held by thumb-screwing through the rails and by glue-blocking. The middle uprights project  $\frac{3}{4}$  in. below the bottom shelf.

*Afternoon Tea Table, the making of which is described in the text*

*Afternoon Tea Table. Fig. 1. Sectional plan, front and end elevations; for lettering see cutting list. Fig. 2 (bottom, right). Principal joints: M, top, leg and rail; N, section of leg and rails; O, notched shelf; P, lower rail joints.*

Lower rails may be arranged as shown in the perspective sketch, or two cross rails (Fig. 1, K) and one central stretcher rail (L) only may be fixed. The rails,  $\frac{3}{4}$  in. by  $\frac{1}{2}$  in. in section, will be tenoned to the legs, the stretcher rail being tenoned to the two cross rails (Fig. 2, P). The shelves are notched to the legs and uprights (see Fig. 2, O). Each shelf may be strengthened by screwing a steel picture eye (angle-wise) into the leg immediately below the shelf. The shelf finds an additional bearing on this, and may be screwed through the picture eye from below.

	Long in.	Wide in.	Thick in.
4 legs (A)	26½	¾	¾
2 uprights (B)	19	¾	¾
2 top rails (C)	22	1½	⅝
2 end rails (D)	13	1½	⅝
Top (E)	24	15	¾
Stiffening top rail (F)	13	1½	⅝
Left hand shelf (G)	13	13	½
Right hand shelf (H)	13	10	½
Ditto (J)	13	10	½
2 cross rails (K)	13	¾	½
Stretcher rail (L)	22	¾	½

Oak, walnut, or mahogany may be used for the table. The wood should be thoroughly sound and free from knots. A cutting list is given above; the lengths quoted allow for joints and paring, but all thicknesses are intended to be net finished sizes.

**AGAVE.** With its large, succulent, shiny leaves, and big trusses of greenish-yellow funnel-shaped flowers, borne on tall spikes, this plant is frequently grown in large pots or tubs. It blooms but rarely, and grows slowly. It needs little attention, and is able to withstand a great amount of drought and hot sun. The best known species is *Americana*, the American aloë, which attains an imposing size, and is grown out of

doors.

*Agave.*  
*Succulent*  
*plant suitable*  
*for growing in*  
*pots and tubs.*

Two varieties often grown are *picta* and *variegata*, both with variegated leaves. Other good sorts are *filamentosa* and *Sartori*. A suitable compost is composed of three parts loam, one part leaf-mould, and one part decayed hotbed manure, with sand. To propagate the plant, pot up the small suckers which form at the base, and grow them on. During hot weather the agave needs copious supplies of water. Pron. A-gay'-vi.

**AGERATUM.** While not fastidious in the matter of soil, the *ageratum* prefers a dry but gritty soil to a stiff, damp medium. If put out in May the plants flower from June till October. The dwarf garden forms of the species *Mexicanum* may be used as bedding plants. Such sorts as *Imperial Dwarf Blue*, *Countess of Stair*, *Swanley Blue*, and *Heavenly Blue*, with slate blue flowers from May to September, are commonly grown as annuals. Pron. Aj-er-ray'-tum.

**AGREEMENTS.** Before any agreement will be enforced by English law there must be present what the law calls "consideration," or else the agreement must be made by a deed—i.e. a document under seal "Consideration" in an agreement means that one party to the agreement is promising to do something in consideration of the other party promising to do or to forbear to do something else.

Agreements are created by an offer made by one party and the acceptance of it by the other. The acceptance must be in exactly the same terms as the offer. For example, if a man offers to buy some boots from another and stipulates the exact quantity and quality and price, and also that delivery must be on a certain day, and the other replies, agreeing to all the terms except the date of delivery, there is no completed agreement, as the offer and acceptance differ on this one point. What purports to be acceptance is really another offer.

Agreements may take any one of three forms. They may be by deed under seal—in which case we have seen they require no consideration—in writing, or by

word of mouth. A transfer of shares in a company or a lease for more than 3 years (but not a mere "agreement for a lease") must be by deed. The following agreements must be evidenced by some written document. (1) guarantees; (2) agreements for the sale of land; (3) agreements by executors to be personally liable for the debts of the estate; (4) agreements in consideration of marriage; (5) agreements which cannot be performed within a year of the date on which they are made; (6) agreements for the sale of goods, over £10 in value, unless some of the goods have been accepted by the buyer or some money has been paid, where some performance of these agreements has taken place, written evidence is not necessary. Agreements with moneylenders not made in a special form are void.

When a man has been induced to enter into some agreement by some fraudulent untrue statement made by the other party to the agreement, he can in some cases have the agreement set aside and in all cases he can sue the fraudulent person for damages.

If one party to an agreement fails to carry out his promise, the other party can in some cases compel him to do so. In all cases, however, the innocent party is entitled to sue for damages and to recover all that he has lost through the failure of the other.

The law of agreements in Scotland differs on many points from that of England. In particular, no consideration is required and a large class of agreements have to be proved by written evidence or by the sworn evidence of the person who is sued. *See* Hire-purchase; Insurance; Landlord; Lease; Rent; Repairs, etc.

**AGRIMONY.** Any fertile soil is suitable for this small genus of hardy herbaceous perennials, growing from 2 to 3 feet high, with yellow, fragrant flowers. It can be planted at any time of the year except the summer, and is propagated by division in spring. *Eupatoria*, *odorata* and *suaveolens* are a few of the best species. The hemp agrimony is *Eupatorium cannabinum*, a good native perennial, growing about a yard high, with purplish dowers. Pron. Ag'-ri-mo-ni.

*Agrimony. Flower spikes of the herbaceous plant*

**Ague.** *See* Malaria.

**AIGRETTE.** It is now illegal to import the osprey or aigrette formed from the tuft of feathers on the head of the smaller white heron, as the capture of the bird for the sake of the plume involves its death during the nesting season. Imitation aigrettes for millinery purposes are composed of various feathers or of wired jewels.

**AIR-BRICK.** These are of the same superficial size as the edge of an ordinary brick—9 in. by 3 in. Air-bricks are cast-iron or terra-cotta, and are placed in the base of all exterior walls, immediately below the damp course, for the purpose of ventilating the space between the ground level and the flooring. *See* Damp Course.

**AIR CUSHION.** In round, square, and oblong shapes, the best cushions are made of pure para rubber, but cheaper kinds are of material like that used for mackintoshes. Air is blown into the cushion through a valve. It should not be fully inflated or undue strain will be put on the rubber.

When, not in use, cushions ought to be hung up by a string fastened to the valve and should always contain a little air; folding them induces cracks in the material. In the event of leakage, cushions can be repaired with a thin cycle-tire patch or sheet rubber attached with rubber solution. This substance can be smeared along the joints if not air-tight, taking care that the material is quite clean.

*Airedale Terrier. Prize-winning specimen of this wire-haired terrier which is an excellent house dog*

**AIREDALE TERRIER.** This is a modern breed of wire-haired terrier and makes an excellent house dog. A large, rather gaunt-looking dog, square built, standing 20 in. at the shoulder, its wiry coat is close-fitting, dense, and a bright, deep tan in colour, except that the back and neck are dark grey and the nose is black. It has a long, straight and flat-topped head with medium V-shaped ears and small dark eyes. The tail, always docked for show purposes, is carried nearly erect. *See* Dog.

*Airer. Fig. 1. Convenient form attached to wall, with arms that fold down when out of use.*

**AIRER:** For Clothes. Several kinds of airers are

used. One is a rack suspended from the ceiling and held in position by cords running over pulley wheels; another is a rack attached to the wall having a number of movable arms (Figs. 1 and 2). Both may be made by any amateur. Ordinary yellow deal may be used, but beech, birch, or oak will make a stronger job.

*Airer. Fig. 2. Simple form with six movable arms.*

For the airer shown in Fig. 2, the back piece is 11 in. by 8½ in. by 1 in., with the corners cut off 1 in. each way. Two grooves, each 1 in. wide and ¾ in. deep, are cut in the back, the lower one being 5 in. up and the space between 1¼ in. Two 7½ in. lengths of 1-in. wood are fitted in the grooves, the width being 8½ in. with the end of each trimmed to a semicircle. Six holes should be bored in the top piece ¾ in. away from the edge and equally spaced along the circumference, the holes being just large enough to take a 3-in. wire nail. The six arms must be cut to a length of 2 ft. 6 in. from straight-grained wood, and carefully planed to 1¼ in. by ½ in., the edges being rounded and smoothed off. A hole, similar to those in the top, should be bored at one end of each arm, 1 in. away and exactly in the centre. The bottom piece must be supported by a bracket cut to a triangular shape and measuring 5 in. on the two right-angular sides. Fit the work together by nailing the bottom piece from the back of the groove and then nail on the bracket. Next nail on the top piece, and finally nail the arms in position.

*Fig. 3. Kitchen airer with five hanging rails, fitted with cords and pulleys for the purpose of raising it to the ceiling.*

Many housewives prefer a ceiling airer (Fig. 3) which can be drawn up out of the way when not in use, and at the same time has the benefit of the hotter air which always rises. It may be made about 3 ft wide by between 5 ft. to 10 ft. long, and is raised or lowered by means of pulleys and rope. A serviceable size is 6 ft. by 3 ft. The end rails should finish ¾ in. thick, and may be about 3 or 4 in. wide. The hanging rails, of which five are shown, but which may be increased to seven or eight, can be of stout bamboo or 1½ in. by ¾ in. laths, as preferred. The latter should be mortised right through the end rails and double wedged. The canes, if used, should be plugged with wood well glued in for several inches at each end. Corresponding holes, equally spaced, will previously have been bored in the end rails to receive them.

A hole in each glued joint, bored and screw-entered from the underside up through the cane and plug into the end rail, will stiffen the frame generally. About 12 yards of stout cord can be allowed, two lengths of which will be cut off for the slings. These can be attached to the end rails by means of stout, galvanised eyes, or the end rails can be holed for the cord to pass through and be knotted. Two single and one double pulley will be required. They should be entered into the joists for a firm fixing. The ends of the remaining length of cord can next be passed over the double pulley by way of the single pulleys and knotted securely to the slings. The cleat hook is screwed to any available woodwork in the room. *See Clothes Horse; Laundry.*

## AIR GAS FOR COUNTRY HOUSES

*Safe Use of Petrol Mixtures for Lighting and Heating*  
For other methods *see Electric Lighting; Gas, etc.*

Air or petrol gas plants are extensively employed for the lighting (and cooking and heating) of private houses in the country, where no public supply of gas or electricity is available. Petrol is highly volatile at ordinary temperatures, and it is thus possible to vaporise it by mechanical means without the aid of heat.

There are two classes of apparatus in use. Both use incandescent mantles, as the flame in each case is non-luminous. Air gas containing from 1.25 in 2.0 per cent. of petrol burns safely with proper arrangements; but if the proportion of petrol be anything between 2 per cent. and 5 per cent. the mixture is explosive. Hence in one of the two systems gas containing just under 2 per cent. is used, and in the other gas with over 5 per cent. Both are equally safe, while each claims to have its own special advantages.

The essential features of a representative type of apparatus are illustrated in Fig. 1. A is a fixed circular casing of iron supported, together with the gearing and other parts, on a suitable wooden or iron stand. The casing is divided by the diaphragm, C, into two compartments, D and E. the former being the mixing or carburetting chamber, and the latter the gas chamber. F is a drum rotated by the shaft, *a*, and gear,

*b.* This drum is in effect a series of circular hollow coils, usually four. Each makes several turns spirally round the drum; a portion of the coils is shown exposed at *d*. A cross-section of this coil drum is shown in Fig. 2. The outer ends of the coils 1, 2, 3, 4, open into the carburetting chamber, *D*, Fig. 1; the other end of each turns down into the small chamber, *e*, formed by enlarging the end of the axle of the drum.

The casing is filled with petrol up to about the level shown, and the outer end of each coil dips in succession into the petrol as the drum turns round, the rotation being in the direction shown by the large arrows in Fig. 2. Each coil, as it passes through the petrol, picks up a certain amount of the spirit; this spirit is carried round inside the coil and, as it goes, drives the air before it through the coil, becoming intimately mixed with it in the process, till both issue from the chamber, *e*. Any petrol not taken up by the air drops into the bottom of the casing *E*, and finds its way back into the carburetting chamber through a small communicating passage, *f*. The air gas passes by the opening, *g*, into a small receiver, whence it is drawn as required.

Air is admitted into the carburetting chamber through the opening, *h*, fitted with a valve which, though permitting air to enter, allows nothing to escape. Petrol is put into the apparatus through the opening, *j*. Very little power is needed to drive the machinery, and in small plants it is supplied by a heavy weight and system of pulleys, as shown at *G*. The frame carrying the upper set of pulleys is attached to a beam in the ceiling. The weight is shown in dotted lines in its lowest position. It is wound up by means of the handle, *k*, the wire cord being at the same time wrapped round the drum, *l*.

When gas is being taken from the machine, the weight, *m*, falls gradually and turns the gearing. As soon as the gas ceases to be taken, the pressure which develops in the casing, *A*, stops the action of the weight, whereupon gas ceases to be made. The only labour needed is that for winding up the weight once a day, and putting in the supply of petrol.

Air gas has many recommendations. Though it has not the brilliance of incandescent gas, it is adequate for ordinary purposes. It can be used for heating and cooking, though it may become expensive when used for these purposes. There is little risk involved in its use, provided only that proper burners are employed and arrangements made to prevent back-flash through the pipes. Low percentage burners must be gauze packed, and in any case, for either system, a safety chamber should be placed on the gas main between the gas-making apparatus and the burners. One point to be noted is to have the pipes large enough and the connexions easy; the free passage of the gas must not be impeded by sharp corners.

**AIR GUN: How to Look After.** The principles on which the various types of air gun work are more or less identical. An air chamber in the form of a cylinder having inside an accurately-fitting piston driven by a powerful spring is attached to the stock. A lever, usually connected to both stock and barrel, which are hinged together, compresses the spring when the barrel is pulled down: the piston is held in position by the trigger, and when the bullet or pellet is inserted, and the barrel replaced and locked by the catch, the gun is ready for use. On the release of the trigger the pellet receives the full force of the compressed air formed by the sudden release of the spring-driven piston.

*Air Gun. Diagram showing the mechanism of an ordinary type of air weapon.*

The only part of an air gun likely to get out of order with ordinary use is the spring. To effect repairs, and also to clean the internal mechanism, the metal cover must be unscrewed, together with any parts attached thereto. If the spring is weak or broken, a new one must be fitted. The piston should be taken out, the new spring compressed in a vice, tied up with twine, and fitted in position. The trigger catch or attached rocking-cam should be examined for signs of wear, and, if necessary, new ones fitted. The parts should be re-placed, and, when secure, the string attached to the spring may be burnt with a red-hot wire and the bits pulled out with a wire hook.

**AIR LOCK.** In a hot water system an air lock is generally caused by faulty pipe arrangements permitting a gap to form in the column of water. The flow of hot water is thereby impeded by the imprisoned air. The remedy is to provide a release valve which can be opened to release the air. It should remain open until the water flows freely. *See Central Heating.*

**AIR-PROOF PAPER.** A dozen or so sheets of

paper may be laid on a table and ironed rapidly with a very hot iron, against which is held a piece of wax. The melted wax is absorbed by the paper through a number of the sheets. Another method is to dissolve one pound of white soap in one pint of water, and in another pint  $2\frac{1}{2}$  oz. of glue and  $\frac{3}{4}$  oz. of gum arabic. Mix the two solutions and warm together, then soak the paper before drying. Air-proof paper is used for jam-pot covers.

**AITCHBONE.** The thick top piece of the leg of beef next to the rump is economical on account of the small proportion of bone compared to the thickness of meat. It is a suitable cut for salting and boiling. *See Beef.*

**AKEBIA.** *Quinata* is the species mostly grown of this pretty rambling plant with its Japanese name and its violet or purple, fragrant, drooping flowers, which are produced in the axils of the leaves in late spring or early summer. It is best to grow it on a wall in cold districts. It likes a fertile and friable soil, preferably one which contains loam and peat. Pron. A-kee'-bi-a.

**ALABASTER.** A translucent form of gypsum which is largely used for ornamental purposes. Strong soap-and-water is best for cleaning alabaster. Rinse afterwards in clean warm water before drying. Alternatively wash with borax and water, half an ounce of the former to a pint of the latter. Dry with a piece of soft silk. Alabaster may be polished by rubbing with pumice-stone and then with a paste consisting of whitening soap and milk, finally finishing with a dry flannel. Another method is to polish with a cloth dipped in melted white beeswax.

The commonest way of mending broken alabaster ornaments is to use plaster of Paris, but this should only be done where the joints are not easily seen. It can be applied cold. A good formula is equal parts of yellow resin, plaster of Paris, and beeswax, this cement being applied hot.

**ALARM.** Fire, burglar, and call alarms are the three kinds in general use. The two former are described under their respective titles.

*Alarm worked by a simple electric apparatus applied to an ordinary clock.*

Call alarms are chiefly used to rouse one from sleep in the early morning. The alarm clock is dealt with separately in the next article, but any person can set up for himself a simple and effective call alarm. The necessary materials are : a plain clock, an electric bell, a small

electric battery (one or two Leclanché cells will do), and sufficient insulated copper wire.

The diagram shows the arrangement : the bell, A, is near the bed head ; the battery, B, in any convenient place ; the wire lead, C, is fixed to the metal frame of the clock, twisted round any accessible part with bare wire against the metal, and goes to the bell. Another lead, D, goes from the bell to the battery, from which a third, E, goes back to the clock. Here it is fixed near the end to the wooden part of the clock, leaving a short free piece, F.

The tip of this piece is exposed and bent into a small hook. If the bell is to go off at 5 o'clock, say, this bare tip is set so that when the hour-hand of the clock gets to that time it will touch the tip and thus complete the circuit, whereupon the bell will ring and keep on ringing until the hand of the clock is released. *See Burglar Alarm; Fire Alarm*

*Alarm clock. Works of an alarm clock removed from the case to show details of action. See text.*

**ALARM CLOCK.** The movement of an ordinary lever drum alarm clock is illustrated. The motive power consists in a spring connected to the great wheel, *a*, which engages with its 48 cogs an 8-point pinion on the spindle of the centre wheel, which has also 48 teeth. This centre wheel makes a complete revolution once an hour, the minute hand being attached to the spindle, *b*. The centre wheel engages with a 6-point pinion on a 45-toothed train wheel, which in its turn engages with a 6-point pinion on the spindle which holds a second train wheel.

The toothed escapement wheel is driven by the second train wheel acting on a connecting pinion. The escape pallets strike against the teeth of the escapement wheel, and the speed of the lever holding the pallets is regulated by the balance-wheel acting on the pronged end.

The hour hand is attached to a loose sleeve, *c*, which fits on the spindle of the centre wheel; it has a pinion underneath which is fixed to the centre-wheel spindle, and this pinion drives a train wheel, *d*, to which is fixed a pinion engaging the wheel, *e*, on the loose hour sleeve.

The alarm action is driven by a spring attached to the wheel A, which drives through a pinion the escapement wheel B, the teeth of which engage a projection C and vibrate the striking hammer. The screw D turns the alarm hand E to the desired hour on the alarm dial. A slotted sleeve F is attached to the toothed wheel G, which revolves at the same speed as the clock hour hand.

On the stationary spindle of the alarm hand is a projection H parallel with the alarm hand. At the hour at which the alarm is set the slot in the sleeve allows the toothed wheel G to slip forward, propelled by the steel catch spring, J. In moving forward J releases the wire arm K attached to the alarm hammer spindle, and allows the alarm hammer to work until the spring is fully unwound. *See Clock.*

**ALBUMEN.** The chief source of albumen is eggs. It is contained in both white and yolk, but the latter has in addition a proportion of fat Albumen is imported, and also prepared in this country in a dried condition known as desiccated eggs. Only the best qualities are adapted for use in cooking.

Preparations of liquid egg are also imported. This form of albumen is sometimes employed in cake-making and pastry. Another form, obtained from milk, is used as a food for infants. *See Diet; Egg.*

**ALCOHOL AND ALCOHOLISM.** Alcohol for household purposes is generally used in the form of rectified spirit, which contains about 90 per cent. of pure alcohol by volume and 10 per cent. of water. In beverages, the highest proportion of alcohol occurs in liqueurs and spirits, the lowest in beers and light wines. Brandy and whisky contain from 40 to 50 per cent. of alcohol by volume; liqueurs from 40 to 52 percent.; port wine from 20 to 30 per cent.; sherry 16 to 22 per cent.; champagne 9 to 14 per cent.; hock, burgundy and claret 8 to 12 percent.; beers from 2 to 9 per cent.; stout from 2 to 5 per cent.; and cider usually less than 4 per cent.

While it may be said that alcohol is never essential or beneficial to a healthy person, on the other hand there is no evidence that, in strict moderation, it is harmful. The effect of small doses on the stomach is to cause the blood-vessels to dilate, and stimulate the secretion of gastric juice. Hence, in some forms of dyspepsia a moderate amount of alcohol promotes the digestive processes. Nevertheless, it is better to cure dyspeptic conditions by appropriate treatment. Large doses of alcohol, taken habitually, cause chronic gastritis and permanent digestive disorder.

The effect of alcohol on the heart is to cause it to beat more powerfully and more rapidly, but this stimulating effect soon passes off, and the heart is left in a more exhausted state than before. Hence the practice of giving alcohol for fainting or conditions of collapse is not to be recommended. (*See First Aid.*) It has been found that alcohol is of no value in assisting Arctic explorers to resist the extreme cold.

The evil effects of excessive addiction to alcohol

may be manifested as acute alcoholism or ordinary drunkenness, and chronic alcoholism. When a large quantity has been taken, the best simple treatment is to empty the stomach by administering an emetic such as a tablespoonful of mustard in a glass of warm water. A doctor may think it necessary to pass a stomach tube and wash out the stomach.

Many preparations have been advertised as cures for alcoholism, but no drug is known which will abate the craving, except at the cost of producing other habits and symptoms equally serious. Real cure can only be obtained by complete abandonment of alcohol. The practice of surreptitiously adding so-called "cures" to an inebriate's food is useless.

Alcohol is not required in convalescence from illness. Most of the medicated wines contain port or sherry, with meat or malt extract, pepsin, iron, or other food or medicinal substance. Alcohol is best avoided by nursing mothers, and should never be given to children.

*Alcove in a modern dining-room fitted with a built-in settee with cupboards at either end. Easton & Robertson, F.R.I.B.A.*

#### **ALCOVE.**

This is a recess in a room or in a garden wall. An alcove was a common feature of bedrooms in older houses, and the fashion has been renewed by some modern architects. The head of the bed with the bedside-table and a chair may be placed in the alcove, the advantage of this arrangement being that there is shelter for the head of the sleeper from any draught, so that the windows can be kept wide open.

In a dining-room which is also used as a sitting-room, the alcove can accommodate the dining-table; or it may serve in a general living-room as a quiet corner where the children can do their lessons or the elders their writing. A shallow alcove may be fitted with a built-in settee and cupboards as in the illustration given.

**ALE.** The term ale is now confined to lighter coloured beer, the black beers being called porter or stout, according to their specific gravity. One recipe of many for mulled ale is to add to a pint of good ale two or three yolks of eggs, two tablespoonfuls of loaf sugar, a pinch of ginger, and the same of nutmeg. Make the ale hot, but do not let it boil; then

take it from the fire and stir in the eggs, beaten with the sugar and spice. Pour it from one vessel to another five or six times until it froths, and drink hot.

Ale can be brewed at home, but it must not be made without a licence, the penalty for brewing without such a licence being £500. The occupier of a house not exceeding £8 annual value may, under certain conditions, brew without charge, but he must first obtain the necessary licence from the local excise authorities. *See Beer; Ginger Ale, etc.*

**ALEXANDRA SOUP.** Take a cupful of lentils and two heaped tablespoonfuls of barley and soak them together for at least 12 hours. Next day chop up an onion and fry it in half an ounce chop up an onion and fry it in half an ounce of margarine, add the lentils and barley with three breakfastcupfuls of water, and cook until the lentils are tender. Add a couple of fresh tomatoes when the soup is nearly ready. Rub all through a sieve and heat before serving. *See Lentil Soup.*

**ALIMONY.** The term alimony is used in law to denote a sum of money agreed, or ordered, to be paid by a husband to a wife at a time when the marriage is still in existence. Thus alimony is payable either (1) while proceedings are pending for divorce, nullity or judicial separation (alimony 'pendente lite'); or (2) after the making of a decree for judicial separation, whether the petition has been presented by the husband or by the wife (permanent alimony). When a decree has been made in a suit for divorce or nullity, and the marriage relationship is thus ended, any money ordered to be paid by the husband is called, not 'alimony,' but 'maintenance.' Alimony pendente lite will usually amount to such a sum as will make the wife's total income (including any private income she may have) equal to about one fifth of the combined incomes of husband and wife. In permanent alimony the proportion is usually one third. *See Maintenance; Separation Order.*

**ALKALIES.** The group of chemicals known as alkalis have a strong cleaning action and an alkaline reaction. The four chief alkalis are:

(1) Ammonia, which has the advantage of being in both liquid and solid forms, and which as a liquid leaves no residue behind.

(2) Freshly slaked lime, a useful scouring agent and water softener. It is best mixed with twice its bulk of dried carbonate of soda for use as a water softener.

(3) Potashes and pearlashes are obtained by burning wood. They are in the form of coarse, white powder, and are used for scouring saucepans, and cleaning sinks and water-closet pans. For the two last-named purposes, the potashes or pearlashes are dissolved in hot water in the proportion of a tablespoonful to a pint. A stronger form of potash is known as caustic potash. It burns the skin unless it is washed off quickly.

(4) Soda, This is the common name for a

crystallised carbonate of soda, also known as washing soda. It is the most used alkali for softening water employed for cleaning purposes. Caustic soda is a stronger form of soda.

Alkalies should not be used for cleaning aluminium ware, as they have a corroding effect on the metal. *See Ammonia; Lime; Soda.*

**ALL FOURS: An old Card Game.** This card game for two or four players is also called seven up.

**Two-handed All Fours.** Players cut for deal, and the dealer then gives six cards, three at a time, to his opponent and himself, and turns up the thirteenth card for trumps. If the turn-up is a knave, the dealer scores a point. The elder hand then plays a card, or says, "I beg," according to whether he is satisfied with his hand or not. If he says, "I beg," the dealer must either allow him to score a point or deal three more cards to his opponent and himself, turning up the seventh card for fresh trumps. If trumps remain unchanged, three more cards must be dealt each player, and the seventh card turned up until there is a change. Any new knave turned up gives the dealer a point.

The elder hand, when he decides to play, leads any card he chooses, and the dealer may take it with a higher card of the same suit or with a trump, the right to play the latter not being affected by his holding cards of the suit led. But if, having a card of the suit led, he neither trumps nor follows suit, he is penalised for a revoke.

The following are the methods of scoring and the names of the scores. High: the highest trump played, scoring one to the original holder. Low: the lowest trump played, scoring one to the original holder. Jack: knave of trumps, scoring one to the dealer if turned up, or one to the winner of the trick to which it falls. Game: one point scored by the player who finally holds the greatest number among the cards won by him, that number being reckoned as follows: For each ten, 10; for each ace, 4; for each king, 3; for each queen, 2; for each knave, 1.

The order of counting the scoring is High, Low, Jack, Game, except where Jack is the turn-up. The object of the game is to capture the Jack and those cards which count in Game. In the case of equal scores in Game, the elder hand scores a point. If only one trump is out, the player holding it counts it High and Low. If no player has an ace, ten, or court card, the elder hand counts a point for Game.

If a player revokes, he cannot win the game on that hand, nor Jack and Game, his opponent adding two to his score when Jack is out and one if Jack is not out. The player first scoring seven points wins the game, though sometimes nine or eleven points are played for.

**Four-handed All Fours.** The rules are similar to two-handed, but the players cut for partners, and each player plays in rotation, the dealer and elder hand

alone looking at their cards in the first instance, elder hand having the option of begging. The other two players must not look at their cards until the dealer has decided whether he will give one or deal three, fresh cards.

**ALLOWANCE.** This term is used for a payment which is voluntary and is not necessarily given in return for services rendered. It is thus entirely distinct from a salary or wage, which is a legal obligation. The sum of money given by a husband to his wife or by a father to his daughter is known as an allowance, the amount varying in accordance with the income and the expenses of the person who makes it. A tenth of a man's income would be a good allowance for a wife, while in most cases much less is given for her personal use.

It is desirable from every point of view for a wife to have a definite sum as an allowance which should be paid to her weekly or monthly according as the husband receives his salary, and from this she should meet certain defined expenditure. A wife's allowance should be sufficient to provide her with clothes and pocket-money, but she is not expected to pay from it the expenses of her holidays or her doctor's bills. Another form of allowance is the separation allowance (q.v.).

A voluntary allowance is not subject to income tax.

**ALLSPICE.** Sometimes known as Jamaica pepper, this pea-like berry, when dried and crushed, provides a spice which seems to combine the flavours of cinnamon, cloves, and nutmeg.

Its common uses are in making gingerbread and pickles, and in curing hams, and it is one of the component parts of curry powder. It is also used for these purposes and for adding to spiced wine as a tincture, made by letting two tablespoonfuls of powdered allspice soak in a pint of brandy for a fortnight, shaking occasionally to extract the flavour. It should be strained and bottled at the end of that time.

*Almond. Fruit split open, showing stone containing edible kernel.*

**ALMOND.** The *Prunus Amygdalus* of botanists is cultivated almost exclusively for ornament in British gardens, where its delicate pale pink blossoms open

before its leaves in March and even in February. The sweet almond is rather earlier in bloom than the common, and has rosy flowers. The bitter almond, *amara*, has paler flowers. The dwarf, *nana* or *Besseriana*, only grows about a yard high, and has rose-pink flowers. There are also white varieties.

*Spray of almond blossom.*

The almonds may be planted as

standards between November and February inclusive. They are not at all particular as to soil, but they like a drained site, and should be well staked. Little pruning is required, but if the head of a young tree contains straggly branches it may be regulated.

**In Cookery.** The Jordan almond from Malaga is the best variety of sweet almond. As a food almonds are highly nutritious, and bulk largely in a vegetarian dietary. They contain little starch, and for that reason are invaluable in the dieting of persons suffering from diabetes. Crushed almonds yield a flour for the bread and biscuits recommended to diabetic patients. Powdered almonds are used for marzipan and macaroons. Essence of almond is a favourite flavouring for cakes and puddings.

To blanch almonds, soak them in boiling water for five or six minutes until the skin can easily be removed by pressing each nut between the thumb and finger. After peeling, rinse the almonds in cold water, then drain dry or rub them in a clean cloth. *See Bitter Almond.*

**ALMOND CAKE.** The ingredients are 6 oz. margarine or butter, two thin slices of citron peel, 6 oz. castor sugar, 1 teaspoonful baking-powder. 10 oz. best white flour, three large eggs,  $\frac{1}{2}$  gill milk (if required), and 1 teaspoonful almond flavouring. Grease a round cake-tin and line with greased paper. Sieve the flour and baking-powder together. Beat each egg separately into the creamed sugar and butter and beat well for a few minutes. Lightly fold the flour into this mixture, which should be soft enough just to drop from a spoon, but not to run off. Add a little milk if too stiff, and last the flavouring.

Put the mixture into the cake-tin already prepared. Bake in a moderately hot oven for three-quarters to one hour. Decorate the top of the cake with the slices of citron peel when about half cooked. When ready the cake should be placed on a sieve to cool.

**ALMOND CHEESE CAKES.** Take 2 oz. ground almonds, 2 oz. castor sugar,  $\frac{1}{2}$  oz. cornflour,  $\frac{1}{4}$  oz. butter, 1 egg, and some raspberry jam. Add the well-beaten eggs gradually and smoothly to the cornflour, following with the sugar, almonds, and butter (melted). Line some patty-pans with scraps of short paste, and spread a little jam in the bottom of each, then pour in sufficient of the mixture to reach within  $\frac{1}{4}$  in. of the top of the paste. The cakes should be baked for 20 minutes in a moderate oven. They are suitable either for tea or as a dinner sweet.

**ALMOND FINGERS.** These are made with  $\frac{1}{4}$  lb. flour,  $\frac{1}{4}$  lb. ground almonds,  $\frac{1}{4}$  lb. butter, 2 oz. almonds (peeled and chopped), 2 oz. sugar, 1 egg and a little raspberry jam. Rub the butter into the flour (margarine may be used instead of butter), add one teaspoonful of sugar with the yolk of the egg and

mix all to a stiff dough. Roll this into a strip 3 in. wide, place on a greased tin and spread the jam on the strip. Mix together the white of the egg, the ground almonds, and the rest of the sugar, and work to a paste, which should be spread on the top of the jam together with the chopped almonds. Bake for 30 minutes in a moderate oven and cut into fingers.

**ALMOND PASTE.** Use 1 lb. ground almonds (in the proportion of one bitter almond to four sweet), the yolks of two eggs, the white of one,  $\frac{1}{4}$  lb. castor sugar, 1 teaspoonful of orange flower water, and a few drops of essence of almonds. Put the almonds, sugar, and yolks of eggs into a pan and stir them over gentle heat until reduced to a paste; add the orange flower water and the beaten white of egg. This will cover a cake of about 3 lb.

**ALMOND PUDDING.** A good recipe consists of 2 oz. sugar, 2 oz. ground almonds, 2 oz. butter or margarine, 2 tea cups of breadcrumbs, 1 egg, 2 oz. chopped peel, and a gill of milk. Beat butter and sugar to a cream, add the ground almonds, breadcrumbs, and warmed milk, and stir well. Add the peel and the egg well beaten. Pour into a greased pie-dish, and bake for 10 or 15 minutes till firm. Serve with custard sauce flavoured with almond essence. This is ample for four persons.

**ALMOND ROCK.** This needs a teacupful of best golden syrup, 1 teacupful of water, 3 teaspoonfuls of vinegar, 1 lb. Demorara sugar,  $\frac{1}{4}$  lb. butter, and a few drops of almond essence. Boil all together for about 15 minutes. Put a little into cold water, and if crisp it is ready. Add one or two tablespoonfuls of blanched almonds and pour all into a buttered tin.

**ALMOND TOFFEE.** This is made from  $\frac{1}{2}$  lb. almonds,  $1\frac{1}{2}$  lb. loaf sugar,  $\frac{3}{4}$  pint water, a little almond essence, and a small pinch of cream of tartar. After blanching the almonds, halve them and dry in a warm oven. Let the sugar dissolve in the water, put in the cream of tartar, and boil until the syrup becomes a deep amber colour. Do not add the almonds until the stew-pan has been taken off the fire; then boil the mixture up again and pour it on to a buttered tin.

**ALOE.** The true medicinal aloes are evergreen, greenhouse plants, ranging from 1 ft. to 30 ft. in height. They thrive best in large tubs, in a mixture of loam, sand and lime, and are increased by seeds sown in pans of sandy soil, and kept at a temperature of at least 65° F. The American aloe is the agave (q.v.).

**ALPACA.** This fine material with a natural lustre is used principally for black linings, aprons, servants' dresses, and men's office coats. It is woven from the hair or wool of the alpaca, which is a South American animal of the camel family. The natural colours are brown, grey, and black. Alpaca cloth is

liable to be confused with mohair, which it somewhat resembles. Alpaca is washable in any flaked soap and warm water. If dried without wringing, it will be crisp and glossy. *See Mohair.*

**ALPINE PLANTS.** The name is applied indiscriminately to plants which are natives of the Alps, Apennines, and other mountainous districts of Europe, and in Britain figure chiefly in the rock garden. Alpine plants do not need anything special in the way of rock-work or stonework to protect them. They will do perfectly well on gritty ground in our cool climate if they are not overrun by coarser plants. Alpine plants are generally low-growing herbs of perennial habit, and thrive in drained soil in which the roots can be kept cool. A garden devoted to these plants is sometimes called an alpine garden. *See Rock Garden.*

**ALSATIAN, or Shepherd Dog.** Introduced into Great Britain in 1918, this breed has achieved remarkable popularity. During the last year or two much has been made of the fact that a few ferocious Alsatians have been banned in the courts, but the breed, like many others, has its bad-tempered representatives. Most Alsatians are good-tempered and obedient.

*Alsatian Wolfhound.  
Champion of the  
breed originally bred  
by the shepherds of  
Alsace.*

The Alsatian has been produced by the union of two or three strains of shepherd dogs, and though wolf-like in appearance, the cross with the wolf is fairly remote. In colour these dogs may be black, brown, fawn, black and tan, iron grey, cinder grey and sable. White specimens are not favoured. The gait should be a wolf-like lope.

Dogs should stand about twenty-four inches at the shoulder, and bitches a couple of inches less. The ears should be stiffly erect, and broad at the base. Faulty ear carriage (a soft ear or ears) is common. The head ought to be clean in its outline, long and strong in the muzzle, and broad in the skull, with dark almond-shaped eyes. A deep chest, straight big-boned limbs, with well-placed hocks and strong feet are points of importance. The tail should be carried down—never curled over the back. Obedience classes for those dogs are a feature at all the leading shows.

**ALTERNATING CURRENT.** This is an electric current which continually changes its direction round a circuit, as distinct from direct current, which flows always in one direction. Both systems are used in electric lighting. For certain purposes, e.g. the charging of accumulators, alternating current cannot be directly

employed. The alternating current in such a case must be transformed by a rectifier (q.v.).

One complete change or alternation of current is called a period or cycle. The voltage of the mains, together with the periodicity in cycles, is marked on the supply meter; the periodicity is shown thus .

The majority of broadcast receivers can be operated entirely from the mains, provided A.C. valves are employed, and sets which utilise ordinary valves can obtain their high tension supply from this source.

*See Broadcast Receiving Sets; Electricity; Eliminator; Valves.*

**ALUM:** Its Many Uses. The kinds sold are potash and ammonia alum. Both have the same properties and are used for like purposes. Alum is sold as crystals and as a powder: the latter is the usual kind.

Alum is much employed as a mordant in dyeing and as a fire-proofing material. It acts as a water purifier when a small proportion of a solution of alum is added to a large bulk of water. The reason for its action is that a gelatinous precipitate is formed when alum solution is much diluted, and as this precipitate settles to the bottom of the vessel it takes down with it any organic impurities in the water. The amount added is not sufficient to give an unpleasant taste to the water.

As a medicine alum is not often given internally. As a lotion to check excessive sweating of the hands and feet, a tablespoonful of alum should be dissolved in a pint of water. As a gargle, mouth-wash, or spray for swollen tonsils, the strength used is ten grains in one ounce of water, sweetened with honey. Care should be taken to rinse the mouth afterwards, as alum has a very injurious effect on the teeth.

**ALUMINIUM.** Cooking utensils of aluminium become heated through more quickly and uniformly than those made of other metals, and this means economy of fuel and generally better cooking. With its lightness and freedom from corrosion, it can be recommended for the kitchen. It requires less polishing, and does not readily tarnish. Gritty polishes should be avoided because its surface easily shows scratches. A good composition is—stearic acid 1 part, fuller's earth 1 part, rottenstone 6 parts.

Soda darkens aluminium and eats it away. For this reason aluminium cooking utensils should not be cleaned in soda-water or have soda put in them when in use. Aluminium can be turned white again by nitric acid followed by careful washing. The acid attacks the exterior and leaves fresh metal exposed.

Pure aluminium easily bends, and is mostly alloyed with small proportions of other metal, usually zinc or copper. For culinary utensils, and articles which have to be bent and pressed considerably in manufacture, it is almost pure. For most other purposes there is nearly 10 per cent, of other metal. For motor vehicles its lightness has caused it to be extensively used.

**Repairing Aluminium Pots and Pans.** To a

large extent articles made of aluminium have no joints.

They are cast in solid metal or pressed from a single piece of sheet. Handles of saucepans and similar articles are generally riveted on, as seen in Fig. 1. The body of the saucepan is a single piece of aluminium drawn to shape in a die, and the handle is of malleable iron. Rivets sometimes become loose and the handle of the utensil no longer holds tightly. The remedy is to tighten the rivet by hammering one end while the other bears on solid metal. If rivets come out and are lost the best method of mending is to use small bolts.

*Aluminium. Fig.1. Saucepan with iron handle attached by rivets. Fig.2. Stove bolt. Fig.3. Method of attaching handle by stove bolt.*

Fig. 2 shows a stove bolt. This is the most suitable kind and is easier to insert than a rivet. After it is screwed up the projecting end should be nipped off or filed till it is nearly flush with the nut. The end can be hammered as well to prevent any risk of the nut working back. If a rivet hole has become too large a washer can be used between the bolt head and the sheet metal. Sometimes damage to the rivet holes in the pan may be made good by covering them with another piece of metal, as in Fig. 3, the metal of the pan being enclosed between.

A hole lower down in a saucepan is not easy to deal with. The quickest and perhaps most satisfactory way is to use one of the pot-menders which are obtainable at most ironmongers. Aluminium is a difficult metal to solder. Fluxes are considered useless, and the general practice is to tin the surface as quickly as possible after it has been cleaned. Solder specially made for aluminium is employed. The efficiency of the joint depends on the adhesion between the tinning coat and the aluminium. The parts can then be united. As heat is conducted rapidly the metal near the joints should be heated almost to the melting point of the solder. The parts should be kept pressed closely together till the solder is set.

*Alyssum. Flower clusters of this spring rock plant.*

**ALYSSUM.** The various species of Alyssum or Madwort are distinguished by hardness, freedom of bloom, brightness of colour, and ease of cultivation. Of those which are grown as annuals, the white sweet

Alyssum (maritimum) is 10-12 inches high, but a more useful variety is the low-growing white compactum or Little Dorrit, 4 inches high, which blooms throughout the summer. A Lilac Queen, 4 inches high, has blush-coloured flowers. All are sown out of doors in spring.

There are many forms of saxatile ("Gold Dust"), a dwarf perennial with yellow flowers. Compactum is more desirable than the type, being of denser habit: flore pleno has double flowers. Alpestre and montanum have yellow flowers; pyrenaicum and spinosum are white; Wierzbeckii has deep yellow flowers on stems 18 inches high. They all like a limestone or sandy soil and a sunny position. Pron. A-liss'-um.

*Amateur Carpentry. Equipment of an amateur's workshop; a key to the tools and accessories are given below*

**AMATEUR CARPENTRY.** In and around every home there is always work to be done which generally requires but simple equipment. A sash-cord may need replacing, a door has to be eased to clear the heavy pile of a new carpet, a spring blind requires attention, a cornice fitment, gilt mirror or overmantel has to be fixed. An extra shelf is wanted in the pantry, or a drop-leaf table for the scullery. Garden requirements include arches, trellis-work, frames, a seat and chairs, a tool-shed, a greenhouse. These are only a few of the innumerable jobs that may be successfully tackled by the home carpenter with a modestly equipped workshop.

A simple and inexpensive kit of tools may include a jack and a smoothing plane, half-rip handsaw, tenon saw, 4 to 6 firmer chisels from  $\frac{1}{4}$  to 1 in. or  $\frac{1}{8}$  to  $1\frac{1}{4}$  in., ratchet brace and 6 assorted bits, claw hammer, pair of pincers, axe, medium grade India oilstone. A work bench is required, and a suitable size would be 4 ft. 6 in. to 5 ft. long, 2 ft. 6 in. high and 16 in. wide on top.

A workshop of some kind is desirable. Wherever the work has to be carried on, be sure that it is well lighted. Get a corner of the room near the window or the best lighted attic, and, if possible, a window that faces north. Probably, however, the ultimate choice will fall on a shed in the garden, and this can be arranged to give the maximum of efficiency. The following notes are based on this assumption, but those who have to be content with a space in the house should endeavour to

adapt the suggestions as far as possible to their personal needs.

A minimum size for the workshop or shed would be 10 ft. long and 8 ft. wide, with an eaves height of 7 ft. A building with a span roof is preferable to a lean-to, as the roof space is valuable as a storage loft for drying off timber. (For both types *see* Workshop.) A portable building may be purchased in sections from a reputable firm. This would be delivered in sections ready to erect. A wooden floor may be used, or one of concrete may be constructed on the site chosen.

*Key to the illustration above. 1. Glue Pot. 2. Stove. 3. Bracket. 4. Brace. 5. Sawing dog. 6. Mallet. 7. Hand Saw. 8. Auger. 9. Tool Rack. 10. Bevel Square. 11. Marking Gauge. 12. Wing Compasses. 13. Combination Pliers. 14. Pincers. 15 and 16. Gimlets. 17. Bradawl. 18, 20, 21 and 22. Chisels. 19. Firmer Gouge. 23. Keyhole Saw. 24. Mortise Gauge. 25. Awl. 26 and 27. Screwdrivers. 28 and 29. Files. 30. Half-round Rasp. 31. Square. 32. Block Plane. 33. Spokeshave. 34. Bench Stop. 35. Work. 36. Smoothing Plane. 37. 2-ft Rule. 38. Spirit Level. 39. Jack Plane. 40. Vice. 41. Bench. 42 and 43. Hammers. 44. Tenon Saw. 45. Bow Saw. 46. Taps and Dies. 47, 48 and 49. Hand-turning Tools. 51. Head Stock. 50 and 52. Calipers. 53. Vice. 54. Lathe.*

The work-bench must be, above all else, strong and rigid. It can be built into the walls. The carpenter's bench shown in the illustration has the advantage of portability, and can also be purchased ready for use. The vice, made of hard wood, can be used, or an all-metal one obtained which has only to be bolted firmly to the bench. While attaching the vice, fix up a bench stop. This is used to keep a piece of wood in place while it is being planed.

The illustration above shows the equipment and arrangement of the workshop. The tools, representing a fairly complete range, are identified in the key. In addition to the carpentry implements a treadle lathe with hand-turning tools is depicted. *See* Bench; Cabinet Making Tools; Wood; Workshop.

## AMATEUR THEATRICALS: PLAYS AND STAGING

### Some Practical Hints on Play Producing for Amusement.

This article contains useful information for those desirous of giving entertainments of this kind in a simple manner. See also Fancy Dress; Make-Up; Stage

When a theatrical performance has been decided on, the most important step is to secure a good stage-manager or producer. A professional is sometimes engaged to produce the play and has the assistance of an amateur stage-manager. For the less ambitious type of performance the amateur stage-manager combines with his other duties those of producer. Some experience, ability to play every part in the piece, tact, imperturbable temper, readiness to listen to arguments, and lack of obstinacy are qualities required in the producer-stage-manager.

The next point is the choice of a play. Consider the area at disposal; twelve people cannot be expected to move and act naturally in a space which can only accommodate three. Consider the height: the balcony scene in "Romeo and Juliet" cannot be given with only seven feet of headroom.

Consider the inevitable limitations of the scenery. Consider the capabilities of the actors as a combination. A simple piece well acted all round is more satisfactory than one star performance badly supported. Consider, above all, the audience; in ninety-nine cases out of a hundred they prefer to be amused. Finally, it is a mistake to select a piece which many of them have probably recently seen performed by a first-rate professional company.

The casting of the piece naturally follows, and there are advantages in leaving this task to the stage-manager or producer. Do not in any case choose hurriedly, for mistakes cannot afterwards be rectified easily.

**Rehearsals.** The producer must study every part. He should work out movements and positions of every character from rise to fall of curtain. When this is accomplished, a convenient date is fixed for the first rehearsal. At this the producer should read the play through, afterwards giving each performer some idea of the character he is playing, and generally clearing away any difficulties. The second rehearsal should take place on the stage, or on a space of the same size, with the furniture arranged as on the night, and the positions should be gone through, giving time to the actors to mark them in their books.

The next three rehearsals, assuming the play to be in three acts, should be devoted to one act apiece in turn. The sixth, seventh and eighth will be well employed in the same way, but now rigidly enforcing the rule "no books," supplying all the properties required, and insisting on the actors playing as if it were the actual performance; paying special attention to the principal characters, and letting no awkward positions, meaningless grimaces, or any exaggerated gestures, or wrong intonations or emphases pass

uncorrected. Two or three rehearsals of the whole play, not counting the dress rehearsal, should then be sufficient.

The dress rehearsal must be carried out as a complete performance, and the stage-manager will then have to see the stage set and all the stage properties in place; perhaps make-up the actors; get the beginners on the stage; draw the curtains; prompt—although it is wiser to appoint a special prompter; see that each actor is at the proper entrance in time, and has at hand any properties needed; close the curtains at the end of the act; change the furniture, if necessary; start the music, if any be provided; and so on until the curtain falls.

**The Stage.** A platform raised two feet from the floor adds to the enjoyment, but is not absolutely necessary, and unless the room is 14 feet high should not be attempted. The drawbacks against using the floor of the room for the stage may be mitigated by setting the front row of seats as far back as is consistent with the number of spectators; by using low seats for the front rows; and by reducing as far as possible the number of scenes in which the actors themselves are seated.

*These diagrams show how metal angle-brackets, diagonal wooden braces and the ordinary wood-joint are used in stage construction, with a slotted hinged brace for securing screens.*

The proscenium is the partition which divides the audience from the stage, carries the curtain, and forms a frame for the scene. One of those rooms partly divided into two by an archway gives a proscenium ready made. Failing this, a built-up proscenium is not altogether essential, as an entertainment can be contrived by selecting scenes from the works of the older playwrights, all of which were so constructed that the dramatis personae simply walked on at the beginning and off at the end, or by picking out more modern plays which do not commence with the discovery of some of the characters or end with an unavoidable picture. A couple of screens high enough to conceal completely those on the stage, and wide enough to meet in the middle when drawn out from either side, will serve as a combined proscenium, curtains, and wings for those waiting their entrances "off," and

entail a minimum of trouble and expense.

**Building a Portable Stage.** Trestles and barrels can work wonders to improvise a platform; but the small expense of buying good, durable timber to cover them is always worth while. Fig. 2. shows what can be done with an area of only 12 feet by 8, allowing for back passage, side spaces, and a foot strip in front of the front curtain. Such a stage can be put together very quickly by three or four people, and little skill is required.

**Makeshift.** "Making things do" is the task of the amateur, as Mr. Rodney Bennett points out in his excellent little book "Let's Do A Play" (Nelson). These limitations are often advantages, particularly in home theatricals. Parish hall or drawing-room can provide all that the dramatic enthusiast needs. For the drawing-room, choose a drawing-room play, such as St. John Ervine's "The First Mrs. Fraser," for which no properties are wanted at all. The box-room makes an excellent "saloon" setting for a Wild West drama; and

if a crowd is required for a larger production—perhaps a Shakespeare play—the audience themselves can be the crowd. Most homes have screens, curtains, and curtained french windows which ingenuity can quickly adapt to theatrical purposes. Fig. 2, above, shows how effectively a couple of posters, a form, and some luggage can be used, with the all-important screens, to make a railway station waiting-room (suitable for the last act of "The Ghost Train," for example). The simplest "properties" are needed: their value lies in suggestion rather than in realism.

A little simple painting will be useful. If possible, a play which retains the same scene for all its acts, or else a one-act play, should be chosen. The scene-painter leaves out as much as he can, remembering that from a distance only the general effect is noticed. In painting a backcloth, a mixture of whiting and size must be laid on first (the packet gives the proportions). The cloth is marked off in squares according to a scale drawing, and powder colours, mixed in jam jars, are applied with large brushes. Above all, scenery should not distract; if the acting is good, the audience will hardly notice the setting; and anything is better than long

waits between acts, for certain plays an arrangement of dark curtains will suffice, without any scenery.

Lighting is very important, and too complicated to be described in detail here. There are plenty of good little books on the subject. In general, safety must come first: never risk a fire. Lights must never be seen by the audience, or the illusion is spoilt.

**The Actor's Job.** One of the hardest tasks is to "be natural" on the stage. The greatest asset is a childlike imagination, the infinite ability to play "Let's Pretend" which enables a woman to play a man's part, or vice versa.

The first thing for the performer is to learn the author's words and the cues—that is, the ends of speeches which precede his own; the second, to read the play through with care to find out what his character is, how to make up, dress, etc., and so form a concrete image of the personality of the part. Tricks and mannerisms which would be appropriate should be tried; those minor movements which come under the heading of "by-play" or "business" and where and when each is to be employed should be settled, and always when going through the part kept to its appointed place. Each speech in turn must be gone through and the meaning duly emphasised to convey it to the audience.

**AMBER.** Ornaments of amber are supposed to bring good luck, and even to bestow on the wearer the gift of eloquence. The usual form of amber necklace is the yellow opaque variety moulded into beads; but there is also a clear amber both in yellow and reddish brown. Sicilian amber is red with green or blue lights in it. Amber is seldom worn otherwise than as a neck ornament and usually in the form of beads.

To join amber cover the parts with linseed oil, warm carefully over a flame until the oiled surface feels sticky, and then press firmly together until cold. Caustic soda may be used in place of linseed oil. A cement for amber may be made by dissolving sufficient gum copal in ether to form a syrupy fluid. Warm the broken portions, apply the cement and bind the two pieces together until the cement has set.

**AMBER PUDDING.** A light steamed pudding is made with these ingredients: 2 oz. flour, 6 oz. breadcrumbs,  $\frac{1}{4}$  lb. suet (chopped), 2 oz. sugar, 1 teaspoonful baking-powder, 2 tablespoonfuls golden syrup and 2 eggs. Add a little grated lemon rind for flavouring. Mix the suet with the breadcrumbs, flour, sugar and baking-powder. Warm the syrup and add it, then the well-beaten eggs. Milk may be added if too dry. Grate in the lemon rind and stir. Place the mixture in a greased bowl and cover tightly with greased white paper. Steam two hours, the water boiling quickly all the time. The pudding may be served with a sauce, and is sufficient for six persons.

**AMERICAN BLIGHT.** Woolly aphis is another name for American blight, which has the appearance of small tufts of cotton wool on the trees. The insect protects itself with the fluffy white covering; when the latter is removed the pest is revealed as a small plump aphis-like body. It is a common apple pest, sucking the sap and so causing swellings or wounds which become the breeding places of other insect pests and fungus. In its earlier stages the blight can be got rid of by using a brush dipped in methylated spirit or paraffin oil, but in the case of larger cultures vigorous spraying or syringing will be required.

*American Blight. 1. Winged female. 2. Wingless female. 3. Twig of an apple tree attacked by the aphid.*

In winter an effective wash may be made up of soft soap,  $\frac{1}{2}$  lb.; paraffin (or solar distillate) 5 pints; caustic soda (98 p.c. purity), 2 to  $2\frac{1}{2}$  lb.; water,  $9\frac{1}{2}$  gallons. In summer use the following: Dissolve 20 oz. of soft soap in about  $\frac{1}{2}$  gallon of hot water. Make up to 10 gallons, and then add 1 lb. of Woburn Tobacco Extract. This should be applied with the aid of a small atomiser to each tuft of aphid.

**AMMONIA:** Its Household Use. Liquid ammonia is really a solution of ammonia gas in water. The strength usually sold is ten per cent., but a stronger kind is used by chemists. Liquid ammonia is poisonous. It is pungent to the nose and makes the eyes water when sniffed, and may injure permanently the sense of smell.

Ammonia is a strong alkali, and on this account is used as a cleansing agent. Added to the water in which articles are washed, it softens it in place of soda, and in cleaning windows, where soda is inadmissible, a little liquid ammonia added to the washing water is effective. Sponged on woollen cloth the colour is revived and grease spots are removed. It also revives the colour of carpets, and is excellent for cleaning tarnished silver. Ammonia often restores the colour to delicate fabrics like silks, especially where acid fruit stains have been the cause of discoloration. Brushes and combs are thoroughly cleansed from grease by a tablespoonful of ammonia being added to the warm water in which they are to be washed.

Cloudy ammonia is made by mixing common yellow soap, 8 grains; lavender water, 20 drops; solution of ammonia, 1 pint. Cloudy ammonia is added to the bath as a refreshing and detergent agent.

Ammonia has stimulating properties which make it a valuable medicinal agent. Spirit of sal volatile, the form in which it is administered, contains both liquid ammonia and ammonia carbonate, with flavouring agents (lemon and nutmeg). It is a domestic remedy for nervous headache and faintness. The dose is a teaspoonful in a wineglassful of water. It must not be taken alone, as it causes a burning sensation in the throat.

Mindererus spirit is a solution of ammonia acetate. It is one of the oldest remedies for feverish conditions and promotes sweating. The dose is from one to two teaspoonfuls.

**Poisoning.** Strong solution of ammonia is sometimes taken in mistake for spirit of sal volatile, with serious effects. Ammonia is a corrosive poison, injuring the surface of the mouth, throat and stomach, in addition to which the vapour inhaled causes inflammation of the lungs. The treatment, which can be commenced while the doctor is being fetched, is to administer weak acids to neutralise the alkaline ammonia.

These are vinegar diluted with water, lemon juice and water, and tartaric acid or citric acid dissolved in water, in the proportion of a teaspoonful of the acid to a breakfastcupful of water. Then the patient should be given demulcent drinks such as milk, olive oil, white of egg.

**AMMONIATED QUININE.** Name of a popular remedy for influenza and cold in the head. The dose is half to one teaspoonful of the tincture in a wineglassful of water or milk. When mixed with water an opaque white liquid is produced, but if aerated water is used no whiteness results. A solid form of ammoniated quinine is made as capsules.

**AMPERE.** In electricity the name given to the unit of current or rate of flow of electricity. An ampère-hour is a current of one ampère flowing for one hour. See Accumulator; Battery.

**ANAEMIA.** This is the name given to a diminution of the whole blood or of some of its main constituents. In two forms, chlorosis and pernicious anaemia, the cause is obscure, and these are known as primary anaemias. When, however, a definite cause is ascertainable, we speak of a secondary anaemia.

**Chlorosis.** This form of primary anaemia is most frequently found in young women or in girls just approaching adult life. It is due to some abnormality in the formation of the blood, the chief deficiency being in the haemoglobin, or colouring matter in the red blood-

cells.

Not infrequently the sufferer is plump, or even fat. In typical cases the face has a yellowy-greenish tinge, which gives the disease its common name of green sickness. The disease, which is now comparatively uncommon, is one requiring medical attention.

**Pernicious Anaemia.** Whereas chlorosis is practically confined to girls and young women, pernicious anaemia is more frequent in men, and is commonest at about middle age. It is a very severe blood disease in which there is an active degeneration of the blood-cells themselves. Its predisposing cause is absorption of poison from a septic mouth or the stomach and intestines. It is considered that there is another poison of obscure nature and origin which breaks down the red blood-cells. In a serious disease like this, the patient must be under medical care as soon as possible.

**Secondary Anaemias.** A quite mild type of anaemia, or "poorness of blood," is one of the commonest conditions to be met with among sedentary workers, particularly women and girls. The chief outward sign is an unnatural pallor. The lips, instead of being bright scarlet, are dull.

Before any cure of the anaemia can be expected, the cause must first be sought out and removed. If this is possible the anaemia will pass off by itself under the influences of plenty of fresh air and rest, an iron tonic, suitable food and general attention to the laws of health. If necessary, the mouth should be cleaned up.

**Anaemia in Children.** This is a much more common complaint than most mothers realize. Lack of fresh air and sunshine, too little outdoor exercise, and rapid growth in the child are among common causes. The diet on which literally millions of children are brought up in this country—bread and butter, cakes, sweet foods, potatoes, and other starchy vegetables, with tea several times a day—is in itself enough to induce anaemia of more or less severity. Bad teeth and the resulting constant pouring out into the mouth of "matter" or pus (which is swallowed and so tends to interfere with the digestion) are other not uncommon causes of anaemia in childhood.

While an iron tonic is an important part of any treatment, it is equally essential to find out and remove the cause of the deficiency in the blood. Sometimes a tendency to rickets or chronic constipation may be the source of the anaemia. In many slight cases more play outdoors, less study or other brain activity indoors, more sleep, and simpler and more nourishing dietary, with some chemical food, may effect a cure. *See Baby; Child; Diet.*

**ANAGLYPTA.** A form of wall and ceiling decoration which is termed anaglypta consists of a good quality pulp board pressed during the process of manufacture to form raised or embossed patterns. It is obtainable from the same sources as wallpaper. It is

applied to the wall and fixed by a good adhesive paste, or flour paste with a mixture of glue. After fixing, it needs finishing with distemper in the case of a ceiling or cornice, or with paint or enamel if used as a dado (q.v.).

*Anaglypta.  
Festoon used  
as a frieze  
decoration in  
Adam style.*

**ANCHOVY.** The anchovy is a small fish of the herring species, chiefly used in a preserved form to make savouries and sauces. The foundation of these sauces is anchovy essence, which is made in this way: Take 1 lb. of preserved anchovies, 1 pint of cold water,  $\frac{1}{4}$  pint of good vinegar, 1 saltspoonful of mace, and 1 saltspoonful of cayenne.

The anchovies must be reduced to a paste by pounding them in a bowl with a wooden spoon, and afterwards passing through a sieve. The parts which will not go through the sieve are then simmered with the mace, cayenne, and water. Simmer half an hour, strain, then mix with the pounded anchovy already in the bowl. Place the mixture back in the simmering pan, bring to the boiling point, add the vinegar and gently simmer for ten minutes more. When quite cold bottle for use. Anchovy sauce is made by adding one teaspoonful of anchovy essence to an ordinary white sauce or to  $\frac{1}{2}$  pint of melted butter. *See White Sauce.*

**ANCHOVY BUTTER.** Having soaked the preserved anchovies in warm water, dry and remove skin and bones. To six add 4 oz. butter and pound in a mortar. Rub through sieve and then pat the anchovy butter into shape. This is a savoury for sandwiches or toast.

**ANCHOVY EGGS.** To make this cold savoury take as many hard-boiled eggs as are required, usually one for each person. Having shelled them, split them lengthways, and take out the pieces of yolk, which should be pounded in a basin with a small piece of butter, a tablespoonful of anchovy paste, some pepper, salt and a sprinkling of cayenne. Fill the eggs with the stuffing, and serve them garnished with parsley, cress, etc. The eggs may be made to resemble baskets by forming handles of parsley stalks.

**ANCHOVY TOAST.** Wash and bone six anchovies and chop them roughly. Heat one ounce of butter in a small enamelled pan, and fry in it a small onion, chopped finely. When the onion is lightly browned, add the anchovies, half a teaspoonful of chopped parsley, and the yolk of an egg. Season with cayenne. Stir this mixture till it thickens, then pour it on buttered toast and serve it very hot.

**ANCHUSA.** This is the name of a sturdy family of biennial plants somewhat resembling forget-me-nots, to which order they belong, but attaining a height of over 2 ft. They flower throughout the summer in sunny borders and need no special cultivation. Anchusas are raised from seed sown under glass in spring, and the seedlings are planted out in the usual way; or by root cuttings after flowering. Pron. An-kew'-za.

**ANCIENT LIGHTS.** Any person who has a window 20 years old and upwards acquires the right that no one shall block out the light from it in such a way as seriously to diminish the amount of light that penetrates into the room. This means for practical purposes: to enlarge the window does not enlarge the right of light.

If anyone is starting to build so as apparently to interfere with an ancient light, the owner should write at once and say in effect: "You have started building, and seem as though you were going to block up my window. I give you notice this is an ancient light, and await your assurance that you will not interfere with it." Failing such an assurance, a solicitor should be instructed to apply for an injunction. It must not be imagined that an ancient light gives the right to a continued uninterrupted view. The only right is to a fair quantity of light.

*Ancona Fowl.  
Cock of good laying  
breed of poultry.*

**ANCONA.** This fowl, of Italian origin, was introduced into England in the early fifties. It is of active habit, and better suited to an unlimited range than to confinement. A prolific layer of large white eggs, as a table bird it has few qualifications. There is a sub-variety, with a rose-comb instead of a single comb. See Egg; Fowl; Poultry.

**ANDALUSIAN.** This is one of the best egg-producing fowls. A native of Andalusia, in Spain, it compares favourably with other Mediterranean types, producing a large white egg. It is also a good table fowl, its flesh being of delicate flavour. Although thriving in confinement, it is better adapted to a wide range. See Egg; Fowl; Poultry.

*Andalusian Fowl. Cock of good laying breed of poultry.*

**ANDIRONS.** More generally known as fire-dogs, andirons were formerly used in open hearths for burning wood, each consisting of a stout horizontal bar of iron raised on iron supports a few inches from the ground. The front support was extended in an upright form and finished with a knob, shield, or other architectural device. The andirons were placed one each side the hearth, and the logs laid across the bars.

*Andirons. Modern adaption of the old fire-dogs, now used to support fire-irons. Waring & Gillow, Ltd.*

The modern adaptation of the andiron is to be seen in the fire-dogs, which are now used to support the fire irons. See Fire Irons.

**ANDROMEDA.** The most popular species of Andromeda is known to botanists as *Pieris floribunda*. It is an American evergreen, with leathery leaves and dense racemes of white flowers, appearing in April. The height is commonly 3 to 4 feet. Another beautiful species is *Japonica*, with tufts of creamy bells in abundance. There is a variety called *variegata*.

(or elegantissima).

*Andromeda Japonica.* Creamy flowers of the evergreen shrub.

The only true distinct species of *Andromeda* is *polifolia*, a shrub growing about 1 foot high with pink drooping flowers in late spring, and evergreen leaves, a native of our peat bogs. It requires a moist site and a peaty compost. Propagation is by seeds sown under glass when ripe, also by layers in autumn. The layers root very slowly. *Andromedas* thrive best in a position where they are not exposed to hot sun.  
Pron. An-drommy-da.

**ANDROSACE.** Some of the gems of the rock garden are found in the genus of Alpines known as *Androsace* or rock jasmine. They are distinguished for the most part by dense habit, great profusion of bloom, and beautiful colours. Among the best varieties are the pink *sarmentosa*, *Chumbyi* with rose flowers, pink-flowered *carnea*, *lanuginosa*, and the scented blush pink *villosa*. They need well-drained gritty soil.  
Pron. An-dros -er-si.

*Anemone: three varieties. 1. Double-flowered Alpine Blanda. 2. Windflower, or wild wood anemone. 3. Violet Pasque flower or Pulsatilla.*

**ANEMONE.** There are numerous species of the anemone or windflower. Two of these are British: *Pulsatilla* or the violet Pasque flower, and *Nemorosa*, which is the wood anemone. *Coronaria*, with its poppy-like flowers, white, purple, or scarlet, is an old garden favourite from six to nine inches high; there are also double-flowered sorts. The *Alpine blanda* flowers from Jan. to April. The *Snowdrop anemone* or *sylvestris* is

about 18 inches high and blooms in May. *Fulgens* and *hortonsis* have scarlet or purple flowers.

The flower gardener should procure a selected strain of mixed varieties. This will give him a beautiful range of colours and forms, including both singles and doubles. The seed is best sown in pans or boxes in a frame in spring. If spring bloom is wanted, tubers ought to be planted in autumn; a succession can be obtained by planting more tubers in spring. Japanese anemones may be planted any time between autumn and spring, and they thrive in most garden soils on a shady or sunny border.

The Japanese anemone is among the most beautiful of late flowering hardy perennials, the white varieties in particular. *Apennina* is sky-blue, with tuberous roots. The *Hepatica* type, both single and double forms, is blue. Pron. A nem'-o-ni.

**Aneroid.** See *Barometer*.

**ANGELICA.** Made from the stalks of the angelica plant, candied angelica is a beautiful shade of green, and is much used as a decoration for cakes, puddings, trifles, etc. Being pliable it can also be used to give the effect of a handle to a sponge-cake basket filled with whipped cream and preserved cherries. See *Crystallised Fruit*.

**ANGELS-ON-HORSEBACK.** For this savoury dish take a thin slice of bacon for each oyster used, and an equal number of rounds of toast or fried bread. Season each slice of bacon by dipping it in a mixture of chopped onion, and cayenne pepper. Lay an oyster on each slice, sprinkling a little lemon juice over it. Wrap the bacon tightly round the oyster, fixing it with a small skewer made of the wooden part of a large match. Fry till the bacon is quite crisp, then serve on the rounds of toast.

*Angels-on-Horseback.* Savoury dish composed of oysters and bacon.

**ANGLE-IRON.** An iron bar bent to form a right angle longitudinally is called angle-iron, and the shape greatly increases the strength and rigidity of the bar. Angle-iron may be had from bar-iron dealers or retail from a blacksmith in sizes 1 in., 1¼ in., 1½ in., 2 in., and 3 in., and is sold by weight.

Angle-Iron in section and perspective.

**ANGLE TEMPLATE.** An angle template is used for marking and testing angles on metal, and other materials. The most commonly used are 45°, 30° and 60°, but when necessary templates are made for any other angle. For use in picture-framing a 45° template is useful, but others are necessary when setting out the angles for hexagonal shapes and other types of frames.

Angle templates are commonly used in building for roof work and other purposes, and in such cases they are made to a large size and framed up with strip material. *See* Roof.

**ANGORA RABBIT.** One of the most attractive of rabbits, the Angora is conspicuous by its long coat of fine silky wool, either white, grey, fawn, blue, or black in colour. The does are good mothers and being very tractable, are among the most popular rabbits kept as domestic pets. When full grown and in good condition the Angora weighs about 7 lb. *See* Rabbit.

#### **ANILINE DYES: For Domestic Use.**

Various dye soaps are made with which the dyeing process is accomplished in one operation. A base of equal parts of powdered soap and bisulphate of soda is employed, and to this is added the aniline dye required. Generally the proper shade is obtained by combining two or more dyes. In another variety the soap is mixed with boric acid instead of bisulphate of soda, and aniline dye added in the proportion of 1 lb. to each cwt. of soap base.

Aniline dye stains are often difficult to remove. Aniline typewriting ink is removed by applying tartaric acid or lemon juice.

**ANILINE INK.** The great variety of aniline colours makes these suitable for the manufacture of coloured inks. A simple solution of the dye in water is generally required, and although some recipes order the addition of gum-arabic, this is not generally necessary. For red ink, the best colours to use are eosine, erythrosine, phloxine and ponceau scarlet. For blue ink, soluble blue or indigo carmine. For violet ink, acid violet; and for green ink, malachite green. The proportion of each dye required is one dram to six or eight ounces of water. The ink used for copying-graphs consists of methyl violet 1 oz., dissolved in alcohol 1 oz., water 9 oz. Typewriter ribbons are coloured with an ink of similar composition.

These inks may be used for home dyeing. Red ink sufficiently diluted tints silk under-clothing a delicate pink. It is as well to wear rubber gloves when using inks for dyeing, or to remove the articles from the dyeing water with two sticks and rinse well before touching.

**ANIMALS: The Legal Aspect.** Sometimes a neighbour objects to noises made by animals such as cocks and dogs. Anyone is at liberty to keep on his own

premises any animal he chooses so long as it is not a nuisance to his neighbour. A nuisance is something which interferes with the neighbour's reasonable enjoyment of his own property.

What is reasonable depends on time and place in a great measure. A man living in the country must expect his neighbour to keep fowls, but a man in the centre of London is entitled to object if his sleep is disturbed by the crowing of cocks in his neighbour's garden. An action for an injunction is the legal remedy for such nuisances. One must not keep animals on one's premises so as to be injurious to health.

Anyone who keeps a dog which he knows to be accustomed to bite human beings is liable if his pet bites anybody. As to a dog worrying sheep or baiting cattle, horses, or pigs, the dog owner is liable whether he knew or did not know that the beast was ferocious.

Cruelty to animals in captivity or domestic animals is an offence. It is cruelty to cause or permit unnecessary suffering, or cruelty to beat, abuse, infuriate or terrify the animal. In the case of a wild animal, imprisonment for three months, with or without hard labour, or a fine of £5 or less; and of a tame animal, three months or a fine up to £25 is the penalty. *See* Cat; Dog; Rabbit. etc.

**ANISEED.** As a cough remedy aniseed is much used on account of its soothing effect, generally in the form of a balsam, which is made as follows:

Liquorice juice	1 ounce
Ipecacianha wine	½ „
Oxymel od squills	4 ounces
Oil of aniseed	20 drops
Treacle	1 pound
Gum-arabic	1 ounce

First boil the liquorice juice and gum-arabic (both broken up into small pieces) in half a pint of water, then add the treacle. Allow it to cool, and add the other ingredients, adding sufficient water to make two pints. The dose is one or two teaspoonfuls three times a day.

Aniseed syrup, given to children for wind, is made by adding one drop of oil of aniseed to two ounces of syrup. The dose is a teaspoonful.

Aniseed cordial, used by adults as a stomach cordial, is made on similar lines, but is stronger in aniseed, and contains a fair proportion of alcohol. It is taken neat or mixed with hot water.

**ANKLE.** The ankle is a hinge joint, the two main ligaments binding the bones together being the internal and external lateral ligaments. These are torn in injuries to the ankle, which stretch them, and especially in those which displace the bones to any extent.

For treatment, a sprain requires the application of cold cloths and elevation of the joint on a pillow. In fracture or dislocation the foot is placed as far as possible in correct position by pulling it downwards,

and well-padded splints are fixed on the outer and inner sides of the leg, reaching from above the knee to below the ankle. The two legs are then tied together and placed on a pillow. A bed-cradle may be used to take the weight of the bedclothes off the toes of the injured limb. This will suffice till the doctor arrives.

*The proper reduction of a fracture-dislocation of the ankle requires special manipulative skill and in first aid only gentle handling is permissible.*

In sprains, as soon as the acute symptoms have moderated, perhaps after three or four days, the parts should be massaged, and as the swelling subsides gentle movements are performed. In cases of slighter sprains, after two days the patient may be able to get about a little. This after-treatment is very necessary, otherwise a troublesome stiffness of the joints may persist.

**Care of the Ankles.** Choice of footwear is important to ankle slimness. Heels of more than 1 to 1½ in. in height should not be worn for walking. High heels, by forcing the foot into an unnatural position, strain and cramp the flexibility of the ankle joint. Weak ankles are subject to swelling, and to remedy this condition remove shoes and stockings on returning home, apply a cold compress to the joint and then, lying down, raise the foot on a cushion. Afterwards lightly massage the ankle and apply methylated spirit. Heels of shoes should be repaired at the first sign of crookedness. Boots should not be worn habitually, except by medical advice, as they provide too much artificial support.

Anaemia may be responsible for swelled ankles; or, in children, they may accompany a tendency to flat feet, and are a sign of general debility. Sunshine, fresh air and a bone-and muscle-building diet are of importance. Paddling in the sea during the summer holidays is beneficial, as salt water has tonic properties.

Skiping and dancing barefooted or in flat-heeled shoes strengthen the ankles, and the following simple exercise imparts flexibility:

Stand with feet close together, toes as well as heels touching, knees braced back and the balance on the balls of the feet. Raise the body on to the toes and hold the position for a moment, then lower the heels. Repeat short series of the exercise several times during the day when convenient to discard heeled shoes. *See Beauty Culture; Dislocation; First Aid; Flat Foot; Foot; Fracture; Sprain.*

**Annealing.** *See Tempering.*

**ANNUALS:** In the Flower Bed. Including what are known as half-hardy annuals which require more care and attention, the range of annuals is a wide one, with a great variety of beautiful colours. Few plants provide a more charming pink groundwork for a bed of white tulips than campion or soapwort. Virginian stock with its slim stems and abundance of mauy pink and white flowers is just as useful, and

blooms in spring if sown in August or September; so also do Californian poppies. Some special favourites are cultivated in the same way, although they are not true annuals, as, for example pansies, lobelias, petunias, verbenas, Indian pinks and the antirrhinum or snap-dragon.

While chrysanthemums and other half-hardy annuals are raised in seed-boxes, it is rare for the hardy kinds to be sown under glass and transplanted. Mignonette and Everlasting flowers do not transplant well. A dozen seeds of each may be sown in 5-in. pots, and the resulting seedlings thinned down to three and five respectively. In many cases gardeners grow most of their annuals in groups, perhaps along the front of mixed borders.

Ageratum, alyssum, campion, violet cress, soapwort, and Virginian stock should be from 2-3 in. apart. For lupins, double poppies, sunflowers, and tobacco plants the distance is from 18 to 24 in. The following are set at 4 to 5 in. apart: Arctotis, Californian bluebell, candytuft, convolvulus minor, cornflower, gilia. Indian pink, limnanches, lobelia. mignonette, phlox (annual), sweet pea, horned poppy, and Venus's looking-glass.

A distance of 9 to 12 in. apart is required for the following: China aster, chrysanthemum (annual), clarkia, coreopsis, godetia, larkspur. love-in-a-mist, love-lies-bleeding, marigold, dwarf nasturtium, evening primrose, petunia, poppy, Prince's feather, salpiglossis, scabious, sweet sultan, verbena, and the zinnia. A remarkable annual recently introduced is the orange-coloured venidium fastuosum; seed is sown under glass in March. *See Border: Flower Garden.*

**ANNUITY.** An annuity in the ordinary sense is a yearly income paid to a person for his or her life. It can be purchased, by those who wish to provide for their old age or for the old age of those dependent upon them, from any insurance office or from the State through the Post Office; the price varies according to the age and sex of the person for whose benefit it is bought. The older the person the cheaper the annuity. Annuities for women cost more than those for men of similar ages.

In addition to annuities of this kind, which are the usual type, there are perpetual annuities, i.e. a charge upon an estate which is paid to a person and his heirs forever. Terminable annuities are annuities issued by the Government in order to pay off the National Debt.

An annuity can be bought by a single payment or on the instalment plan. The table in the next column shows the amounts payable to secure a Post Office annuity of £50.

From the figures the amount necessary to secure an annuity of £100 or any other income can easily be ascertained. The State pays on death a sum which is equal to one fourth part of the annuity.

The amount charged for an annuity by the insurance offices varies. For instance, a man of 60 can purchase with £100 an annuity of £7 19s. from one

office, while another will give him as much as £8 8s a year. The variations are due partly to the class of business done by the various offices and partly to some slight differences in benefits. For instance, some insurance offices pay the whole or part of the stamp duty, which is charged on annuities. Those wishing to purchase an annuity should remember that the main object is to obtain a secure income, and therefore only deal with the State or with an office whose reputation is sound. *See Insurance.*

**ANT: How to Destroy the Pest.** These little insects often prove very troublesome in the garden by their attacks on ripe fruit. They will swarm upon ripe strawberries, and an apple or plum whose skin has been pierced by a bird's beak and an apple or plum whose skin has been pierced will be hollowed out by them. If the direction of the stream of ants is followed, they can be tracked to their nest, and this should be forked up and dusted liberally with air-slaked lime. As many of the inmates will be in the chrysalis stage and protected by tough cocoons—the so-called "ants'-eggs"—the operation must be repeated several times at two-day intervals. Kerosene oil, diluted with six or seven times its bulk of water, and carbolic acid, in water ten times its bulk, are equally effective.

Where ants have invaded the house the problem is more difficult. The principal offender is a minute reddish-yellow species, a twelfth of an inch in length, which finds its way, through cracks in the floor or skirting, to the pantry, and takes toll of meat, pastry, jam, and dripping. Here the use of any strong-smelling deterrent like carbolic or paraffin is liable to make the food uneatable. So far as possible all crevices should be sealed with putty or cement, and a watch kept for the new entry these insects are certain to attempt.

It is, of course, very dangerous to lay poison

anywhere in the neighbourhood of food. A simple syrup sufficiently viscid to clog the ants' limbs will serve as a trap, from which the insects can be plunged into boiling water. The syrup may also be made to kill by adding a few drops of formalin.

Ant bites are treated by the application of ammonia (q.v.), sal volatile, solution of permanganate of potash, or a strong solution of common salt. *See Insect.*

**ANTHRACITE STOVE.** The modern anthracite stove, designed to burn on the closed or open fire principle, provides more heat than any other solid fuel, and maintains a continuous fire day and night at a surprisingly economic cost. It obviates the drudgery of daily re-laying and lighting, and the total absence of smoke and soot makes for health and comfort.

*Fig. 2 Anthracite cooking range. The two ovens are kept at different temperatures.*

Fig. 2 shows an anthracite cooking range having two ovens with different temperatures, controlled thermostatically. The heat from the burning anthracite is conveyed to the ovens and the top-plate, which are carefully insulated to prevent waste of heat. The fuel costs about 4d. for 24 hours. Some of the ranges are provided with pressure boilers for the domestic hot water supply.

An anthracite stove for use in sitting rooms is shown in Fig. 3. This is the closed type, with a small filling door above the fire door, into which the end of a tapered coal hod may be inserted, so that the fire door need not be opened. It requires to be filled only once every twelve hours. The ash is shaken down and need not be removed oftener than twice a week. As the

heat is made to pass through tubes before it enters the chimney, the wastage is practically nil. These stoves will burn coke nuts satisfactorily. In another kind, in which there is an open fire, very small anthracite ("peas") is the fuel.

*Anthracite Stove. Fig. 3. Closed type, for the hall or sitting-room. (Smith & Wellstood, Ltd.)*

*Anthracite Stove. Fig. 1. Open fire model, with doors for night burning. Suitable for rooms 14 to 18 feet square. (London Warming Co.)*

Fig. 1 shows another kind of anthracite stove, which always gives a bright fire, whether open or closed. There is no danger of fumes escaping into the

room and, by means of a damper at the top of the stove, the fire can be perfectly controlled.

**Sizes of Anthracite.** Various stoves need various grades. For most purposes, Boiler Nuts are cheapest: they are about as big as walnuts ( $\frac{3}{4}$  in. to  $1\frac{1}{4}$  in.). In small heating stoves, grain-size is preferred. Anthracite at 75/- per ton burning 24 hours costs less than 5d. a day, as compared with ordinary coal at 52/- burning only 15 hours and costing over 8d. a day. Use only pure anthracite: bituminous substitutes burn noisily.

**ANTIDOTE.** Substance which neutralises or counteracts the effects of poisons. A list of the appropriate antidotes is given under the heading Poison.

**ANTI - FREEZER.** To prevent water freezing in radiators of motor-cars, household radiators, and in the generators of acetylene gas, certain substances are added, and from their action in lowering the freezing-point, these are known as anti-freezers. The substances employed are glycerine and liquid glucose, the proportion required of either being 32 oz. to each gallon of water. *See Radiator.*

**ANTIMONY.** Apart from its value in the making of type metal, one of the chief uses of antimony is in the preparation of the Britannia metal and pewter (q.v.) employed for making teapots, coffee-pots, spoons, and other domestic articles. It is also used for trinket boxes, dressing-table trays, and ornaments. It does not tarnish and can be kept clean by simply washing with soap and water. *See Poisoning.*

#### ANTIQUE FURNITURE IN THE HOME

Notes for the Amateur on Its Collection and Care  
Details of Styles and Pieces are given under Chair;  
Chippendale; Hepplewhite, etc.

English furniture is divided into the four periods of oak, walnut, mahogany, and satinwood, many examples of which can be seen in the Victoria and Albert Museum, South Kensington. In the reign of Elizabeth, ornamental carving was employed for four-post bedsteads and tables. A reaction set in, mainly under the influence of Inigo Jones, when upholstered furniture came into fashion.

Hampton Court Palace has good examples of the furniture of the later Stuart period. This was the time of the gate-legged table, also of the "drawing" table, one with a contrivance by which the two ends were drawn out for the purposes of expansion. Chairs had carved backs and seats with panels of canework which were often covered with loose cushions of velvet; bedsteads had rich hangings of silk and velvet, and a good deal of luxurious furniture, carved, gilt and upholstered, was imported from Venice and the

Netherlands while lacquer from the East came into fashion.

With the accession of William III, walnut began to replace oak. Dutch furniture was brought over to England, and lacquered cabinets from China and Japan. Marqueterie, which may be defined as an inlay of coloured woods, came into vogue as a decorative treatment for surfaces of furniture, such as doors of cabinets, the drawer fronts of chests of drawers, clock cases, and the tops, sides, and fronts of the smaller pieces. The curved or cabriole leg was introduced from Holland for chairs and tables; ebony and silver, with ivory and mother of pearl, were also used in inlay. Chairs and window seats were covered with beautiful needlework.

### Queen Anne and Chippendale Styles

Grandfather clocks, their cases inlaid with marqueterie flowers and birds, and also with a more delicate pattern of stained holly-tree wood, termed "seaweed marqueterie," on a groundwork of walnut, are of Queen Anne's time. Card tables with cabriole legs, sometimes carved with a nulled edge and a shell ornament on the knees of the legs, belong to this time, as do handsome cabinets, presses, and chests of drawers decorated with marqueterie or with different veneers of walnut arranged in geometrical designs. A peculiar and very beautiful feature of some of the Queen Anne walnut furniture is the veneer known as "oyster shell," which has a natural marking of the wood resembling the shell of the oyster; it was obtained from boughs of old and matured trees.

The name which stands out most prominently as a maker of mahogany furniture from the middle of the 18th century is that of Thomas Chippendale, but the first designer to use mahogany was William Kent, whose best work was done between about 1735 and 1740. Thomas Chippendale was established as a chairmaker in St. Martin's Lane about 1754. His rococo style lasted until nearly the time of his death in 1779. Chippendale should be taken more or less as a generic term, for it is impossible that a hundredth part of the old furniture of this time and style could have been produced in his workshop. Gillow made a good deal of the so-called Chippendale furniture, and his book of designs, which were available to every contemporary cabinet maker, furnished the patterns adopted by many craftsmen whose names are now forgotten. Hepplewhite's designs come a little later than those of Chippendale and are more severe, generally in good taste, and his work is invariably well constructed. The decoration of chairs and settees by beautifully executed japanning was also a particular speciality of Hepplewhite's.

### Sheraton and the Adam Brothers.

The name of Sheraton looms large in the history of furniture, but his work more properly belongs to the age of satinwood. The influence of Robert and James Adam, particularly the former, towards the end of the 18th century must be borne in mind, as the Adam style was a distinct reaction from the rococo ornament of

Chippendale to the more classical lines of design.

Satinwood came into use towards the end of the 18th century, being generally used as a veneer. The lines of satinwood furniture did not differ from those followed by mahogany, but this dainty wood suited smaller articles.

The following table of dates, corresponding with the various periods of British furniture making, will serve as an aid to the identification of the different styles:

Elizabeth, 1558-1603	"Elizabethan (Tudor)"
James I, 1603-1625	"Jacobean"
Charles I, 1625-1649	"Jacobean"
Commonwealth, 1649-1660	"Jacobean"
Charles II, 1660-1685	"Jacobean"
James II, 1685-1688	"Jacobean"
William and Mary, 1689-1702	"Queen Anne"
Anne, 1702-1714	"Queen Anne"
George I, 1714-1727	"Queen Anne"
George II, 1727-1760	Chippendale's work, about 1754
George III, 1760-1820	Hepplewhite's work, about 1780. Adam Bros' work, about 1780. Sheraton's work, about 1791.

There are at least two courses open to one who has decided to collect old decorative woodwork for pleasure or profit. The first is to employ an expert whose daily experiences render him difficult to trap. The other and more fascinating course is that of collecting personally. It is, however, better, until experience in the little ways of the sale room has been gained, to enlist a dealer of repute and pay him 5 p.c. for purchasing. It is a good plan to examine thoroughly old pieces on sale in the auction marts—to watch their sales before attempting to buy personally.

Obviously there are several degrees of faking or imitating. The piece in its entirety may be an absolutely modern copy of an old specimen; it may be a copy made so many years ago that it has acquired a certain amount of patina and wear and tear; or it may be, in part, genuinely of the period.

The steady appreciation in value of old decorative furniture offers irresistible temptations to the maker of pseudo antique woodwork. It is an important weapon in his armoury to increase the value of plain but genuine old pieces by ornamenting their surfaces with the detail of the period. Formerly the process revealed itself by incongruity or over-elaboration of detail, but the carver of today often produces work instinct with the spirit of the past. Jacobean, Queen Anne and Chippendale furniture all lend themselves to carving. Genuinely old pieces have their carving skilfully restored by lowering the ground.

The modern cheap copyist of Chippendale usually stints himself in the thickness of his wood, and is therefore unable to obtain the relief and depth of the original in his carving. No such complaint of undue reticence in his use of fret-cut veneers glued

together can, however, be made. He regards these as the hallmark of Chippendale, and applies them to plain friezes, chair legs, and other vacant spaces (leaving their edges unfinished) with a prodigality undreamed of by the master whose fret-cut work was finished by the carver.

#### Detecting the Copyist

Inlaying and veneering are necessarily confined to "Queen Anne" pieces or to the periods identified with the brothers Adam, Hepplewhite and Sheraton. However skilful the modern inlayer and polisher may be, the soft mellow tone effected by time cannot be attained, whilst the veneer used is seldom so rich yet subdued in tone—or so fine in figure—as the old mahogany or walnut.

Over-elaboration is the pitfall of the imitator of these periods; he endeavours to atone for his inability to obtain the finely figured veneers of the originals by lavish use of vases, paterae, shells, lines, or other details of the typical style.

The black-stained, cheap, antique oak, ornately carved, deceives few nowadays. The colour of genuine old Stuart furniture is almost invariably warm, and differs radically from the dead tones of the black imitations. Its fine patina is better imitated by brown fuming.

Antiques are specially liable to the insidious attacks of the wood worm (q.v.). (See also page 36)

**ANTIRRHINUM.** Snapdragon or antirrhinum is a true old English plant. It was originally a wall plant. Modern cultivation has raised its height from six or nine inches to two feet or so, diversified and multiplied its colourings and increased the size of the individual flowers.

While, strictly speaking, a perennial, the snapdragon is often at its best if treated as an annual or biennial: the plants can be raised (1) from seed, sown in August where they are to flower, under the protection of a south wall, and thinned out in the following spring; (2) sown in open seed-beds in exposed positions in June, and planted out during the early months of the next year; or (3) sown in a heated greenhouse in February, the seedlings being planted and out of doors in May. The snapdragon can also be propagated by cuttings.

Among the tall sorts, growing from 3 to 4 feet in height according to the nature of the soil in which they are planted, the following are noteworthy:

White King (pure white), Yellow King (strong-growing deep yellow), Crimson King (deep velvety crimson), Cottage Maid (pink and white), Moonlight (apricot yellow flushed with red), Vermilion Brilliant (orange scarlet), Pink Beauty (rose pink), Venus (delicate pink), Nigrescens (dark crimson).

The following are twelve fine intermediate varieties (18 to 24 in. high):

White Beauty (pure white). Yellow Queen (large yellow flowers), Amber Queen (canary yellow, flushed pink), Bonfire (orange buff), Carmine Queen (rose carmine), Coccinea (orange scarlet), Cottage Maid

(pink and white), Fascination (pink), Fiery Belt (orange red with white tube), Nelrose (deep rose pink), Nobile (white and crimson). The Fawn (terra-cotta and pink).

*Antirrhinum. Intermediate variety of this old-fashioned English garden flower. (R.A. Malby)*

Most seedsmen have their own named varieties. The tom thumbs (about 12 in. high) are generally grown under colours. Most of these choice varieties must be treated as annuals or biennials except in the favoured districts of the south and west of England, where they often establish themselves permanently.

Bedding antirrhinums are largely planted instead of the tom thumb varieties: they grow from 10 or 12 inches high and make a brilliant show, as most of the flowering shoots are of uniform height.

If sown in summer and planted in well-drained soil in sheltered places in September antirrhinums will stand most winters and flower a month earlier the following year than spring-sown plants. They are then biennials. When treated as annuals they are generally sown in February in boxes in a greenhouse where there is a gentle heat, or in a heated frame; germination is then rapid.

The most difficult stage in culture is before the seedlings obtain their second leaves. Then they are liable to damp off or to be scorched out of existence by strong sunshine unless carefully looked after. When the plants are big enough to handle easily they must be transplanted 2 to 2½ in. apart, into other boxes or frames where they will grow till planting-out time,

*(Continued in page 37)*

A room with panelling brought from the Old Palace at Bromley-by-Bow. Chronologically Jacobean, with a Jacobean ceiling, it is mainly Tudor in style with florid carving, chimney piece with family heraldry, royal arms and date, an extending table, and numerous panel-backed chairs.

An early Georgian room from Hatton Garden, London. Carved pine and mahogany have superseded oak and walnut. The furniture has the paw-like feet, curves and delicate rococo ostentation of the Kent period; but the classical lines of the fireplace and the simpler hoop-backed chairs and veneered cabinet anticipate the age of Chippendale, Hepplewhite and the Adam brothers.

being gradually hardened in view of this.

Planting or transplanting in the open beds in borders should take place in April or early May. If in lines, the intermediates ought to do well at 12 in. apart, the tall at 15 in., while the tom thumbs require 9 in. After the first two have grown to a height of 6 or 8 in. each plant must be staked, 12 in. stakes for intermediates and 18 in. stakes for tall. Pron. An-ti-ri-num.

**ANTISEPTIC.** The chief use of an antiseptic is to prevent the growth of organisms which cause putrefaction. Disinfectants (q.v.) have a different purpose. They are used to kill the microbes which cause communicable diseases like diphtheria or enteric fever. Some substances are both antiseptic and disinfectant, but a solution of sufficient strength to suffice for the former use would not serve for the latter. A deodorant (q.v.) removes disagreeable odours due to decomposition, but it, may do this without making things safer, e.g. in the case of eau-de-Cologne, camphor, or tobacco smoke. Some of the commonest antiseptics are:

Perchloride of mercury (corrosive sublimate).

Binioidide of mercury.—Solutions in water of strength 1 to 1,000 or 2,000.

Carbolic Acid.—In water, 1 to 20, 40, or 60. In mixing the water should be hot.

Tincture of Iodine.—Can be painted on or used as a lotion, a teaspoonful to the pint of warm water.

Potassium Permanganate.—Dissolve sufficient grains in water to produce a solution of a port wine tint.

Solution of Potassium Permanganate B.P.—A tablespoonful in a pint of water.

Hydrogen Peroxide Solution.—Diluted with five parts of water, this makes a good mouth wash, and is used in pyorrhoea.

Compound Glycerin of Thymol. B.P.C.—This makes a useful mouth wash.

Boracic Acid.—A saturated solution (obtained by mixing an excess of the powder in warm water and pouring off the clear solution). This can be used as a lotion, gargle, or mouth wash. For an eye wash dilute the above with five parts of warm water.

Cresol Soap Solution or Lysol.—A teaspoonful in a pint of warm water.

Perchloride and biniodide of mercury are very poisonous, and if sold dry, to make the solutions, should be in the form of coloured tablets, which will tint the water and prevent their being drunk in mistake for water. Tablets of perchloride of mercury are sold, which are blue, and biniodide of mercury red. Antiseptics are useful internally, e.g. for fermentation in the stomach, diarrhoea, enteric fever, dysentery, etc., but should only be employed in this way under the direct supervision or instructions of a doctor. See Sanitation.

**ANTLER MOTH.** This is a greyish-brown moth, with an expanse of wing varying from 1¼ in. to 1½ in., the female exceeding the male in size. The

caterpillar feeds below the surface of the ground on the roots of grasses. In this way it frequently becomes a scourge, rendering acres of grassland, as well as smaller lawns, useless. Although it occurs throughout the British Islands, its devastating work is largely confined to the northern districts. The only remedy for its attacks is the encouragement of rooks, lapwings, and other insectivorous birds that have a bill fitted for digging up the caterpillars. The caterpillars' activities extend from March to June, and the moths fly by night in August and September.

**ANTOFRET.** Antofret is a form of woodwork decoration by which it is possible to create raised and sunk panels and other features without employing more than a single thickness of wood for the whole. The cutting of the wood is executed with a hand fretsaw or a treadle fret machine.

*Antofret. Figs 1-4. Diagrams illustrating principle on which sunk or relief patterns are done.*

The basic principle is that all the pattern lines are cut to a slight bevel. Fig. 1 shows a section of a piece of thin wood; the bevel cut of the fretsaw is indicated by the thin lines at B. If the interior panel C is cut out all round at the bevel shown, it will be found to fit loosely in its surrounding wood by virtue of the loss of the thin line of sawdust which has been cut from the path of the saw; therefore, the section C can be pressed upwards until it tightens on the surrounding wood of A as shown at Fig. 2, and thus a raised effect is secured.

Similarly, if the bevel is in the opposite direction, as at Fig. 3, the central part C is depressed and produces a sunk panel, Fig. 4. This principle may be applied to any shape either of a raised sunk panel or of a formal floral decoration.

In practice the work itself is placed on the slant and the fretsaw is kept in a vertical position throughout the cutting. For this reason Antofret is best done on a

machine with an adjustable cutting-table which can be tilted to any angle as well as used for horizontal work. Fig. 5 shows one of these adjustable tables in use. A is the table, B the wood, and C the saw blade fixed in a hand frame in the position of cutting. The card tray in Fig. 6 gives a good idea of the solid effect which can be obtained from one piece of wood. The rim is made by pressing up the various steps of wood, and the sharp corners shaped down by filing and sandpapering. In the diagram of a section through the tray, the various steps are marked off, A, B, C, etc. An embellished diamond in the centre, also shown, is an additional improvement.

After the Antofret panels have all been cut each must be secured with glue. The parts should be pressed out to their final position and the glue applied on the reverse side to the face in the right angle made by the raised rings, etc.

Antofret is frequently used in combination with ordinary fretwork. There exists a large number of specially printed designs which may be obtained from Hobbies, Ltd., Dereham, Norfolk. *See* Fretwork; Woodcarving.

Fig. 5. Adjustable cutting table in use.

Antofret. Fig. 6. Card tray in antofret, with a sectional view showing the series of steps.

#### ANTO-TURNING.

This is a simple method of producing square turned columns, finials, or other similar woodwork decorations. A column such as that shown at Fig. 2, or any other pattern desired, can be produced with an ordinary fretsaw. The wood required for this work may be of any suitable size, but it must be of square section and all surfaces should be planed up smooth.

Anto-Turning, showing how a square turned column can be cut with a fretsaw.

First draw the design carefully upon a piece of good quality paper and then transfer the design to two surfaces of the wood as shown at Fig. 1. The tracing can be done by means of carbon paper and a stylus or a hard pencil. It is important to see that the features of the pattern come level with each other upon the two surfaces.

When the pattern has been placed on the wood, the latter is laid upon the fret-cutting table and the fine fretsaw blade enters the wood at the line A shown on the end of the wood. Thence it cuts along the pattern line until it reaches the dotted line D; the fretsaw should not be permitted to emerge from the wood at the other end, but should be unthreaded and withdrawn by releasing its clamp. After refixing, cut the line C on the opposite side, again cutting down the entire pattern line until it reaches the dotted line D, when again the blade is released and withdrawn from the cut.

The wood is then turned over so that the pattern on the side shown at E will be uppermost and the previous process is repeated. When the four cuts have thus been made down to the dotted line D, the surrounding waste wood is severed from the finished column by cutting through the line D squarely with a tenon saw. In the

case of terminals, the point or terminal end should come at the commencement of the cut. Anto-turnery is useful for the decoration of mantels, timepieces, cabinets, brackets, etc.

**ANTWERP PIGEON.** Unlike other breeds, which are subdivided according to colour, the Antwerp is classified as short - faced, medium-faced, and long-faced, according to length of skull. It is characterised by unusual strength and pugnacity, and is one of the strongest fliers.

*Antwerp Pigeon: the red chequer short-faced variety.*

### APARTMENTS.

Considerations of letting and obligations of landlady and tenant in both apartments and lodgings are similar in nature. Information on these points will be found under Lodgings. *See also* Boarding House.

**APERIENT.** Under this name, and also under that of laxative, are grouped the milder purgatives, such as cascara, castor oil, sulphur, etc. Their effect is to produce one or more soft motions. Doses of common preparations of aperients in general use are:

Dry extract of cascara sagrada, 2 to 8 grains in tablets.  
Liquid extract of cascara sgrada,  $\frac{1}{2}$  to 1 dram.  
Castor oil, 1 to 8 teaspoonfuls.  
Castor oil mixture, 2 to 4 tablespoonfuls.  
Flowers of sulphur, 20 to 60 grains.  
Confection of sulphur, 1 to 2 teaspoonfuls.  
Milk of sulphur, 20 to 60 grains.  
Sulphur lozenge, 1 to 2 at bed-time.  
Compound liquorice powder, 1 to 2 teaspoonfuls.  
Syrup of figs, one teaspoonful for children.  
Liquid paraffin, 1 teaspoonful to 1 tablespoonful.  
Powder of magnesia or magnesia carbonate, 5 to 30 grains, repeated doses; 30 to 60 grains as a single dose.  
Liquor of magnesium citrate, 5 to 10 ounces.  
Olive oil, 1 to 2 tablespoonfuls.  
Tamar Indien lozenges, one.

*See* Constipation; EpsomSalts; Magnesia; etc.

**APHIS.** This is the scientific name for the family of insect pests which includes the blue fly (q.v.) and the green fly (q.v.). The plural is aphides. *See* American Blight; Apple; Plum. etc.

**Apiary.** *See* Beehive.

**APOPLEXY.** This is loss of consciousness due to sudden interruption of the normal blood circulation through the brain. The commonest cause is the bursting

of a brain vessel, the walls of which have become degenerated and brittle. Conditions conducing to this disease of the blood vessels are continuous hard drinking, syphilis kidney disease, prolonged severe physical exertion, and lead poisoning. The condition is not often seen before middle life and is more common among men than women.

How so to regulate one's life as to minimise the danger of apoplexy is one of the problems of this strenuous age. The disease is without doubt commonest in people who constantly work at high pressure, who regularly eat more than is good for them (particularly meats and rich, highly-seasoned foods), who take alcohol regularly in any quantity, and who are careless about their health generally. There are certain warnings, such as dizziness on getting up from the lying down position, constant headache, numbness, or a slight loss of strength of an arm or leg.

When an attack of apoplexy occurs, the patient suddenly loses consciousness and collapses into complete helplessness. His face may be pale, but is usually flushed, and the head and eyes may be turned to one side, commonly the damaged side of the brain. The breathing is laboured and noisy.

Whenever there is the least doubt, a case of complete collapse should be treated as if it were apoplexy till its true nature be determined. Unconsciousness usually passes off in a few hours, perhaps three or four.

Treatment during an attack begins with laying the patient on his back. Loosen everything about the throat, raise the head a little.

*Be sure to prevent anyone from moving him until the doctor comes. Many a life has been lost from apoplexy through over-zealous helpers carrying the victim upstairs, lifting him into bed, undressing him, etc.*

Beyond placing an ice-bag on the head, there is absolutely nothing to be done until the physician's arrival.

**APOTHECARIES' WEIGHT.** This weight is chiefly used in the sale of drugs. It is as follows:

20 Grains	1 Scruple (℞)
3 Scruples	1 Dram or drachm (ʒ)
8 Drams	1 Ounce (℥)
12 Ounces	1 Pound (lb.)

The pound in this weight is somewhat lighter than the lb. avoirdupois, containing 5,760 grains against 7,000. The apothecaries' ounce, on the other hand, contains 480 grains against 437.5.

**APPENDICITIS.** This is an inflammatory disease of the vermiform appendix, a small blind tube of gut 3 or 4 in. long leading off from the junction of the large and small intestines. It may occur at any age,

but is commoner in young people, and especially males.

The appendix contains a large amount of adenoid tissue like the tonsil, and is sometimes called the "abdominal tonsil". It is narrow, and if there is a slight swelling of the lining at the entrance, or if the appendix is kinked, secretions may be imprisoned and decompose. Foreign bodies such as grape seeds and fruit pips are not found so frequently as was at one time supposed, but what is found quite frequently is a little piece of hardened faeces, probably resulting from chronic constipation, and this mass may even have ulcerated its way into or through the wall of the appendix.

*Appendicitis. Diagram indicating where pain is first felt in early stages of the disease. A. The neighbourhood of the navel, where it begins, then quickly moving to B.*

The symptoms of the disease in the first instance are pain around the navel (see diagram), nausea and sickness, a rise in temperature, perhaps between 101° and 102°, a quickened pulse, and constipation. After some hours there is tenderness at a point to the right of and below the navel, and the muscles of the abdominal wall become firm and resist any attempt to press in with the fingers. To ease the pain the patient often lies with the right leg bent up.

*The patient must be in the care of the surgeon at the earliest possible moment. Many cases have got better without operation, but a deplorable number of people lose their lives because operation has been delayed till too late.*

For relief of pain till the doctor comes a hot-water bottle may be laid by the side of the patient, or an ice-bag may be applied to the part, and as this should not press on the belly, it is suspended from a bed-cradle, placed under the bed-clothes, so that the bag touches but no more.

**APPETISER.** Besides grape-fruit, hors d'oeuvres served at the beginning of a dinner are appetisers. They usually contain vinegar, something extremely savoury, like anchovy or sardine, and an active condiment, such as Chili pepper. Cocktails are used as appetisers, and often contain orange bitters to give them pungency. *See Appetite; Bitters; Cocktail.*

**APPETITE.** When the system requires nourishment there arises automatically the natural craving for food which we call appetite. It is this and the taste of food which start the flow of the gastric juices. The appetite may be affected psychically and an ill-cooked

and badly-served meal may do much to reduce it, as may any depressing emotion. To a certain extent appetite is a measure of the quantity and a guide to the nature of the food one should take; what we fancy is likely to be good for us. But there are exceptions to this, as a poor appetite may not represent the needs of the body, but may be due to faulty hygiene, such as sedentary habits, too little exercise, or the abuse of tobacco, tea, alcohol or other drugs.

Where a poor appetite is part of a disease its treatment is included in that of the particular disease. In cases where the habits are at fault the obvious thing to do is to correct such a habit. However, something may be done to improve the appetite by the use of "bitters," such as calumba, gentian, quassia, cascarilla, or a little orange peel. The following is an excellent example of an appetiser:

Compound tincture of cardamoms	1½ drams
Concentrated compound solution of sarsaparilla	1 dram
Spirit of chloroform	1½ drams
Tincture of calumba	4 drams
Water enough to make	6 ounces

Take half a small wineglassful ten minutes before dinner. *See Diet; Digestion; Invalid Cookery.*

## APPLES: HOW TO GROW AND USE THEM

### Practical Hints Concerning All Varieties of the Tree and its Fruit

Numerous separate entries give recipes for dishes in which apples are used. For insect pests and diseases that attack the apple see Apple Aphis; Apple Sawfly, etc.

There are nearly 2,000 varieties of dessert and cooking apples, yet new ones are still sought for and produced. A list of the best sorts for domestic use is given below.

### DESSERT APPLES

**ALLINGTON PIPPIN.** A juicy, well-flavoured apple for eating in October, November and December. It crops surely.

**BLENHEIM ORANGE.** Good alike for dessert and baking, but not boiling.

**COX'S ORANGE.** Probably the best dessert apple.

**JAMES GRIEVE.** Good late autumn variety with large handsome fruit of good flavour.

**LAXTON'S SUPERB.** The best of the new dessert apples; of first-rate flavour; crops well; at its best from Christmas to March.

**LORD LAMBOURNE.** One of the best of the newer dessert apples; well-flavoured and highly coloured. In season October-December.

**ORLEANS REINETTE.** One of the very best winter dessert apples; of medium size; well coloured and first-rate flavour.

**WORCESTER PEARMAN.** Early autumn apple. Fine colour, medium size, and good flavour. An excellent cropper.

### KITCHEN APPLES

**BRAMLEY'S SEEDLING.** Late apple, and an excellent keeper. Useful where the soil is very heavy or damp; it has a red cheek and a tart flavour.

**LORD DERBY.** One of the heaviest and most regular cropping varieties. It grows well on all types of soil and bears large fruits; ready for use in November-December.

**GRENADIER.** One of the best early cooking apples, yellow in colour and fine in flavour. Being very prolific, it is of great use in small gardens.

**EARLY VICTORIA.** A remarkably prolific codlin, suitable for use in July-August.

**REV. W. WILKS.** A large cream-coloured apple; ready for use in October-November; drops heavily and cooks well.

**LANE'S PRINCE ALBERT.** Large, striped fruit which "hangs and keeps" for half the year. Like Cellini, the very ripe fruit can be used for dessert purposes.

**NEWTON WONDER.** Late variety suitable for eating raw late in the season.

**EDWARD VII.** A splendid late variety for small gardens; in season January to April. The fruits are very large and produced freely.

**STIRLING CASTLE.** Large, very prolific variety; in season from Sept. to Nov. Of good flavour, it is one of the best for small gardens.

**ARTHUR TURNER.** An excellent new cooking apple that bears heavy crops and is fit for use at any time from July to October. It is of upright growth and suitable for small gardens.

*Cox's Orange Pippin on bush tree.*

Being naturally a small tree of the hedgerows and coppices, the apple is not happy in bleak, windswept places. A southern, south-eastern, or south-western slope suits it admirably, if there is a good depth of soil. So long as the roots are kept clear, grass or vegetables may be grown between trees.

Apples thrive in most gardens, if reasonable care is taken to cultivate

and feed the soil. A deep, mellow, loamy soil suits best. A light, shallow, fibreless soil on sand or gravel does not suit, but chalk is no detriment if it is four feet or more below the surface. The apple will thrive on clays and marls if well drained.

*Laxton's Superb, trained grid-iron style for good fruiting.*

Apples may be planted any time between autumn and spring. The best time is when the soil is moist, but not wet enough to be squelchy, and that may be from Nov. to Feb. or March. It is desirable to plant before the trees actually break into leaf. Wide but not very deep holes should be made.

*Allington Pippin, a favourite dessert apple.*

Most of the manure should be put above the roots. The soil should be trodden firmly around and among the roots. Stakes for standard trees should be driven down before the trees are planted. It is a good plan to mulch trees with manure after planting.

*Methods of training the apple tree. King of the Pippins apple in full fruit. This is a cordon tree which has been trained horizontally and supported on props.*

*Methods of training the pyramid apple tree.*

Some apples are self-sterile and if planted alone will not bear satisfactory crops. A mixed plantation of varieties alone is profitable; it is advisable to plant cooking and dessert apples near each other so that the flowers may be cross-fertilised.

Apples are best turned into good fruiting trees by shortening the heads for three successive years in decreasing degrees of severity, and subsequently summer pruning the side shoots. If the tree grows very strongly root pruning may be desirable in winter. Whether for bush or standard the maiden is shortened to about half a yard. The two-year-old tree is pruned back to about one-third, the three-year-old to about half.

Most varieties reach the maximum of health, strength and fruitfulness with ten or a dozen strong branches a foot or half a yard apart near the base, all growing upwards and outwards, so that there is no intercrossing, and with the head of the tree cup-shaped.

*Espalier trained apple tree, the best method with apples of prolific habit, procuring the maximum amount of fruit in the minimum space.*

**Grafting and Budding.** Excellent methods of propagating apples are described by the Ministry of Agriculture in Leaflet 49, from which much of the following is taken:

Apples are grown in many forms, the most popular being standards—that is, trees with clean 6-ft. stems; half-standards, or trees with clean 3 or 4-ft. stems; bushes, that is, open-headed trees on short stems; cordons, or trees restricted to one stem, whether perpendicular or horizontal; and espaliers, or trees trained on walls, fences, or wires. These and many other forms are developed from a young tree obtained from a bud or graft, and called in its first year of growth a maiden.

*Apple: method of pruning.*

*Left, pyramid apple tree pruning. Right, the same tree after it has been properly pruned.*

The best

stocks are the broad-leaved Paradise for dwarf bushes, and the Crab for the more vigorous and standard trees.

Scions for budding or grafting should be cut from prolific and healthy trees. For budding, firm wood of the current year's growth should be cut just prior to use, and kept fresh by standing in a pail containing a little water. For grafting, well-ripened yearling wood should be cut in the winter prior to pruning, and after labelling with the variety, bedded in a shady position. In this way the buds will remain dormant until after the stocks have commenced growth.

Bud the stocks in July or Aug., and graft any which have failed to take in the following spring. All stocks, and particularly those which are dwarfing, should be grafted or budded as close to the ground level as possible. There is then no difficulty in planting the young trees so that the union between the graft and stock is below ground level.

The requisites for budding are a budding knife with bone handle; a pail in which to keep the scions; raffia for binding. For grafting they are pruning knife, bone or wood carving chisel to open the slits, raffia for binding, and wax or grafting clay. For top-grafting a saw is also required. Grafting wax can be bought ready prepared.

*Apple: Left, a badly balanced young bush apple tree which has been wrongly pruned in earlier stages of growth. Right, the same tree after correct pruning.*

The season for grafting is during April and May, when the stocks have just commenced growth, but while the scions are still dormant. Success in grafting can only be accomplished by making clean level cuts so that the exposed surfaces of the graft and stock correspond in size and fit together tightly at least on one side.

**Tongue Grafting.** There are two methods: (a) When the stock and scion are of the same size (Fig. 1). First remove all the side shoots from the base of the stock. Then cut it off 2 in. or 3 in. from ground level by an upward oblique stroke  $1\frac{1}{2}$  to 2 in. long (Fig. 1 A) Across the middle of this cut surface, and by means of a downward stroke of the knife, a thin tongue should be carefully raised pointing upwards (Fig. 1 A<sup>1</sup>).

Next cut a graft containing three or four well-developed wood buds from a piece of the wood selected for the scions. The uppermost cut should be made slightly obliquely across the wood just above the top

bud. The lower cut should be about  $\frac{3}{4}$  in. below the lowest bud of the graft, which is known as the stock bud (Fig. 1 B<sup>1</sup>). With a downward stroke of the knife make an oblique cut  $1\frac{1}{2}$  in. to 2 in. long across the graft on the opposite side to the stock bud, so that the exposed surface corresponds in size to that of the stock (Fig. 1 B<sup>2</sup>). Finally, by an upward cut across the middle of the cut surface raise a thin tongue pointing downwards (Fig. 1 C<sup>1</sup>).

*Apple: tongue grafting. Left. Method when stock and scion are of equal size. A, stock cut to receive graft; A', position of tongue; B and C, grafts ready for applying to stocks; B', stock bud; B'', long oblique cut surface; C', position of tongue; D, graft and stock fitted together; E, graft and stock bound together with raffia; F, arrow, stock-bud left uncovered; G, the operation completed; all the cut surfaces covered with grafting wax.*

*of equal-sized stock and graft after one year's growth. (By permission of the Ministry of Agriculture and Fisheries.)*

The graft is then applied to the stock and the two tongues fitted together tightly, so that the rinds of each coincide as far as possible (Fig. 1 D). The manner in which the tongues should fit into each other is well shown in Fig. 2. Now bind the graft and stock tightly together with raffia, leaving the stock bud free (Fig. 1 E with arrow), and cover all the cut surfaces with grafting wax (Fig. 1 F) or clay (pug) to prevent drying.

For the second method (b), when the stock is larger than the graft (Fig. 2), the graft is prepared in the same way as in (a), except that the tongue is made at the top instead of across the middle of the oblique cut surface.

The stock, after trimming, is cut almost square across 2 to 3 in. above ground level. By an upward

stroke of the knife expose a clean surface on the longest side of the stock slightly wider than that cut on the graft. At the top of this surface make a tongue to receive the graft. Apply the graft to the stock so that the tongues fit together closely and the rinds coincide (Fig. 2). Complete the operation as before by binding tightly with raffia and covering all the cut surfaces with wax or clay.

As soon as the grafts begin to grow it is a good plan to tie the main shoots to sticks to prevent the wind breaking them and to secure straight main stems. The raffia ties must be cut as soon as growth commences, otherwise the ties will cut into the wood. When the main shoots are 18 in. to 2 ft. long all the lateral growths from the grafts should be stopped. The suckers sent up from the stock should also be removed two or three times during the summer.

**Shield Grafting, or Budding.** The season for budding is from the end of June to the beginning of Sept. Stout well-ripened buds from the current year's growth should be used and all fruit buds or young unripened buds should be discarded. The method usually adopted is known as "shield" or "T" budding.

The bud is removed from the selected wood growth together with a semicircular shield of wood and rind, about  $\frac{3}{4}$  in. in length (Fig. 4 A). To remove this shield, the cut should commence about  $\frac{1}{2}$  in. below the bud and finish about  $\frac{1}{4}$  in. above it. The blade of the leaf is then removed, leaving the leafstalk A<sup>1</sup>, intact for pressing the bud under the rind of the stock and preserving it from damage. Next, the portion of wood cut away with the shield is removed from the rind with the point of the knife (Fig. 4 C), but leaving the bud on the shield undamaged. Care must be taken to leave intact the small protuberance at the base of the bud, inside the rind (Fig. 4 B<sup>1</sup>).

*Apple. Fig. 4. Preparation of the bud shield by removing core of hard wood. See text.*

*Below: processes in budding. Fig. 5. T-shaped cut on the stock ready for the bud. Fig. 6. Bud shield slipped beneath lips of the downward cut.*

Fig. 7. Bud shield pressed completely beneath rind of stock. Fig. 8. Bud shield bound to the stock with raffia. Fig. 9. Bud united to the stock after removal of raffia. (By permission of the Ministry of Agriculture and Fisheries)

To prepare the stock, remove all suckers and side growths within 6 in. of the ground. Next make a "T" shaped cut in the rind as close to the ground level as possible (Fig. 5). The down stroke of the "T" should be about 1 in. long and the cross-cut about  $\frac{1}{2}$  in. The bark on both sides of the downward cut is then raised slightly with the back of the budding knife. The bud shield is slipped beneath the lips of the downward cut on the stock (Fig. 6) until the top of the shield is below the crosscut of the "T" (Fig. 7). Tie with raffia over all the cuts, but take care that the bud is left uncovered (Fig. 8).

Later in the autumn, as soon as the buds have taken, the ties of raffia should be cut to allow the stock to swell normally. Fig. 9 shows the budded stock after the raffia has been removed. Suckers or shoots arising from the stock must be removed two or three times during the summer.

Fig. 10. Tree to be top grafted, having been cut back in the winter and with the faggot-wood removed. Fig. 11. The same tree after top grafting, showing length at which top branches of stock are left. (By permission of the Ministry of Agriculture and Fisheries)

**Top Grafting.** Rind or Crown Grafting is the method recommended for top grafting. The trees which are selected for this purpose should have their main branches sawn off during the winter and the faggot wood removed. Fig. 10 shows the tree cut back in this way. At grafting time—that is, when the rind peels quite easily from the wood—the branches are sawn square across (Fig. 11) where they are stout enough to support the large branches which will grow from vigorous grafts. The sawn surface at the end of each

branch is then pared smooth with the pruning knife to facilitate healing (Fig. 12 A). Afterwards a longitudinal cut 2 in. to 3 in. in length is made in the bark, and the rind at the top of this cut is then raised slightly on either side (Fig. 12 A<sup>2</sup>).

A graft (Fig. 12 B), containing 3 or 4 buds, similar to that used for tongue grafting but with no tongue, is cut and slipped beneath the raised lips of the rind on the stock. It is then pressed downwards until the long cut surface is level with the top of the branch (Fig. 12 C). The graft is then bound tightly to the stock with raffia, but the stock bud (C<sup>1</sup>) is left uncovered. The top tie should be as tight as possible to effect a perfect union at this point and so prevent the graft from breaking when it commences to bear fruit. The operation is completed by covering the cut surfaces around the graft with wax or "Pug" (Fig. 12 D). One graft is sufficient for branches under 2 in. in diameter. Above this size two or even three grafts should be used. Fig. 11 shows the tree depicted in Fig. 10 with the top grafting completed.

Fig. 12. Rind or crown grafting. A, branch of stock prepared to receive graft; A<sup>1</sup> pared surface at top of branch; A<sup>2</sup>, longitudinal cut in rind. B, graft; C, graft slipped beneath rind of stock; C<sup>1</sup>, stock bud. D, completion; grafts bound to the stock and cut surfaces waxed. (By permission of the Ministry of Agriculture and Fisheries)

**Picking and Storing.** The right time to pick apples is when the fruit parts readily from the spur on being lifted gently, but certain varieties part more easily than others. Early varieties are often intentionally picked a little earlier than late varieties, which should hang until some of the fruit has dropped naturally. If picked too soon fruit will shrivel. Fruit should be picked carefully and placed gently in the picking apron, or into a basket lined with soft material. The fruit should be handled as little as possible.

For fruit to keep well the store must be (1) Slightly moist. (2) Well ventilated; extra ventilation is required for apples during the first three weeks or so, while they are sweating. (3) Cool and of even temperature; warmth causes shrivelling, and frost generally causes decay. (4) Dark or only dimly lit; daylight spoils the quality.

Large quantities of apples may be laid in heaps, not more than 2 ft. deep, on 6 in. of clean, dry, wheat straw laid on the floor, and covered with a good thickness of straw; but this is not the best method for small quantities. Apples may also be stored in boxes, barrels, or baskets placed one upon the other in the store, so as to allow air to circulate. Special trays may be used which rest one upon another and economise space (*see* Fruit Tray).

The ripening of apples is usually well marked, the green part becoming distinctly yellow. As a rule, the later an apple ripens the longer it will keep in good condition. Early apples should keep about a fortnight after ripening, Worcester Pearmain a month, James Grieve six weeks, Cox's Orange and King Pippins two months.

**How to Cook.** From the health point of view, for most children and adults apples are excellent, but in some cases only agree with the digestion when cooked. For very young children raw apples should be grated into a dish just before a meal and made into sandwiches with bread and butter, or eaten with a spoon.

Apples are particularly good for casserole cookery; in this way the whole fruit is preserved, and can be served more effectively than when stewed to a pulp. Baked apples make a wholesome dish when peeled, the cores removed, and the centres filled with sugar and one clove in each. Having put them in a casserole, add a little water with some grated lemon-rind. Cover the dish and bake in the oven or stew in the hay-box until they are tender.

To stew apples, wipe eight large apples and quarter them. Stew gently with 1 teacupful of sugar, strips of lemon-peel, and  $\frac{1}{2}$  pint water, and serve with custard sauce or cream.

**APPLE AMBER.** To make this take 6 oz. breadcrumbs, 4 oz. suet, 2 oz. castor sugar, 2 eggs, 2 oz. flour, 1 lb. apples, 1 lemon, and  $\frac{1}{2}$  oz. fat. Chop the suet finely and mix it with the flour. Peel and core the apples and put them through a mincer, or chop them finely. Add the breadcrumbs, sugar, chopped apple, grated lemon-peel, and nutmeg to the flour and suet. Beat up the eggs and mix them well together with the other ingredients. Grease a pint mould or basin with the fat; then pour in the mixture, cover it with a greased paper, and steam it for  $3\frac{1}{2}$  hours, or cover it with a floured pudding-cloth and boil it for 3 hours. It should be served with sweet sauce. This is enough for six persons.

**APPLE AND PEAR SCAB.** Great damage is caused in orchards every year by the ravages of scab, which is one of the most widely distributed fungus diseases. The information given is taken from the Ministry of Agriculture Leaflet 245.

During early spring the part of the leaf which bears the fungus becomes a dark olive-green or sooty colour. Sometimes the fungus confines its attack almost entirely to the veins of the leaf, while in other cases it

forms distinct and sharply-marked patches scattered over the surface. The early infection of the fruit takes place almost entirely from the leaves. The wind-borne spores alight on the fruit, germinate, and penetrate the skin, beneath which they form a mass of fungus tissue. In time the skin of the fruit is broken, and dark-coloured spores escape.

Affected wood is readily distinguished by its blistered appearance. It should be cut out when pruning the trees in winter. Badly diseased wood should be cut out as far as possible without injuring the trees, and this should be completed by the middle of March. To prevent the new wood being affected, it is necessary to spray during spring and summer:

There are two mixtures which may be used. Bordeaux Mixture (q.v.) and Lime-sulphur (q.v.). Bordeaux Mixture is the more effective though in the case of a few varieties of apples it is apt to cause scorching. These varieties include Beauty of Bath, Cox's Orange Pippin, Duchess's Favourite, Gladstone, James Grieve, Lady Sudeley. On all of these a lime-sulphur spray only should be used.

In bad cases of apple scab several applications are necessary, the first immediately before flowering, the second as soon as the petals fall, and a third about three weeks later. On pears the first spraying should be given directly the fruit is set, and a second spraying three weeks or a month afterwards.

**APPLE APHIS.** Blue bug blight, otherwise apple aphis, is a pest of apple trees. A description of the symptoms and treatment is given in the Ministry of Agriculture Leaflet 106. The damage is mainly to the foliage and young wood, though the fruit may be stunted.

The blue bug or rosy apple aphis causes the leaves to curl up, and beneath this shelter the lice reproduce, poisoning the foliage by their secretions. They swarm on the leafstalks, shoots, and fruitlets, and by their punctures deform them. The leaves may fall and only a few stunted and galled apples remain. The green apple aphis feeds upon the young top growths.

Apple aphides can be controlled by spraying. Limewash should be sprayed early in the season when the eggs are about to hatch. The normal time to apply this wash is when the leaf-buds are swelling and about to burst. The whole tree must be covered, and especially the twigs and smaller branches. A contact insecticide, such as nicotine (q.v.) and soap, or pyridine (q.v.) and soap, may be used during the period between the opening of the leaf-buds and the bursting of the bloom. A contact insecticide such as paraffin emulsion is used from the middle to the end of October, when the leaves are falling. The aphides are then laying the winter eggs, and can be killed by a thorough application of aphis wash.

**APPLE BLOSSOM WEEVIL.** A small black beetle barely a third of an inch long, known as the apple blossom weevil, feeds on the leaves of the apple

tree in summer. During the spring the female weevil pierces the buds of the fruit spurs and lays one egg in each bud. The Ministry of Agriculture Leaflet 28 describes its effect on the apple tree.

*Apple Blossom Weevil in various stages of life. 1. Larva. 2. Weevil. 3. Pupa. 4. Blossom bud containing weevil. In 1, 2, and 3 the insect is much enlarged.*

Certain of the blossoms fail to expand, the petals having died and become brown in colour without falling off. Such blossoms are known as "capped blossom," and underneath the brown petals is a small yellowish grub (or later a pupa), which has eaten away the base of the flower. The blossoms attacked invariably die and fall off.

Weevils hibernate on the trees, and a winter wash, or later a limewash, will destroy many of them. In small orchards it is worth collecting capped blossom by hand before the beetles emerge. The weevils early in June may be trapped by bands of sacking tied round the tree. The bands should be removed and burned in the autumn. It is possible to reduce the number of the beetles by shaking them off the trees just before they lay their eggs. A large sheet is spread under the tree, and the beetles which fall down are tipped into a pail containing a little paraffin.

**APPLE CHARLOTTE.** Line a greased pie-dish or pudding basin with slices of bread and butter, leaving no crevices. Fill the dish with stewed and sweetened apples and add a clove, if this flavour is liked. Cover the top of the dish closely with slices of bread.

**APPLE CHUTNEY.** A good recipe is composed of 4 lb. sour apples, ½ lb. Demerara sugar, ½ lb. onions, ½ oz. dry chillies, ½ lb. seedless raisins, 1 oz. salt, 2 oz. ground ginger, 1 oz. mustard seed, 1 quart vinegar, ½ oz. garlic (if liked). Peel, core and slice the apples, and simmer with the sugar and vinegar in a pan. Peel and mince onions, garlic and chillies. Wash mustard seed and dry in oven. Chop raisins. Pound them in a mortar with the onions, etc., and the ginger. When the apples are soft add the other ingredients and mix well together. Bottle and cover as for pickles. The chutney improves by storing for two or three months previous to being used.

**APPLE DUMPLING.** The ingredients required are ½ lb. of flour, ½ tea-spoonful of baking powder, ¼ lb. of margarine, 6 apples, 6 teaspoonfuls of sugar, and 6 cloves.

Peel the apples and take out the cores with an apple corer. To make the short crust, sift the flour and baking powder into a basin, and rub in the margarine until it is as fine as breadcrumbs. If self-raising flour is

used the baking powder must be omitted. Add a pinch of salt and mix with a teacupful of water. Use a knife for this purpose, and when a ball of dough or paste is formed take this up in the hand, and use it like a sponge until all the flour is worked into a stiff paste. Mix more water as required in lightly without kneading it. Turn on to a floured board and divide into six pieces.

Roll each piece into a round shape, and place an apple on each. Put a clove and a teaspoonful of sugar into the centre hole of each apple. Damp the edges of the pastry, and draw it up round the apple to the top; squeeze the edges together and make it look as round as possible. Press it well, and turn it down on to the sealed end. Brush it over with white of egg or milk, and bake in a hot oven about 30 minutes. Try with a skewer near the bottom to see when the apple is done. The pastry should be a light brown in colour. Sprinkle with sugar, and serve hot or cold. Sufficient for six persons.

**APPLE FRITTERS.** These require ½ lb. of flour, 1 lb. of apples, 2 eggs, ¾ pint of milk, and deep fat for frying. Put the flour into a basin and make a well in the centre. Break the eggs into a basin, and drop each into the flour unbeaten. Add half the milk gradually, stirring all the time, and letting the flour fall in from the sides of the basin to prevent lumps. Do not add all the milk at once, or the batter will be too thin. Work it until it is smooth, like a thick custard, and beat it well for 10 minutes. Stir in the remainder of the milk and stand on one side for an hour for the batter to thicken. A coating batter should be thick enough to cover the back of a wooden spoon as it runs off. If it is too thin, add more flour; if too thick, gently stir in more milk.

*Apple Fritters. Top. Slicing the apple after they have been cored. Bottom. The fritters as they should be served.*

Peel the apples and take out the cores with an apple corer. Cut them into rings about ½ in. in thickness. Put into a deep-fat frying-pan enough dripping, lard, or salad oil to fill half the pan. Heat this until it begins to send up a faint blue smoke, dip the apple rings into the batter, and then take out and drop them into the hot fat—about four pieces at a time. Fry them a golden

brown, turning them in the fat; then drain them on kitchen paper. Bring the fat to smoking heat again and continue until sufficient apple-rings have been fried. Sprinkle with castor sugar and serve very hot. The fat can be used again and again for frying. This makes a dish for six persons.

**APPLE JAM.** Good flavoured cooking apples should be selected, and there should be enough to weigh 6 lb. after being peeled and cored. Peel them thinly, cut into quarters, and, after removing the cores, slice them and put into a pan with a pint and a half of water. Peel 2 lemons thinly, and tie the rind in a piece of muslin with 8 cloves, and add to the apples. Cook until the apples are a soft pulp, remove the clove-bag, and pass the apple purée through a sieve.

Put this pulp back into the pan, add 4½ lb. of lump sugar, boil for 1 hour, skim and stir frequently. Be careful to put it into clean dry jars when it is cool. A few drops of cochineal added when the jam is boiling improve the colour. Tie the jars down closely, and keep in a very dry place. *See Jam.*

**APPLE JELLY.** An important requisite is to have a proper jelly bag (q.v.) ready for use.

The apples are cut up in the rough, neither peeled nor cored, though bad parts should be removed. Rinse the fruit and cover with cold water in a stew pan. Add some strips of lemon peel and boil quickly until tender.

Next pour the pulp into the jelly bag and let it drain slowly. Do not squeeze the bag, or the jelly will be cloudy, and no boiling will clear it. Measure the liquid obtained, return to the pan, and bring to the boil. Add 1 lb. of lump sugar to each pint. Remove scum and boil fast for 30 minutes. Drop a little on to a cold plate; if this forms into jelly it is ready for the jars. When set, cover the jars with air-proof papers and store in a dry place.

**APPLE PIE.** The ingredients are 1 lb. flour, 3 oz. lard, 3 oz. margarine, 1½ teaspoonfuls baking powder, 3 lb. apples, 6 oz. sugar, 1 oz. lemon rind and 3 cloves. First peel, core, and slice the apples. Put half of them into a pie-dish, in the middle of which is an inverted egg-cup, add the sugar and flavouring, and on this lay the remainder of the apple slices. Let no sugar be on top of the fruit next the pastry, as this makes it heavy. Pour in 1½ teacupfuls of water.

To make the short crust that is usually employed to cover the apples, sift the flour with the baking powder into a basin, add a good pinch of salt, and then rub in the margarine and lard; 6 oz. margarine alone can be used. It should be well rubbed in with the fingers till the whole flour is mixed with it and looks like fine breadcrumbs. Then pour in enough water to make it a dry paste. The water should not be added all at once, but gradually, though not too slowly. Mix it in with a knife, not a spoon. Turn the paste on to a well-floured board, and roll it out with short forward rolls, lifting the pin up between each roll.

The crust should be about a quarter of an inch thick.

Cut a strip from the pastry. Moisten the rim of the pie-dish, and put on it the strip, cut side outward. Damp this, and cover with the pastry, pressing the edges together. Cut off the rough edges, and mark the edge with the back of a knife or fork dipped in flour. Bake in a hot oven for 30 min.

The pastry should be a light brown and the apples soft. If the pastry browns too quickly, remove the top browning shelf of the gas stove, or put on to a lower shelf in the oven, and cover with a greased paper. Sprinkle the pie with castor sugar, and serve hot or cold. If the apples are not good cookers, they should be stewed before being put in the pie-dish, and allowed to get cold before adding the crust.

**APPLE PUDDING.** In the first recipe given, which contains suet, the following ingredients are required: ½ lb. flour, ¼ lb. suet, 1½ lb. apples, 3 oz. Demerara sugar, 3 cloves, together with some grated lemon rind.

*Apple Pudding. 1. Lining the basin with a suet crust; it should be pressed well down. 2. Fixing on the top crust to the edges of the lining pastry.*

Peel, core, and slice the apples. Chop the suet finely and mix with the flour, add a pinch of salt, and mix to a stiff paste with water. Cut off one-third of the pastry for the top of the pudding. Flour the board and rolling-pin, roll out the larger piece of crust to a round shape about one and a half times the size of the top of the basin. Grease the basin and line with the pastry, working the creases evenly into the sides and pressing well up to the top of the basin. Put in half of the sliced apples, sugar, and flavouring, and fill up with the remainder of the apples, and add a teacupful of water to make a syrup.

Roll out the small piece of pastry to the size of the top of the basin, moisten the edges, and fix on to the pastry lining the basin, not round the outside rim of the basin. Cover with a greased paper, tie it on, and steam for 3½ hours. If boiling, cover with a greased paper, and then a floured pudding cloth, and boil 2½ hours. For steaming, have sufficient boiling water to come three parts of the way up the basin, and add more boiling water as it boils away. Boiled puddings must be immersed in boiling water, and be kept covered and boiling fast all the time.

To serve, loosen the edges from the sides of the basin with a knife, put a flat dish on the top of the pudding, gently and carefully turn the pudding basin over, shake it, and the pudding should leave the basin quite clear.

Prick with the knife to allow the syrup to run round the dish, and serve at once.

A recipe in which no suet is used can be made thus: Mix four teacupfuls of flour with an equal quantity of breadcrumbs, two teaspoonfuls of baking powder, and a good pinch of salt. Rub in 6 oz. of margarine, and then add enough cold water to make a stiff dough. Knead on floured board, and roll the pastry into a round. Line a greased bowl with it, and put in slices of apple covered with sugar. Cover it with pastry and then with greased paper. Steam for two to three hours.

**APPLE ROLY POLY.** Prepare the pastry as for apple pudding. Roll it out into a strip 8 or 10 in. wide and  $\frac{1}{3}$  in. thick. Spread over it apple jam, or minced raw apples and sugar, leaving 1 in. at the sides untouched by the fruit. Moisten the edges, roll it up, and put it into a greased 3-lb. stone jam jar. Cover with a greased paper, tie down, and steam for 3 hours. If it is to be boiled, tie it in a floured pudding cloth, immerse it in boiling water, and boil for 2 hours. This is enough for six persons.

**APPLE SAUCE.** Peel, core and slice 5 large apples. Place them in a saucepan with half a teacupful of water. Simmer and stir over a slow fire until pulped. Turn them into a basin, beat well with a fork, add 1 teaspoonful of sugar, half a teaspoonful of made mustard, a pinch of salt, and a small piece of butter. Squeeze in some lemon juice, and serve in a sauce tureen. This sauce is eaten hot with roast goose, roast duck, and roast pork.

**APPLE SAWFLY.** The injury caused by the apple sawfly resembles that of the codlin moth, the attacked fruit seldom growing to any size and generally falling off in July. The pest is dealt with in Leaflet 13 of the Ministry of Agriculture.

*Apple Sawfly. 1. Adult fly. 2. Larva of the pest. Both are shown considerably enlarged.*

The measures which have been found of service are as follows, but they are suited to small gardens rather than to fruit-growing on a commercial scale. All attacked fruits should be picked off the tree and destroyed before the larvae have left them. The pupae in the soil may be destroyed by carbon bisulphide injections or by the use of some other powerful soil fumigant. By thoroughly working the soil under attacked trees some of the pupae may be exposed to the attacks of birds, while others may be prevented from emerging. A dressing of kainit is said to be beneficial.

**APPLE SNOWBALLS.** Peel four apples and remove the cores with an apple corer. Place them on a baking-dish, and put half a teaspoonful of sugar and a clove into the centre of each. Put a little water into the bottom of the baking-dish, and bake in a moderate oven 20 to 30 min. until tender. Beat the whites of three eggs stiffly, and whip into them  $1\frac{1}{2}$  dessertspoonfuls of castor sugar. Remove the apples on to a shallow dish, and cover each with the white of egg mixture. Place in a warm oven for 15 min., to set the meringue. Garnish with angelica or glacé cherries and serve cold. The snowballs can be made to look more attractive if surrounded with chopped jelly.

*Apple Snowballs. Attractive way of serving baked apples, the snow being white of egg and sugar.*

**APPLE SUCKER.** The apple sucker is a green, filmy fly about one-twelfth of an inch long. It is seen flitting about in autumn, and does double injury, as its larvae feed on the buds in spring. How to deal with this pest by spraying limewash and contact insecticide is set out in Leaflet 96 issued by the Ministry of Agriculture. The formula for limewash is 10 to 15 lb. of best quicklime in lumps to 10 gallons of water. The trees are sprayed about the time when the buds begin to swell. Shortly before the blossoms open a contact insecticide of nicotine and soap should be applied. The following formula has proved satisfactory: Nicotine (98-99 per cent.),  $\frac{3}{4}$  oz.; soft soap,  $\frac{1}{2}$  - 1 lb.; water 10 gallons.

*Apple Sucker. Above, larva in third stage; below, insect. Both magnified.*

**APPLE TART.** Pastry as for apple dumplings or apple pie is made. Line a shallow tart-dish, with pastry and spread over with stewed apples.

Cut strips of pastry and lay them in cross-bars over the tart. Bake in a good oven for 20 min.

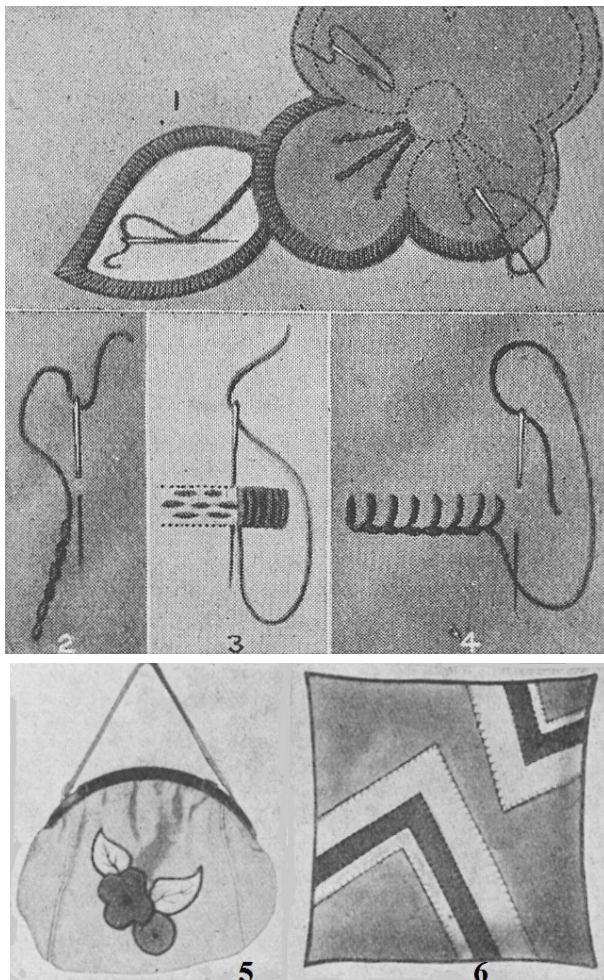

Another apple tart is made by lining a greased pastry ring with puff pastry. Bake in hot oven, scoop out the soft centre and fill with stewed and sieved apples. Whip the whites of 2 eggs to a stiff froth, and fold in lightly 1 tablespoonful of castor sugar. Put on the top of the apple to cover, and return to the oven for 5 to 10 min. to bake the meringue a light brown. Decorate with a few glacé cherries and serve cold.

**APPLE TURNOVER.** Make the pastry as for apple pie. Cut it into rounds, and put in each a tablespoonful of chopped apple with a sprinkling of sugar. Moisten the edges and double the pastry over.

Bake it in hot oven for 20 min.

**APPLE WATER.** Take 4 large cooking apples, 2 quarts of cold water, the juice of a lemon, a strip of lemon peel, and enough sugar to sweeten. Cut the apples into rough pieces and boil them until soft with the lemon peel, water and sugar. Strain off, add the lemon juice, and serve cold. This is a good drink in hot weather.

**APPLIQUÉ NEEDLEWORK.** This French word is used for a form of decorative trimming in which one kind of material is "applied" upon another to form a pattern. Thus lace is often appliquéd on washing satins and crêpes for blouses or underwear, and scraps of coloured silks, satins, velvets, linens or cretonnes can be utilised for making gay patterns on cushions, bags, curtains and table sets. Motifs, ready made for appliqué, can be purchased in lace and in such diverse materials as tinselled braid and brushed wool (the latter in white 'animal' shapes for applying to nursery coverlets), but more originality can be displayed by cutting out designs suitable to the work in hand.

*Appliqué Needlework: Stitches used in the work. 1 and 4, buttonhole; 2, stem stitch; 3, satin stitch. 5, Bag trimmed with appliqué work. 6, Cushion decorated with geometrical patterns appliquéd with buttonhole stitch in coarse silk.*

Lace, for instance, particularly lends itself to good effects when a needlerun kind is chosen with a large flower design, which can be cut out and sewn or embroidered on to the garment, smaller pieces of the lace design being used to fill out the pattern as required. Special lace motifs can be made for household linens, but a brighter note in decoration is the coloured border to white linen, wide enough to take motifs designed each from a different fruit, apple, pear, cherries, grapes, etc. These can either be drawn on the coloured linen selected, or transfers can be obtained. Flower designs can be applied in the same way if preferred. Luncheon sets and afternoon tea cloths are most successful with this appliqué, the colours of which should harmonise with the china and table decoration in use.

A simple form of appliqué is shown in the bag illustrated in Fig. 5. Such designs can be used for cushions, blotters, sachets, etc. Buttonhole stitch, Figs. 1 and 4, and satin stitch, Fig. 3, are the two simple stitches employed for appliqué, and the design should first be neatly tacked on to the article in the correct position. Where possible edges should be turned in, especially for linens which will have to be frequently laundered. Details too small for appliqué, such as stalks of flowers or tendrils of vines, can be embroidered, using stem stitch, Fig. 2.

The simpler the design the more effective the work. Conventional or geometrical patterns are particularly good for colour notes on cushions or curtains. The stitch employed for the appliqué of the angular design in coloured satins on the cushion illustrated in Fig. 6 is buttonhole stitch in coarse silk. *See Embroidery; Lace.*

**APRICOT.** A heavy, clay soil suits many fine plums, but the apricot requires a fertile, mellow and friable loam, with sand or chalk not far from the surface. If the soil is stiff it can be lightened and sweetened by breaking up, and adding lime rubbish and gritty matter. Do not overdo the use of yard manure, which is rich in nitrogen.

*Apricot trained against a sunny wall, and protected at the top by a glass frost-shelter.*

The following is a good annual dressing: if no yard manure is used, an addition of one part of sulphate of ammonia may be made: 4 parts, by weight, superphosphates of lime; 3 parts sulphate of lime; 2 parts sulphate of potash;  $\frac{1}{2}$  part sulphate of iron. The mixture is spread round the trees at the rate of  $\frac{1}{4}$  lb. per square yard. Mulching with yard manure might be practised in early spring. Every third year a

dressing of ground lime or slaked lime at the rate of 1 lb. per sq. yd. might be given.

Both for size and flavour of fruit no variety of apricot equals Moor Park, but there are other good kinds, as the following list shows:

**BREDA.**—Very old variety, fruit small, but of good flavour, ripe in August on a wall, but somewhat later in the open. About the best variety for growing as a standard.

**HEMSKIRK.**—Large fruit, ripe about mid-August, resembles Moor Park, and must have a wall.

**LARGE EARLY.**—Large fruit, ripe early in August.

**MOOR PARK.**—Large fruit, very rich in flavour. Ripe at the end of August. Liable to loss of branches by gumming.

**POWELL'S LATE.**—Large fruit, paler than Moor Park, ripe in September.

The apricot is trained with main fruiting branches spaced a foot or more apart over the face of the wall, diagonally, in the familiar fan shape. It is best to renew the fruiting wood every few years by taking up shoots from wood-buds at the base, and turning them into fruited by summer pruning. Apricots are generally propagated by budding them in early summer on Mussel or St. Julien Plum stocks, the former being used for Moor Park and other choice varieties, while the latter is employed for standards.

**APRICOT BATTER.** Take one small tin of apricots, a pinch of salt, 3 oz. of castor sugar,  $\frac{1}{2}$  lb. of flour, 2 yolks and 2 whites of eggs,  $\frac{1}{2}$  pint of milk and water, 2 oz. of dripping, and one gill of apricot syrup. Mix the flour and salt together, and put through a wire sieve. Then make a well in the centre of the flour and place in the yolks of the eggs, gradually mixing the flour into them. Gradually add the milk and water, and as it is added more flour must be mixed in. An even consistency about the thickness of custard must be maintained all the time the batter is being mixed. When well mixed, beat it until the surface is covered with bubbles.

Strain the syrup from the apricots and lightly stir one gill of this into the batter, and put aside for an hour. Cut the apricots into quarters; use only about half of them, as too many would make the batter heavy. When ready to cook the batter add the sugar and apricots and lightly fold in the whisked whites of egg. Melt the dripping in a pie-dish, and when hot pour the batter into it. Bake in a moderately hot oven for about forty-five minutes. Place carefully on to a hot dish, cut into six, and serve at once. This is sufficient for six persons.

**APRICOT CREAM.** Sieve enough tinned or stewed apricots to make  $\frac{1}{2}$  pint. Dissolve without boiling 1 oz. of gelatine in 1 gill of water, or in syrup from the apricots. Mix with 3 oz. of castor sugar and the strained juice of half a lemon, and whip  $\frac{1}{2}$  a pint of cream until it will nearly, but not quite, hang on the whisk. Having strained the gelatine into the fruit, mix and lightly stir in the whipped cream. Pour the mixture

into a mould that has been rinsed with cold water and leave it till it is set. Dip the mould into warm water and turn the whole on to a dish. This is sufficient for 4 or 5 persons.

**APRICOT EGGS.** A simple sweet for children's parties is made from apricots without any cooking. Cut some plain cake into large rounds. In the centre of each place the half of an apricot to look like the yolk of an egg. Surround the yolk with a thick layer of whipped cream flattened till perfectly smooth. The result will resemble poached eggs on toast.

**APRICOT GÂTEAU.** Take one small tin of apricots in syrup, 2 eggs, 1 pint milk, 4 small sponge cakes, and 1 dessertspoonful of sugar, with a little vanilla flavouring and cochineal. Grease a border mould with margarine or butter. Heat the milk in a saucepan with the sugar and add it to the beaten eggs, crumble the sponge cakes and mix with the eggs and milk, and finally add vanilla for flavouring, together with a few drops of cochineal, sufficient to make the custard look deep yellow in colour.

*Apricot Gâteau. Sweet made with sponge cakes, apricots and egg custard.*

This mixture should be poured into the mould and covered with a greased paper, the mould being then put into a saucepan of boiling water, on an inverted saucer, the water reaching only half-way up the side of the mould. It should not boil, but simmer, otherwise the custard will curdle. Steam until it sets, which will be in from 30 to 40 minutes. When cooked, turn it carefully on to a dish, and leave until cold. The apricots should be arranged round the top of the gâteau, the cut side being placed downwards, and the apricot syrup poured all round. The custard may be baked instead of steamed. This is sufficient for 4 or 5 persons.

**APRICOT JAM.** The ingredients are 2 lb. dried apricots, 6 pints cold water, 6 lb. lump sugar, and 2 oz. almonds. Thoroughly wash the apricots in two or three warm waters and cut into quarters. Place in a basin, cover with the water and soak for 72 hours. Put the whole into a preserving pan with the sugar, and boil the jam for about one hour. Blanch the almonds and split them in half. Add them to the jam about ten minutes before it has finished cooking.

To make jam of apricot pulp, which can be bought ready for this purpose in large tins, take 6 lb. of fruit and 4 to 6 lb. of sugar, 6 lb. if the jam is to be kept. Boil all together until a little sets when put on a cold plate.

Mix in 2 oz. of blanched almonds when it is done.

**APRICOT JELLY.** Add the grated rind and strained juice of a lemon to 1½ pints of apricot pulp, or 1 large tin of apricots pulped and put through a fine sieve. Shell and shred four sweet almonds and add them. Dissolve ¾ oz. of gelatine in a gill of water, taking care that it does not boil, and strain it into the fruit, etc. Mix all thoroughly in a basin, and occasionally stir until it begins to set, then pour into a wet mould. Serve with whipped cream.

**APRICOT MACAROON.** Take a small tin of apricots, half a dozen macaroon biscuits, a quarter of a teaspoonful of castor sugar, a little vanilla flavouring, and one gill cream. Place the biscuits in a dish, soak them with the apricot syrup and then place an apricot on each macaroon. Add to the cream the vanilla and sugar, and then whisk it lightly until it thickens, taking care not to overwhisk it, or it will curdle; it should be poured round each macaroon and on the top of each apricot, placing a crystallised violet and angelica strip for purposes of decoration.

#### APRICOT PUDDING.

Sieve together 4 oz. of flour and half a teaspoonful of bicarbonate of soda. Beat 4 oz. each of butter and Demerara sugar till the whole is as soft as whipped cream. Beat 2 eggs till frothy, then work them gradually into the creamed mixture. Stir in 2 tablespoonfuls of apricot jam and 2 tablespoonfuls of milk. Mix well and quickly, turn into a thickly greased mould or pudding basin; twist a piece of greased paper over the top and steam for 2 hours. This will be found sufficient for 6 persons.

**APRICOT SAUCE.** This useful sweet sauce can be made with jam or sieved pulp. Put 1 large tablespoonful of the jam or pulp into a saucepan with ½ pint of water, and then heat until it boils. Mix 1 tablespoonful of cornflour smoothly with 2 tablespoonfuls of cold water. Stir this into the boiling jam or pulp, and stir and boil gently for 5 minutes. Add 1 tablespoonful of cooking sherry or lemon juice and then strain. Sufficient for 4 persons.

**APRICOT TART.** An open apricot tart, served either with custard or cream, may be made by lining a greased dish with short-crust pastry, and covering this with apricots and a little of the syrup; one tin of 13 oz. will be ample for a large tart. Sprinkle the whole with castor sugar and bake in a fairly quick oven till the pastry is a light brown. This tart is sufficient for 6 to 7 persons. A closed apricot tart is made in the same way, except that enough syrup to half fill the dish is poured over the fruit, and a covering of pastry added.

**APRON.** Domestic servants require a stock of aprons. Plain white linen is used for nurses, for cooking and general morning wear, and fancy lawn or muslin

for parlourmaids, often lace-trimmed or embroidered, for afternoon duty. These last-named aprons may be in a coffee shade if brown or green uniforms are worn. *See Overall.*

**Aqua Fortis.** *See Nitric Acid.*

### AQUARIUMS FOR THE HOME

#### How to Construct and Stock Them

*Related articles under Fern; Gold Fish; Plumbing; Slate, etc.*

The bowl of goldfish is, of course, the simplest type of aquarium, though it may not be usually thought of in that light. It is a charming, colourful thing, especially near a window, a relief piece to the rest of the furniture, and an amusing diversion for the children, but for the fish inside it, if they could make their wishes known, it is a veritable torment.

The reason is that the ordinary glass bowl in general use excludes air, it admits far too much light, and its all-round transparency is harmful to the health of the fishes.

*Aquarium. Slate and plate-glass tank.*

The best type of aquarium—which does not at all mean the most expensive—is that which is as near to natural conditions as possible. In a pond, for example, the light only enters from above, and there is plenty of air for its animal, or plant, life. True, one cannot in a pond study the movements and habits of its inhabitants as well as one can in the more artificially constructed, portable type of aquarium. But the principle of pond, river, or lake must be the guide, and in constructing an aquarium many advantages that nature “in the raw” frequently fails to provide, can be embodied. Unlike nature, sanctuary is not given to fish that prey on other fish. Plants can be chosen, especially those which are valuable as oxygenators, and the occupants of the aquarium can be looked after in many other ways which nature quite ruthlessly leaves to chance.

**Window Tanks.** Choice of site is very important. A north window will avoid too much sunlight entering to irritate the fish, or plants, or to cause harmful vegetation to flourish. If placed on the window-ledge, it will be built to suit the site. It can be made of suitable upright dimensions, if preferred, especially for inside the room, so that it will be in keeping with the rest of the furniture; Aquariums can, of course, be bought of any shape and size, and at all prices. If one is to be made to be placed outside the window, a small supply

*(Continued in page 53)*

# APRIL

## What to do in the Garden

### Flowers

Sow in the open:  
Hardy annuals, e.g.  
alyssum; Californian  
poppy; calliopsis;  
chrysanthemum, an-  
nual; clarkia; flax or  
linum; godetia; lupin;  
nasturtium; nemophila;  
poppy; sweet pea;  
sweet sultan

Plant border chrysan-  
themum, viola, pentste-  
mon, old stored dahlia  
roots. Layer violet run-  
ners for fresh supply

Plant out herbaceous  
perennials from glass

Plant gladiolus bulbs  
for autumn flowering

Move seedlings from  
glass to cold frames

Re pot azaleas,  
camellias, heaths, and

other hard wooded plants after flowering in greenhouse required for climbing purposes

Roll and mow lawn frequently, and reno-  
vate bare patches with  
seed to match the turf

### Fruit

Graft apples and give  
a spraying of Bordeaux  
mixture to fruit trees  
before blossom opens

Thin early grapes and  
pinch off tips of shoots,  
leaving one leaf above

Plant out straw-  
berries

Look over gooseberry  
bushes for caterpillars

Re-pot seedling  
melons, and pinch off  
the shoots of those not

### Vegetables

Plant late potatoes

Plant out lettuces  
and onions from  
frames

Put in last sowings of  
onions and parsnips

Sow early beetroot;  
carrots; salsify; scor-  
zonera; sweet and  
pot-herbs; also bore-  
cole; broccoli; Brussels  
sprouts; cauliflowers;  
savoy for transplanting  
at midsummer; dwarf  
French beans to-  
wards the end of the  
month; and spinach,  
keeping on sowing at  
intervals of three  
weeks.

## Food in Season

### Fish

Bream; brill; dory;  
flounder; haddock;  
halibut; mullet; sal-  
mon; shad; skate;  
sole; turbot; trout;  
whitebait; whiting

### Shellfish

Crab; crayfish; lob-  
ster; oyster; prawn;  
scallop; shrimp

### Meat

Beef; lamb; mutton;  
pork; veal

### Poultry & Game

Chicken; duckling;  
fowl; gosling; pigeon;  
guinea fowl; ortolan;  
ptarmigan; rabbit

### Vegetables

Watercress; lettuce;  
tomato; radish; aspara-

gus; broccoli; cabbage;  
cauliflower; early potato;  
seakale; spinach; rhu-  
barb; forced French  
beans; Jerusalem arti-  
choke; beetroot; carrot;  
mushroom

### Fruit

Apple; banana;  
grape; grape - fruit;  
orange; pineapple;  
lemon; forced straw-  
berries.

## Notes for the Month

APL. 1.—Refreshment  
house licences require  
renewal

APL. 7.—Time limit  
for Fire Insurance expires

APL. 14.—Parish coun-  
cils required to hold  
annual meeting on or  
within seven days

APL. 19.—Primrose Day

APL. 23.—S. George's  
Day

Summer Time starts  
at 2 a.m. on day follow-  
ing third Sat. in April.

of slate and plateglass will be required, obtainable from any merchant who deals in these commodities. Avoid wood, for it is too susceptible to extreme heat or cold. The most convenient shape is, of course, rectangular.

Get slate 1 in. thick and 30 in. long by 16 in. wide for the bottom, and 16 in. by 13 in. for each end. At 1 in. from the extremity of each end, that is, across the broad part, cut a groove  $\frac{1}{2}$  in. deep and  $1\frac{1}{4}$  in. broad. First mark with an awl the exact place and dimensions of the groove, then get two straight-edged pieces of wood some inches longer than the breadth of the end; place them each side of the line which is to be cut, and nail them to the bench—they should be just wide enough apart to admit a tenon-saw—and with the saw cut the line to the required depth,  $\frac{1}{2}$  in.

Having sawn to the required depth, take an old chisel and a mallet, and cut out the slate which lies between the lines.

Before chiselling, be careful to put some heavy material between the slate and the bench, to prevent cracking. The grooves receive the ends of the bottom. Strike the chisel against the edge, and not on the top, to split the slate cleanly.

Now along both sides of the bottom, and across the narrow part of each end, cut, at a distance of  $\frac{3}{4}$  in. from the edge, grooves  $\frac{1}{2}$  in. deep and  $\frac{3}{8}$  in. broad. These grooves receive the plate-glass sides, which should be  $\frac{1}{4}$  in. thick. After this bore four holes,  $\frac{1}{4}$  in. in diameter, right through each end. Two of these to be  $1\frac{1}{2}$  in. from the edge and  $\frac{1}{4}$  in. below the groove which is to receive the end of the bottom, and two 1 in. from the top and just within the grooves cut for the glass.

The holes are for bolts to run across from end to end to hold the sides together. Bore them with an ordinary brace and a bit used for metal. Brass bolts are best. Before putting the ends, plate-glass, and bolts into position and screwing the nuts home, place a little cement in all the grooves, and press the glass gently downward to force it firmly into place. Carefully finish filling up the grooves with cement, and the aquarium is ready.

The cement can be red and white lead mixed into a stiff paste; or one pint each of plaster of Paris, litharge, and fine white sand, and one-third pint of finely powdered resin; or Portland cement; or, finally, four parts pitch and one part gutta-percha, applied when warm.

A strong stand under the tank will be required for support, and if the window is an upper one, the tank must be secured by iron brackets let into the wall.

The frame, back, and sides must be glazed with tinted cathedral glass. The near side only should be clear glass.

**Aeration Methods.** In an aerated tank a greater variety of species of fish, etc., can be supported than in a still one, and various electrical appliances are available. But simpler methods are quite practicable; either fix up a regular supply of water to drip into the tank from above, from a canister, say, regularly refilled—or run a pipe to the right spot—and provide for the overflow to drain away. In most cases, however, the

movements of the fish and the oxygenating powers of the plants will provide sufficient aeration; many varieties of life thrive in perfectly still water.

To furnish the tank, get a supply of small shingle to make a flooring of about 3 inches deep and, over this, place a 2-inch layer of sand. Silver sand is best for enabling dirt or discarded food to be detected and removed, and the shingle offers a secure anchorage for plants. You may fix up a little retreat for the fishes by placing a small piece of rock over two stones a few inches apart.

In filling the tank do not use water from the main, especially in chalky districts. Take water from a stream or pond, or rain water. Let it settle for a day or two before filling.

**Choosing Aquatic Plants.** An enormous variety of plants is sold by the aquarium dealer, or nurseryman. Choose plants for their value as oxygenators. The so-called Eel Grass, *Vallisneria spiralis*, is one such, and a most graceful plant into the bargain. *Vallisneria* has long ribbon-like leaves, and coils like spirals. The allied eel grass, *Sagittaria nattans*, with its broader leaves, also gives off a large amount of oxygen. *Myriophyllum*, the Milfoil, a feathery plant of many varieties, is worth getting for fish that spawn on plants. The water thyme, *Elodea*, grows very rapidly, is a splendid oxygenator, and is not spoiled if nibbled by fish or water-snails. There are also the fanwort *Cabomba*, and the swamp plant, *Ludwigia palustris*, the water moss *Fontinalis*, which grows in floating platforms, and many others.

In planting, use small pots filled with heavy loam and a little clay, and conceal them under the sand or gravel before filling with water.

**Stocking with Fish.** Give the plants a few weeks in which to become thoroughly acclimatised before introducing the more active inmates. Under-stocking is better than overstocking. Let the guiding principle be “an inch of fish to a gallon of water,” and don’t put in any “fighters.”

Small carp, goldfish, golden orfe, tench, rudd and bitterling are “still-water” fish that thrive well together.

Rather avoid putting in pond snails. They damage the plants and devour fish eggs.

As to food, the most nourishing for most fish is small earthworms or raw meat, finely minced, and heart or liver. If you have any duckweed plants in your aquarium, you will find that they are a favourite food with carp and goldfish, which also accept spaghetti and macaroni. For small fishes the gnat larvae, and water fleas, *Daphnia*, are plentiful in all ponds during the summer months. *Daphnia*, in bulk, are especially good in another way, for they clear the water of those minute pests called algae which darken the water, and turn it green, and often obscure the glass.

**Fish Ailments.** The chief of these is fish fungus

(Saprolegnia), a white film or scum on the fins and sides of the fish. In its early stages this highly contagious disease may be cured by introducing a salt solution—one tablespoonful of salt to a gallon of water.

If any fish rolls or moves about the surface of the water with difficulty, its swim bladder is probably affected. In that case, segregate it in a shallow pan of water, kept at a temperature slightly above the normal.

Parasites are the bane of many fish. Salt and pepper disease (Ichthyophthirius), caused by a minute protozoan parasite, results in an outbreak of white specks on the sides and gill covers. For this not uncommon and very contagious disease the best remedy is 5 drops of a 2 per cent. solution of mercurochrome to a gallon of water. Place the fish in this healing solution every day for a week for at least four hours at a time.

Among other enemies and intruders are beetles and water scorpions. The larvae of the beetle, Dytiscus, will attack fish several inches in length. The fish-louse, Argulus, is less easily detected. Other foes are the leech, and the fresh-water anemone, Hydra, which latter also robs the fish of their food. Suspect the presence of parasites when a fish rubs itself impatiently against rock or the floor bottom, and relieve it at once. Experience will show how to detect and deal with these pests.

**Some Golden Rules.** (1) If a plant becomes uprooted, it can be put back into position with the aid of a long flat piece of wood about half an inch by 12 inches in length, having a little cleft cut at one end.

(2) Remove and trim plants by tying two sticks to a pair of scissors, one to each handle.

(3) If more sand or gravel is needed, do not empty the tank—it is disturbing to the inmates and causes changes of temperature. The new sand or gravel can be poured into the tank by means of a long tube.

(4) Keep the glass clean by means of a wash-leather, rubber, or small brush mounted on a long handle.

(5) Never introduce tap water in bulk. The sudden change of temperature may give rise to that dreaded fungus disease, Saprolegnia. When introducing new fish, see that the temperatures of the aquarium and of the travelling water are the same. A cold-water aquarium should not be lower than 45° F. in winter, or above 65° F. in summer.

(6) Remove any fish that is ailing, and so avoid infection of its tank-mates.

(7) Remove any stale food, or dregs, with a small pair of pincers, treated as in (2) above.

(8) Remove creeping algae with a brush, or stand the aquarium for a few days in complete darkness.

(9) Always keep a close watch for parasites. For the success of your home-aquarium, a clean tank is the first and final necessity.

If in doubt refer to an aquarium dealer, a nurseryman, or the keeper of a public aquarium. They are usually ready to help. (See also page 55)

**ARABIS.** Hardy perennial of low-spreading habit,

suited either spring beds or the rockery, and thriving in almost any soil. The two chief species are the Caucasian albida and the Swiss alpina; both have white flowers and are at their best in early spring. They can be raised from seed sown in late spring, the seedlings being transplanted in autumn. The double Arabis albida produces large spikes of pure white double flowers. Lucida variegata has light green leaves edged with yellow. Arabis Billardierii bears pink blooms. Pron. Arrer-bis.

*Arabis. Profusely flowering clump of this low-growing rock plant.*

(See also page 55)

**ARBOR VITAE.** Two kinds of Arbor Vitae are commonly grown—the Chinese, *Thuja orientalis*, and the Western or American, *Thuja occidentalis*. They belong to the conifers, and are well adapted for small gardens, where they may be used in shrubberies, on lawns, and even as hedges.

*Arbor Vitae. Spray of a golden-leaved variety.*

(Continued in page 56)

Left, *Vallisneria spiralis*, easily recognised for its ribbon-like, spiral coils. A splendid oxygenator. Centre, *Cabomba fanwort*, an exotic-looking plant, growing in successive clusters up each stem. Right, *Elodea Densa*, or water thyme, a graceful and vigorous plant, plentiful in most ponds

Left, a Perch chasing a Minnow. Above, the Common Sunfish. These fish are voracious cannibals fit only for their own company

#### COLD-WATER FISH AND PLANTS: SUITABLE FOR A HOME AQUARIUM

This picture will give the reader a good idea of an aquarium in running order, but it has to be remembered that though the fish are represented relatively to scale, the actual size of the tank would have to be much bigger. The three fish on the left (top to bottom) are a Mirror Carp, Golden Orfe, and a scaleless Shubunkin Goldfish. Centre, a young scaleless Fringetail Goldfish above a Golden Rudd. Right (top to bottom), a Common Goldfish, a Minnow, and a Prussian Carp. The plants are *Vallisneria* and *Sagittaria*, *Ludwigia*, *Elodea*, etc.

From a painting by Felix Gandon, based on material supplied by Mr. A. E. Hodge, Editor of "The Aquarist and Pondkeeper."

The American Arbor Vitae has many varieties, including Ellwangeriana. The most popular of the other forms is dolabrata, with drooping branches, and leaves silvery beneath. There is a dwarf form, nana. Gigantea is of pyramidal habit.

All these thrive in any good soil that is fairly substantial and moist. Light, thin, dry soils do not suit them. Planting should be done in April or September and October. Pron. Ar'-bor vi'-tee.

**ARBUTUS.** The principal variety of arbutus is the Unedo, or common strawberry tree, which has many lance-shaped, bright green leaves, and drooping clusters of white flowers borne in September, and followed by strawberry-like fruits. There are several varieties, such as coccinea rubra and croomei. Andrachne has smooth, oblong leaves and greenish white flowers, produced in spring. Most varieties attain a height of 6-10 feet.

*Arbutus. Leaves and fruit of the common strawberry tree.*

They thrive best in a sandy loam or peat, and are suitable for the shrubbery. Propagation is by seeds for species, and by layers or grafts for varieties. Planting maybe done in Feb. Pron. Ar-bew'-tus.

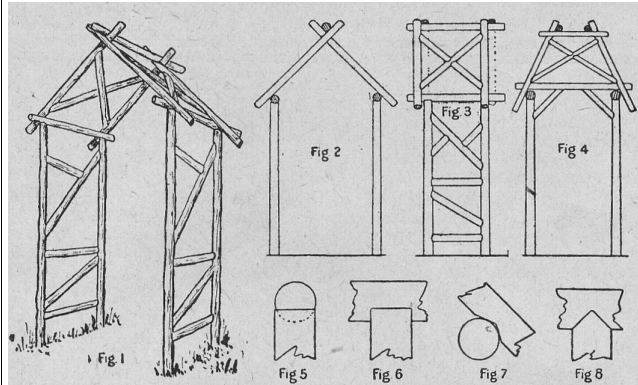

#### ARCHES AS A FEATURE OF THE GARDEN

##### Decorative Fixtures in Rustic and Plain Wood

Further information is given under Pergola; Rustic Work; Summer House, etc.

Arches for use in gardens are described as rustic when they are made of poles and branches in a natural state, with or without the bark. They are easily made if suitable material is available. Larch poles, about 3 in. in diameter, are best for uprights and framing; the smaller branches of oak, about 2 in. or so in diameter, provide good material for filling in spaces. The joints should be as simple as possible, and strongly nailed with stout wire nails. An effective design is given with the necessary joints in detail.

Timber with the bark on gives the ideal rustic appearance, but it is more difficult to make and does not last as long as timber which has had the bark removed. It is advisable in the latter case to varnish the wood in order to preserve it. That portion of the arch which is placed in the ground should be coated with or soaked in creosote, or given two or more coats of tar.

*Arch. Fig. 1. Simple rustic arch made of larch wood. Figs. 2 and 3. End and side elevations of the simple arch. Fig. 4. Side view of a larger rustic arch. Figs. 5-8. Various forms of notched joints used in making arches.*

**Rustic Arches.** An arch made from larch is shown in Fig. 1. The end elevation will be as Fig. 2, and the side elevation as Fig. 3. To build this arch, the four posts are first planted in the ground and cut off to the required level. The two horizontals are then fixed to the top of the posts, allowing them to overhang the latter some six inches. The four rafters come next. Nail them together where they cross at the top ends, and then lay in the top horizontal, and nail each of the rafters to this. The various other horizontal and diagonal pieces can next be fitted and fixed by side nailing.

Another style of arch is shown in Fig. 4, the different arrangement of the top of which gives it a more important appearance, especially when covered with climbing roses or creepers. Such an arch as this should be braced at the corners as shown.

There are certain rules of construction which should be carried out. The best way to fit a horizontal piece to an upright one is shown in Figs. 5 and 6, cutting a piece out of the underside of the former so that it will fit on to the flat top of the latter; this will give firmness and strength, while no depression will be formed in which water can lie. In all cases where a horizontal piece comes to an upright, the former should be notched to fit on to the latter; but do not make the angle of the notch too acute, or there will be a risk of splitting the wood in forcing it in. This will also apply to the fitting of the diagonal pieces.

In fixing the rafters, do not cut the horizontal piece to make a flat bed for them, but cut away the underside of the rafter slightly, which will answer the purpose better; it is quite as easily done, and makes not the slightest lodging-place for water. The proper method is shown in Fig. 7.

The mitre joint shown in Fig. 8 is a very good one, provided that the timber is nearly all of one size, and that the joint is always on the underside as shown. It has, however, the drawback of weakening the horizontal piece.

**Timber and Trellis Arch.** A garden arch of stronger build is shown in Fig. 9. It is designed for the best timber. The wood may be oak, beech, American whitewood, or red deal. Oak will be finished by varnishing; the other woods will be well painted, a fresh coat being given each year. The height must be in proportion to the width, and the width is usually determined by the path which the arch spans.

Here we assume a width of 3 ft. 6 in. over the posts. The height from the ground to top of the crossbar (B) is 6 ft. 6 in., the total height to apex of arch being 7 ft. If the arch is wider, a little more may be allowed in height, to give a pleasing proportion. The depth of arch over the posts is shown as 1 ft. 9 in. In speaking of height, it is, of course, the height above the ground that is referred to. For an arch of this size, the posts have to enter the ground from 18 in. to 24 in.

*Arch. Fig. 9. Heavier type of arch constructed of quartered timber and trellis work. Fig. 10. Side elevation. Figs. 11-13. Diagrams and working scale in making the arch. See text for an explanation of the lettering.*

From Fig. 9 and the section shown at Fig. 13 it will be seen that rebated posts are used. The upright laths (E) are nailed to the top and bottom rails (C), the short horizontal laths (F) lying against the upright ones and resting in the rebate. By this method the laths are not nailed over the post, and a better appearance is secured.

	Long ft. in.	Wide in.	Thick in.
Four posts (A)	8 6	2¼	2
Two top bars (B)	3 2	4	1½
Four rails (C)	1 9	2	1½
Four shaped braces (D)	1 6	4½	2
Six laths (E)	5 3	1¼	¾
Fourteen cross laths (F)	1 6	1¼	¾
Six cross pieces (G)	2 6	2	1½
Twelve top laths (H)	3 0	1¼	¾

The posts (A) are of 2½ in. by 2 in. material, and a

length of from 8 ft. to 8 ft. 6 in. should be allowed. Framing timber 2½ in. by 2 in. may be purchased with a rebate as indicated at Fig. 13. The posts are mortised for the rails (C) to enter, and should have a tenon cut to go right through the top crossbar (B). The lower ends must be well tarred for entering the ground.

The top crossbars (B) are 4 in. wide by 1½ in. thick, lengths of 3 ft. 2 in. being required. The ends should be chamfered off as indicated, and the bars are mortised for the post tenons, which should pass right through and be wedged. They should also be mortised on the underside for short tenons on the shaped braces (D).

The section at Fig. 13 shows a rail (C) 2 in. by 1½ in. which will be tenoned (and pinned) to the post so that it is flush at the outside. The upright laths (Fig. 13) are nailed to the rails from inside. The rails (C) may be made 2 in. thick, so that they are flush with the posts on both sides. In this case they must be mortised for the upright laths to enter. The shaped braces (D) may be straight if preferred, but the shaped ones shown are an improvement. The shape may be taken from a width of about 4½ in. The thickness may be the same as the posts (2 in.) or may be reduced to 1½ in. It is well to provide a short tenon for entering the top crossbar (B), and the braces may be dowelled or simply nailed to the posts.

The laths E, F and H are 1¼ in. wide and may be ¼ in. or ⅜ in. thick. For the sake of appearance as well as for durability ⅜ in. laths are recommended. For an arch of this size, three upright laths may be fixed at each side. The horizontal ones may be spaced so as to give square openings, in which case twelve a side will be necessary, but probably the 6 in. by 3 in. openings indicated in the illustration will be preferred. For the top of the arch, allow six laths on either side. In regard to the top cross-pieces, the apex of the arch is shown as a very wide angle, this being appropriate to the type of design illustrated.

The wood for the top cross-pieces (G) may be 1½ in. square or 2 in. by 1½ in. (set 2 in. deep by 1½ in. wide), and to allow for the overhang and the halved centre joint, lengths of 2 ft. 6 in. should be provided. The outer ends are chamfered, and the pieces should be cut as shown to fit close down on the top bars (B). At the centre the pieces are lap-jointed (as Fig. 12) and pinned, care being taken to get all three pairs exactly alike. These top pieces are nailed to the crossbars and the laths nailed on above.

All joints should be painted before putting together, and every care taken otherwise to protect the arch from damage caused by rain. It will be found easier to fit up the two sides complete and fix these in the ground before putting on the top. The earth must be rammed down around the tarred post ends so as to avoid the risk of any sinking. A plumb-line can be used to keep the posts vertical whilst ramming, and if a couple of laths are temporarily nailed across the top the two sides can be kept in line. The upper part is easily completed after the sides are erected.

The sizes of the wood required are shown in the above list, which is given for guidance only. The lengths allow for paring, but widths and thicknesses are net.

## ARCHITECTURE: THE MEDIUM-SIZE HOUSE

### Professional Advice on Choice of Site and Construction of Attractive and Economic Dwellings

The information here is supplied by two well-known experts of wide experience in domestic architecture and relates to the scale plans and sketches in our colour plates, pages 63-64. For fuller details see numerous separate entries throughout the Encyclopedia, e.g. Attic; Bungalow; Cesspool; Concrete; House; Roof; Septic Tank; Water Supply; etc.

Before selecting a site, the client will do well to consult his architect as to cost and conditions of purchase, aspect, boundaries, easements, road charge liability, artificial lighting, water supply, drainage, subsoil, etc. The following points might be borne in mind:—

A good and uninterrupted view will provide an amount of restfulness and satisfaction which cannot be over-estimated.

The entrance roadway is best on the north side of the site. The best rooms can then be placed to the south and thereby enjoy the advantage of a sunny aspect and the best available distant view.

A site having a steep slope or gradient is costly to deal with, because the foundations will require to be much deeper than normal if subsequent subsidence is to be guarded against. Avoid a site containing live springs.

Chalk or stone subsoils are the best, but stone rubble, firm gravel and the like are quite good, and less costly to build upon. Rock is the best, but the most expensive to excavate. All the latter subsoils will yield good material at little cost for concrete, paths, etc. Sandy subsoils, unless free from running water and of very stiff formation, should be avoided.

Clay subsoil is generally considered to be damp, and not good for those suffering from rheumatism, asthma, and similar complaints. This is, however, frequently exaggerated. If building on clay the foundations should be not less than 3 ft. below the surface of the ground to avoid unequal settlement of the subsoil during very hot weather.

Tipped or made soil should not be built upon unless it has been standing in its present position for at least 15 years. In any case, it is advisable that the house foundations should rest upon the natural subsoil. This involves additional excavation.

### How the Plans are Worked Out

The site settled, the client conveys to his architect in general terms the accommodation desired and the amount of money to be spent. The architect proceeds to scheme his plans in a manner calculated to give the best arrangement of the rooms in relation to each other. He

will also give consideration to the aspect of the site, and any natural features it may possess, such as distant or near view points of interest, trees, etc. In the planning of the house he will, in addition, have clearly in mind the lay-out of the garden, so as to provide an appropriate setting for the house.

The three sets of plans in pages 63-66 illustrating this article are typical of the form in which the architect conveys to the builder what is desired, and upon which, in conjunction with the written specification, the builder bases his estimate. The first set deals with a medium sized house having four bedrooms, and the second set with a cottage dwelling of the better type, in which the general principles laid down in the first part of the article are worked out in detail.

The ground floor plan of the medium priced house has first to be considered.

The architect first roughly sketches to scale (generally  $\frac{1}{8}$  in. to 1 ft.) the entrance hall and main rooms with their fireplaces, doors, windows, etc., and then fits into their appropriate places the stairs and the various smaller apartments. In the same manner the rooms on the upper floor are dealt with.

These rough sketch plans in turn are superseded by plans worked out to scale in the more exact and careful manner shown in the illustrations. Here the front entrance porch is recessed to give shelter to visitors when waiting at the front door. The hall is so arranged that easy access is gained to the stairs, living-room, dining-room, and kitchen without an unduly long corridor. A small cupboard for hats and coats is provided under the stairs. If space and cost permit, a basin and w.c. in addition will be of great convenience.

The living-room, measuring 18 ft. by 12 ft., is planned with an outlook to the road on the north, a larger window to trap the sun on the S.W. side, and a pair of glazed doors to the S.E. giving access to the pergola and garden. The fireplace is shown in recess with a beam over the recess—denoted by dotted lines—the ceiling of which is lower by 12 in. than that of the room. The fire is of the open-hearth type with glazed tiles around the fireplace and hearth, at the side of which a small window has been placed as a peep into the garden. A picture-rail fixed to the wall, low skirting and the sparing use of enriched plaster on the ceiling, a point for electric light (or gas) in the centre of the ceiling or wall bracket, and a plug point or two for a standard lamp or vacuum cleaner should be provided. The use of pale cream paint for the woodwork, cream distemper for the walls, and broken white distemper for the ceiling will produce a satisfying architectural expression.

### The Dining Room and Kitchen

The dining-room, measuring 16 ft. by 14 ft., is entered off the hall near to the kitchen in order to reduce this distance to a minimum. The fireplace has been arranged to back against the living-room fireplace, which makes for economy in cost of erection

and gives additional heat. Owing to the more occasional use of this room a gas or electric fire might be substituted for a coal fire. On each side of the fireplace cupboards are placed for china and glass. On the opposite wall an arched recess is provided for the sideboard. A large window gives an outlook over the garden to the S.E., and in addition small windows are placed in the east and west walls to trap the early and late sun. A picture-rail and low skirting, and the use of enriched plaster on the ceiling, an electric or gas fitting in the centre of the ceiling, together with paint and distemper as described for the living-room—of perhaps a darker shade appropriate to the use of the room—will make this a comfortable and pleasing room. A plug point for vacuum cleaner is desirable.

The kitchen, measuring 12 ft. by 10 ft., gains access off the end of the hall; and is lighted on the south side. This room, in conjunction with the scullery, should be very carefully planned with the object of reducing labour as far as possible. The fireplace is situated on the wall at the side of the window (opening to its full height) which will ensure its good lighting.

A cupboard for the storage of oddments and a separate store for dry goods are provided near the dresser.

The dresser is placed on the wall in close touch with the scullery, in which position it will be found to save a great many steps. It should be enclosed at the top where the china is kept. The lower portion can be arranged either with drawers or cupboards or left open with what is known as a potboard. If the potboard is not fitted to the dresser, shelves must be provided for this purpose in a convenient position. The architect, by giving careful consideration to this fitting, will save a great deal of work and labour, and produce an article of great convenience. A good modern type of cabinet might to advantage take the place of the dresser at about £7 to £12 extra cost. Rails will also be provided for the dish-covers, etc.

The floor might be made of tiles for cleanliness, or of wood blocks or ordinary boards— whichever is preferred—for comfort. The walls might be lined with tiles, or if this method is too expensive, painted or distempered. A drying line fixed to ceiling, raised and lowered with cords attached to pulleys, will be found useful in wet weather.

The larder (facing north) is entered off the scullery. Ample shelf room should be provided, including, if possible, at least one slate shelf. A ventilating brick should be fixed in the external wall near the floor and another near the ceiling. The window should have perforated wire fixed to a light frame, and be hinged on the inside to keep out the flies. The walls should be tiled or distempered, and the floor either tiled or cement finished. If space can be provided for a refrigerator so much the better.

#### The Scullery and its Fittings

The scullery should be in the closest touch with the kitchen, and in size about 70 to 80 square ft. It is lighted on the north side by a window about 3 ft. 3 in. off the floor. The sink should be placed near the

window, and be of glazed stoneware about 8 in. deep, 16 in. wide, and 24 in. to 27 in. long, with a grooved, hardwood draining board at each side if possible. A deal plate-rack will be fixed in a convenient position on the wall over the draining board, and glazed tiles should be fixed to the wall around sink and draining boards.

The copper, if of the coal-consuming type, should be fixed near a fireplace for the easy connexion of the flue. If a gas copper is installed, a flue is not so essential. In the illustration the gas copper is shown under the draining board, which is made hinged to lift up for economy of space. The floor should be of tiles or cement, and, if cost will permit, the walls also should be tiled. As an alternative, plaster and painting, or even distemping direct to the bricks, is often resorted to. The woodwork for the whole of the kitchen quarters will be painted or stained.

Servants' w.c., coals, and trades entrance complete the ground floor. The two former apartments are conveniently planned near the scullery door, and entered off the back entrance lobby, the floors in all cases being of cement, and the walls distempered.

The ground floor is 8 ft. 6 in. high, and the staircase has 15 steps to the first floor landing.

#### Arranging the Upper Floor

Coming to the first floor, the stairs are of deal about 3 ft. 3 in. wide, the treads being 9½ in. or 10 in. wide, with a "rise" of about 7½ in. If an additional step can be introduced, the rise will be reduced to 7 in.

The bedrooms are entered off the landing, and are approximately alike in all particulars except size. Care must be exercised in their planning to permit of the convenient placing of the bed, dressing-table, wardrobe, etc. Cupboards convenient in size, arrangement, and position should be provided. Where practicable, a fireplace should be provided, but the type of fire to be fixed is not of such importance as in the sitting-rooms.

The floors generally will be boarded, and the walls and ceilings plastered and distempered pale tints. A picture-rail will be provided in each room about 7 ft. off the floor, and one window at least in each room should open to its full height. Where a bedroom is not provided with a fireplace, a ventilating brick should be placed in an external wall.

The bathroom should be placed as nearly as possible over the kitchen, thereby ensuring a ready supply of hot water and economy of service from the range. This room will be fitted with a porcelain enamelled bath fitted with taps of at least ¾-in. bore. The lavatory basin will be enamelled fireclay fixed on chromium brackets with chromium taps of easy cleaning pattern, and a towel-rail with hot-water circulation will be provided if cost permits. The walls should preferably be tiled or painted and the floor of deal or an impervious composition material. A ventilating brick should be fixed near the ceiling in an external wall. The w.c. should be separate from

the bathroom and fitted with a wash-down glazed stoneware pedestal w.c. with enamelled cistern as silent as practicable. A ventilating brick should be fixed in the external wall in addition to the window.

The elevations represent externally the four sides of the house as they will appear to the spectator looking directly at it when completed. It is in the elevations that the external architectural expression of the house will be imparted by the architect, who will so arrange and treat the doors, windows, chimney-stacks and roof lines that not only will they be well suited to their various practical uses, but they will be of good proportion and have a proper relation to each other.

The section is a form of elevation of the inside of the building. It is assumed to cut through the building in a vertical plane. It shows the depth of foundation, heights of the various rooms, together with certain features of construction and interior design.

The perspective sketch shows a general view of the house. The general lines of the garden are here shown, since the setting of the house will have an important bearing upon its effect.

### Preparing the Specification

Before reliable competitive estimates can be obtained, the architect must prepare a specification setting out in detailed form everything needed for the erection and completion of the house.

Good stone is the best material for external walls, and sound, well-burnt bricks are next in value. If exposed to weather, bricks known as facing bricks only should be used, but frequently cheaper bricks are available locally at a much less cost and are therefore resorted to. In such cases the external surfaces are generally covered with cement roughcast in various forms to withstand the weather. Where facing bricks are used for external walls it is usual to build them in two thicknesses with a cavity between. These are generally known as "hollow" walls.

The ground floors may be of ordinary deal floor boards, pine blocks, concrete with cement mortar finish or some form of impervious composition material. Ordinary deal floor boards on joists are, as a rule, cheaper than any other form, and are less tiring to walk upon. Pine blocks laid on cement concrete might be used to advantage in the hall, and are sometimes used in the kitchen. Cement concrete floors finished with cement mortar are suitable for the floors of scullery, larder, etc. Skirtings might be of the same material.

Air bricks for ventilation should be inserted in all external walls under wood floors. A damp-proof course of asphalt or slates in cement is essential through the full thickness of the outer walls about 6 in. above the ground.

Ordinary plastering remains the best material for finishing the internal surfaces of walls and ceilings.

Deal is the timber most generally used for windows, doors, skirtings, stairs, picture rails, etc. It should be of good quality and free from sap and loose or decayed knots. Similar timber is most generally used for floor joists, rafters, plates, lintels, etc., and should be selected

with equal care.

Tiles are generally preferred to slates for roofs. They need a steeper roof and are therefore rather more costly than the commonest Welsh slates; they look much warmer, however, and time improves their appearance. Thick Westmorland or Cornish slates are very beautiful in appearance, and vary considerably in shade. Their cost, however, is much in excess of ordinary tiles. Hand-made sand-faced tiles are the best. Machine-made and pressed tiles are not so durable, nor are they so beautiful. Asbestos slates are cheaper than any other form, but less beautiful. Previous to fixing tiles to the roof cover the slopes with boarding and felt; where both make the cost too high the boarding should be retained.

With regard to the decorations, where plaster is used in new work, coloured wallpapers should be avoided for a year or two, until the surfaces are thoroughly dry. Distemper is the best finish for all new plaster work, and the many shades in which it is now procurable make good decorations easy.

Exposed joinery work is usually either painted or stained. The former is generally preferred for lasting effect, but it is more costly. New work if painted should have at least four coats, and all knots in the wood should be treated with a solution known as knotting, or in due time they will deface the painted work. Enamel is more lasting than oil paint as a last coat, or two coats.

### Medium Size House Plans in Colour

The house illustrated in the colour plate, page 63, should under ordinary conditions of labour and materials, and providing the site is within fairly easy reach of a railway station, say within two miles, be built for about £1,400 to £1,500, which allows for good, sound, well-designed and executed work throughout.

Another medium-sized house providing four bedrooms and a very attractive modern layout for about £1,100 is illustrated in the colour plate, page 66. The plan is for a north or east aspect, and has been contrived within a simple shape. On the ground floor, a large lounge occupies half the plan. This feature is especially called for in the modern house as a room for daily use, replacing the old-fashioned drawing-room used for "special occasions." The hall staircase is broken up into easy flights for comfortable mounting. The kitchen is compact and designed as a room where a maid could live if necessary, although it is primarily a working kitchen for a maidless house. A particularly useful combined service or buttery-hatch and cupboard connects kitchen and dining-room. On the first floor the linen cup-board is almost directly over the kitchen boiler, ensuring quick circulation. The whole plan aims at simple design, easy domestic running, generous layout and economy.

The cost of a house can be reduced by using inferior materials, but economically this is unsound because of the increased cost of subsequent upkeep. Approximate estimates for a house are generally

prepared by means of measuring up its cubical contents. This is done as follows: Take the superficial area of the plans measuring to the outside face of the walls, then multiply the result by the height of the building measured from the top of the concrete foundations to half way up the roof. The price per foot cube for the two houses described will depend upon quality of materials specified, perhaps 1s. 2d. to 1s. 5d. per cubic ft.

### What a Building Contract should Contain

To get the actual cost, the specification should be carefully compiled and invitations extended to several reliable builders to give competitive tenders. Estimates having been received and the builder decided upon, a contract is entered into between the client and builder. This contract stipulates for the completion of the house within a prescribed time, in accordance with the drawings and specification, and to the complete satisfaction of the architect. The work is thereupon commenced. During the process of building, the architect issues to the builder certificates for payments on account, in accordance with the contract, which certificates are honoured by the client. The architect, together with his client, selects the fittings required.

A well-drawn contract should contain a clause that the builder shall not be entitled to be paid for any extras unless these have been ordered in writing by the architect or by the owner. A careful architect, if he is advising a client on this matter, will always make a stipulation with the builder that the extras ordered shall be supplied at an inclusive or contract price. If he does not, the builder is entitled to charge a "reasonable" price; and the builder's idea of what is "reasonable" may differ very widely from the idea of the building owner. Out of the neglect to observe this simple precaution of stipulating for a fixed price for extras when they are ordered arise much litigation and consequent cost.

Upon completion of the house the architect certifies to the builder for the balance of the amount of the contract not previously paid to him, less about 5 per cent, of the contract price, which amount is retained on behalf of the client for a period—usually about six months—during which time the builder is responsible for all defects arising in his work, and must rectify such defects to the architect's satisfaction before the balance is certified as due.

## ARCHITECTURE: THE SMALL HOUSE

Detailed Description of the Coloured Plans in page 65.

The plans and perspective sketch given in the colour plate, page 65, illustrate a small cottage dwelling designed for a family that do not require accommodation for a maid. It may be taken as a typical dwelling for any self-contained family.

The design being governed by strict economy without undue cramping, every foot of space is thrown into the rooms, instead of being wasted on passages and staircase. The main considerations were that both living-room and parlour should look on to the high

road, and that the living-room and scullery should also get the morning sun. The bathroom is placed downstairs, and the bath can be filled directly from the copper adjacent, and hot water obtained without the expense of any circulating system.

The larder, facing north, opens from the scullery, near the sink and back door, whilst outside, under cover, are the closet and coal house. The staircase rises between two walls, both for economy and to obviate dirt-collecting balusters, etc. Upstairs there are three bedrooms, each with large hanging closet, and on the miniature landing, below the window, is a long cupboard with shelves. The walls are 11 in. hollow—i.e. two half-brick walls with a cavity between, and whitewashed outside.

The problems which meet the designer here are different from those in a larger building, but certainly no less difficult. He is in most cases bound by the strict limits of economy, and in planning must always bear in mind the need for economy of housework. At the same time many good examples, both new and old, show that charm is the result of care and skill rather than money.

As regards the site, this will probably be a compromise between one's own desires and what actually can be obtained. The presence or otherwise of such services as water, gas, electric light, and drainage will greatly affect the price of the land, and, inversely, of the building. The question of sewage disposal will depend upon the nature and extent of the land, probably by a cesspool or septic system.

Considering internal accommodation and the disposition of rooms, the question of the preparation of food and the elimination of useless walking to and fro will be the main factors. The arrangement shown here—that of a small parlour, separate from the other rooms, with one large living-room with range and dresser—is probably the most generally suitable. The adjacent scullery in this case becomes the working centre of the house, and it may be used for cooking if required. A small gas-cooker may be provided if gas is available. Sink, larder, hot water, fuel, and copper are all concentrated here. If the bath is placed downstairs it must be in a separate room instead of in the scullery, otherwise all the ordinary work of the house must be interrupted every time a bath is taken.

The position of the larder is of importance, it should be near the back door, readily accessible to sink and range, and away from the heat of any flue. A north aspect is best.

The position of bath, sink, w.c.'s, etc., will mean a simple drainage scheme or the contrary. If these, in planning, can be arranged along one side or round one angle of the house, much piping will be saved. If the outside w.c. and fuel store can be approached under cover, especially the latter, it will be appreciated in bad weather.

In designing bedrooms, not only the position of beds should be considered in relation to doors and windows while in the plan stage, but also the possibility of

getting a dressing-table in a good light before a window.

Much room is often wasted by placing a house in the middle of the frontage. If it is on a high road, and the light and other services run along this, it must not be forgotten that the farther it is placed back, to avoid dust and noise, the greater the cost of connexions. Externally, the charm of the small building will be found to consist in simplicity and good proportion; to attempt absolute balance is usually unhappy in result.

Brick still remains the most generally satisfactory material for walling. If cost precludes good surface bricks, or the building is in a district, such as many parts of the Midlands, devoid of good brick earth, a good effect may be obtained by slightly raking out the joints and covering with two coats of limewhite and Russian tallow, or one of the many substitutes now on the market. If the situation is at all exposed, it is advisable to build the walls hollow, that is, two 4½ in. brick walls with an air space between, bonded together by galvanised ties.

Roofs may be of tiles, slates, straw, or reed thatch. This last makes an excellent and warm roof with a life of 70 years or more. Straw thatch is cheaper and looks neater at first, but has a shorter life and is liable to fire.

As to windows, whether these are of steel or wood, the main consideration is their proportion and placing. In considering the interior, light and simplicity should be aimed at. Plastering, for instance, if done with a wooden float and left with a granular face, presents a delightful surface without the addition of paper or distemper of any kind. In all simple building, and especially in the cottage, the three essentials are good materials, good plan, and good proportion. The first two will give a sound and economical building, while the third will add an unconscious charm to the home.

**ARCHITRAVE.** The moulding employed for fixing around doorways, windows, etc., is known to the builders as the architrave. It is made in a variety of patterns, and in sizes 2 in. by ¾ in., 2½ in. by ¾ in., 3 in. by 1 in., 3½ in. by 1 in. *See Door.*

*Architrave of a room doorway.*

**AREA.** The area of a house is the sunken space before the basement found in the older class of town houses. The basement is approached from the area, to which a flight of steps leads from the street. It is important to see that the area steps are in good repair, while a watch should be kept upon the fittings of the gate that guards it. *See Basement.*

**ARECA NUT.** This is the seed of the betel tree

and resembles the nutmeg, but is harder and red in colour. The powdered nut is used as a remedy for tapeworms in dogs, the correct amount being estimated as two grains for every pound of the dog's weight. It is not advisable to give the powder to puppies under six months. Areca nut powder loses its strength on keeping. The quantity to be administered to the dog is best mixed into a paste with a little butter. The remedy is not safe for cats. Pron. A-ree'-ker or Arry-ker.

**ARM: Fractures and Care.** Extending from the shoulder to the hand, the arm is described as the upper arm above the elbow and the forearm below. The former has one bone, the humerus, and the latter two, the radius and the ulna.

Fracture in any of these situations will be marked by pain, perhaps a sense of snapping, deformity, and loss of power in the limb. First-aid treatment consists in pulling on the lower fragment of the bone and the application of padded splints. These are applied on the outer and inner sides of the upper arm for fracture of the humerus and when one or both bones of the forearm is broken, this is bent to a right angle at the elbow, in a position midway between pronation and supination (that is, with the thumb looking upwards), and the splints are applied on the front and back of the limb, reaching from the elbow to beyond the wrist. In fractures of the upper arm a lesser arm-sling is used, that is to say, the weight is taken on the wrist only, but for fractures below the elbow a greater arm-sling is put on, thus supporting the whole forearm.

#### Beauty Culture for the Arms

For improving the colour, texture and shape a simple night treatment is as follows:

Rest one hand, palm downwards, on the edge of the bath and with a loofah or rubber friction glove on the other hand, stroke firmly in one sweep from fingers to shoulder, returning down the arm with a light touch. Repeat the movement several times, apply to under side of arm and then treat the other in the same way. Sponge with warm water and while wet spread over the skin enough toilet almond meal, first mixed to a stiff paste with extract of witch hazel, to cover hands and arms. Leave on till quite dry, then brush off and gently massage the arms with this cream:

Coconut oil, castor oil, sweet almond oil, each 2 oz.; hydrous lanolin and white vaseline, each 3 oz. Melt together the coconut oil, lanolin, and white vaseline in a jar placed in hot water, stir in the castor and almond oils, perfume, and allow the mixture to cool.

Should the arms be sore from exposure the cream only can be used without friction or massage for a few nights, smearing on thickly and leaving to soak in, covered by a pair of old long white gloves, with fingertips cut off. Ugly elbows can be improved by massaging with the palm of the hand each time an emollient is used for arms or face.

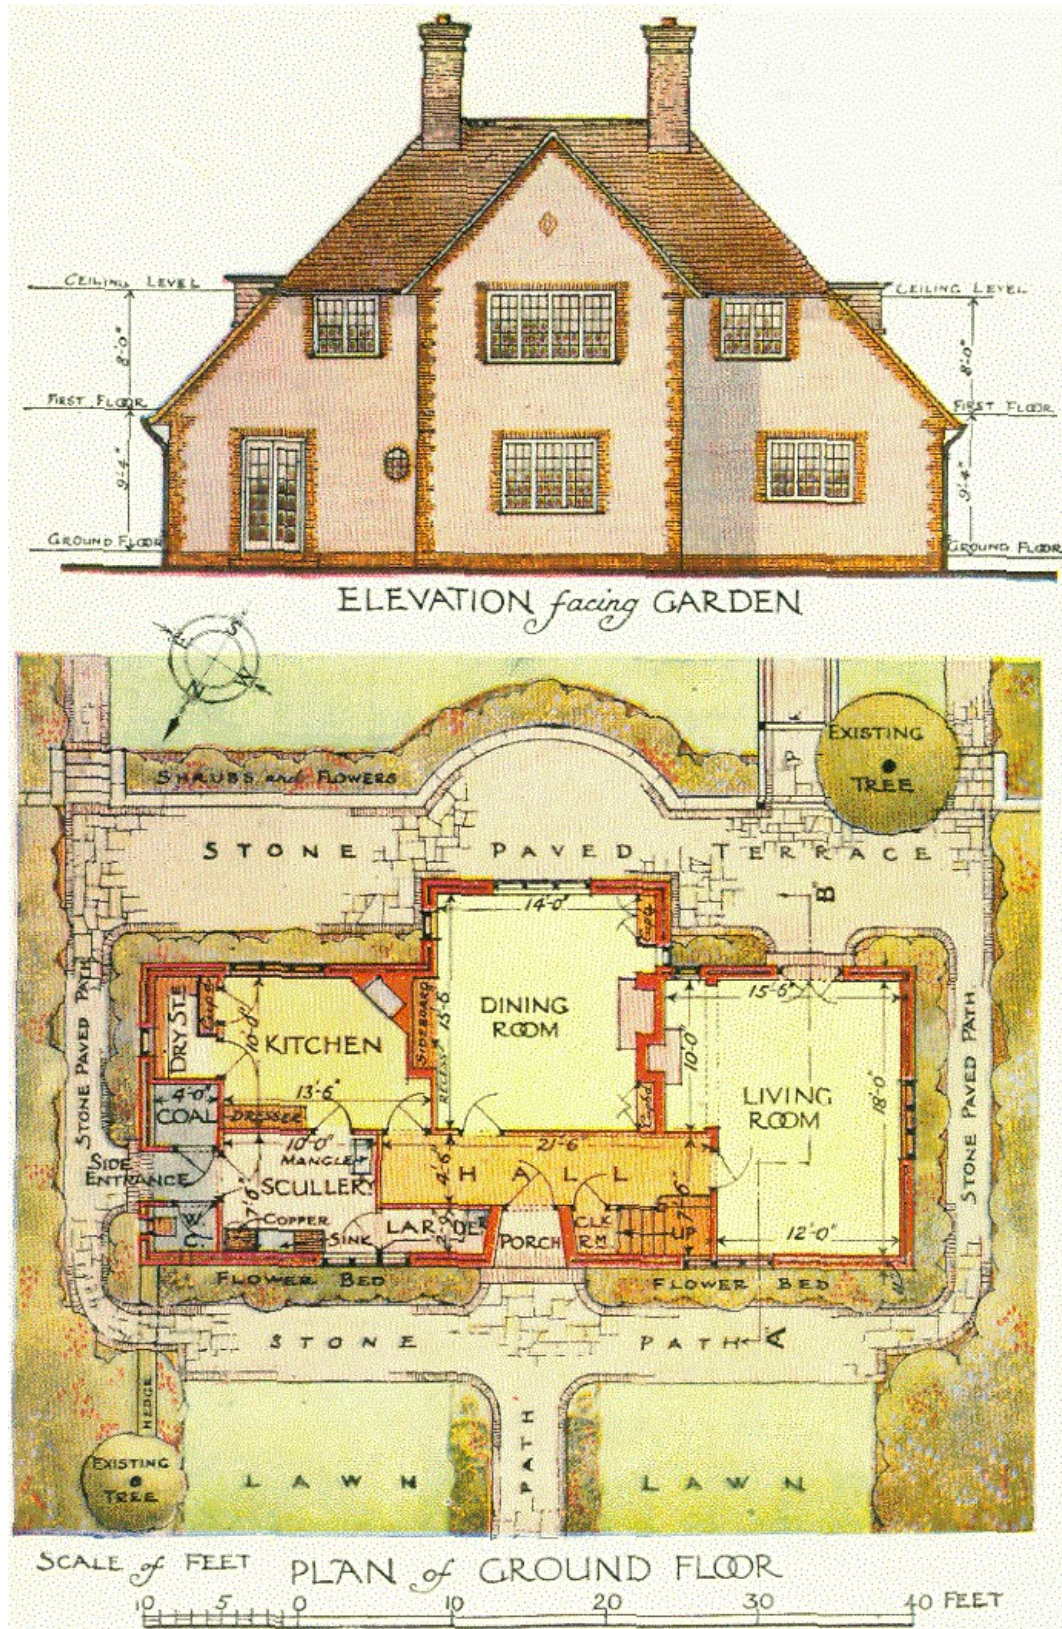

*(Continued in page 68)*

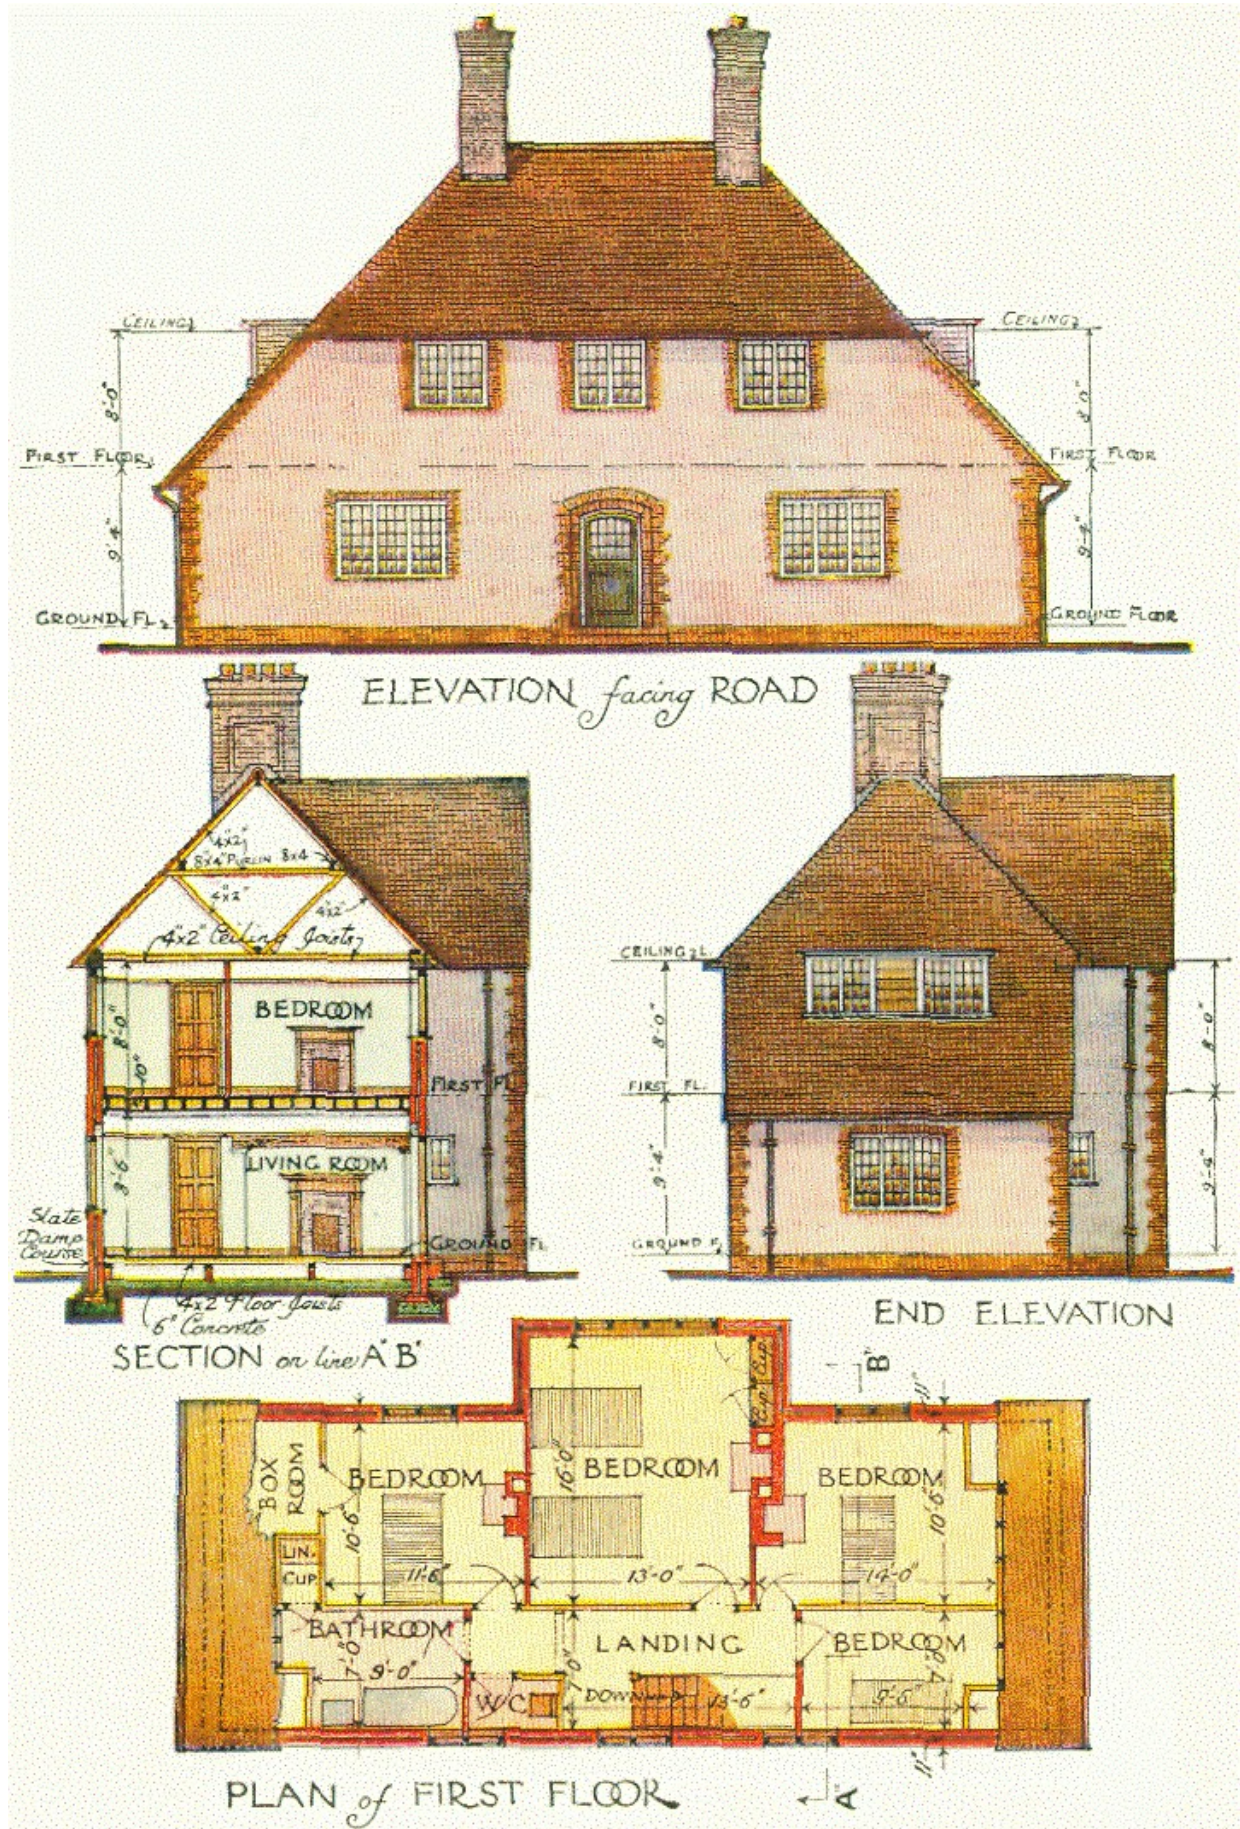

## ARCHITECTURE OF THE HOUSE

This set of working drawings is to scale. The plans show the arrangement of the house by floors, the Elevations the external appearance of the completed house, and the Section gives room heights and foundation and roof details. Perspective Sketch in page 65.

Specially prepared for this work by Herbert A. Welch, F.R.I.B.A.

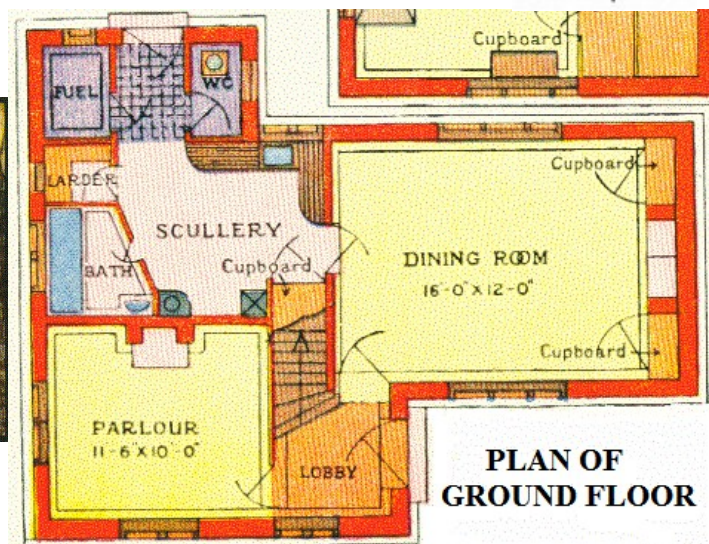

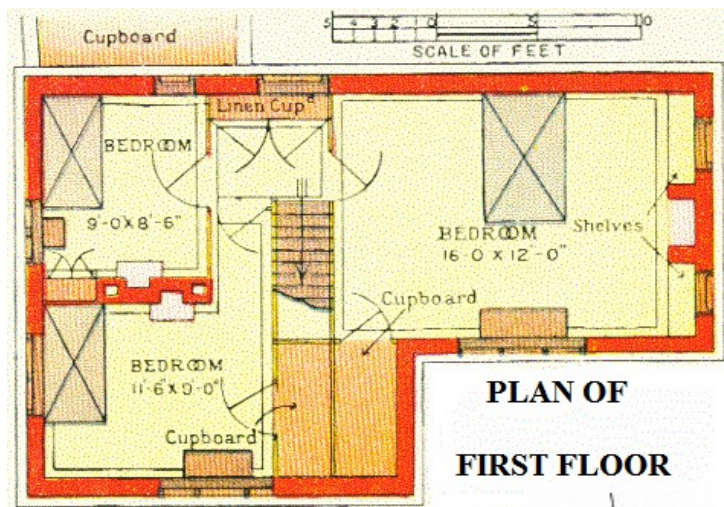

## ARCHITECTURE: AN ATTRACTIVE SMALL HOUSE

Specially prepared for this work by P.D. Hepworth, F.R.I.B.A.

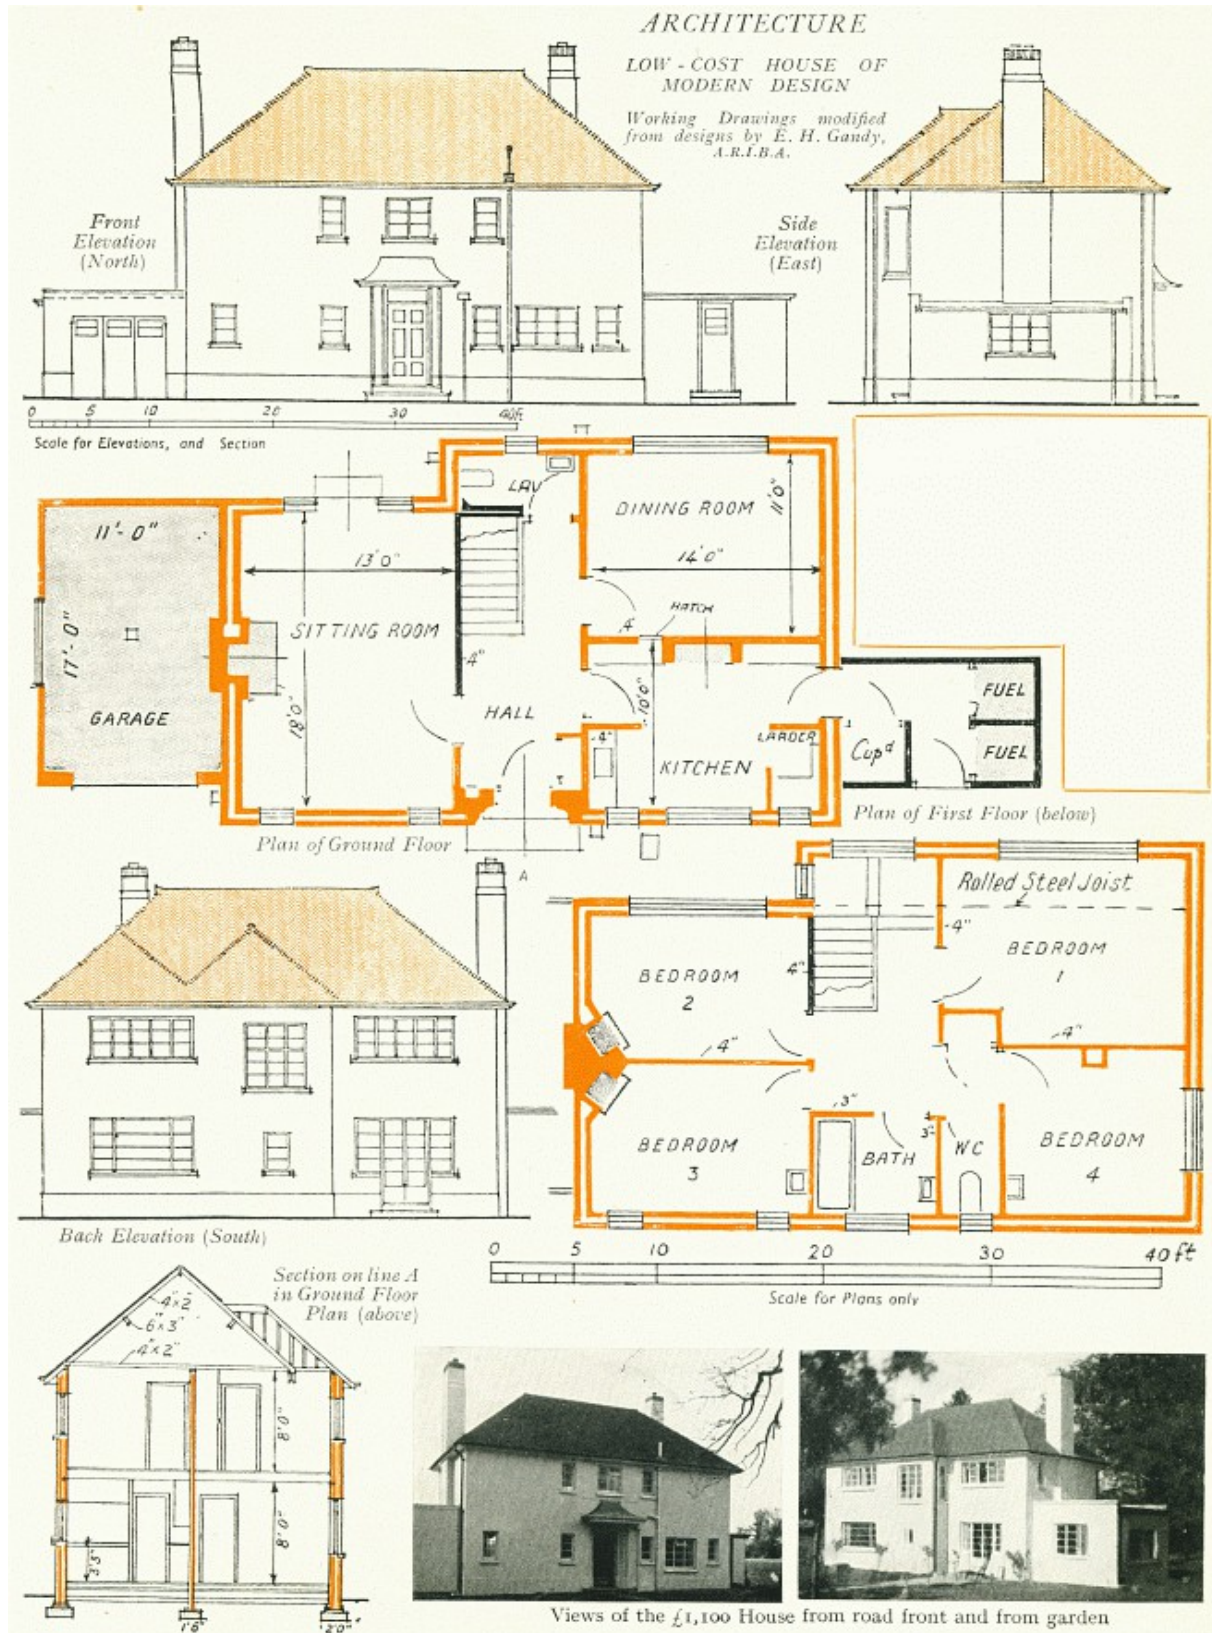

The Plans and Perspective View above show the style and arrangement of an attractive six-roomed house suitable for two or three persons or for a small family where no resident maid is kept. For descriptive details see pages 61 and 62.

## ARCHITECTURE: THE MEDIUM SIZE HOUSE WHEN FINISHED

Top left, Perspective Sketch accompanies the series of working drawings for the medium size house designed by Mr. Herbert A. Welch, of which Plans, Elevations, and Section appear in pages 63 and 64. The complete set, together with the contract and specifications (see pages 58 and 61), provide the builder with the main details required for the construction of the house. Plans of another medium-size house are given in page 66.

### **MEDIUM-SIZE £1,100 HOUSE**

This exceptionally good example of a straightforward and thoroughly modern design is built in brick, cement-rendered and painted cream. It gives four bedrooms, a large sitting-room and excellent working kitchen at the low cost of about 1s. 2d. per cube (*see p. 36*). The elevations, plans, and photographs of the house as built differ slightly, bedrooms 2 and 3 being made one large room and an extra room being built on the garage site.

## ARCHITECTURE: MODERN SMALL and MEDIUM HOUSES

In the photographs above two examples of the smallest types are seen. Left, a five-roomed cottage in lime-washed brick and weather boarding; cost about £350. Right, a cement-rendered brick bungalow at Wembley of modern design with five rooms; cost about £750. (*Dalgliesh & Pullen and Montague Elliot, Ltd.*)

Left, an excellent specimen of the modern concrete house with four bedrooms, large living and dining rooms, garage, etc. Cost about £1,900. (*Architect Sir John Burnet, Tait & Lorne*)

Right, medium size house in Surrey with four bedrooms, lounge hall, dining room, lounge, etc. Note Mansard tiled roof and deep eaves. Cost about £1,600-£1,650.

Left, an example in brick and cement rendering from a London building estate, the cost being about £1,095. The long metal-frame curved windows are pleasantly modern in design, and give well-lighted rooms.

(1. *G. Alan Fortescue, F.R.I.B.A.*; 2. *Allen Fairhead & Sons, Ltd., builders*)

A safety razor for the armpit is more sensible than the use of depilatories (hair removers), which sometimes cause irritation. *See* Bandage; Beauty Culture; Dislocation; First Aid; Sprain; Strain.

**ARMCHAIRS: HOW TO CHOOSE & HOW TO MAKE**  
Antiques for the Connoisseur and New Chairs  
for Home and Garden

Other varieties are described under such headings as Cane; Chair; Garden Chair; Rustic Work, etc.

The first English armchairs were of solid wood and box-seated. Often the backs were adjustable as tables and the wood oak. Many Tudor chairs were carved, had leather seats and low backs, legs and stretchers turned. Jacobean chairs were mostly high straight-backed, with scrolled carving extending on the arms well beyond the supports. Late Stuart chairs were luxuriously upholstered and walnut was used instead of oak, as the former wood can be more finely carved. Cane panelled backs were introduced within the framework of carved wood. Upholstery was kept within the back framework, but often carried over the sides and finished with fringe or a braid. Arms were not padded.

*Armchair by Hepplewhite in walnut, with shaped back and Prince of Wales's feathers splat.*  
(Victoria & Albert Museum)

With the Queen Anne period came the fully upholstered winged armchair, needleworked or tapestry-covered, with cabriole legs and delicate stretchers, both turned and carved. In the great designer Chippendale's work a French influence is apparent, which continued throughout the Georgian periods of Hepplewhite, Sheraton and Adam, introducing more refinement, well balanced frames and beautiful decoration and upholstery.

*Armchair. Carved walnut chair said to have belonged to Nell Gwynne, Charles II period.*  
(Victoria & Albert Museum)

Modern chairmakers either base their work on these classical designs or break away completely with the lounge and divan types fully upholstered, springs being used in seats and backs and also sometimes in arms.

For garden, bungalow and bedroom armchairs, fine examples in canework are also made, while designs are also carried out with metal framework and proofed fabric upholstery.

Many modern armchairs are upholstered all over. Some have merely an upholstered seat, or seat and back, or perhaps have padded arms as well. Others are bare wood. The cheapest variety are of wicker. Another kind, costing a little more, is of cane wound over a slender wood framework. After these come the comparatively heavy and substantially built chairs of the cabinetmaker.

The wood used may be oak, mahogany, birch, walnut, or beech. In a cheap class of chair, deal may be employed for parts that are covered by upholstery. A covering of morocco leather is the most expensive, but it is durable and retains its colour, while roan leather is inferior. Most of the imitation leathers are very good; they consist of linen or duck coated with a composition. Other coverings are velvet, tapestry, cretonne, and linen. Tapestries may be wool, silk, or mercerised.

Best quality curled horsehair is used for the more expensive chairs, being more springy than any other kind of stuffing. Vegetable fibre resembles hair, and

is often employed in combination with it. Flock of various kinds and qualities is used, alone or with wood fibre or wood wool, or a dried seaweed called Alva. Canvas coverings vary in quality. Springs are used in the seat of an armchair, sometimes in the back, and occasionally for the arms, other parts being padded only.

*Armchair. Modern easy chair, upholstered in printed tapestry, with unstained oak frame, shelf for workbox, ashtray, etc., newspaper rack, and adjustable back.*

**Adjustable Armchairs.** The armchair shown in Fig. 1 has a movable seat and back, with separate cushions, and can be made by the amateur woodworker. The four legs should be prepared to 2 in. x 2 in., cut off to 2 ft. ½ in., with the lower ends trimmed off to 1¼ in. square. The rails are 1 ft. 11 in. long, with tenons cut off ¼ in. on one side only and left 1½ in. long.

**Fig. 1**

Fig. 2 shows details of construction. The top rail is 2 in. wide and 1 in. thick, and mortised in ½ in. down from the leg tops so as to leave a space of ½ in. each side of the rail. The middle rail is 3 in. wide and 1 in. thick and is mortised in 10 in. below. The bottom rail, 1½ in. wide and 1 in. thick, is mortised in 2½ in. below the middle rail. The mortises should be so gauged that

a space of ½ in. is left on each side of a rail with the flat side of the tenon on the inside, as shown in the diagram. Four uprights, each 11 in. x 2 in. x 1 in., with a tenon ½ in. long and ½ in. thick, should be equally spaced out and mortised in between the top and middle rails.

**Fig. 2**

*Armchair. Fig. 1. Adjustable armchair with movable seat and back. Fig. 2. Working drawings giving measurements and details of joints employed.*

The arm-pieces are 2 ft. 9 in. x 3 in. x 1 in., with about 12 in. at the end cut back to 2 in. wide, the top corners and the front end being carefully rounded. A dovetail should be cut on the top of the legs to hold the arms, as indicated in the diagram. The two side frames are joined at the front with two rails and at the back with three; two being seat rails, two bottom rails and one joining the arm-pieces.

*Armchair. Fig. 3. How slots to hold supporting rod may be cut in arms.*

The seat rails are 1 ft. 11 in. x 2 in. x 1½ in., with tenons 1½ in. x 1 in., with the cut on one side only, and they should be mortised in 10 in. from the bottom of the legs so that the notch is on the inside of the tenon and the front is set back ½ in. The bottom rails are 1 ft. 11 in. x 1¾ in. x 1 in., with tenons 1½ in. x ¾ in., and should be mortised in 3 in. below the seat rails and spaced centrally. The arm rail is 1 ft. 11 in. x 2½ in. x 1 in., with tenons 1¾ in. wide and ¾ in. thick and so sawn that one edge of the tenon is flush with the outside. The mortise in the arm-pieces should be set back ¾ in. to

bring the back rail flush with the ends.

Two rails, each 2 in. x 1 in. and 2 ft. long, should be tenoned into the seat rails and run from front to back 1 in. away from the legs. These lengths provide runners for the seat frame, the tenons being 1½ in. x ¾ in. The two side frames should now be glued up with very hot and thin glue.

The seat frame is composed of two sides, 1 ft. 10 in. x 2½ in. x 1 in., two ends, 1 ft. 8 in. x 2 in. x 1 in., and four rails, 1 ft. 8 in. x 1½ in. x 1 in. The ends should be tenoned into the sides and the rails into the ends, all tenons being ¾ in. thick, and full width, with the exception of the front and back, which should be 1½ in. wide. For a distance of 9 in. the front of the seat frame should be cut back ½ in., to allow of it sliding between the front legs.

The back is composed of two sides, 2 ft. 6 in. x 2 in. x 1 in., and six rails each 1 ft. 6 in. x 1½ in. x 1 in. with the exception of the top and bottom rails, which are 2 in. wide. The seat and back frames should be hinged and fit easily in position.

In some adjustable chairs the hinged back frame rests against a hardwood or metal rod which lies in slots cut in the arms, as shown in Fig. 3. The backward slope can be varied by changing the rod from one pair of slots to another. The cross rail which ties the arms together forms a secondary support for the back frame, should the rod become dislodged.

The arms for a chair of this kind are shown in plan in the illustration, which also clearly indicates the shape and arrangement of the slots. Four slots are cut in each arm, 1 in. wide at the top and ¾ in. high by ¾ in. deep, cut on the slope in the manner shown. The slots are 1 in. apart.

The cushions are both 1 ft. 8 in. wide and 3 in. thick, one being 2 ft. 3 in. and the other 1 ft. 10 in. long. Two bags should be made of hessian to these dimensions, and filled with either horsehair, fibre or flock, and sewn at intervals of 4 in. all over to keep the filling in position.

The covers should be made separately and fitted on, but they may be buttoned, especially if made of imitation leather or tapestry. A better decorative effect is given if either brown velveteen or hair seating is used for the cushions, without buttoning, and the edges piped. Closely woven tweeds in tones of beige, piped with imitation brown leather, or heavy corded fabrics in geometrical patterns are suitable to the lines of this framework. The seat and back may be upholstered direct, and in this case the inner rails of both frames should be omitted, and webbing used instead.

**Garden Armchair.** Fig. 4 shows a comfortable garden armchair. It should, if possible, be carried out in oak, but any of the harder whitewoods may be substituted. The chair is as suitable for indoor use as for the garden, and, fitted with loose cushions, it will make a comfortable seat for the sitting-room or library. A feature of the design is that the legs are not square posts, but are of 2 in. x 1¼ in. section.

The construction is simple and straightforward, and is shown in detail in Fig. 5. The legs may be tenoned

right through the struts and wedged.

*Armchair. Fig. 4. Strong chair suitable for garden use.*

The seat rails and back rails are tenoned in the usual way, while the strut rail, the side slats, and the back slats are rebated in. The seat laths are nailed on, and the side slats may be nailed or screwed to the side seat rails. The arm is tenoned to the back leg, and is secured to the front leg by means of a stub tenon.

	Length	Width	Thick- ness
Two front legs	25	2	1¼
Two back legs	38	2	1¼
Two struts	26	3	1¾
Strut rail	23	4	⅞
Front seat rail (shaped)	24	3	⅞
Back seat rail	24	3	⅞
Two side seat rails	22	3	⅞
Seven seat laths	24	3	¾
Two arms	24	1	1½
Six slats (sides)	22	2	¾
Lower back rail	24	2	1
Top back rail (shaped)	24	4	⅞
Middle slat (back)	16	5	½
Two slats (back)	16	2	½

The wood required is shown in inches in the above list. The lengths quoted allow for joints and paring, but all the thicknesses given are strictly net.

(See page 71 for armchair working drawings and details of construction)

**ARMORIAL BEARINGS.** An Englishman may legally assume any armorial bearings he pleases. Thus a chimney sweep from Whitechapel can, if he pleases, assume the arms of the Stanleys, the Grosvenors, or the Howards. If, however, he has them painted on his carriage, he pays two guineas a year tax, and if he displays them in any other position, e.g. on

**ARMCHAIR WORKING DRAWINGS AND DETAILS OF CONSTRUCTION**

his notepaper, he must pay one guinea a year. If a man is left an estate on condition that he assumes the name and arms of Blank, his best plan is to apply for a royal grant of the name and arms, which will probably be issued, but he will pay £50. He may get the same royal licence on a voluntary application for £10. If he covets armorial bearings, and applies to the crown or the College of Heralds for a grant of a coat of arms, it will also cost him £10. The penalty for displaying arms on a carriage or elsewhere without paying the tax is a fine of £20.

**ARNEBIA.** The best known species of arnebia is *echioides*, a hardy perennial from Armenia. It is about 12 in. high, and produces yellow flowers in May. Each blossom has five dark spots, fabled to be the marks of the fingers of Mahomet, hence its popular name of the Prophet flower. It is a curiosity for the rock garden (q.v.). Pron. Ar-nee'-bi-a.

**ARNICA.** The flowers and root of *Arnica montana* are employed in making preparations for bruises and sprains. Arnica flowers are to be preferred to the root for the purpose.

Tincture of arnica is made by soaking an ounce of arnica flowers in half a pint of weak alcohol or brandy for ten days, then pouring off the liquid. Squeeze the flowers in muslin, so as not to waste any of the tincture.

To make a lotion for sprains and bruises mix two tablespoonfuls of this tincture with enough water to make one pint of lotion.

*Arnica opodeldoc* is a handy form for rubbing purposes. It is made by mixing:

Soap	4 oz.
Camphor	1 oz.
Tincture of arnica	5 oz.
Strong alcohol	10 oz.

Carefully heat together until dissolved. It sets to a jelly when cold. To use it rub a small quantity in until the paste disappears.

Arnica should not be used on broken skin, as a disagreeable rash may be produced.

**ARRAS.** Named after the French town, the original Arras was handworked tapestry hung before the wall of the room, leaving a passage behind. An arras of cretonne will assist in making a loft or outhouse habitable at a minimum of cost, because it serves to exclude draughts. *See* Tapestry.

## ARROWHEAD.

The best known species is the native *Sagittaria sagittifolia*, which has arrow-shaped leaves 3 in. to 6 in. long, and white flowers in widely spaced whorls in July. The numerous stamens have purple anthers. It is found in pools and is a good plant for the water garden, but the water should not be more than about 1 ft. in depth.

*Arrowhead. Flowering shoots and arrow-shaped leaves.*

**ARROWHEAD:** In Tailoring. Arrowheads are used on coats, skirts and tailored dresses, to give a decorative finish to dartlike seams and pleats, the sides of pockets, to cuffs, collars and the like. They are worked in coarse, buttonhole silk twist to match exactly the shade of the garment, except on navy blue when they are worked in black. Mark in chalk a triangle the size desired, with a straight line down the centre.

*Arrowhead in tailoring. Diagram showing the stitch.*

For the first stitch push the needle, from underneath, through the lower left-hand corner, carry up to top point of the triangle, and take up a tiny running stitch here towards the left, then carry needle down to the right-hand corner and insert here, bringing up the needle again at the left-hand side, but within the stitch first made, as in A.

Again carry the thread up to the apex, take up another running stitch, but this time just below the first, so that the thread crosses right-hand stitch and will cross both left-hand stitches when carried down alongside the right-hand stitch as in B. Continue thus, working first along one side of the triangle and then the other, the running stitches getting each time farther from the apex, and the others nearer to the centre of the base, until the arrowhead is completed as in C.

**ARROWROOT.** A pure starch powder, obtained from the maranta plant, grown in the West Indies and Bermuda. English arrowroot is prepared from potatoes. It is a valuable invalid food, being easily digested in cases of gastric irritation. To prepare, blend a dessertspoonful of the powder with two tablespoonfuls of milk or water, and pour over it half a pint of boiling milk or water. Stir briskly, then add a teaspoonful of sugar. If ordered, a teaspoonful of brandy or cream can also be added. *See* Cornflour.

**ARROWROOT BISCUITS.** Sieve  $\frac{1}{2}$  lb. of arrowroot together with  $\frac{1}{4}$  lb. of flour and a dessertspoonful of sugar into a basin and rub into them  $\frac{1}{4}$  lb. of butter until the mixture is free from lumps. The whole should then be formed into a stiff paste with the aid of a beaten egg, and, if necessary, a little milk. Knead the paste well, and when smooth roll out very thinly on a floured board. Cut into shapes and bake until golden brown in colour.

**ARROWROOT PUDDING.** Mix two dessertspoonfuls of arrowroot with a little cold milk, boiling what remains from a pint of milk, and pouring it over the mixture. If the latter does not thicken immediately the arrowroot is not sufficiently cooked, and the whole needs to be boiled up in the pan. After adding a dessertspoonful of sugar, leave the mixture to cool; then add the yolks of two eggs and lastly beat two whites of eggs to a stiff froth, folding them lightly into the mixture. Turn the pudding into a thickly buttered dish, and bake it in a fairly hot oven for a little more than half an hour.

**ARSENIC.** In medicine, arsenic is best known in the form of the oxide or white arsenic; it is used in anaemia, and also as a general tonic. A favourite preparation is Fowler's Solution or Liquor Arsenicalis. Arsenic is very useful in the debility which results from malaria. It is found in rat poisons and in weed-killer.

**Arsenic Poisoning.** In cases where an overdose of arsenic has resulted in acute arsenical poisoning the chief symptoms are vomiting, continuous diarrhoea, abdominal pain, and great weakness. Give the patient emetics of warm mustard and water (a tablespoonful of mustard to half a pint of water).

The antidotes for arsenic are dialysed iron, tablespoonful doses in water every ten minutes, or magnesia given freely in water. Later give the whites of two eggs beaten up in a glass of equal parts of milk and water. The patient should be kept warm in blankets, with a hot water-bottle at the feet. Nothing but milk should be allowed for the first week after recovery.

The earliest symptoms in chronic poisoning may be cold, running eyes, sneezing and cough; or there may be loss of appetite, nausea, vomiting and diarrhoea. Itching of the eyes is a usual sign when a person is taking arsenic that the dose should be reduced. More serious effects are observed—inflammation of nerves leading to weakness and unsteadiness of the gait, drop-

foot and drop- wrist, and increased sensitiveness of the skin.

The only treatment of any avail is to remove the patient from all possible contact with arsenic, and to build up his general health by some tonic, such as Easton's syrup,  $\frac{1}{2}$  to 1 teaspoonful in a little water three times a day after meals, while nature expels the absorbed arsenic from the system. If the digestion has been greatly upset a very light diet, consisting chiefly of milk, milk puddings, custards, etc., is necessary. Where there is the slightest suspicion of chronic poisoning the advice of a physician must be sought. *See* Antidote; Poisoning.

**ARSENICAL SOAP.** This is a paste employed by taxidermists for preserving the skins of birds and animals that are stuffed and mounted. Its use depends upon the fact that arsenic is a very powerful antiseptic and preservative, but its poisonous qualities render it necessary to use it with great care. The paste or soap is made as follows:

White arsenic	4 oz.
Camphor	6 dr.
Charcoal	1 oz.
Slaked lime	4 oz.
Carbonate of soda	12 oz.
Soft soap	4 oz.
Water sufficient to make a stiff paste.	

It should be mixed in a mortar.

The charcoal gives the paste a grey colour that prevents it being mistaken for a harmless preparation. The soap is used by spreading it on the inner side of the bird or animal skin. *See* Taxidermy.

**ARSON.** This word is used in English law for the wilful burning of a house belonging to someone else, or of a place of worship, public building, or building owned by a public company. Arson is a felony. *See* Fire; Insurance.

**ARTHRITIS.** Term used by medical men for inflammation of a joint or joints. *See* Inflammation; Joints; Rheumatoid Arthritis.

**ARTICHOKE: To Grow and Cook.**

Plants belonging to three different genera are grown under the name of artichoke in Great Britain, namely, the true or Globe Artichoke, *Cynara scolymus*; the Jerusalem or tuberous Artichoke, *Helianthus tuberosus*; and the Chinese Artichoke, *Stachys tuberifera*.

**Jerusalem Artichoke.** The plant is a hardy perennial, growing from 8 to 12 ft. high in a season, the stiff green stem, without side branches, bearing roundish rough leaves on short stalks. The rootstock is tuberous. In the common species, the tubers are pink,

very numerous, and variable alike in size and shape. Each plant will produce from half a peck to a bushel of tubers per annum. The white-tuber variety is superior in flavour to the other kinds.

*Large patch of Jerusalem artichokes, growing to well over 6 ft. high, showing their close resemblance in foliage and growth to giant sunflowers.*

Planting should be done in early spring and the sets covered 4 in. deep. They may be planted about 18 in. apart, rather more in rich soil. A light hoeing up of the soil over the tubers once or twice during the summer is beneficial. In September the plants cease extension and the leaves lose colour and droop. The stems may be cut down in October. From that time the tubers may be taken up at intervals for use as required. The plant enjoys a liberal dressing of decayed manure. In fertile soil the smallest of sets or seed-tubers will produce a strong plant and a heavy crop.

**Globe Artichoke.** This is a perennial and the young flower-head forms, with the fleshy receptacle, a close ball, globular in shape; it is this which is the edible part. Seedsmen usually list at least two varieties—the Green Globe and the Purple Globe; the seed may be sown out of doors in spring in a drill and covered with an inch or so of soil. The seedlings should be thinned and planted out about 4 ft. apart when strong.

Those who have established plants can get strong plants from suckers. In each case three or four shoots should be left on the old plant. Those removed should be set 3 ft. apart, with 4 ft. between the rows, and bedded firmly in with moist soil.

*Artichoke. Tubers of Jerusalem or white artichokes ready for cooking. (Photo from Sutton & Sons)*

The stage for gathering the globe is when the scales begin to spread and before the flowers have time to

open; a portion of stem should be taken with each. When all have been gathered the stems may be cut hard back, together with the decayed leaves, and the soil round the plants mulched with fine ashes, seaweed, or stable litter. In cold districts the soil ought to be ridged up over the stools and litter thrown on. In spring a dressing of manure may be given. After the fourth year the plants, having become exhausted, should be replaced by fresh stock.

The Chinese artichoke is an edible-rooted species of *Stachys*, growing about a foot high. The tuber ranges from 1 in. to about 3 in. in length and may average an inch thick at the centre. The flavour resembles that of the Jerusalem artichoke.

Medium sized tubers are selected in spring and planted 3 in. deep and a foot apart in rows 18 in. asunder. Any well-drained soil will do, but it should be friable. Fresh manure is not desirable. In autumn the tubers should be lifted and stored in dry sand.

**How to Cook.** When Jerusalem artichokes are peeled place them immediately in a bowl of water to which a little vinegar has been added or they are apt to become discoloured. Have ready a pan of boiling salted water, add a little vinegar, put in the artichokes and boil gently for about twenty minutes. They break easily, hence the water must not boil too fast. When the artichokes are tender, drain them, place in a vegetable dish and send to table well covered with white sauce.

Jerusalem artichokes may be mashed if preferred. When boiled, rub them through a fine sieve, flavour with butter, pepper and salt, add a little cream and heat up in the oven.

*Artichoke. Basket of young flower-heads of the globe artichoke. (Photo from Sutton & Sons)*

To make artichokes and cheese, boil six artichokes till tender, then mash them with a fork, and add pepper, salt, lemon juice, and some cayenne pepper. Place a layer of this in a small pie-dish, then a little grated cheese, and then a little more of the artichoke mixture. Scatter breadcrumbs and cheese over it, bake for 10 min. in a quick oven and serve very hot. This is

sufficient for four persons.

Globe artichokes are served as a separate course, usually after meat, with either a sauce made of equal parts of oiled butter and lemon juice or sauce Hollandaise (q.v.). Only the lower portions of the leaves and centre of globe artichokes are edible.

Before boiling take off coarse outer leaves and cut away the stalk. Wash thoroughly to remove any grit or insects. Place the artichokes in boiling salted water, head downwards, and boil quickly without putting on the lid of the pan for about half an hour. Drain in a colander and arrange in a dish, tops uppermost. The sauce is sent to table in a sauce-boat and not poured over the vegetable as with Jerusalem artichokes.

**ARTICHOKE SOUP.** Also known as Palestine soup, this requires 2 lb. artichokes, 1 small turnip, 1 onion, ½ pint milk, 2 pints white stock (2½ pints milk if a meatless soup is preferred), 1 small head of celery, ½ oz. flour, 1 oz. margarine. Pare and wash the vegetables, cut up and boil gently in the stock till tender. Melt the margarine in a separate saucepan, stir in the flour and add milk, stirring till the thickening is smooth. Rub the vegetables through a sieve, return to the stock, add it to the thickening, season to taste and boil up. Serve very hot with dice of fried bread. Sufficient for five persons.

**Artificial Fertilisers.** This term is used for manures manufactured by the aid of chemicals. See Fertiliser.

### ARTIFICIAL FLOWERS:

#### HOW AMATEURS CAN MAKE THEM

Using Materials of Many Kinds for Dress and the Decoration of the Home

Related information will be found under the particular materials used, e.g. Paper; Raffia; Shells; Silk, etc.

Made of shells, fish scales, glass, knitting yarns, raffia, scraps of silk, cotton, velvet or felt, of crêpe paper and of leather, artificial flowers of all kinds can be selected for dress, fancy work, table and Christmas decoration.

Shells and glass lend themselves to original and striking designs for conventional vase sprays and for floral trees of the weeping willow type on solid glass blocks and fancy stands. Glass flowers are brittle for personal wear, though used in small posies, and shell flowers are rather stiff. Fish scales are light and adaptable for this purpose. For shell and glass flowers, leaves of the same material have a better effect than the ordinary artificial foliage which is often used. Mother of pearl shells, which do not require tinting, are sold from 1s. a dozen (prices vary according to required size), miscellaneous shells from 3s. a pound, and fish scales about 1s. an ounce. French enamel varnishes are suitable for colouring all shells and scales, and cost 9d. a bottle. These can be intermixed to obtain other shades

and removed or lightened in colour by use of methylated spirit. Leaves and petals are supplied in crystal or in coloured glass for a few shillings a hundred. Where a pearly sheen is liked on glass flowers, a mother of pearl solution is obtainable, to coat the petals.

*Artificial Flowers. Mixed bunch of flowers made from shell, felt, cork and raffia, and mixed with dried grasses.*

*Artificial Flowers. Glass camellias with glass leaves.*

Besides these materials, flower centres, varieties of stamens and foliage, stems, wire, brown or green gutta

percha, various kinds of calyx and tools for piercing shells can be obtained or ordered at art shops and art departments in stores. Small camel-hair brushes are best for tinting; clean them with methylated spirit after using the enamel varnish.

*Artificial Flowers. Conventional flowers, buds and leaves made in glass and stuck in sand.*

*Artificial Flowers. A flower greatly enlarged to show the details of construction.*

#### **Anemones Made From Shells**

Anemones are effectively made in shells and are easier to tackle than roses, water lilies, camellias or apple blossom, though all these

flowers are suitable for this work. Select five shells the required size of anemone petals, pierce, from inside, the thickest part of the shell where the hinge is, with two holes, a quarter of an inch apart, thread with wire, working from inside shell. Wire the five thus, and then colour. For a red anemone, a brushful of crimson enamel varnish would start from the top of the petal and blend with a little mauve from the base, where afterwards a small dab of black should be used, as seen in the natural flower. The painted shells will dry in about five minutes. Both sides must be coloured and various tints will be suggested by the real flowers for sufficient blooms to make an effective vaseful. Have at hand a little cotton wool and dab off colour if wrongly applied.

Take an anemone centre, surround with stamens (ready made), wired together and spaced evenly round the centre, and then wire to a piece of galvanised wire

for the stem. Next wire the coloured petals to this stem by the wires already fixed to them. Green sealing wax may be used to hide the mass of wires beneath the petals. After a short piece of rubber tubing has been pushed up over the wire stem a special readymade anemone stem is used to which short leaves, as found on the real flower, are attached. This should be gummed on to complete the flower.

By piercing the shells at the thin top edge incurving petals are obtained. Thus, when making a rose or a water lily, the central petal shells are pierced at the thin edge and the outer or open petals are pierced, as in the anemone described, at the hinge side. For a bud all the petals would be pierced on the thin top edge. A special calyx is obtainable for a rose and double-ended yellow stamens.

Natural twigs are often used for almond or apple blossom, gutta percha strips in a matching colour concealing the wiring of the bloom to the twig. For large leaves, flat sun shells are obtainable from 3 to 4 in. in diameter, and can be cut with special cutters to the desired shape and coloured after piercing.

With large shell flowers, rattling of petals caused by too loose wiring must be carefully avoided. Glass flowers are made in the same manner as shell, but gold, silver or silk-covered wire is used. For heavy flowers or tree effects the stem wires must be extra stout.

*Artificial Flowers. Narcissi made from shells, the leaves being of cardboard covered with green raffia. The rose is also in shell.*

Fish scales are good for making small flowers when an enamelled effect is liked for millinery purposes. One side of the scale has a satin finish and should be used for the upper sides of petals. These can be curled round

on a knitting needle if desired, cut to shape with scissors and holes pierced for wiring with a stout needle.

#### Fish Scales Used for Violets

To make violets, select five fish scales, four about the size of a sixpence and one of a three-penny-piece: cut five lengths of wire, 7 in. long, wire up the scales, and then colour both sides with violet enamel varnish. Take a violet centre and arrange the coloured petals, two at the top, one at each side and the small one at the bottom, overlapping. Twist the wires of the petals together firmly to make the stem foundation. Bind a narrow strip of green gutta percha round this and finish. Ordinary artificial violet leaves may be used, or leaves cut out of green suede, to complete a bunch of a dozen violets tied up with raffia.

*Artificial Flowers. Fig. 1. Daisy made in raffia.*

*Fig. 2. How to start making the flower.*

*Fig. 3. How the petals are formed.*

*Fig. 4. Simple shapes for cutting out flowers in silk, cotton or crêpe paper.*

Wool or chenille flowers for attaching to knitted work or for posies are usually very simple, effect being obtained by the use of bright colours. A wool needle may be threaded with the yarn, a loose knot made and loops worked with this, overlapping each other all round. About a dozen loops of wool should suffice. The centre is formed either with a bought flower centre

with a wired stem, or by attaching the flower to the article to be trimmed with French knots of wool in a contrasting shade. Leaves are easily crocheted to shape and wired if necessary, or cut-out felt leaves may be used for a posy.

Raffia flowers usually start with a canvas foundation, from which the loops of raffia may be worked. Daisy-like flowers (Fig. 1) can be made on a circle of canvas rather larger than a penny with an inner circle marked the size of a farthing. To start, thread a raffia needle with the selected colour and darn into the canvas to avoid a knot (Fig. 2); from the centre circle edge make a loop 1 in. in length, taking the needle back close to the starting point (Fig. 3). Pass the needle under the centre circle, bringing it out opposite loop just made. Take needle back again, leaving a similar loop, making it as close as possible to the first one, and continue all round till the circle of petals is complete.

The centre may be of looped yellow wool or small wooden beads sewn on the canvas. The back is finished off by cutting away the canvas near to where the petals start and covering with green raffia in loops until the remaining canvas is hidden. Through the back, wire is passed to form the stalk about 8 in. long. Use double wire and wind round with brown raffia. To keep the raffia in place, pass it through the flower, when it may be bound with a little brown cotton. Wire in an occasional loop of green raffia on the way down the stalk, as shown in Fig. 3.

#### Flowers of Ribbon, Silk and Paper

Narrow ribbon flowers can be made in the same way. Circles of felt, skiver or suede, with slit edges, in diminishing sizes, form conventional asters with bead flower centres and wired stalks covered with gutta percha or raffia. More ambitious leather flowers require a knowledge of tooling and use of leather implements (see *Leather Work*).

Simple shapes for cutting out flowers in silk, cotton or crêpe paper are shown in Fig. 4. Ready-made stems, centres, stamens and leaves can be used if an attempt at natural flowers is desired. After cutting out, if the petals are to be coloured, it is a good plan to pin material to white blotting paper, wet slightly with clean water on a small sponge, and tint with water colour to which add a little gum. Aniline dyes are quite useful for this purpose."

In using crêpe paper for decorative flowers suitable for Christmas, cut the paper with the grain, use as little adhesive as possible, and allow pasted petals, etc., to dry before using them. Fold the paper into several thicknesses so that several petals or leaves may be cut out at one time, draw or trace design on top fold and use a sharp pair of scissors.

To make a daffodil or a bell flower, turn down the end of a wire and cover with the paper to make a small head on to which to fix six stamens, each made from a square inch of paper, twisted tightly between the fingers to form a thread. Cut the bell or cup three inches square and join with paste. Turn the top edge

slightly over, stretching the paper a little. Put over the centre of the flower and bind with fine wire. For the daffodil cut six petals and also bind these with a sheath of brown crêpe, pointed at one end, at the base. The bellflower is finished underneath by a calyx cut from a circle of green paper into points. Stalks are bound with crêpe.

Many variations on these schemes will soon suggest themselves. Glass beads may be used for blossoms with shell or glass leaves, and effective flowers can be made of American cloth with wool or bead centres.

### ARTIFICIAL LIMBS: Their Care.

The sockets of artificial limbs (those portions which enclose the stumps or remains of the lost limbs) are made of wood, composition such as celluloid and certalmid, etc., or of metal such as aluminium alloy. They should fit the stump accurately.

For the sake of cleanliness the socket should be sponged out with warm water and then carefully dried with a cloth, at the end of each day's wear. In the case of a wooden socket, if the varnish has been rubbed off, it should be renewed; if the surface of the wood is rough or uneven it must be smoothed down with fine glasspaper before the varnish is applied.

Metal joints, except those which have leather bushes, should be kept lubricated with oil. If from wear they become too loose so as to rattle, or allow improper movement, they will need repair or renewal by the limb maker. The joints which are usually bushed with leather are the knee and the ankle. The leather which is used for this purpose is thoroughly impregnated with grease, and needs no additional lubricant. When a bushed joint becomes too loose it must be rebushed by the maker.

In some of the older pattern legs the ankle-joint is of wood of the mortise and tenon type, connected by means of a leather-bushed bolt. When these joints become worn so as to allow of undesirable side play, they must be rebushed and packed. These joints are usually controlled by tendons and steel spiral springs.

In the standard types of limbs generally supplied by the Ministry of Pensions, the ankle-joint is fitted with rubber buffers, which are compressed by tightening two nuts in the sole of the foot. If adjustment of these nuts fails to make the ankle movement satisfactory, it is probable that new rubber buffers are required. The foot is easily detached when the nuts and locking plate have been removed. Certain limbs are fitted with rubber feet. All others have a separate toe-piece, hinged on its lower edge and having steel or rubber compression springs which maintain extension.

As a rule, wearers of artificial limbs should not attempt to take them to pieces themselves, as special tools are needed and special experience to reassemble the parts. Oil gradually disintegrates rubber, and care must be taken to prevent its coming in contact with the buffers.

**ARTIFICIAL RESPIRATION.** This is a method of restoring breathing in cases of drowning,

gas-poisoning, etc., by alternately expanding and contracting the patient's chest, so that air is drawn into and expelled from the lungs. The method usually employed is Prof. Schäfer's. The subject should be placed face downward on the ground, with the arms-stretched out in front, and the face turned to one side. The operator kneels astride or sometimes beside the prone body, facing the head, his knees being about the level of the unconscious man's hips. He then places his hands, one on each side of the patient, over the lowest ribs, with the thumbs parallel and nearly touching. Leaning forward and downward, he presses the base of the ribs upwards and inwards.

In this movement the arms should be kept quite straight. The result is that the air is expelled, and any water in the lung tubes is pushed out through the nose and mouth. At the end of the movement the rescuer swings back into an upright position, still leaving his hands flat against the patient's side. The first part of the movement should occupy the time necessary to count slowly 1, 2, 3, and the second, 1, 2. Care must be exercised that the hands are actually on the ribs, as seen in the illustrations, and not down on the loins.

*Artificial Respiration. In Schäfer's method the ribs are alternately compressed (2) from behind and released (1), this last causing chest expansion.*

The whole double movement, consisting of the pressure forward and the withdrawal of pressure, should take about five seconds, and should be continued rhythmically until the patient shows signs of recovering consciousness.

When the patient begins to breathe by himself, artificial respiration may be discontinued and the operator should now turn his whole attention to

stimulating the circulation by various means.

As soon as possible, in a drowning case, the patient's wet garments should be removed and he should be wrapped in warm flannel blankets, and carefully protected hot-water bottles or bricks warmed in the fire should be placed in the armpits and against the soles of the feet. The arms and legs should be vigorously rubbed, always in the direction towards the body, to force the stagnant blood back to the heart.

After the patient is sufficiently recovered to swallow, a little hot water may be given, or small amounts of heart stimulants, such as a teaspoonful of brandy in warm water or a small cupful of hot, strong coffee or tea, or a teaspoonful of aromatic spirits of ammonia in a small wineglass of water.

**ARTIFICIAL SILK.** Artificial silks are made by different processes, and there are various qualities. They are made by forming artificially a gelatinous material, hardened in contact with air or in passing through a trough of hardening fluid. This jelly-like compound is obtained by dissolving raw cotton or wood pulp. For artificial silk it is made into fine threads by being forced through minute holes, and endless lengths of filament are thus secured. Usually about a dozen of these are twisted lightly together to compose a single thread for machine-knitting or weaving. In the ordinary thick 2-ply cord used for knitting there are generally about 24 of such threads and nearly 300 original filaments.

Short-fibred artificial silk can be spun like wool or cotton, and certain mixed artificial silk and wool knitting yarns are made by blending the two materials together, when the bright silk speckles the yarn.

A good point in artificial silk for furnishing fabrics is its brightness of surface, and this varies with the amount of twisting received in making the ultimate filaments into yarn. Tight twists wear better than slack ones, but they make the thread wiry and less flexible. To reduce the brilliance and obtain a crêpe de-Chine lustre, several fancy-twisted knitting cords are made.

Reckoned per 4 oz. hank, artificial silk is cheaper than real silk, but it is not actually so much cheaper to use because it is heavier than natural silk, of which fewer hanks are required to knit the article. Artificial silk should not be knitted or crocheted too tightly or with too fine a needle.

Artificial silk can be distinguished from natural by touching an end of thread with a match flame. The artificial will burn freely with a white flame, leaving little ash behind. Natural silk is nearly non-inflammable. The flame does not run and the ash forms itself into a knob and at the same time a slightly unpleasant smell is emitted.

Care must be exercised in washing. Tepid water should be used and a pure soap. On no account should the article be mangled. After rinsing, the excess of water may be gently squeezed out inside a towel.

Artificial silks made by different processes behave differently in the dye bath, and an experiment should first be made by dyeing a sample of the material.

**ARTIFICIAL SKIN.** Collodion, or a preparation like it, is used to paint over fresh, clean cuts or hacks to protect them from irritation or infection. These preparations should not be used where the wound is dirty or discharging, as harm is done if the discharges are pent up. *See Collodion.*

**ARTIFICIAL TEETH:** Their Care. Knowledge with regard to the care of sets of artificial teeth or dentures is necessary on account of the different nature of the material composing the teeth, and the base or plate to which they are attached. The artificial teeth or porcelain part should not be rubbed by anything in the nature of a tooth powder, otherwise the translucency and polish of the enamel may be lost or injured. When the surfaces of the teeth become discoloured, they should be well rubbed with the forefinger covered with white muslin moistened with soap and water.

The plate to which the teeth are attached may best be cleaned with a small toothbrush and whiting, special attention being given to hollows and crevices. Time and trouble are avoided by placing the denture at night in water to which a few drops of antiseptic have been added. By morning matter which is apt to adhere tenaciously to artificial plates is easily removed.

The difficulty of keeping gold plates and clasps bright is greatly overcome by putting them into a chlorinated antiseptic. Special care is necessary in the cleansing of bands or clasps and the parts in direct contact with the natural teeth.

Artificial teeth should almost invariably be taken out of the mouth overnight. Particularly is this necessary when some natural teeth are still present. In addition to the cleaning of the denture in the morning, it should be rinsed after every meal. Artificial teeth are fragile and easily broken.

*Arum Lily which has produced a considerable number of blooms although grown in a small pot.*

**ARUM LILY.** In spite of its name this beautiful plant, with its rich, green leaves and pure white flower

spathe, does not belong to the genus *Arum*, but to *Richardia*, and as *Richardia Africana* it is also known as the Lily of the Nile. It is grown in a fertile compost of loam and a third of decayed manure (preferably cow manure) with sand. Splendid plants can be grown in 6-in. pots, with abundant watering and liberal feeding with liquid manure.

In summer the plants are put out into the open garden in well-manured soil, and given occasional soakings of water in dry weather. They are potted up in September, and kept in a cool greenhouse in winter. Little Gem is a favourite variety, of which Godfrey's arum lily is a special form. There are also two yellow-flowered species, *Elliottiana* and *Pentlandii*, which are best grown in pots throughout the year. Pron. Air'-um.

**ASBESTOS.** Being a fibrous material which is non-combustible, asbestos has many uses for fire protective purposes. It has a low thermal conductivity, and is thus an excellent heat insulating material. As an electric insulating material it has been extensively used in electric heating devices of various types. It is made up in a number of different forms, such as cord, felt, mill-board, and in sheets suitable for building purposes.

Asbestos mill-board can be purchased in sheets from about  $\frac{1}{8}$ -in. thickness upwards. The thinner boards can readily be cut to shape with strong scissors or a sharp knife, and used, for example, on cooking stoves to protect the utensils. When such boards are covered with linen or some similar material they make excellent table-mats. Asbestos can also be used to make joints in hot water-pipes, or on exhaust pipes of gas engines. Asbestos cord bound around the handles of pots and pans or on the knob of an oven door prevents burnt or blistered fingers.

Moulded asbestos is used in the form of briquettes, balls, etc., for gas heating stoves, the most efficient types being those with ample air spaces, as they radiate the heat better than the more solid patterns.

For building purposes asbestos is generally combined with other materials, such as magnesia or Portland cement, and is treated in various ways to render it waterproof. For amateur use sheets of such a material are very effective. There are several proprietary brands which can be obtained from most builders' merchants in convenient size. It has to be cut to the desired shape and nailed in place. The joints between the sheets are covered with strips of wood nailed to the "studding" or framework. The material can also be obtained in the form of tiles.

**ASH.** Tough, flexible, and able to resist shock without breaking, ash is a wood that is extensively used in many trades. It is light brown or nearly white in colour, with rather coarse grain, and the several varieties show certain differences in colour and appearance. For the handles of garden implements, hammers, hatchets, and other tools, ash is peculiarly well suited. It is used also for barrows, sticks and umbrellas, tennis rackets, hockey sticks, oars, and in gymnasia. It is also employed for furniture, and a thin

veneer of ash does well on other wood. *See Wood.*

**Ashbin.** *See Dustbin.*

**ASHES.** The ashes from household grates may be utilised for various purposes. The first care is to see that all fuel and kitchen waste is so completely burnt that the ashes are thoroughly dry and powdery. Ashes should be well sifted and the coarser pieces burnt. The cinders are useful for the garden path or the hen-run. The fine, dry powdered ashes that pass through the sieve can be made up into a paste with water and used for cleaning the outsides of saucepans. *See Dustbin; Refuse.*

**ASH TRAY.** A simple form of tray is illustrated, which may be made without any of the special tools of the metal or repousse-worker. A piece of thin brass or copper sheet of No. 18 standard wire gauge, measuring 5 in. square, is required, both sides being first cleaned with fine emery cloth and oil, and the design drawn on with a lead pencil. The pencil lines may be lined in with a sharp metal point.

The plate must be secured to a piece of wood with strong tacks driven in close to the edge, and the background of the pattern covered with indentations made with the point of a large wire nail. The plate should next be removed from the wood and the edges lightly tapped over with a hammer, holding the metal on the edge of a narrow strip of wood and at an angle of 45°. The surface of the metal should be rubbed over with dry pumice powder, applied with a hard nail-brush and, after being warmed, coated with colourless lacquer.

*Ash Tray made of thin metal sheet. A, finished tray. B, punching the pattern. C, bending the edges.*

**ASPARAGUS:** Culture and Cookery. Asparagus is propagated almost exclusively from seed.

The kitchen garden species is officinalis, belonging to the order Liliaceae, a native of Great Britain. Favourite sorts are Connover's Colossal, Battersea and Reading Giant or Large Reading (Perfection is the modern type of this variety). The Giant French or Early Giant Argenteuil is grown by those who appreciate the large French type.

No crop of any importance can be obtained until the plants are three years old. The seed may be sown in spring, in fine, friable, well-prepared soil, and covered an inch or so deep. If more than one drill is sown, it is wise to allow a space of 18 in. apart. The seedlings may be thinned gradually to 6 in. apart and alternate seedlings transplanted in the following spring, leaving the others a foot apart. They may remain for a year in order to make strong rootstocks.

Asparagus is fond of salt at all stages, and sprinklings may be laid along the rows of seedlings during their first and second years. When the growth of seedlings decays at the end of the season, it should be cut away, and a dressing of manure spread over them.

**Soil Preparation.** The plant likes abundance of moisture while in full growth in summer, but is not suited by stagnant soil during the dormant period of winter. It does not dislike heavy soils, and will thrive on clay, provided the soil is well drained and is made friable. The soil should be laid up roughly in autumn or winter in order to let the frost get well into it. Any disintegrating material available may then be added. After lying for a few weeks exposed to frost, the soil may again be dug over, preferably with the fork. On a substantial loamy or clayey soil asparagus will thrive for many years with nothing more than an annual top dressing of salt and wood ashes, but in light land a heavy preliminary dressing of manure is desirable.

The laying-out of the beds should be completed sufficiently early in the spring to permit of planting before growth is much advanced. It is not advisable to plant more than four rows at the most, and three, or even two, suffice. The rows may be 2 ft. apart, with a foot and a half of space at each side.

**Planting and Cutting.** The correct time to plant asparagus is late in March or in April. In the first summer keep down weeds. In autumn the decaying tops can be cut away and the beds furnished with a suitable winter dressing.

In the absence of seaweed, a dressing of salt may be given to the bed in spring, a quarter of a pound per square yard being a suitable quantity; or the following dressing of chemical manure may be given:

*Superphosphate of lime* 2 oz.  
*Sulphate of ammonia* ½ oz.  
*Sulphate of potash* ½ oz.

Cutting may begin on established beds at or after the middle of April, according to the soil and district. With a strong bed any shoots of about the thickness of the little finger may be severed or broken off just below

the surface. The first weakly shoots of young beds should be left intact. The crop is improved if soakings of water containing ½ oz. of nitrate of soda per gallon can be given during May and June.

Cutting should cease at the end of June, in order to allow the plants to make their annual growth, which will extend with great rapidity in July and August. Afterwards with the routine advised above a bed ought to yield heavy crops annually for a quarter of a century.

*(For detailed methods of planting and forcing of asparagus see page 82)*

**Forcing Methods.** Only strong roots, three years old or more, are suitable for forcing. These may be taken up in November and onwards throughout the winter until the season of outdoor cutting approaches. In large places there are frequently houses or pits with bottom heat which can be utilised, the roots being packed in boxes. Cucumber or melon frames may be used, the bottom heat being provided by a bed of manure and leaves. In this case, when the heat of the manure has begun to decline, a layer of three or four inches of soil may be placed on as a base for the roots, which may then be set close together and covered with the same depth of soil. A steady temperature of about 55° to 60° Fahr. is desirable. Produce may be expected to be ready for cutting in five to six weeks from the commencement of forcing. Tepid water may be given through a rose can if necessary to prevent the soil from becoming dry, and air should be admitted in favourable weather. The frame light should be covered in hard weather. The roots are of no further use after forcing.

**How to Cook.** Asparagus as a rule is served as a separate dish. If fresh when bought, the tips stand up firmly. The utensil used in cooking is a deep pan in which the bundle can be placed straight, only the tips being above the water. Should this not be at hand, put the bundle of asparagus flat in a large pan; and when done, lift out very carefully, so as not to break the points. Sauces to use are equal parts of oiled butter and lemon juice Hollandaise, or, when cold, vinaigrette.

To boil asparagus, cut the stems to an even length to fit the pan. Scrape the stalks clean from the tips downwards, taking care not to break off the heads. Tie in bundles of about eighteen, and place in cold salted water until needed. To cook them, put into boiling salted water and simmer until the heads are tender. Twenty minutes is long enough if the shoots are young. Take out carefully and drain, then place in a dish upon a slice of dry toast, which will absorb remaining moisture. The water in which asparagus has been boiled makes a good stock for soup. Drop a little butter over the tips of the asparagus before sending it to table. Serve the sauce in a sauce-boat.

*(Continued in page 83)*

## ASPARAGUS

### Asparagus: methods of planting and forcing.

1. Soil preparation and planting.
2. Where to cut stems.
3. Method of planting with crowns on ridges of soil.
- 4,5 and 7. One, two and three year old crowns.
6. Forcing in a frame over a hotbed of manure, with frame ventilated at A.
8. Forcing in a frame between sunk pathways filled with manure. B.
9. Measurements of bed for planting in the open.

**ASPARAGUS AND CHEESE.** Place a layer of boiled tops of asparagus in a pie-dish, and over it grate Parmesan cheese. Add a few pieces of butter and pepper and salt to taste; then add a second layer of asparagus with more cheese, etc., till the dish is full. Heat in the oven for 10 minutes.

**ASPARAGUS BEETLE.** A small beetle with black head, dull red fore-body, and the wing-covers over the hind-body glossy black with an outer edge of brown connected with four yellow spots. The grey-green grubs are a pest on asparagus. The surest way to be rid of them is by hand-picking and destroying the beetles as soon as they emerge. In the grub stage they may be treated in like manner. Where this is not practicable, when the foliage is wet with dew dust it with finely-powdered charcoal, soot or lime, which will adhere to the larvae and destroy them.

They may be syringed with a solution prepared as follows: Boil 2 oz. of soft soap in a quart of water, stir in whilst hot 2 quarts of paraffin oil, and dilute for use with 4 or 5 gallons of water.

*Right. Asparagus Beetle greatly magnified.*

*Below. Asparagus Fern. Foliage and flowers of a plant much used for table decoration.*

*(Courtesy of Country Life, Ltd)*

**ASPARAGUS FERN.** The orange or black berries of the asparagus fern are pretty, but it is the decorative lightness of the foliage which is most admired. Among several ornamental forms Sprengeri is a good indoor plant, enduring the dry air as few others will. Retrofractus is a similar variety. Smilax (Asparagus medeoloides) is useful for table decoration. Plumosus and nanus are used with flowers for buttonholes. A compost of loam and leaf-mould in equal parts, with a sprinkling of sand, suits the plant best.

**ASPARAGUS FLY.** This is a small fly whose two wings are banded with brown. The body is dark brown and its hinder division crossed by four lighter lines. The flies may be seen from April to July, depositing eggs about the scales and leaves of asparagus. From the eggs, a fortnight later, emerge legless yellow maggots with dark heads. These bore downwards into the shoots and stems, causing them to turn yellow and rot.

The flies may be caught early in the morning, settled on the plants; or traps may be set for them overnight by thrusting in the ground sticks whose exposed parts are smeared with bird-lime or other sticky substance, by which the insects will be held. Egg-laying is discouraged by dusting the young shoots with charcoal in fine powder. The grubs can only be destroyed by cutting out all yellow or brown shoots and burning them.

**ASPARAGUS SOUP.** Seasonable from March to July, for this soup buy the cheap bunches of slender green asparagus. Cut off the tips and boil gently for 10 minutes, then take out and set aside to garnish the soup when done. Now take the stalks of the asparagus, cut into pieces, and place in the boiling salted water, together with 1 pound of well-washed spinach. When tender, rub this through a sieve, and also set aside for a few minutes. In the saucepan melt 1½ oz. of butter, and gradually rub into it 1 tablespoonful of flour. When smooth, add to this mixture 1 pint of milk, heat, and put in the purée made of asparagus stalks and spinach, with enough boiling water to make the soup rich and creamy. Add pepper and salt to taste. Take off and garnish with the asparagus tips already boiled. Cream may be added. This is sufficient for four persons.

**ASPHALTE.** Strictly speaking, asphalté is pure bitumen, or natural pitch. Rock asphalté is a limestone naturally impregnated with asphalté. It is applied in its natural form, after suitable treatment, for the construction of road surfaces and other purposes. The term is frequently applied to natural and artificial compositions of a bituminous character. The most practical way to use asphalté for domestic purposes is to buy it in one of its many specially prepared forms. Bitumen or asphaltic damp-proof courses can be laid by obtaining the material in the form of a sheet or roll, and setting it in position between the brick courses, or

wherever needed. To render a flat roof watertight there are numerous asphaltic compositions on the market that give good results. *See* Paths; Paving.

**ASPHODEL.** The sacred lily of Greek mythology is in gardening phraseology the Asphodelus, a hardy herbaceous perennial of Southern Europe, with white or yellow flowers. The species *ramosus* attains a height of 4 ft. in good soil; it has long, sword-shaped leaves and bears white flowers in late spring and summer. It does well in a shady place. *Albus*, closely related, is a smaller plant; *acaulis*, 18 in., bears pink blossoms, and *comosus*, 2 ft., white.

*Asphodel. Flower spikes of the giant variety. (Courtesy of Country Life, Ltd)*

Closely related to the Asphodel is Asphodeline, the principal distinction lying in the upright stems. The species *lutea* produces a tall stem, sometimes 3 ft. high, clothed with dark green furrowed leaves, and studded with large yellow fragrant flowers in early summer. It is a hardy perennial, well worthy of a place in the herbaceous border. There is a double form. Pron. Ass'-fo-del.

**ASPHYXIA.** The condition in which aeration of the blood has ceased or almost ceased owing to interference with respiration is termed asphyxia. It may occur in the course of disease or it may be accidental. Thus it occurs in (1) Drowning, when water takes the place of air in the lungs. (2) Blocking of the air passages, as in strangling, hanging, or choking, where a piece of meat or other foreign body gets into the windpipe, or where a large mass sticks at the back of the mouth or in the gullet. Or the blocking may be due to swelling produced by stings or by swallowing boiling water or corrosive poisons. Choking may also occur in diphtheria. (3) Compression of the chest, as

when a person is buried by falling earth, etc, (4) Inhalation of coal gas, chlorine, sulphurous acid, and other poisonous gases. (5) Disease of the respiratory centre in the brain or paralysis of the nerves or muscles of respiration, as by certain poisons. (6) The treatment is to remove the cause, loosen tight clothing about the chest, draw forward the tongue and see that the mouth and throat are clear, and if breathing has stopped begin artificial respiration. Remember that more than one cause may be present. The cause will be dealt with as follows:

**Strangling:** loosen, or, if necessary, cut whatever is constricting the neck. **Hanging:** cut down. **Choking:** prize open the jaws, if necessary, with the handle of a spoon covered with a handkerchief, and endeavour to hook forward the obstruction, or, especially in children, invert the body and slap the back. **Compression of the chest:** uncover properly if from falling earth, or secure space when the cause is compression in a crowd. *See* Artificial Respiration; Suffocation.

*Aspic. Savoury dish of hard-boiled eggs served in aspic jelly. (Courtesy of Ward, Lock & Co., Ltd.)*

**ASPIC.** This savoury jelly is made from meat stock and gelatine or from calves' feet, and flavoured with herbs and sherry. Cutlets, eggs, prawns and other foods are embedded in the aspic jelly, to form dainty entrees or supper dishes. A recipe for aspic jelly is as follows:

Put  $\frac{1}{2}$  pint of water and  $2\frac{1}{2}$  oz. French gelatine into a clean saucepan, together with  $\frac{1}{4}$  pint of sherry, the same quantity of chili, tarragon, and malt vinegar mixed, a bunch of mixed herbs, the juice of two lemons and the rind of one, a good sprinkling of salt, ten white peppercorns, the whisked whites of two eggs and their shells crushed, an onion, a carrot, and a turnip, and a stick of celery. Whisk all these together till they boil, and, after boiling up well, strain them through a cloth until clear. Serve in small moulds containing the prawns or other food required.

**ASPIDISTRA.** Green and variegated are the two forms of the aspidistra. They benefit by having the leaves sponged frequently with soapy water.

The variegated is the more delicate, and apt to revert to the type. The green leaves should be cut away as they come, and the plant kept away from draughts and fire heat. Compost, three parts loam, two parts leaf-mould, and one part sand. Propagation is by root

division and suckers in spring. Pron. Aspy-dis'-trēr.

*Aspidistra: dividing and re-potting. 1. Plant that needs re-potting. 2. Single leaf division. 3. Six-leaf division, the best way. 4. Root, showing the leaf buds at A. 5. Section of pot, showing correct preparation of soil.*

**ASPIRIN.** Acetyl-salicylic acid, a drug used to relieve pain, reduce fever, and combat rheumatism, is equally known under its trade name of aspirin. It gives relief in most cases, but in some people it produces gastric acidity. In feverish conditions it induces perspiration, and exposure must then be avoided. Combined with quinine it is useful at the beginning of malaria and influenza, and 5 grains of each might be given for the latter. The same dose would help neuralgia.

**Asplenium.** See Spleenwort.

**ASSAULT.** In English law an assault is "an attempt or offer with force or violence to do corporal hurt to another." It is thus more than a threat, although it is still an assault if a person attacking another with a stick or other weapon misses his aim. Battery is an aggravated form of assault in which actual injury has been done. The maximum punishment for a common assault is 12 months' imprisonment with or without hard labour. If bodily harm has been done, three years' imprisonment may be given. See Separation Order; Summons.

**ASSESSMENT.** The term assessment is applied to the annual value of land or income in order to ascertain the sum which a man should pay in rates or taxes. Houses and other property are assessed at a figure, known as the rateable value, and on this the rates are calculated. The valuation is made by the assessment committee in each area.

Assessments are revised from time to time. A man who considers his property is assessed at too high a figure should apply to the clerk of the local assessment committee. See Income Tax; Rates.

**ASSETS.** In the case of a deceased person the assets are estimated by a valuation.

Stocks and shares are reckoned at the price they stood at on the market on the day of the death of the deceased. Shares in a company not quoted on any Stock Exchange should be valued by the directors or the secretary. If the deceased had a business, an estimate is made of the machinery, stock-in-trade, etc., and something added for goodwill—from three months' to two years' profits according to the kind of business. But the test is, what price would be paid by a person who wanted to buy a business of that kind. See Executor; Will.

**ASTER.** This name is usually, but incorrectly, given to the popular summer-flowering annual, the China Aster. The real aster is the perennial Michaelmas Daisy (q.v.).

### ASTHMA: Self Help for the Patient.

The chief symptoms of asthma, which is a disease of the chest, are attacks of great difficulty in breathing. They often come on suddenly, and may be followed by equally sudden relief. The disease is due to a spasmodic contraction of the smaller branches of the windpipe. Some shock to the nervous system is probably the primary cause.

The circumstances which bring about this nervous activity are numerous. The inhalation of such substances as pollen, horse dandruff, cat or dog hair, the ingestion of some foods, e.g. white of egg, or infection with pus-producing microbes, appear to be responsible in many cases. At other times there is irritation from some condition inside the nose. The disease is often an inheritance from parents who have themselves suffered from it. It affects mainly males, and frequently begins in childhood.

During the attack the patient should be allowed to place himself by an open window and to get into any position which appears to him to minimise his difficulties in breathing. When it can be taken, a mustard emetic (a tablespoonful of mustard in a glass of warm water), by making the patient vomit, sometimes relieves the spasm and terminates the seizure. A cup of strong coffee is useful.

Medicated papers and powders are sold by chemists to be burnt during asthmatic attacks, the resulting fumes having a sedative effect on the excited nerve-endings in the lung. A simple but useful fumigant of this kind can be prepared at home by soaking thick blotting paper in a strong solution of nitrate of potash, and then drying. Bend the dried paper into a cone and set light to one corner, letting the patient inhale the fumes.

It is not desirable, however, that the patient should rest content with a fumigant, a spray or anything else which relieves his paroxysms. The causes underlying these must be investigated, and he can help his physician by carefully observing and making notes of the circumstances which precede the attacks, e.g. the food he eats, or contacts with animals or plants. The

pollen variety is likely to be seasonal. His adviser can help him to fix responsibility on anything suspect by testing solutions of it on scarifications on the skin. If there is a reaction there, he will know what to avoid, or his resistance to such a substance can be raised. Or it may be found that a vaccine does good, or the correction of some intra-nasal condition.

The medicinal remedies most in use are arsenic and the iodides. The patient should live a well-ordered life, with sufficient exercise and plenty of fresh air. His meals, of moderate size, should consist of good, plain food, and the evening meal should be small. He should avail himself of the bracing qualities of baths as cold as he can bear them, followed by a brisk rub down. It is worth repeating that if a man, early in his disease, explores every avenue for escape, there is hope for him; but there is little if he accepts a destiny of invalidism in a drug-impregnated atmosphere.

In children treatment should be under medical supervision.

*Astigmatism. Simple test for normal vision. If the sight is correct, all the lines in the diagram should appear equally distinct.*

**ASTIGMATISM.** Abnormality of vision, due to the bulging, transparent portion of the eye (the cornea) not being equally curved in all directions, produces astigmatism. Rays of light striking on the deformed cornea are not accurately reflected on the inner, sensitive part of the eye (the retina), with the result that the vision is inaccurate. It should be corrected by spectacles. *See Eye; Spectacles.*

**ASTRAKHAN.** The cured and dyed skin of certain lambs used for trimmings on coats and dresses, or coats are made entirely of it. The real skin is imitated by knitted and woven goods, an astrakhan cloth being made with mohair curls on a foundation of threads.

**ASTRINGENT.** Alum and sulphate of zinc, are examples of drugs which are used as astringents to control bleeding, to reduce the outpouring of fluids from mucous surfaces, and to stop discharges. Other drugs similarly used are tannic acid, perchloride of iron, and lead acetate. Astringent lotions containing benzoin, witch hazel, etc., are used for the face. *See Beauty Culture; Complexion.*

**ATHOL BROSE.** To make athol brose, mix in a tumbler a wineglassful of whisky with a large teaspoonful of honey, and fill up with milk that has been nearly brought to the boil. A well-beaten egg may be added.

**AT HOME.** This term is employed for an afternoon party to which formal invitations have been sent out, but occasionally means the periodically fixed At Home day of the hostess. These have decreased in popularity, but where still continued a lady notifies on her visiting cards the day (weekly or fortnightly) on which she will be at home to callers. The usual hours are from four till six, and tea is served in the drawing-room, poured out by the hostess or by a daughter, not by maids. Gentlemen leave their hats and coats in the hall. Ices are not usually served at such At Homes, but there may be a great variety of dainty small cakes, cut cake, paste or cress or cucumber sandwiches; also thin bread and butter and, in winter, small hot buttered scones.

Guests, on arrival at any At Home, do not inquire if the hostess is in. At very large formal parties they may be offered tea at once and taken to the tea-room before going to the drawing-room; but in any case the servant precedes them to the drawing-room and announces them. The hostess stands near the door to receive guests when a number are expected. When dancing, bridge, or a special programme of music are the objects of the party the hours are usually from three o'clock to six, or later, and the guests remain for the whole afternoon; otherwise people come and go as they please, and move about the room to talk to their friends, or go to have tea, when this is served during the party in another room. Only at a small party can the hostess talk to all her guests or introduce them generally. It is unnecessary to take leave of the hostess, unless she is standing near the door, or it is the guest's first visit, when it would be more formal to do so. Guests make their way to the hall, and servants call up cars or taxis, if required. Gratuities are never offered to servants.

For the formal At Home party invitations are sent out a week or two weeks in advance, and acceptances are expected in writing. The card of invitation bears the printed name of the hostess, with At Home underneath then the date of the party beneath that. The address should be in the right-hand bottom corner, and in the left "Bridge," "Music," or whatever form of entertainment is to be provided, and the time. The guest's name is written in ink on the top left-hand corner. An increasingly popular form of At Home is the sherry party. More formal than the cocktail party, which it has to some extent superseded, it is held usually from 6 to 8 p.m. Sometimes dancing is included to enliven the party; and this is stated clearly on the invitation: "Sherry and Dancing, 6 to 8," with the name of the person invited written in the top left-hand corner. Bridge-party clothes, i.e. fairly elaborate afternoon wear, are usual. Women generally keep their hats on. The sherry party is also a good way of celebra-

ting an engagement or "house-warming." "Softdrinks" or gin, for those who prefer them, are often served as well; but the sherry is the important thing. Good sherry (q.v.) is the same price as bad: let your wine-merchant advise you. You are not obliged to buy it by the crate. 4s. 6d. per bottle is a reasonable price. Food at sherry parties nowadays includes Danish delicacies such as Smorrebrod (a kind of large savoury sandwich of which there are many varieties), chipolata sausages, stuffed olives, and cheese-straws, with perhaps some salted almonds and raisins. *See* Cocktail; Dinner Party Etiquette; Reception; Sherry; Wedding.

Atomiser. *See* Spray.

**ATROPINE.** Atropine or atropia is the active principle of the belladonna plant or deadly nightshade. It is much used in eye diseases, as it dilates the pupil widely.

Both atropine and various preparations of belladonna are dangerous drugs, and should never be used except on a physician's directions. The practice of using drops of a solution of atropine in the eyes to make them lustrous is most dangerous. *See* Belladonna.

**ATTACHÉ CASE: Its Renovation.** The best attaché cases are made of cowhide, but cases of similar appearance are made with a cardboard foundation covered with thin leather and lined either with leather or cloth. The solid leather case will stand much wear and tear, but the leather-covered varieties are liable to break away at the corners and get out of shape. Cheaper kinds are made of compressed fibre.

The leather covering is kept in good condition by rubbing over occasionally with brown boot polish; fibre covers should be treated with furniture polish. When the sewing at the corner of leather cases gives way or shows signs of wear, a thin leather corner piece may be sewn on; further strength may be given inside by fitting a tin or thin brass corner plate, which is attached by means of bifurcated rivets. To clean an old leather attaché case, use a weak solution of oxalic acid, applied with a rag; polish when dry with a good brown boot polish.

**ATTACHMENT.** A person can be attached—that is, arrested—by any judge of a court of record if he is guilty of contempt of court. Attachment of debts is the process by which one person can obtain money which is owing to another who in turn owes money to him. For instance, A owes B £100, which B cannot obtain. B, however, knows that C owes A £200, so he can obtain an order of the court by which he attaches £100 of this debt; i.e. C, instead of paying £100 to A, pays it to B. The order by which this is done is called a garnishee.

**ATTESTATION.** This word is used by lawyers for the act of testifying or witnessing to anything, either by signature or on oath. All wills must be attested by two witnesses, who must be present at the same time,

and must sign their names on the document in the presence of the testator and of each other. *See* Will.

**ATTIC.** If left in an unfinished state by the builder, the attic is not of much use until the walls and ceiling have been plastered and papered; but this is easily done. At the same time it should be ascertained that the roof and window are watertight. The fireplace usually possesses a chimney that smokes in a high wind, so lighting and heating should be carried out, if possible, by gas or electricity.

An attic window sometimes lends itself to picturesque treatment with a window-seat. For an attic bedroom quaint chintz or cretonne may be used for the curtains, window-seat, chair cushions, and bed drapery. If children are to play in the room a large table should be provided, covered with brightly coloured American cloth, the same fabric being used for the curtains, as it can be easily and frequently washed with a damp cloth and soap.

Any odd pieces of furniture may furnish an attic, and if they are shabby they may be scraped and enamelled in some suitable shade. The floor should be stained or painted if good,—or, if not, covered with parquet linoleum and a rug or two. As draughts enter below attic doors, felt weather stripping is often necessary, or a piece of boarding arranged to keep away the draught. A screen adds cosiness.

It is not difficult to convert an attic into a sitting-room. As its window will doubtless be small, the walls should be made light in colour; cream or light grey distemper gives a satisfactory effect, or primrose yellow, or pale green plastic paint for a bad wall surface. A thick coat of the paint is laid on and finely stippled.

A cheap seat can be made from a wood frame on short legs, adorned with cretonne hangings and provided with a cretonne-covered cushion. Easy chairs which are no longer required for rooms downstairs can be given a new lease of life by means of loose covers of cretonne to match.

Wood shelving, enamelled or stained, will conveniently fill the odd corners. A bureau or tallboy affords a good deal of storage space. The bureau should be placed by the window to enable the writer to see well.

Should the room be disfigured by means of a chimney passing through it, the latter can be encased by bookshelves stained to match the rest of the woodwork. Treated in this way it will be hidden from view.

Many people who convert their attics into sitting-rooms have the walls panelled in such a way that one of the big panels can be lifted out at a moment's notice. When this is done a large cupboard running the entire length of the room is disclosed, and this contains trunks and a collection of other miscellaneous articles usually stored away in a loft. A wardrobe is not recommended

on account of the space it occupies, and because a curtained recess can be fitted up with hooks and stretchers to do equally well.

*Attic. Two views of an old-fashioned wallpapered attic converted into a comfortable bedroom. The grate is filled in and a gas stove fitted. Furniture is rugged and "dumpy"; electric light is let into the ceiling. (Photos: Lincoln Collins Studio)*

In the case of a girl's bed-room, a long mirror can be fastened against the wall. A pedestal desk with a glass top and swing mirror makes an effective dressing-table, while for a washstand a small table with a coloured rush mat behind it will serve. A bedstead without a foot rail gives an attic the appearance of roominess.

A small bedside table, a bookshelf made from a long narrow box and stained to match the rest of the furniture, together with an easy chair, brightly coloured rugs and a harmonizing cretonne will furnish a pretty room.

The storage space provided by an attic or loft is often wasted because there is no ready access to it. Many attics are entered only by a rectangular trap door, and steps or ladders have to be carried up every time there is any reason to go into the attic. The illustration shows a type of disappearing stairway which can readily be brought into use when required. This is made in a wide range of standard sizes, and is sent out ready to be installed by the user. Should it be necessary to do so, the stairway can easily be removed. *See Bedroom; Chair; Curtains, etc.*

*Attic. Sliding stairway which is lowered and raised with ease. When out of use (above) it is concealed behind a panel in the ceiling. (Courtesy of H.C. Slingsby)*

*Attic. How it may be transformed into an attractive sitting-room.*

**ATTORNEY.** Power of attorney is the authority which one man gives to another to carry on his business for him. Sometimes power of attorney is only given for a single purpose. Sometimes it is a general power of attorney which enables the holder to do all things which normally require the signature of his principal. The stamp duty is 10s.

**ATTORNMEN.** The attornment of a tenant to a landlord takes place when the property passes from one owner to another, and the tenant acknowledges the new owner as his landlord. After attornment the tenant is not allowed to deny that his new landlord has

a good title to the property. *See Mortgage.*

**AUBERGINE.** The seed is sown in a box or pan in late winter or early spring, set singly in small pots, and transferred to larger ones, using good loam with a quarter each of leaf-mould and decayed manure with sand, and giving plenty of water. There are white varieties, but the best cookers are the Early Purple, Long Purple and New York Purple.

*Aubergine in fruit. It has a delicate flavour.  
(Photo from Country Life, Ltd.)*

**Baked Aubergines.** To prepare these wipe and put in a casserole with a very little water at the bottom. Cover them and bake in a moderate oven until tender. They can be served in the casserole. In eating cut them open and mash them with a little butter, pepper, and salt.

**Fried Aubergines.** Take two aubergines, one egg, and a little flour, salt, pepper and breadcrumbs. Remove the peel and cut the aubergines into slices. Soak these in strong brine for about 2 hours, as the plant seems more bitter when fried. Drain them in a cloth, dip in flour previously mixed with salt and pepper, brush over with beaten egg, and coat with breadcrumbs. Fry in hot fat, drain on soft paper, and serve hot. A frying batter may be used instead of egg and crumbs. Pron. O-ber-zheen'

**AUBRIETIA.** Coming into bloom before spring is far advanced, the purple rock cress or Aubrietia is generally at its best in April or May, but loses brilliance in summer, and after being cut back soon begins to grow again. On the rockery these plants form cascades of colour, while in beds they are a ground work for tulips. They are propagated by seed sown in spring, preferably under glass. The seedlings should be pricked out in a spare bed for the summer, and planted where they are to flower in autumn.

Only one species is in general cultivation. This is

*Aubrietia. Clump of this quick-spreading, brightly coloured plant which thrives in rock gardens.  
(Photo from Sutton & Sons, Ltd.)*

deltoidea, with purple flowers. Modern varieties of it include Bougainvillea, Fire King, Royal Purple, Dr. Mules, Lavender, H. Marshall, Leitchlinii, J. S. Baker, Pritchard's A1, Violaacea, Moerheimi, Lloyd Edwards, Excelsa, and Violet Queen. Pron. O-bree'-sha.

**Auction Bridge.** *See Bridge.*

## AUCTIONS AND AUCTIONEERS.

In most cases people prefer to do their own bidding at auction sales, but a broker may be employed at a small commission to bid up to a certain figure for any articles desired, and his services are useful in a crowded sale-room. He is also useful in arranging for the removal of purchases the day after the sale—a matter of expense which must not be overlooked in determining limits of prices to be bid.

There are special sales in various places, and on the premises of certain celebrated firms where the word antique in the catalogue is a genuine guarantee; but in the mixed sale of furniture and effects antique is used indiscriminately to describe anything not in the style of the last thirty years.

For the casual buyer, cash payments are the rule—a deposit being paid to the clerk for each article as it is knocked down, and the remainder before the goods are removed. After one or two visits resulting in business a client's cheque will be accepted at the conclusion of the sale for the amount owing.

For the vendor also there is opportunity in the auction sale. Instead of bargaining with a private buyer, the haggling is done by the bidders, and there is the possibility of a price being obtained in excess of expectation. In selling a houseful of furniture and effects, it is well to consider the question of a sale on the premises, placing the business in the hands of a good firm of local auctioneers. The usual commission charged on each article is 10 p.c. of the sum realized.

A reserve price should be put on valuable pieces.

The vendor is then responsible to the auctioneer for a commission on the highest figure bid, should it fall short of the reserve and result in no sale—but such commission is usually only 2½ p.c., with a minimum of 2s. 6d.

Good furniture and effects which have intrinsic or fashionable value are best sent to sale-rooms which attract a large number of well-to-do buyers, where sales are held once or twice a week regularly, and goods received to be catalogued four or five days before the sale. Sotheby's is a recognized mart for rare books, and Christie's for valuable china. Advice and valuation can be obtained from an expert for a small charge.

**Legal Aspects.** From a legal point of view the auction is an offer of property to the highest bidder. It follows (1) that the owner of the property cannot bid himself, so as to run up the price. If he does so, the buyer can cancel the sale, return the property and demand his money back; (2) that unless it is duly advertised, or stated by the auctioneer, there can be no reserve price. The only exception to (1) is that in the case of a sale of landed property the owner may employ one person to bid for him. The sale is complete on the fall of the hammer.

Although a sale of goods, etc., may be advertised without reserve for a certain day, the owner is not obliged to put them up on that day or at all. He may sell by private treaty beforehand, or withdraw the property from the auction. This will not deprive the auctioneer of his right to be paid. The auctioneer need not accept a bid; but once he has accepted it he is bound to knock the property down to that bidder unless there is a higher bid. If two persons simultaneously bid the same amount, the auctioneer can accept which of the bids he pleases. An auctioneer is not entitled to sell except for cash. Those who bid at an auction should read the conditions of sale carefully. Anyone entering into a "knock-out," i.e. an agreement among dealers not to bid against one another, is liable to a fine of £100 or 6 months imprisonment or both.

*Auger. Correct manner of holding the tool.*

**AUGER.** This tool is used for boring holes to a greater depth than is practicable with brace and bit, especially in hard wood. It consists of a steel shank terminating in a twisted cutting-bit, the wooden handle passing through the eye of the shank. Augers may be obtained in sizes from ¾ in. up to 1½ in. In using this tool it is essential to keep the shank in a true vertical position while cutting, watching it from two different angles. *See Boring.*

**AU GRATIN.** A dish served au gratin is one

covered with sauce and grated cheese or breadcrumbs, and brought to the table in the dish in which it is cooked. Fish and vegetables are frequently prepared in this way. *See Cauliflower; Egg; Macaroni; Sole, etc.*

**AURICULA.** Hardy and half hardy perennial, easily raised from seed. The indoor or show varieties are always grown under glass. The soil should be good loam with some root fibre in it, about a third part of leaf-mould, some decayed hotbed manure, and a little sand for drainage.

*Auricula. Fine specimen of the plant allied to the primrose. (Reginald T. Malby)*

Potting is generally done in spring, soon after the flowering is over, and the plants kept in a frame facing north throughout the summer, but they are given a south exposure after the end of October. Towards the end of winter gentle heat may be given, but no attempt must be made to force. Water carefully as growth proceeds, and the reward will be a crop of exquisite blooms in March. A small brown grub often causes trouble, and this must be watched for and destroyed.

Propagation is by division after the flowering period, each of the crowns making a new plant.

For outdoor cultivation seedlings are generally sold under the name of border auriculas, but a beautiful yellow strain is to be obtained separately. Border auriculas require to be sown in cold frames in February and planted out in a semi-shaded nursery bed in June if they are to make good plants for bedding out in autumn.

Border auriculas are charming in clumps along the front of herbaceous borders, and also in beds, where they may be associated with hardy primulas in spring.

# AUGUST

## What to do in the Garden

### Flowers

Sow mignonette  
Take layers of carnations.  
Take cuttings of geraniums, antirrhinums, pansies, pentstemons, and violas, and put in cold frames  
Pot up Roman hyacinths for Christmas flowering  
Pinch off all seed pods from sweet peas  
Fumigate greenhouse, and syringe plants during hot weather  
Bud roses

### Fruit

Gather early apples, and summer-prune old-established apples and pears  
Finish budding as early in month as possible  
Keep roots of cherry-trees well moistened  
Gather peaches before full heat of sun  
Cut out old wood from black currants  
Re-pot young strawberries rooted from runners in July

### Vegetables

Break leaves over tops of cauliflowers when hearts are developed  
Earth up celery  
Sow cauliflower seed in frames, also sow pickling cabbage  
Sow winter onions, and tread soil down firmly beforehand. Sow turnips for winter use.  
Put in last sowing of radish seed  
Cut herbs for drying, and hang them upside down, in a cool place

## Food in Season

### Fish

Bass; bream; brill; dory; eels; flounder; haddock; hake; halibut; mullet; plaice; perch; pike; salmon; shad; sole; tench; trout; turbot; white-bait; whiting

### Shellfish

Crabs; crayfish; lobsters; prawns; shrimps

### Meat

Beef; lamb; mutton; veal

### Poultry and Game

Chickens; ducklings; ducks; fowls; geese; goslings; pigeons; turkey poults; black-game; capercailzie; grouse; hares; plover; rabbits; venison; woodcock

### Vegetables

Cresses; cucumbers; lettuce; radishes; endive; celery; mushrooms; onions; tomatoes; watercress; artichokes

chokes; aubergine; beans; beetroots; Brussels sprouts; cabbage; carrots; cauliflower; leeks; marrows; peas; potatoes; spinach; turnips

### Fruit

Apples; apricots; bananas; cherries; damsons; grapes; green-gages; melons; medlars; nectarines; nuts; oranges; peaches; pears; pineapples; plums; quinces

## Notes for the Month

AUGUST 1.—Lammas, quarter day in Scotland

AUGUST 4.—Great Britain declared war on Germany, 1914

AUGUST 5.—Oyster season opens

AUGUST 11.—Half quarter day

AUGUST 12.—Grouse shooting begins

The first Monday in August is a bank holiday in England and Wales

The plants may be lifted from the beds or borders towards the end of May, and planted in a reserve bed, preferably in a rather shady place. Pron. Or-rik'-u-la.

**AUTUMN:** In the Garden. Strictly speaking, the autumn season extends from September 21 to December 21, but popularly it is regarded as covering the three months of September, October and November.

Apart from the routine work of each month, autumn is the proper time to take in hand the lay-out of a new garden, or to make any alterations required. Rough turf should be dug up, piled and systematically fired from time to time to destroy weed seeds. Afterwards the residue may be spread upon the ground to await further cleansing and disintegration by winter frosts.

Hardy spring flowering bulbs, crocuses, snowdrops, and daffodils, may be planted at any time during the autumn, though daffodils yield the best results when planted in September. April tulips should be planted during the month of October, whatever the existing climatic conditions, to obtain the best results. May flowering tulips are planted early in November.

In the gardens of the protected southern and western districts of the country the autumn is the time for planting roses and fruit trees. In the northern and eastern parts of Britain planting is better deferred until the spring, unless it can be completed by the end of November.

The greenhouse needs careful management in the autumn. An important detail is to close the ventilators early in the afternoon; this has the effect of maintaining the required temperature without the aid of much fire heat. Watering should be done in the morning so that the atmosphere may be dry by even-ing. See Gardening; September; October; November.

**AVIARY.** As generally understood this is an outdoor cage for captive birds, sufficiently large to permit the birds inside to fly. One portion should have close walls and roof, and be fitted with nesting boxes and natural branches for perching, the remaining portion (say three-fourths) being left open save for wire-netting of small mesh. This portion should be furnished with growing shrubs in tubs, drinking water, bath, etc.

For the construction of an aviary, the chief materials required are 2 in. deal quartering, feather boards and wire-netting. If possible, it should be built against a wall, and should face S. or S.W. Supposing the length decided upon to be 12 ft., the height 8 ft. and the depth from back to front 6 ft., the quartering for the framework would be three lengths of 12 ft., three of 9 ft., five of 8 ft. 4 in., and nine of 6 ft. ; the 8 ft. 4 in. to have their lower ends tarred for 6 in., of which 4 in. will be inserted in the ground.

The 9 ft. uprights having been fastened to the wall at equal distances apart, a 12 ft. horizontal is attached to their tops, a simple joint being made by cutting half through the wood, so that they interlock. The remaining two 12 ft. lengths and the five 8 ft. 4 in.

lengths are joined up in similar fashion to make the frame of the front, which is then connected with the back by means of the 6 ft. lengths, as shown in the diagram. The side, front and roof of the eastern fourth are boarded in and tarred on the outside, roofing felt being added here.

The remainder of the structure is then covered with wire-netting. A small door should be contrived, hinged on an upright and opening inwards to a sort of wire "lock" to prevent birds escaping as anyone enters the aviary. In selecting tenants, the seed-eating woodland and hedgerow birds will be found the most suitable. The tits, which are mainly insect eaters, may be included, and meaty bones, suet, and coconut substituted for insect food. See Bird Cage; Canary.

*Aviary for hardy birds, built against a garden wall. It is constructed with a boarded shelter to protect the inmates from the weather.*

**AVOIRDUPOIS WEIGHT.** By far the most used of English weights is avoirdupois, food and materials being usually sold by it. It is as follows:

16 Drams = 1 Ounce (oz.)  
 16 Ounces = 1 Pound (lb.)  
 14 Pounds = 1 Stone  
 28 Pounds = 1 Quarter  
 112 Pounds = 1 Hundredweight (cwt.)  
 20 Hundredweights = 1 Ton

In the case of certain articles the stone is less than 14 lb.

**AWL.** A fine-pointed tool, the awl is used by bootmakers, saddlers, cobblers, and all leather workers for making holes to receive the thread when handstitching is being done. Its blade is not edged but pointed. See Boot Repairing; Bradawl.

**AWNING.** The fittings of window awnings must be strong and well made, so that they may be drawn in and out with ease. Where a large French window opens on to a garden a wide awning, the full width of the window, fitted in the same way as the ordinary awning

used for shop windows, adds to the amenities of a small house in summer.

Awnings for the garden range from the giant sun umbrella and the simplest awning spread over four uprights to what becomes virtually a summer-house. The favourite material for making these is striped cloth in red and white or green and white.

Awnings should not be exposed to dew and rain without being properly dried. Before they are put away for the winter they should always be well laundered so as to keep the material in sound condition. *See Tent; Waterproofing.*

**AXE.** This tool for cutting wood and felling timber consists of a weighty head with sharp cutting edge, the helve or handle being of varying length according to the work required. It is employed with a wide swinging stroke, at the beginning of which the right hand is just under the head, the left at the other end of the helve. During the swing the right hand slips down the handle, until, as the axe is brought down, both hands are together. For lopping light branches a blow is given on the under-side of the branch.

*Axe. How to hold to obtain the correct swing in felling a tree.*

For felling trunks the axe is wielded first in a downward sloping direction, then in an upward direction, to take out a V-shaped chip; the V is then gradually increased to the centre of the trunk. A notch is then commenced on the other side, and continued to meet the first V in the centre, when the tree falls away from the cutter.

If the edge of an axe is rubbed occasionally with a carborundum, the tool will require less frequent grinding. The wedge that secures the head is made of some hard wood. If a new wedge is needed, cut one longer than the depth of the cut in the handle, and sufficiently wide. Hammer it in as far as it will go, and then saw it off level with the axe head. *See Chopper; Hatchet.*

**Axle.** *See Front Axle; Live Axle; Motor Car.*

**AXMINSTER CARPET.** A tufted, machine-made fabric, the pattern being formed by tufts of woollen yarn, cut off and inserted in the body of the carpet. It is made in different qualities and in two

kinds, seamless squares and in breadths. *See Carpet.*

**AZALEA.** These flowering shrubs, now classified as rhododendron by the botanist, consist of several species and numerous varieties of three types:—the Indian azalea (*rhododendron indicum*), the Ghent, and the mollis azaleas. The Indian azalea, largely imported from Holland, is grown chiefly under glass for spring blooming. The Ghent and mollis azaleas are used similarly and also as hardy summer-flowering shrubs; the flowers are brilliantly coloured—orange, apricot, salmon, rose, etc. They thrive best in soil mixed with peat or leaf mould. The correct potting compost for Indian azaleas is peat and loam with sand added freely.

*Azalea. Luxuriant bloom of a potted plant. (Courtesy of Sutton & Sons).*

When the plants are potted, room should be left for adequate watering, as many failures occur because of dryness at the root. Periodical syringing of the foliage before the plant comes into bloom is also beneficial, and as the buds swell an occasional top-dressing of manure should be given. After flowering the plants should be stood out of doors for the summer on a bed of ashes. Repot immediately after the flowers have faded.

To propagate azaleas, cuttings are taken when the plants are making new growth. Young but sturdy shoots should be chosen, and they will root better if they are pulled off the stem, so that they retain a heel of the old wood.

Good varieties of Azalea Indica: Deutsche Perle (white), Fielder's White (white, large flowers), Alice (deep rose, double), Bernard André (violet purple, double), Souvenir de Prince Albert (rosy salmon with white edge), Criterion (salmon pink), John Gould Veitch (lilac rose), Madame van Houtte (carmine and rose, flaked), and Vervaeana alba (white).

*(Continued in page 95)*

**'A' RECIPES: A SELECTION SHOWN IN ACTUAL COLOURS**

Alexandra Pudding, made of 6 oz. bread cut into cubes and soaked in 2 eggs beaten up with  $\frac{3}{4}$  pt. milk. Add 3 oz. currants, 2 oz. sultanas and 2 oz. chopped candied peel; grated rind of 1 lemon, 3oz. sugar. Colour with browning. Put in greased basin and steam for 1½ hr. Apple Hedgehog, i.e. baked apples with almonds, covered with icing sugar and browned in oven. Amber Jelly: Follow general directions for Jelly and add a little sherry, lemon-juice, two eggs and pieces of any fruit desired.

## BABY: THE FIRST YEAR OF LIFE

### Practical Advice for the Young Mother

For infant care from the second year onwards, *see* Child; other information is given under Baby Chair; Cot; Perambulator; etc.

Mother ignorance is responsible for a fair proportion of the children we lose before their first birthday. Unhealthy motherhood accounts for many of these deaths, so that the first duty of every expectant mother is to care for her own health. The ante-natal period of life is also very important to the health of the baby. That is why ante-natal clinics have been organized so that mothers may attend during pregnancy to receive medical advice.

The expectant mother should always see a doctor three or four times before the baby is born, and before the first baby's birth this is especially necessary, as certain simple measurements have to be made in order to know that the young mother is capable of bearing a fulltime child of average size.

The term "hygiene of pregnancy" includes proper diet and exercise for mothers during the months before the baby is born, and the provision of fresh air, rest and healthy sleep. The expectant mother ought not to over-feed. Indiscretions in diet cause the dyspepsia with heart-burn which makes so many mothers miserable at this time. Light, nourishing food, with flesh meat served certainly not more than once a day, must be the rule.

Eggs, cheese dishes, and fish can take the place of meat at two of the three substantial meals, and, in addition to these, a cup of tea with biscuits or bread-and-butter at 4.30 p.m. If an evening meal is not served later than 7 p.m., a glass of milk at bed-time is permissible. During the last month some doctors advise that no flesh meat should be taken at all. Plenty of fruit and vegetables should be eaten, and as much of them be taken uncooked as possible.

The breasts require a little special attention, in order to prevent cracked nipples, which interfere with natural feeding. The nipples should be washed daily with warm water, carefully dried, and hardened by gentle friction. If the nipples are small, they should be rolled between an oiled finger and thumb to develop them. Clothing should be light and loose, without any constriction of the body, and supported from the shoulders. Special maternity corsets or belt may be worn if desired. Garters must be discarded and suspenders used instead. High-heeled shoes should be avoided; they are apt to cause loss of balance when walking during pregnancy.

#### Expectant Mother Must Take Exercise

Regular exercise and a certain amount of work are far better for the health than the sort of sofa existence some women think justifiable at this time. The expectant mother can do light housework, even light gardening. She can carry on her business or profession for several months at least, providing her work is not physically or mentally exhausting. A brief rest of 20

minutes after luncheon and also before the evening meal is excellent. Every effort should be made to obtain restful sleep by regular bedtime, a well-aired room, a comfortable bed and a tranquil mind. It is usually necessary to cultivate a restful outlook, and not to be emotional or to exaggerate trifling grievances.

Indigestion and constipation are perhaps the commonest ailments at this time. The only medicine which should be taken without a doctor's prescription is a tumbler of hot water, with a pinch of bicarbonate of soda added,  $\frac{1}{2}$  to  $\frac{3}{4}$  of an hour before meals.

For constipation take plenty of water and raw fruit between meals, regular exercise, and a tablespoonful of liquid paraffin once or twice daily. If these simple measures are not successful consult a doctor without delay. Morning sickness is not so much a digestive disorder as a symptom caused by chemical changes in the body at this time; it usually passes off at the end of the third month.

Varicose veins are often quite painful in pregnancy. When they appear it is necessary to wear a crêpe velpean bandage, and this must be applied round the instep first (not the ankle, or the feet may swell) and then upwards to the knee. Rest is *most*, important. When resting, keep the feet up on a couch or stool, and do not stand more than is strictly necessary. The teeth should be watched stoppings attended to and decayed teeth removed before baby is born. Bad teeth, by infecting the milk, will jeopardise the child's health and development.

#### Feeding the New-Born Baby

The average normal child weighs from 7 to 7½ lb. at birth. Mother's own milk is baby's right and natural food. In almost every case it is possible for a mother to feed her child herself. Nevertheless quite a common mistake is lack of patience because the breast milk does not seem to satisfy the baby, and artificial feeding is resorted to to help the breasts. Test-weighing will show whether or not there is need to complement the breast milk. Sometimes all that is needed is a little sweetened water after the breast-feed. Keep baby a little hungry, otherwise he has not an incentive to suck strenuously, and the milk is apt to go.

During the first two days he should be fed every six hours; on the third day at four-hourly intervals, and after that every four hours, or every three hours in the case of a weakly or premature baby. No night feeds are given to the modern baby from birth, unless to a premature or very weakly child.

When the milk is insufficient, the baby should not be weaned, but the natural food is supplemented by giving a feed immediately after the breast of diluted and modified fresh cow's or dried milk. Give both breasts at each feed, so that each is regularly stimulated.

When baby cannot be breast fed through abscesses of the breast or other serious cause, then the child must be brought up on the bottle. His chances of health and even of survival are diminished by bottle-feeding. It is

the duty of every woman to nurse her own child unless advised not to do so by the physician for serious health reasons. Breast milk is free from germs; it is most easily digested, and it is of the right temperature.

*Baby. Above: cleanse the teats by rubbing them inside and outside with kitchen salt. This will remove milk slime. Below: whole day's supply of modified fresh cow's milk mixture can be made in the morning, bottled and stoppered with sterilized cotton-wool. Stand the bottles in cold water and keep them in a cool place.*

To improve the quantity of the mother's milk, she should take extra water to drink between meals. To improve the quality she should see to her health. See that she has more rest—two hours' rest in bed every afternoon may make all the difference—and teach her to douche and massage the breasts. This is done as follows:

Get a basin of hot water and a basin of cold water and put a piece of Turkish towelling in each. Bathe the breasts alternately with hot and cold water for 10 minutes once or, better still, twice daily. Dry and massage for 10 minutes. With proper care, 90 per cent, of women can nurse their babies.

When bottle feeding has to be resorted to, use the best quality cow's milk which can be modified so that the sugar fat and protein content approximates to that

of human milk. Dried milk can be modified in the same way. The vitamin destroyed by boiling the former or in the preparation of the latter can be replaced by orange juice. Give half a teaspoonful of orange juice after the first two months in the same amount of cool boiled water and work up to three teaspoonfuls at six months and six teaspoonfuls at one year.

The following table shows the percentage in human milk and cow's milk:

	<i>Sugar</i>	<i>Fat</i>	<i>Protein</i>
Human milk	7%	3-5%	1-3%
Cow's milk	5%	3-5%	3-3%

To reduce the protein content, dilute with boiled water. As this reduces also the sugar and fat contents these must be made up.

The proportion for an average baby of 3 to 10 months are as follows: To make 5 oz. of food take  $2\frac{1}{2}$  oz. of cow's milk, 1 teaspoonful of sugar,  $2\frac{1}{2}$  oz. of water and  $\frac{1}{4}$  oz. of lime water. 1 teaspoonful of emulsion of cod liver oil is given to make up the fat content. A younger baby would need more dilution, an older less.

To Prepare: Stir milk before measuring off desired quantity. Bring milk with sugar quickly to the boil in clean open saucepan. Add lime water and cold boiled water and strain.

Make the food once in 24 hours, and always stir the mixture before measuring off into the feeding bottle. Before giving to baby stand bottle containing milk in hot water to warm to 100° Fahrenheit. Cover bottle with flannel bag to maintain temperature during feed.

This table may be taken as a guide to the quantities required, although it must be modified as required:

*Total in 24 hours.*

1st week	5 - 15 oz.
2nd „ .	15 - 20 „
2nd month	25 „
3rd	27½ „
4th	30 „
5th	32½ „
6th	35 „
7th	37½ „
8th	40 „
9th	40 „

The most careful attention should be given to the bottles. The upright type of bottle *without* valve is recommended (*see above*). Wash in cold water and then in hot water after use, and keep dry, standing on a saucer underneath a cup or mug.

The bottles should be boiled before using again, a special saucepan being kept for this purpose. Place the bottles in cold water, boil for five minutes and cool before the bottles are removed.

Turn teats inside out, rub well with dry salt inside and then out. Scald teats once a day, *never* boil.

Much fretting is saved by correct attention to warmth and skin-comfort. Three photographs, left, show some simple garments. Top: stretchable long-sleeved vest, rib-knitted in soft silk-and-wool mixture. Next: warm, long-legged bootees to protect knees from chilling. Bottom: a romper for the time when baby begins to crawl, particularly useful if he has sunbaths. For ordinary bathing, the right-hand photos show what to do. Above: soap baby all over with your hands before putting him into the bath. Below: hold his head over the bath and wash gently with soft cloth or cotton-wool

Final stages in baby's toilet. Left: lower him gently into bath, supporting spine and holding feet. Centre: let him splash freely, but always support his back. Right: after drying and powdering, give his hair a leisurely brushing

**BABY: CLOTHES AND CLEANLINESS IN HIS FIRST YEAR**

*Baby. A cosy corner for baby's bath-time. Note the folding rubber bath, low nursing chair, clothes horse, and all other necessities close at hand. Pour in cool water first, then add warm.*

**Clothing and Bathing.** Whilst the diet is obviously the most important factor during the first year, attention must also be given to daily regimen and to clothing. No binder is needed after the cord has healed at about five or six days, the vest being pinned down on to the napkin to protect the abdomen. The clothing should consist of silk-and-wool vest, a soft napkin of muslin and another of Turkish towelling, petticoat of loosely woven flannel or Viyella, dress of soft all-wool material and a knitted matinee jacket in cold weather. Also a shawl when he is being nursed. The dress and petticoat should reach only a few inches below the feet. Nothing longer than 23-24 inches, which should be the length of the nightgowns.

It is often forgotten that babies need their own pocket handkerchiefs, particularly soft and small ones.

The baby should be bathed in the morning and sponged at bedtime. The bath may be enamel, papier maché, rubber or tin. If it has not a stand it must be stood on two chairs at bathing time so as to escape draughts from the floor.

A face cloth and a buttock cloth, a piece of pure soap, and a soft Turkish towel and one of old diaper for the face complete the requisites for the bath, together with a good baby powder. At first the temperature of the bath should be blood heat, 98° to 100° F., and the water is gradually made less warm until it is about 80° F., at six months or so. The bath water should be tested by a thermometer. Thorough removal of soap and careful drying, especially where two surfaces of the skin are in contact.

After the bath the baby has a feed and is put to sleep. He should sleep in his own cot from the beginning, as it is both unsafe and unhygienic to sleep with mother or nurse. He should lie on a firm mattress of hair and wool mixture with overlay of chaff, and bed and bed-clothing should be thoroughly aired daily in a current of fresh air, except, of course, on damp or wet days. It need not be emphasised that a child must live and sleep in fresh air every day of his life. The night air is just as healthy as the day-time air, and the only time that windows should be dosed, for a healthy baby, is in foggy weather.

**Weights.** A baby should be weighed once a week, a

regular gain being the best indication of progress. A few days' sickness or unsuitable food will immediately affect the weight. After baby regains his birth weight, which is usual at the end of the second week, there should be a gain of from 4-8 oz. a week until the 4th month, the birth weight being doubled between the 5th and 6th months. At six months the average weight is 15½ lb., the weekly gain being 4 oz. At one year the average weight is 20-21 lb.

*Baby. Enamel bath which fits into a stand at a convenient height for bathing the infant.*

**Teething.** Teething and weaning are the two milestones of the first year. He begins to cut teeth in the sixth month, although they have, of course, been in the gums since birth, their formation beginning about the 16th week of pregnancy. The cutting of the teeth is a physiological process and ought not to be attended by any adverse signs or symptoms. There is an increased flow of saliva (dribbling) and some heat and tenderness in the gums, but he should not otherwise be sick or sorry. Give him something cool and hard to bite on with frequent sips of water, and see that the bowels are acting well, and he should have no trouble with teething. The comforter or dummy teat does not find its way into any properly conducted nursery.

The first teeth are the lower central incisors, or the biting teeth, which should appear about six months, the upper central incisors in the ninth month, and the lateral incisors a month later, i.e. at nine months, which is the time to begin weaning baby. At the end of the first year the first molars are cut; the remaining teeth belong to the second stage of child life.

Weaning from breast or bottle should be completed at ten to eleven months.

From four to eight months, start baby with fruit and vegetable juices and purees. His taste for these will thus be trained before starch, which is not given as early nowadays as formerly.

At eight months give rusks or baked crusts before three of the feeds.

At nine months continue with rusks and introduce a little barley or oat jelly.

At ten months give, at one meal, soup or vegetable puree or egg (not more than three times a week) or gravies.

At eleven months introduce also milk pudding (sieved) and grated or pulped fruits.

After the first birthday the child's meals can be adjusted to those of the household.

Napkins are essential for a baby's comfort. Fewer than two dozen will mean that they will never be properly washed, boiled and aired, and three dozen is the number recommended. The most useful size is 22 in. square after the hems have been turned. Suitable material is butter muslin (made of four thicknesses stitched together) or old soft sheeting (torn into squares and neatly hemmed) for the napkin going next to the skin, and Turkish towelling for the outer napkin.

Never allow a baby's legs to be cramped and deformed by the bulk of the napkins he wears. The better way is to draw one only between the legs folded in a triangle, and over that a second square of Turkish towelling folded round like a pad. Some woolly jackets and a warm shawl complete the necessities of the infant's wardrobe.

Baby is better without a pillow. If one is used, it should be of chaff. As well as the mattress and overlay of chaff, an underblanket, rubber draw sheet, flannel draw sheet, enveloping blanket (70" x 44"), pair of small blankets (36" x 27"), and porous coverlet of cellular material will be needed.

It is handy to have a special basket to hold his immediate requirements, and there are varieties to suit most purses. In the basket the expectant mother should place in readiness the following articles:

Linen thread; one box or string of safety pins; one tin of starch, zinc, and boracic powder; one cake of super-fatted soap; one small tube of vaseline; a case containing needles and white cotton, for stitching the first binders; thimble and sharp square-pointed scissors; a packet of white absorbent cottonwool; a small bottle of pure olive oil; a soft hairbrush; screw top jar for cotton-wool swabs, and small enamel chamber.

Elaborate robes of any kind are not to be encouraged, but prettier day gowns are easily managed by the addition of a little fine lace or embroidery. Babies are rarely dressed in long robes nowadays. Deep embroidery flouncing makes a dainty gown for any baby. There is a Shetland wool which is ideal for making a baby's shawl. It is light in weight, easy to wash and wears well.

*Baby. Hamper basket in wicker with a tray in which to keep the toilet requisites. (Treasure Cot Co., Ltd.)*

The following list

summarises a baby's accessories:

Four long-sleeve vests (silk and wool); four petticoats (loosely woven flannel or Viyella); four frocks (soft all-wool material); four nightgowns (flannel); three knitted coatees; four pairs bootees; large shawl; two small shawls; six bibs; 2 doz. soft napkins; 2 doz. Turkish towelling napkins; ½ doz. small handkerchiefs; crêpe bandage, 2½ - to 3 ins. wide.

There are various types of fitted baskets. A hamper basket is made of strong wicker or cane with side handles, the lid fastening with a rod which runs through cane loops and can be padlocked if necessary. It frequently has fitted castors, which run easily over the floor. On removing the tray, there is a deep recess for the baby's clothes. It can be lined and trimmed to suit the colour scheme chosen for the cot curtains and any other decorations in the night nursery.

The tray has a pincushion attached, and two pockets for brush and comb and powder-box. Clean clothes can be kept in the lower part of the basket; those actually in use remain on the tray when discarded night or morning. This form of basket is dustproof when closed and handy for travelling.

A table basket, trimmed and fitted, is easily carried from place to place and will rest on any table. It is less expensive and also makes a useful work-basket. One of this type has been successfully made out of a white chip basket, without a handle, used for picking fruit in the strawberry fields. The basket is wide and shallow and can be covered daintily with a length of white muslin.

**BABY CHAIR.** For sitting at table, a baby chair needs to be high, but it should preferably be low for play.

*Baby Chair. Adjustable chair with play table attached. It can be raised to a high position.*

Baby chairs are often fitted with a bar or board in front of the arms, and this must be easily removable. A footboard is generally provided, and in some chairs this is adjustable for height. In the folding chair illustrated the legs are hinged so that the lower part can be turned up the reverse way, the tray at the base serving as a table as shown. It is provided with wheels,

which allow it to be pushed about when in its low position.

Parts of chairs likely to need repairing are, first, the rails or horizontal rods which unite the legs. Often these are plain parallel rods of small diameter, and if broken a new one must be put in, for a strong repair of the old one is difficult. If it is turned to an ornamental pattern not easily matched, a repair may be attempted by gluing the broken place and perhaps screwing a strip of metal beneath to assist in holding the parts together.

Often a rail becomes loose without breaking, and when this happens other rails soon go the same way and legs become rickety. The ends of rails are glued into bored holes, as in Fig. 1. If they come out it is generally sufficient to glue them in again, but the parts must fit properly, and must be forced right home into their original positions. If the gluing does not seem satisfactory, a fine wire nail with small head can be inserted, as in Fig. 2, either crosswise or endwise. The latter is shown dotted. In some cases screws may be better than nails.

*Baby Chair. Figs. 1-3. Diagrams illustrating correct methods of replacing rails and mending breakages. See text.*

Next in importance to leg and rail joints are breakages like that in Fig. 3, where a portion is split off a flat piece of board. Here also it is stronger to repair with nails, rather than trust to glue, as is shown in the dotted lines on the diagram.

**BACHELOR FLAT.** Bachelor flats in Westminster or other expensive residential districts in London undertake to provide full service, including that of a valet, while meals are charged at fixed prices and, if a restaurant is attached to the block, served there or brought to the flats. Accommodation includes a bathroom and either one room with sometimes an alcove for the bed curtained off, or a bedroom and sitting-room.

Many bachelor men and women are unable to afford suites of this kind, but must simplify domestic arrangements so that they occupy the minimum of attention. In some cases where houses have been converted into single flats, with use of bathroom on each floor, cleaning service is provided but no cooking. In others no such arrangement can be made on the premises, and a charwoman may be employed to clean and, where there is a kitchenette, sometimes returns in

the evening to prepare dinner.

Where only one room without service can be afforded, simple labour-saving devices should be installed where possible, and the idea of a bedroom should be remote during the day time. Comfort is essential to the worker, but all unnecessary ornaments and draperies should be discarded. Colour-schemes create beauty with simplicity of detail and thus reduce the cleaning problem.

Every day new devices appear for adding to the attractiveness and space-saving needs of the modern bachelor "flatlet": combined writing-desks and dressing tables, with detachable mirrors; sets of chairs which, placed together, form an extra divan to accommodate a guest at the last minute; dining tables which fold away into cupboards; and many others.

Parquet floors with rugs or small carpet squares are ideal, but, failing these, unless the boards are good, linoleum, which can be easily polished, is more satisfactory than mere staining. A vacuum cleaner is a practical help, but a carpet sweeper will serve. A corner cupboard fitted as wardrobe utilises space, the bureau or chest of drawers on legs and the long mirror can all fit into a sitting-room scheme. A divan lounge with separate mattress, and under the padded spiral springs a box for linen, is a suitable bed. The eiderdown rolls up into a case and forms a bolster cushion by day, and a fitted loose cover conceals all bedclothes. Small dressing tables can be obtained, which open out to disclose the toilet articles, but when shut look like an ordinary table. Unless accommodation provides a kitchenette or cupboard large enough to contain sink and small gas cooker and fitted with shelves for crockery and cooking utensils, the most convenient combination cooking and heating arrangement is a gas fire with a concealed boiling ring on top and a flap that lets down for grilling and reveals a small oven, together with a separate gas ring alongside for a kettle.

A gate-legged folding table for meals, and shelves fitted below window seats, for which cushions can be made to measure, are space savers. While it may be possible to make arrangements with the caretaker to receive parcels, it is desirable to provide a store cupboard so that catering emergencies can be met. The tenant may have little time available when shops are open to do marketing. *See Attic; Bed-Sitting-room.*

*Bachelor's Button, the garden Ranunculus. (Sutton & Sons)*

**BACHELOR'S BUTTON.** The name is locally applied to two distinct varieties of flowers. One is a form of the species of buttercup known as *Ranunculus acris*, which produces double yellow flowers. It thrives in ordinary border soil. The other is a variety of *Ranunculus aconitifolius* which bears double white flowers; this plant, which is known also as Fair Maids of

1. Two views of a modern bachelor (single-room) flat in which simplicity of line and economy of space predominate. Left: the unobtrusive dressing-table, with a mirror which can be removed, and an adjustable lamp for shaving. Right: the other end of the room, showing the divan with built-in bookshelves, reading lamp, and easily accessible switch

2. What can be done with a much larger room at one's disposal. At first glance, they appear to be separate dining- and sitting-rooms. Right: the collapsible dining-table, wooden chairs to match; the bedroom section is just visible on the extreme left. Left: sitting-room section, with fabric chairs for contrast, which, placed together, form an extra divan

3. The two flats illustrated in the first four photographs are "medium-sized" and "large," as bachelor flats go. Finally, we see some devices for making the most of a very small room. Left: a corner used as part of the seating for the dining-table. Right: a flatlet specially suitable for the "bachelor girl" who demands a kitchenette. Notice the partition which corners it off; also the home-made day cover for the divan. The tiny folding table and "baby-sized" telephone are in proportion, and help the illusion of making the room seem larger than it is.

#### BACHELOR FLATS

France, likes moist soil and flourishes by the waterside.

**BACKACHE.** This may be part of a general condition, may be due to a local cause, or may have its origin in one of the internal organs. Influenza and smallpox frequently commence with a severe backache, and it is found in anaemia, hysteria, and neurasthenia. Examples of the local cause are backache from lumbago, stiffness from over-exercise, chill or weakness. Bright's Disease, gall-stones, and various feminine ailments are instances of pain referred from an internal organ. Pain between the shoulder-blades occurs in flatulence, and pain at the bottom of the spine is common in piles.

Where the pain is due to muscular stiffness or lumbago, the surest relief is given by rest in bed with warmth applied to the back either by hot-water bags or a mustard plaster, and later the rubbing in of a soap liniment or other embrocation.

Some people find comfort in a menthol or a belladonna plaster. Internally 10 grains of aspirin will be useful. In backache due to other causes the application of a hot bag may give ease. *See* Bright's Disease; Lumbago.

**BACKGAMMON.** Backgammon, or trictrac, is a game for two persons. It requires a special board and 30 draughtsmen, 15 white and 15 black or red. The board usually consists of two equal compartments with raised sides hinged together. The backgammon-board is marked with a series of 12 points at each end. The points are alternately coloured black and red, and each player has six points on each side of his board.

To begin play the board is placed between the players, so that the points lie in the same direction as the players' faces. One compartment of the backgammon board is known as the outer table, and the other as the inner or home table. These tables are not fixed by name, but depend upon the position of the men when the game starts.

With each backgammon-board two dice-boxes and a pair of dice for each player should be provided. After the men have been arranged ready for play, the right of first move is settled by the throw of the dice. The first player then throws two dice, and the two numbers he throws decide his move. The object of his game is to get all his men into his own inner table, and to play them out again before his opponent is able to succeed in attaining a similar object.

The actual ability to move certain pieces depends upon the position of the opponent's pieces. A single piece on a point is known as a blot. If such a piece is legitimately in the way of a player's move after a throw, it is removed and placed on the bar, and has to begin its move over again from his opponent's inner table. A player, having succeeded in getting all his pieces into his home table, begins to remove them from the board, or bear them off. At this stage of the game each throw of the dice enables a player either to advance his pieces according to his throw, or remove one from the board. He can remove only one, however, if his throw

specifically allows it. The game is won by the player who first succeeds in removing all his pieces from the board.

When the winner has borne off all his pieces before his opponent has started to do so the game is called gammon, and if he succeeds in bearing off all his pieces while his opponent has still one or more pieces on the bar or in the winner's home table the game is called backgammon. For a gammon and backgammon, double, treble, or other increased stakes are paid.

## BACON: THE CUTS AND THEIR COOKING

How to Choose and Prepare it for the Table  
Separate Recipes follow, and related information will be found under Ham; Pig, etc.

*B a c o n . S i d e marked off to show the cuts.*

- A. Fore hock.
- B. Collar.
- C. Thick streaky.
- D. Back and ribs.
- E. Thin streaky.
- F. Long loin.
- G. Flank.
- H. Gammon hock.
- J. Corner gammon.

The flesh of the pig when cured, salted, or otherwise treated comes from all parts of the world. Wiltshire bacon, sold under that name, is from Wiltshire, but Wiltshire Cut on a label may refer merely to curing after the method of that district. There are four principal cuts — back, gammon, collar, and Bath chaps, or cheeks. The back is divided into best cut or loin, best streaky and flank. The best cut is favoured for breakfast rashers, though streaky parts are excellent. The flank is good for baking and boiling.

The gammon is divided into three cuts: upper, middle, and bone end or hock. The upper part makes a substantial joint for boiling, the middle is excellent for thick rashers to fry or grill. These are suitable for

lunch. The hock is useful for boiling, and with yellow split peas the stock makes good pea soup.

**Boiled Bacon.** Bath chaps are generally bought ready boiled and served cold. Prime or small back, gammon, corner and collar are all good boiling cuts for serving hot with chicken, turkey, etc., or as a cold breakfast dish.

Put the bacon after washing it into a saucepan of cold water to cover it. Bring gradually to boiling point, skim well and simmer until it is very thoroughly cooked. For one pound allow an hour, and an extra half hour for each pound after that weight. When cooked, peel off the skin, which should come away quite easily, and dust thickly with browned crumbs. The liquor in which the bacon was cooked must be thoroughly skimmed when cold and the fat put into a basin. Then pour boiling water over it, and let it stand. The cake of fat that rises to the top can be used for making pastry.

**Fried Bacon.** In a clean, heated frying-pan lay slices of bacon. Turn frequently and cook gently so that the lean is tender, but never let the fat become so hot that a smoke rises from it, or its value as bacon dripping is lost. When cooked, the fat should be tinged with brown and slightly crisp, but not chippy.

Toasted rashers are cooked either on a fork over a baking-tin in a Dutch oven before the fire, or can be grilled on a tin under a gas toaster. In each case the slices must be turned. Thin, trimmed rashers can be rolled to garnish chicken, veal, etc. Thread them on a skewer, running it through each and pushing them closely together to keep them rolled. Lay the skewer on a tin in the oven till the bacon is delicately crisped and browned, then draw out the skewer.

For baked bacon, take a piece of flank or any streaky cut and score the rind across with a sharp knife. Make the oven very hot and put the bacon in a baking-tin. When the rind has become crisp reduce the oven heat and cook gently to avoid excessive shrinking, allowing 20 min. to the lb. It should be served cold for breakfast.

**Bacon Dishes.** French beans first boiled till tender, then fried in bacon fat with two sliced peeled tomatoes and served with rashers, are a change for breakfast. Bacon with cabbage is a favourite Welsh dish, being savoury for lunch or supper, as well as nutritious. Trim, wash carefully, and boil quickly about 2 lb. of spring cabbage. Then drain off the water, pressing the greens well, and chop. Trim and cut  $\frac{1}{2}$  lb. of bacon into largish cubes, and fry till crisp and lightly browned. Keep the bacon hot, and into the fat from it stir the cabbage, and a seasoning of salt and pepper. Add the bacon, mix and heat well, and pile on a hot dish. Garnish with fried bread. Shake over two tablespoonfuls of grated cheese. Heat in a quick oven till cheese is browned and serve. This quantity will be found sufficient for about four persons.

Bacon with macaroni is a useful dish for breakfast or supper. Break 6 oz. of macaroni into short lengths, about an inch long. Put into a saucepan with plenty of boiling water, salted, and boil until quite tender.

Meantime trim and cut the bacon into cubes. Fry till lightly browned, and add the strained macaroni, one large peeled, sliced tomato and a careful seasoning. Heat all these very thoroughly, serve them piled in a hot dish, with crisp fingers of toast. This is sufficient for about four or five persons.

*Bacon: principal cuts. 1. Gammon. 2. Gammon Hock. 3. Fore end. 4. Thick streaky. 5. Forehock. 6. Flank. 7. Thin streaky. 8. Corner gammon. 9. Long loin. 10. Back and ribs.*

A good supper dish can be made from bacon and cheese. Toast on one side only as many slices of bread as there are persons to be served. Butter the side that has not been toasted and cover thickly with shredded cheese, pepper, salt, and a little made mustard. Lay on top of this two rashers of bacon and place in a moderate oven to cook slowly.

**Bacon Curing.** This is only undertaken safely in the cold months of the year from November to March. The first point in home curing must be to obtain a stone-  
?ld side of best fed pork.

Salt, sugar, and saltpetre are the usual ingredients employed in the cure, the first two being antiseptic, and the third bringing out the fine, rich, colour of good bacon. The sides can be cured either by the dry-salt process or the pickle process. The former commences with a vigorous rubbing of salt, repeated several days in succession, and then the side is left with a thin covering of salt, followed by a light sprinkling of saltpetre and granulated sugar. In 10 days from the last rubbing in, the salt, etc., may be removed and the side hung up in a cold, dry place. For protection from dust and other contamination it should be enveloped in a thin butter muslin covering.

To ensure adequate curing, the thicker parts, such as the gammon and the fore end, should be injected with brine by an ordinary pickle pump. A good pickle for this purpose is composed of 1 lb. of saltpetre, 1 lb. of Demerara sugar, 11 lb. of salt, and 4 gallons of water. This same pickle is sufficient for curing by the wet process, which is done by immersing the side, or parts, in the pickle and keeping it for 10 days, covered with the brine. The result of this cure, either by the dry or the wet process, is known as green bacon. For added flavour the bacon can be smoked by being suspended in a square stone cubicle, with an opening at the top to let out the smoke, the floor being covered with peat and set alight, and the bacon kept therein from 36 to 40 hours.

**BACON CUTTER.** A bacon cutter suited to domestic needs consists essentially of a strong base,

generally of cast-iron, heavily enamelled. Mounted upon an upright is a circular steel knife or cutter rotatable by a crank handle and gearing.

A tray or carriage provided with a safety guard is pushed along on guides on the base, and carries the bacon or other food to be cut into slices, means being provided to adjust their thickness. In operation the crank is turned with the right hand; the left holds the bacon on the carriage, which is pushed past the revolving knife, and a slice is cut off, the process being repeated as often as required. The same machine may also be used to cut bread.

**Bacteria.** *See* Microbes.

**BADGER BRUSH.** For shaving, tooth and painter's brushes badger hair is used on account of its softness. It is grey on the end with a black portion under, the lower portion being of a creamy shade. Being an expensive article, it is widely imitated, e.g. by dyeing hog and similar bristles. The real hair is fine, silky to the touch, straight and springy. A badger-hair shaving brush will wear right down to the stump and still remain soft and springy.

Painter's brushes must be cleaned directly after use. They should be washed in warm water with a little washing soda and rinsed in clean water. If used with varnish or varnish paint, this should be dissolved with turpentine before washing. *See* Brush; Shaving.

**BADMINTON:** How to Play it. The popularity of this game has increased astonishingly in recent years, rivalling that of squash rackets. Badminton clubs are widespread, and All-England championships are held.

The strokes are not unlike those in lawn tennis, but a shuttle takes the place of the ball. The shuttle is in play from the time that it is hit by the racket until it touches the ground or the person or dress of any player, or until a fault or let occurs, this period being known as a rally. There is no first bound as in lawn tennis and the service may not be overhand. The shuttle, at the instant of being struck, must not be higher than the server's waist. Most players hold the shuttle loosely close to the cork part, and the object is to hit the shuttle in such a way as to make it difficult for an opponent to return it.

#### Scoring at Badminton

The scoring is adapted from that used in rackets. In the doubles, when one pair of players opposes another pair, and in the men's singles, when there is one player on each side, the game usually consists of 15 aces. When the score happens to reach 13 all, the side which has first arrived at 13 has the option of setting the game to 5. In other words, the side may, and generally does, elect that the game shall continue until one side or the other has won five additional aces.

In the same way, when the score is 14 all, the side which has reached 14 first has the option of setting the

*Badminton. Left, court as it should be marked out for singles; right for doubles game.*

game to three. In either case, when the game is set, the score is called love-all, and the side which first scores 5 in the first instance or 8 in the second, wins the game. Generally in ladies' singles the game consists of 11 aces. Here again the game may be set at 9 all to 5, and at 10 all to 3. The match is decided by the best of three games, which is the rubber.

In badminton, as in rackets, a side (or in singles a player) is either in or out. The scoring can only be done by the in side; the business of the out side is to put the other side out. In the doubles the side (A and B) which begins the game has only one hand in its first innings. Thus when A is put out, B does not serve, and the service goes to the other side (C and D). But after D is put out the turn of the other pair comes, and so on to the end. The service is delivered alternately from each half court into the half court diagonally opposite. After the service the players can take up positions where they please till the rally is ended.

The diagrams show that the court for singles is as long as that for doubles, but not quite as wide. For convenience both courts are generally marked out in one, the dotted lines in the diagram of the doubles showing where the singles court comes.

## BAGS AND HOW TO MAKE THEM

### Some Attractive New Ideas for the Needlewoman

For details of Methods employed see Applique; Beadwork; Embroidery; Tapestry; and for Bags in other Materials see Leather; Raffia, etc.

A shopping bag is shown in Fig. 1. It may be of American cloth, hessian, or striped canvas. It should be lined through with cretonne or similar fabric to give extra strength, and requires  $\frac{1}{2}$  yard of 24-in.-wide material, with the same quantity of another fabric for lining. Take the material for the outside, and cut a 3-in.-wide strip from one of the cut edges, not the

selvedges; then cut this strip in half, to obtain two strips 3 in. wide and 12 in. long.

*Bag. Fig. 1. Simple shopping bag. Fig. 2. How it should be cut out and the gusset inserted.*

Cut a V-shaped piece out from one end of each of the two strips, as in left-hand side of Fig. 2. Fold each strip lengthwise down the centre, and sew the edges of the V-shaped opening together. Now fold the larger piece of material to bring the selvedges together, as in Fig. 2, with right side inside. Join the long edges of the folded strips to the side edges of the larger piece (Fig. 2) so that the narrow strips are sandwiched between the two layers; then turn the bag right side out.

Make up the lining in the same way, and slip it inside the bag with seam turnings facing, turn top edges in to meet, and oversew along with embroidery silk, a fine coloured twine, wool or raffia, finishing the remaining edges with decorative oversewing to match. Next cut small holes within the top edges to take handles, and oversew or buttonhole the edges round for strength; then add handles of cord, or strips of material doubled and stitched along. Hand embroidery or appliqué work can be added as a decoration.

*Bag. Figs. 3-5. Details for making a silk bag to be sewn to a frame*

**Frame-mounted Bags.** Handbags of silk and other materials, mounted into a frame of ivory, tortoiseshell, or an imitation of either, or of metal, with chain handle, or one made of the material can be easily worked at home, frames being purchased. These are made with rows of tiny holes through which the bag is sewn on. The bags are lined and may be supplied with pockets to contain powder puff or mirror, while the top of the

lining is finished off with a narrow ruching, galon, or silk floral trimming.

Details for making such a bag are shown in Figs. 3-5. The mount or frame illustrated measures about 6½ in. in width; ½ yd. of 18 in.-wide silk for the outside of the bag is required, and also ½ yd. of 18 in.-wide silk for the lining. If there is no handle to the frame, to make one cut a strip off the width of the material 1½ in. wide, fold double, and stitch along for strength.

Begin by taking the silk for the outside of the bag, folding it into halves, and then cutting off the two top sets of corners to form a circle. Now turn in the edge of the silk circle to the wrong side and run in a gathering thread, leaving long ends of cotton. Open out the frame or mount to its full extent, so that it will lie flat on the table as in a circle, and measure all round the inside edge of the frame where the tiny holes are. Then draw up the gathering thread along the silk edges to make them the same size as the mount. Sew the bag into the mount, working from the inside, according to the pattern sketched in Fig. 3.

Pass the needle through the edge of the bag and through one of the holes to the outside; then carry the needle below the frame edge, and push it through the silk to the inside again, then passing on to the next hole. Take the silk for the lining, and from it cut a strip measuring about 17 in. long (an inch less than the length of the bag silk) and about 8½ in. wide; that is, 2 in. more than the width of the frame. Fold this strip in halves with the right side inside and curve off the top corners slightly. Then seam up the sides as far as the commencement of the curves.

A pocket for holding a small mirror and comb, and made of a square of material, hemmed at the top and having an elastic run-through hem, can be stitched to one side of the lining before it is seamed up, as suggested in Fig. 4.

Turn in the curved top edges of the lining and gather up lightly, then slip them inside the bag, and hem them to the top of the latter. Finally, add a strip of floral trimming, or ruching, over the edges. Ruching is made by cutting on the cross a long strip of the lining silk, about 1½ in. wide, folding it over with the wrong side outside and running it along as though for an ordinary rouleau. Turn inside out with the aid of a small safety pin, and with sewing silk to match, run it in a zig-zag line from side to side, as shown in Fig. 5. When this gathering thread is drawn up, a pretty trimming is the result. This can be sewn to the bag along the gathering thread, which should now run in a straight line down the middle.

Flat shaped bags on stiff, one-piece tortoiseshell or wooden mounts show off embroidery or make up well in heavier materials such as tapestry, tweed or moiré. To make such a bag in brown moiré silk, with shell mount and lining of moiré to tone, cut two pieces of moiré, one for cover and one for lining, 9 in. wide and 14 in. long; fold in half, making depth of bag 7 in. Join up the side seams and slip the lining into the bag, oversewing together at top; attach a small square tab on one side, made of double moiré. Turn in corners, fit into frame and finish off lining with a narrow gold

galon.

An effective way of using strips of embroidery with a right-angled silver frame and cord-padded handle is shown in Fig. 6.

*Bag. Fig. 6. Brocade bag mounted upon a silver frame and having a handle of covered cord.*

A variation of the framed bag has a yoke piece as in Fig. 7. A paper pattern can be cut to desired size from the diagram (Fig. 8). It requires a gilt frame, ¼ yd. black silk, and the same amount of lining silk, and may be embroidered on one side. Cut a strip of covering and lining silk, each 23 in. long and 2 in. wide. The yoke part must be stretched flat. Join the two main parts of bag to edge of 23-in. strip, letting in piping cord covered with black silk (the lining requires no piping). Turn up the scalloped edge of yoke pieces and sew over a strip of cord. Fix lining to yoke and invisibly sew to gathered lower part. Sew top edge to frame and cover stitches with narrow bead trimming.

*Bag. Fig. 7. Silk bag gathered on to a yoke piece the top of which is sewn to a gilt frame.*

Pochettes. Two pieces of material, for lining and for cover, each measuring 18 in. by 9 in. and folded in three, are needed for a simple pochette bag. If to be embroidered, trace the pattern on the first 6 in. of cover and press before making up.

*Bag. Fig. 9. Pochette in heavy corded silk with an appliqué trimming outlined with tinsel thread.*

Interline with buckram to stiffen before folding the bag into three and oversewing the two sides. Such pochettes are useful for evening bags, but not for hard wear. They may be fastened by press studs concealed under the flap or by a jewelled button and tinsel cord.

For a more practical pochette side gussets are required. Fig. 9 could be carried out in heavy corded silk and lined and trimmed with the same in contrasting shade. The trimming has been edged with tinsel thread (six rows) and couched on to the flap. Cut cover and lining, as shown in Fig. 10, to measure 9 in. by 20 in., also a piece of buckram  $\frac{1}{4}$  in. smaller all round; draw and cut a paper pattern of the trimming, three times size of diagram, lay on material and cut out (see diagram). Having marked position, tack neatly and sew the trimming to bag, pressing afterwards with a slightly warmed iron on the wrong side of material. Tack cover to buckram, turning edges of material over the buckram so that the trimming comes on edge of bag. Then slipstitch lining to cover. Cut the gussets in covering and lining silks, turn in the edges and stitch together. Fold the bag and neatly sew in gussets. Such a shape lends itself to a variety of trimmings; a central applique ornament may be used, a monogram, or the whole flap may be gaily embroidered; or it may be cut

out in an envelope shape and made of brocade.

**BAGATELLE: How to Play.** The bagatelle board or table is usually from 6 to 10 ft. long, and from  $1\frac{1}{2}$  to 3 ft. wide. It is made to fold up, can be placed on a table for play, is of wood covered with green cloth, and the sides are cushioned with rubber. When open the top is in the form of a semicircle, and let into the surface are nine rounded holes or cups, each the size of the nine balls used. These holes are numbered 1 to 9. Some tables have pockets in addition to holes, but with these the game is more akin to billiards.

*Bagatelle Board*

The players, using a cue on the model of an ordinary cue, play from the end of the table opposite to the holes. Each player in turn takes eight balls, 4 white and 4 red, while a ninth, a black one, is placed on a spot in front of the holes. His object is to drive the balls one by one into the holes, but before scoring he must hit the black ball.

The scores count according to the holes into which the balls are sent, save that the black ball counts double. A player will aim at driving all the balls into holes, reserving the black ball for the one marked 9. The game is usually for a n agreed number of points, and most boards have holes and pegs at the sides by which the marks can be recorded. If the game is played by more than two persons, sides will be chosen, and members of each will play alternately.

A number of other games can be played on the bagatelle table. One is the cannon game, in which only three balls are used, as at billiards, by two players. Two of them are placed in position, the black on the spot and the white between holes 1 and 9. The striker plays with the third ball, and to score must cannon before driving a ball into a hole. If he drives one without cannoning the score counts to his adversary. Two is scored for a cannon, while points go to the other side if the balls are missed. As in billiards, he continues to play until he fails to score. For this game there is a special table without holes.

**BAKED JAM PUDDING.** Take  $1\frac{1}{2}$  breakfastcupfuls breadcrumbs and pour over half a pint hot milk to which has been added  $1\frac{1}{2}$  oz. margarine or butter. Sweeten with 2 tablespoonfuls sugar, flavour with a few drops vanilla essence, and add the beaten yolk of an egg, and bake in a moderate oven. Then add the white beaten up with sugar and spread on the top over a thick layer of jam. The pudding must then be put back in the oven for the white of egg to brown. Serve sprinkled with fine sugar.

**BAKELITE.** This is a synthetic resin formed from phenol and formaldehyde. It is infusible, resists acids and solvents, and has great strength as a dielectric. For use by manufacturers it is supplied in a form allowing of fusion, but after heating to a certain temperature the material solidifies, hardens, and thereafter resists fusion.

Bakelite is readily moulded into intricate forms, and is extensively employed for switches, plugs and other electrical apparatus, as well as for household utensils, being practically unbreakable.

**BAKEWELL PUDDING.** For serving either hot or cold, this is a convenient sweet. To make it, line a pie-dish with ordinary short crust. On top of the crust spread a layer of jam, and fill in remainder of dish with the following mixture. Cream together 2 oz. each butter and castor sugar, and add to this a beaten-up egg and 2 oz. ground almonds, with a little almond essence. Beat well and put in the pie-dish on top of the jam. Then bake the pudding in a quick oven until thoroughly browned. Sufficient for 6 or 7 persons.

**BAKING AND ITS UTENSILS.** While a roast of meat is cooking in its later stages, baked puddings, scones, buns and short-crust pastry needing the same heat may share the oven; but puff pastry, which requires a very hot and dry oven, would be spoiled if

cooked in the same oven as meat. Much good pastry is ruined in baking. For ordinary pastry, the oven should be 375 to 380 degrees in temperature; for puff pastry 400 degrees. Otherwise the pastry will be heavy and oily. Bread requires to bake in a moderate oven. Joints of meat should first be placed in a very hot oven to seal up the surface and prevent too much of the juice escaping. When the meat is well browned the heat can be moderated. Milk puddings without eggs should at first be placed in a hot oven to bring near boiling point, then allowed to cook slowly. Eggs may be stirred in at this stage. Custard pudding, or any pudding containing eggs, requires a moderate oven.

*Baking. Up-to-date glass overware: the top is either a lid or another dish.*

*Baking. Fireproof earthenware of the casserole type, double and divided.*

To bake a cake well is one of the most difficult branches of the cook's art. To ascertain the heat of the oven, sprinkle a little flour on a baking-tin and place in the oven. If the heat is just right for the cake the flour should be of a good yellow colour in about one minute. The oven should be kept at this moderate heat throughout.

Opening and shutting the oven door should be avoided as much as possible, as draughts cause a sudden drop in temperature which often spoils cakes and pastry.

Special thermometers for baking are now made, and if used the following temperatures (Fahrenheit) should be recorded:

Meat	300-10
Pies	290
Cakes and pastry	320
Bread and puff pastry	340

All kinds of pastry require to be baked in a very hot oven at first, to expand the air enclosed in the pastry, so that it raises and lightens the flour. If the temperature of the oven is not sufficiently high to set the pastry quickly the air or gas will escape, and the pastry sink again and become heavy. A sharp heat is also needed to swell quickly and burst the starch-grains in the flour, and thereby enable them at once to absorb the fat used as it melts. Unless this happens the warm butter or lard merely oozes out on to the baking tin, and the pastry

becomes hard and chippy. It must always be remembered that the richer the pastry the hotter must be the oven. When the pastry is set, the heat must be slackened to prevent it burning.

Heat the oven whilst preparing the dish for which the pastry is to be used. If a coal range is used, make sure that the flues at the back of the stove and round and under the oven are clean and free from soot, otherwise a proper heat will never be attained.

An oven with a good bottom heat is desirable for pastry-baking, and the top shelf is always the hottest. This shelf throws down the heat on to the food and thus browns it. Should the pastry seem likely to be too dark before everything is cooked through, this shelf can be pulled right out from the oven. Another plan is to lay a sheet of stout paper over the pastry.

When putting pastry into or on to tins it is unnecessary to grease them, as there will be sufficient in the pastry itself to prevent it sticking, and to add more only wastes fat and increases the risk of burning. After the pastry is completely baked, let it cool down in a warm place, and not in a draught. It is a mistake to hurry it away into a cold larder, as by so doing the steam in it condenses and the pastry loses its crispness and becomes tough.

**Baking Utensils.** Double baking pans are best for oven roasting. They can be obtained in oblong or square shapes and in all sizes. Patty pans for baking cheesecakes, mincepies, etc., are made of tin, fluted or plain, and may be oval, round, shallow, or deep. Open jam or syrup tarts require tartlet pans, with plain or fluted edges. Raised pie-moulds, in which raised pork, veal, or game pies are baked, are made to open at the side, and the bottom is movable.

Flan rings consist of a plain or fluted ring with no bottom, and stand on the baking sheet. Cake tins of all sizes are made in strong tin; the bottom may be movable.

A border mould with a hole in the centre, so that a cake border can be made if required, must be kept only for that purpose, not used for jellies, etc. One or two bread-tins should be in every kitchen, for home-made bread is not difficult to bake, and a cake baked in one of these tins looks inviting. Shallow tins, about one inch in depth, are used for Yorkshire puddings; several baking sheets are necessary on which to place small

patty and queen-cake tins.

Dishes and pans in fireproof ware and also fireproof glass, an apple-baker, with wells for the fruit, ramekin cases in which to cook and serve numerous dishes, and soufflé dishes, in various sizes, are all baking requisites.

**BAKING POWDER.** Baking powder is made as follows: (a) Tartaric acid, 18 oz.; bicarbonate of soda, 20 oz.; ground rice, 2 lb.; (b) cream of tartar, 2 lb.; bicarbonate of soda, 1 lb.; ground rice, 1½lb. Cheaper ingredients used in place of tartaric acid and cream of tartar are acid phosphate of calcium and acid sulphate of potassium.

As the chemical action begins as soon as water is added to the baking powder, any dough in which baking powder is used should be put into the oven as soon as it is made. The heat of the oven causes the gas to be given off more quickly, so that the dough rises rapidly. At the same time it is forming a hard crust, so the gas cannot escape.

**BALATA.** This is a combination of guttapercha and other natural gums and cotton dux. The gum of the S. American bully tree (balata) enters largely into its composition.

Its original use was as a substitute for leather for the driving belts of machinery, but it was discovered that it had qualities which made it eminently suitable for soling footwear, being not only very durable, but light, flexible, and absolutely waterproof. Boots and shoes soled with Balata should not be placed near artificial heat to dry.

**BALDNESS: Its Treatment.** A prevalent cause is scurf or dandruff. Frequent washing of the head should be avoided, and growth may be induced by the use of a stimulating lotion.

During convalescence from typhoid or severe measles or scarlet fever there may be a sudden and pronounced falling of the hair. This may also occur after a perfectly normal pregnancy, but in these cases new and vigorous growth will take place within a few months' time.

Alopecia areata or baldness in circles may occur in several members of a family through some infection which is often traced to the mouth, nose, or tonsils. The patches may be painted with iodine or sulphur, or a stimulating lotion may be used. At the same time attention should be directed to improving the general health. *See Hair.*

**BALL BEARINGS.** These comprise all types of bearings where the working parts are separated by means of metal balls, relatively small in diameter. The chief advantages from the use of ball bearings are the easy running qualities due to reduced friction between the bearing surfaces, simplicity of adjustment, and long life, if properly cared for.

There are two great classes of ball bearings: (1) the cup and cone type, as extensively used on bicycles; and (2) radial bearings, used on small electric motors, and

for bearings in motor-cars and other purposes. Ball thrust bearings are adapted to take an endways thrust. An example is the bearing in a cycle steering-head.

**Ball Bearings.** Hub of a bicycle partly cut away to show cup and cone bearing.

A typical cup and cone bearing, as used on a cycle hub, is shown in the illustration. The cones are mounted on a spindle, one is firmly fixed thereto, the other works on a screw thread, and provides the means of adjustment.

The balls run between the cup and cone, and sufficient of them are used to form a complete circle. To adjust any bearing of this type, slacken the locking nut and rotate the movable cone until every trace of slackness or shake has been eliminated. The locking nut is then tightened up hard.

To clean a ball bearing, take out the cones and spindle, placing a clean piece of paper or a large tray on the ground to catch the balls as they fall out. Then wash the balls, cups and cones in paraffin, and clean the hub or part from which the bearing has been removed. Assuming there is no wear or damage, the bearing may then be reassembled. First fill one cup with vaseline or thick grease and place it on the bench with the cup horizontal. Insert the balls one by one into the cup (the vaseline will prevent them falling out), then insert the spindle and fixed cone. Hold the spindle in place and invert the bearing, thus allowing the spindle to rest upon the bench. Support the bearing with blocks of wood if necessary. Insert the balls in the other cup as before. Finally, screw the adjusting cone on to the spindle and adjust as already described. *See Bicycle; Motor Cycle.*

**BALL COCK:** In House Cisterns. The principal purpose of a ball cock is to regulate the flow of water into a tank or cistern, its action depending on the buoyancy of the ball, which is hollow and made of copper. It is attached at one end of a lever arm, the other end of which is pivoted to the valve body or tank. Near this end of the lever is a small plunger that moves loosely in the valve body and is arranged to close the water inlet.

Assuming the cistern to be empty, the ball hangs down, the lever is depressed, the plunger falls, and water is admitted. As it rises in the tank the ball floats on the water, and gradually lifts the lever. Finally, when the desired height of water is attained, the lever has lifted sufficiently to close the water inlet by forcing

the plunger hard up against the valve face. It remains in this position until the water level falls, when the same cycle of operations is once again gone through.

**Ball Cock.** How the floating ball controls inlet of water. Inset, valve part of high-pressure type.

Should the cistern overflow, the remedy will not be far to seek if these facts are borne in mind. Examine the ball itself; see if it leaks; if so, remove the ball and lever complete by removing the pivot pin. Then drill a small hole to allow the water to escape and carefully heat the ball over the gas flame to dry out all moisture. Finally clean the ball and resolder it, making sure it is watertight. If the water level is too high, bend the lever down; if too low, raise the lever. If the water inlet valve leaks, the leather or fibre washer may need replacing. *See Cistern; Water Supply.*

**Ballroom.** For instructions how to prepare *see* Dance.

**Ball Valve.** Section of the simple type of ball valve used in tire pumps.

**BALL VALVE.** The particular advantage of a ball valve is that it opens readily and gives a free and unrestricted passage through the valve body. Typical examples are the oil pump of a motor-cycle and the foot valve of a tire pump. The valve consists of a metal ball. To ensure perfect functioning, the ball must be clean, must seat on a knife edge, or very narrow seating, and must be prevented from lifting too high off its seating.

The diagram makes the construction of such a valve quite clear. Ball'sum.

**BALM.** The plants of the genus *Melissa*, a hardy herbaceous perennial with aromatic stems and leaves, are classified as balm. They flower in the summer months, at which period the stems should be cut off and stored for winter use. Balm leaves make a good pot-herb and were formerly used extensively. The plants may be increased by division of the roots in autumn, or by seed sown in March. Any ordinary garden soil suits them, but they prefer a sunny border.

*Balm. Aromatic leaves of this garden pot-herb.*

#### **BALM OF GILEAD.**

This is the popular name of *Cedronella triphylla*, a sage-like plant from the Canary Isles: it bears purple flowers but is valued chiefly for the sake of its fragrant leaves. It is hardy only in mild districts. Propagation is by cuttings under glass in spring. When nosegays were fashionable, they invariably contained a few fragrant sprigs of Balm of Gilead.

**BALSAM.** This is a half-hardy annual belonging to the genus *Impatiens*, the main types being camellia-flowered and rose-flowered. The balsam is liable to damage in bad weather and it is thus more useful for the greenhouse than for flower beds. When balsam is grown in greenhouse or conservatory, it should be watered freely when well rooted and must be potted in rich soil.

*Balsam The double camellia-flowered variety. (Sutton & Sons, Ltd.)*

It is raised from seed sown under glass in February or March, and potted in a compost of three parts loam, one part manure, and a little sand. The double white camellia-flowered balsam rivals the begonia in beauty. The common *Impatiens glandulifera* has white and pink flowers, and in a shrubbery is often a nuisance because of its enormous faculty of reproduction. Pron.

**BALUSTER.** The term is given to the supports of handrails, barricades, etc., which may be turned, shaped, or square, the last named being sometimes fixed at an angle. See Railing; Staircase.

**BAMBOO.** The genus of grasses known as bamboos belong to three groups, *Arundinaria*, *Phyllostachys* and *Bambusa*. They are graceful evergreens which flourish best in moist soil and a sheltered position. They are most attractive from midsummer to early spring; between February and July the leaves become shabby. Some of the best hardy bamboos for British gardens are *Arundinaria anceps*, 8-10 feet, *A. nitida*, 8-10 feet, *A. Simoni*, 12-15 feet; *Phyllostachys fastuosa*, 15-20 feet, and *P. nigra*, 8 feet. Attractive low-growing kinds are *Bambusa tassellata*, 3 feet, with very large leaves; *pygmaea*, 15 inches, and *Veitchii*, 15 inches. The two last named are improved by being cut down almost to the ground each year.

**BANANA.** A natural food containing all the substances of which the average meal is composed, namely protein, fat, carbohydrates, salts and water. It is deficient only in Vitamin C. Bananas should not be eaten raw unless quite ripe. On account of its slipperiness, the fruit is often swallowed without proper mastication, and may cause indigestion, especially with children, for whom it should preferably be mashed. See Diet; Food; Vitamin.

**BANANA CHARLOTTE.** Line the bottom of a plain charlotte tin with a layer of sweet jelly and decorate with strips of angelica and glacé cherries. Trim the required number of finger biscuits and line sides of mould so that they fit closely. Beat up 3 fresh eggs and stir into them a pint of boiling milk sweetened with 2 oz. castor sugar. Put this in the pan and stir over the fire with a wooden spoon; when the consistency of cream add the pulp of 4 ripe bananas.

Stir in ½ oz. dissolved gelatine, add ½ teaspoonful vanilla, and lastly ½ pint whipped cream. Just before the cream begins to set pour it into the prepared mould and place it on some ice to set firmly. The shape should be un moulded carefully on to a cold dish and then served.

**BANANA ECLAIR.** Put ½ pint of water and 2 oz. of butter in a saucepan. Boil and having removed to a slow fire, add 6 oz. flour and stir well with a wooden spoon for 10 minutes. When cold, add 4 eggs, one by one. Next pass the mixture from a large pastry bag through a large piping tube on to a buttered dish, making each piece about the size of a walnut and about an inch apart. These should be baked in a moderate oven for half an hour and then taken out to cool. To prepare the cream take 2 eggs, 1 oz. flour, 1 oz. sugar,

$\frac{1}{2}$  pint milk, and 6 ripe bananas, which should be passed through a sieve. Boil the milk, add the flour and sugar, and beat all up well with the eggs. Cook a little without boiling, add the banana puree, and mix thoroughly. When cold, cut off the tops of the pastries and stuff each with the cream, afterwards replacing the tops and sprinkling them with sugar.

**BANANA PRINCESS PUDDING.** Peel and mash 6 bananas, afterwards placing them in a greased pie-dish. Add a layer of apricot jam, and let it get warmed through in a moderate oven. Whip the whites of 2 eggs with castor sugar until they are quite stiff, cover the pudding with it, return to the oven and bake until a golden brown. This will take about 5 min. This pudding may be served either hot or cold.

*Banana Princess Pudding with angelica and cherries.*

**BANANA TRIFLE.** Take 8 sponge cakes, a pint of custard, some jam, 3 bananas and 1 oz. of blanched almonds. Cut the sponge cakes in half and place a few in the bottom of a large crystal dish. Spread them thickly with strawberry jam, and add a layer of sliced bananas. Repeat the process until the dish is full. Make a good custard flavoured with vanilla essence, and pour over the trifle while hot. Leave it to soak well, garnish the top with blanched almonds and a few strawberries out of the jam. The top may be decorated with whipped and sweetened cream and crystallised cherries, violets and angelica, as shown in the illustration.

**BANBURY CAKE.** These are scraps of pastry with a mincemeat of fruit in the centre. To make this mincemeat, cream 2 oz. butter and add to it  $\frac{1}{4}$  lb. chopped orange and lemon peel,  $\frac{1}{2}$  lb. currants,  $\frac{1}{2}$  teaspoonful ground cinnamon, and the same of ground allspice. Lay a little of this mincemeat between two oval pieces of puff pastry, pinch the edges, brush over with egg, and sift powdered sugar over the top of the cake. Bake in a quick oven till the pastry is browned lightly and has risen well. Sprinkle again with sugar and serve hot. This quantity is sufficient for 10 or 12 cakes.

**BANDAGES FOR WOUNDS AND DRESSINGS**  
Simple Instructions and Diagrams for the Home Nurse  
For the Application of Principles given here see Arm;  
Bleeding; First Aid; Fracture; Leg, etc.

Bandages are used to fix on dressings and splints, to give support or to restrain movement, and to arrest haemorrhage. Various forms are employed, e.g., the

triangular, the roller, the T-shaped, the many-tailed. Of these the triangular is the easiest to apply and is usually chosen in rendering first-aid.

A triangular bandage is made by taking a piece of calico, 38 in. square and cutting it diagonally across. The parts of the bandage are named, thus the longest border is known as the base or lower border and the others are the side borders. The angle opposite the base is the point and the others are the ends. The bandage may be used as the whole cloth, the broad fold and the narrow fold. If the point is brought down to the middle of the base and the bandage again folded we get the broad fold; folded once again it is the narrow fold. In fastening the bandage the two ends are tied in a reef knot. The diagrams in the next column show the difference between a reef knot and a granny.

The various methods of fixing a triangular bandage or dressing are as follows:

(1) Greater arm sling. This takes the weight of the whole forearm. Use the whole cloth and place one end over the sound shoulder, the point being towards the injured limb. Carry the limb across the cloth and carry the other end over the shoulder on the injured side. Knot off behind the neck; take the point, carry it forward in front of the elbow and fasten with a safety-pin.

(2) Lesser arm sling. This takes the weight at the wrist. Use the broad or the narrow fold and apply as shown in the illustration. The pressure of the knot may be relieved in either sling by placing a folded bandage or a piece of cotton-wool beneath it.

(3) To fix a dressing on the neck, the forearm, and arm. Take the narrow fold, place the centre over the dressing, cross the ends and bring back; then knot over the dressing.

(4) For the thigh and leg use a broad fold and tie as above.

(5) For the elbow. Take a broad fold and place the centre over the point of the elbow. Cross in front and carry round the forearm, overlapping the lower edge of the bandage already applied. Cross again in front and carry back round the arm, knotting over the upper border.

(6) For the knee. Take a broad fold and apply the centre over the knee-cap, then proceed as above, making the knot, however, below the knee-cap.

(7) For the shoulder. Take the whole cloth and lay it on the shoulder with the point upwards. The lower

border is placed opposite the middle of the upper arm. Cross the ends on the inside of the limb and bring back and tie off. Fix a lesser arm sling to carry the injured limb. Take the point first beneath, then down over the sling and pin off.

(8) For the hand. Take the whole cloth and lay the hand on it palm down, with the fingers towards the point. Carry this back to the wrist and cross the ends over it. Cross again in front and tie off on the back. Pull the point up and carry down over the knot and pin off on the back of the hand.

(9) For the foot. Place the sole on the cloth, toes towards the point, and proceed as above.

(10) For a wound on the top of the scalp. Take the whole cloth and make a hem on the lower border of about an inch. Place the centre of this border on the forehead over the nose, the point being thrown back over the head. Carry the ends round and cross below the prominence at the back of the head. Then bring these ends forward and tie them securely in front, drawing the point well down under the bandage at the back of the head, carry forward and pin into position.

(11) For a wound of the chest, in front. Take the whole cloth and lay the point over the shoulder on the wounded side. Carry the ends round to the back and tie, leaving one end long; then tie this end and point together.

(12) For the eye. Take a narrow fold and place the centre over the eye. Carry one end obliquely across the brow and the other over the ear. Cross below the prominence at the back of the head, bring forward and tie over the dressing.

*Bandage. Above, reef knot, the best to make. Below, granny knot, which is unsafe.*

*Bandage. Left, greater arm sling: the whole cloth is first placed with one end over the sound shoulder and the point towards and beneath the injured limb. Right, bandage for shoulder combined with lesser arm sling.*

The roller bandage may be from one to six inches wide and for fixing dressings should consist of cotton or linen; for binding or splints calico is better; a flannel bandage is very comforting for painful joints. To give support to the legs in cases of varicose veins a woven crêpe or elastic bandage is used.

In bandaging a limb always begin on the inside and unroll the bandage outwards, but do not uncover more than three or four inches at a time. First take a few turns round the limb to fix it, and then proceed upwards obliquely, each turn covering two-thirds of the width of the preceding turn. (*See diagram above.*)

It will be found before one has gone very far that the bandage will not lie evenly, and then it is necessary to reverse. The thumb of the free hand is placed in front of the turn which is being made, the roll is twisted round towards the operator, and the turn is completed with the reverse side of the bandage in contact with the skin. When the bandage comes to the front it is again reversed, and this is continued till it lies evenly without reversing. The first method is the simple spiral, and the second the reversed spiral.

When a joint is reached a turn is taken round the joint, at the knee, for example, across the knee-cap. The next turn overlapping this turn goes below and the next overlaps above, and so on, till the joint is covered in. This is the figure of eight bandage, one loop of the eight being above the joint and the other below. When the bandage is completed it should be fixed with a safety pin.

Certain rules must be carefully observed: Do not apply a damp bandage, as it will shrink on drying and be too tight. Apply the turns with uniform pressure and parallel to each other. Do not reverse over a sharp, bony edge. While bandaging, the nails should be left free, because pressure on them will show whether or not the bandage is interfering with the circulation. In removing a bandage do not roll it up in the process, but before re-applying it. If no bandage roller is available it is possible to roll the bandage quite tightly between the fingers, purchase being obtained by taking it over the back of a chair.

**Finger Bandage.** To cover a finger, using an inch-wide bandage, take a couple of turns around the wrist, not covering the free end of the bandage, but leaving this loose for tying later. Carry the roll from the inside of the hand over the back of the wrist outwards. After it is firm at the wrist, bring it down across the back of the finger to be bandaged and then make a series of spiral loops, the one overlapping the other, downwards to the tip of the finger, and back again to the root of the finger, thence crossing over the base of the finger and over the back of the hand to circle the wrist in the opposite direction to the point where the end can be easily tied into a knot with the free end of the bandage.

**Foot and Leg Bandage.** Laying the free end on the back of the foot, the roll is carried around the outer surface of the foot across the sole, up over the inner border of the foot across the instep, round the back of

the ankle, and again over the instep. This figure of eight is repeated, each layer of bandage overlapping the one below by half its width, until the ankle has been passed, and then, commencing from the ankle, spiral turns may be used. At the knee a return to the "figure of eight" may be made.

*Bandage. Three stages in the spiral application of a roller bandage to the leg; top, right, shows a reverse being made.*

**Hand and Arm Bandage.** With the arm and hand palm downwards, the bandage is laid across the back of the wrist, the free end towards the patient's body, and kept in position by the operator's free hand. The roll is then carried across the back of the hand from thumb side to little finger side, around the outer side, across under the palm, up through the angle between the thumb and first finger, over the back of the hand, around the wrist and again over the back of the hand from the thumb side towards the little finger side.

*Bandage applied to hand and arm in figure of 8 loops and spirally.*

Two or three of these figure of eight loops will cover in the hand. A spiral bandage is then continued up the arm, the spiral being reversed when necessary. At the elbow a return may be made to the figure of eight

turns, similar to those described above.

**Head Bandage.** The best head bandage, if no pins are to be used, is the double roller "capelline." This latter is simply a long single bandage, the two ends of which have been rolled up in contrary directions until the rolls meet. If the rolls are of the same size, one should be unrolled about a couple of feet, the slack being taken up by rolling up the other bandage until the two rolls again lie side by side. The surgeon stands behind the seated patient. Taking the large roll in his

*Bandage. Use of a double roller 'capelline' bandage for a head injury: one roll is brought round the head and the other across the top.*

left hand and the small roll in his right, he first applies the portion of the bandage connecting the two rolls horizontally across the patient's forehead.

It is important that the beginning fold of the bandage be low enough on the brow. The two rolls are then brought round, one on each side of the head just above the ears, until they meet well below the prominent back of the head. The left-hand roll is now brought over the top of the right-hand roll, the operator taking it in his right hand, while the other bandage is folded over this and carried forward over the top of the patient's head until below the level of the brow.

The original left-hand bandage, now in the operator's right hand, is continued horizontally around the right side of the patient's head to the forehead, where it crosses over the top of the bandage which has been brought forward over the centre of the head, and is continued around to the back again. As soon as it has covered over the fold crossing the forehead vertically downwards, this latter is brought upwards, and carried back again over the top of the skull, a little to the left of and overlapping the first strand brought forward. At the back of the head it is again crossed by the horizontal roller, and then is brought forward to the forehead again, this time overlapping the central vertical bandage a little on the right side. The process is continued until the scalp is covered, each horizontal layer serving as a fixation point for the overlapping vertical bandages. When enough backward and forward turns have been taken to cover the dome of the head thoroughly, a few extra horizontal turns may be taken in order to keep the headdress firmly in place.

**Thumb Bandage.** Begin by fixing the bandage with

a couple of turns around the wrist, carrying the bandage from the thumb side over the wrist, and leaving a free end of five or six inches. After the second turn, bring the bandage down as far as it is necessary to bandage, and make a loop around the thumb here by carrying the roll around the thumb from without inwards, crossing over the back of the thumb and the back of the hand from thumb side to little finger side as the hand is held palm downwards. The roll is again carried round the wrist, and a second loop is made around the thumb as before, this loop overlapping the former and not extending so far down as the first. The loops are continued until the thumb is covered with the bandage from the end joint well up to the wrist, when the bandage is finished off by tying with the free end around the wrist.

**BAND-SAW.** The wood-worker's band-saw is a comparatively large and heavy machine saw used for cutting flat material into curved shapes. It is used extensively in the cabinet-making and joinery trades. The blade is made of thin steel varying in length from 12 to 24 ft. and in width from  $\frac{1}{4}$  in. to  $1\frac{1}{2}$  in. The saw is joined by brazing the ends and forms a continuous band. *See Saw.*

**Bangle.** A thin bracelet made of metal, glass, ivory, or jade. *See Bracelet.*

**Banister.** *See Baluster; Railing; Staircase.*

**BANKING.** Banking accounts are either current or deposit. The latter is only for the investment of money, but a current account is useful even to persons of small means. It enables them to deal easily with cheques, dividend warrants, coupons, and the like. It is a convenience to pay by cheque, which minimises the risk of loss by reducing the amount of ready money a person must have in his house or on his person. Unlike a Treasury note or a coin, a cheque, if lost or stolen, can be stopped and probably traced.

The customers of a bank enjoy other advantages. These include the privilege of depositing deeds and other securities and valuables in the custody of the bank, usually without charge, and that of obtaining drafts on foreign and other banks in case of travel abroad, while the bank will purchase and sell stocks and shares for them. It is useful also for certain purposes to be able to give a banker's reference.

A banking account may be opened by applying to the manager at any convenient branch on production of a reference or introduction. The bank supplies a pass book for recording the customer's receipts and payments. The counterfoils and the book should be compared periodically with the pass book, which is made up by the bank every day and balanced every half-year.

The charges made by the bank vary as between London and the country, and, to some extent, with the nature of the account. Small accounts in London pay from £1 1s. to £2 2s. a year; in the country 2s. 6d. is

charged on every £100 turnover. If, however, a certain minimum balance, say £50, is kept in the bank, usually nothing is charged. *See Cheque; Pass Book.*

**BANKRUPTCY.** Any man may be made a bankrupt, but a married woman cannot, unless she carries on a business or trade. When a husband has lent money to his wife for the purpose of her trade or business, and she is made a bankrupt, he cannot claim for his money until all other creditors have been paid in full. The same holds good when a wife has lent money to her husband for the purpose of his trade or business. The whole of a bankrupt's own property belongs to the creditors except the tools of his trade, necessary apparel and bedding of himself, wife and children to the value of £20.

When a man has made a marriage settlement before his marriage, it holds good against his creditors.

If a man settles money or property on wife or children after marriage, and becomes bankrupt within two years, the transaction is void and the creditors take everything. If more than two but less than 10 years elapse, the creditors still take the money, etc., unless it can be shown that the bankrupt at the time of the settlement was able to pay all his debts without the money or property settled.

**BANTAM.** Although regarded in many households as a pet for the children and nothing more, the bantam may be made a source of profit. Being the smallest of all poultry, it eats less and takes up less room, but it lays as well as most other fowls. Its egg, averaging  $1\frac{1}{2}$  oz. in weight, has a delicate richness of flavour.

*A Bantam Cock.*

**BARBERRY** or Berberis. These are hardy shrubs, comprising both evergreen and deciduous species. They thrive in any fairly good, friable ground, and may be raised by seed sown either in autumn or spring, or suckers springing up from the rootstocks may be removed and planted. Cuttings of the ripened wood may be inserted in sandy soil in a frame in autumn.

*Barberry. Fruit sprays of a variety of the shrub.*

Among the species and varieties of berberis are many of the best hardy ornamental shrubs.

The mahonia (*Berberis aquifolium*, 3-5 ft.) bears yellow flowers in spring and purple fruits in autumn; it will thrive under large trees and is a good covert shrub. *Darwinii*, and *stenophylla*, two vigorous evergreens 8 ft. or more, bear orange yellow and yellow flowers respectively in spring; *buxifolia*, 8 ft., bears yellow fragrant blooms in April.

In recent years many new barberries, valued for their brilliantly coloured fruits, have been introduced from China, including *Wilsonae aggregata*, *polyantha* and *dictiophylla*. They are invaluable for the front of shrubberies.

The common barberry (*Berberis vulgaris*) is a large leaf-losing bush or small tree which bears bunches of scarlet fruits in autumn. *Candidula* is a low-growing evergreen, with purplish fruits, and suits a rock garden (q.v.).

**BARK.** The exterior covering of trees has many uses. Bark can be removed from a tree-trunk by cutting round the tree with a sharp knife or saw. A second cut is made below the first, and the two cuts joined by a vertical cut. The bark can then be peeled off. Coloured barks are employed effectively as coverings for the walls and roofs of summer-houses and similar outdoor structures. The variety of bark known in the trade as virgin cork has a rough surface not unlike rock, and is used to some extent in building up internal ferneries and such-like greenhouse fitments. It is preferable to wire this material to the wooden framework. *See Summer House.*

*Plum Bark beetle, much enlarged.*

**BARK BEETLE.** The fruit-tree most often damaged by this insect is the plum, but the beetles are also found on apple, pear, cherry, apricot, peach, and quince.

In the case of an infested plum-tree it will usually be noticed that some of the twigs or smaller branches are dead, and that numerous holes have been bored through the bark, which peels off easily, disclosing little tunnels between the bark, and the wood of the tree. The trouble may extend to the larger branches and even to the trunk itself, and the entire tree may thus be killed.

The adult beetles are brownish-black insects about one-sixteenth of an inch in length. During warm weather in spring the beetles leave their burrows, flying away in search of fresh trees to attack. On discovering a suitable tree the female selects a twig or branch and bores a hole vertically through the bark. It then turns and bites out a tunnel or brood chamber  $\frac{1}{4}$ - $\frac{1}{2}$  in. in length along the branch between bark and wood, laying eggs as it goes. This information is given by the Ministry of Agriculture (Leaflet No. 159). *See Plum.*

The measures to be adopted are preventive rather than remedial. Trees in an unhealthy state are preferred by the beetles, and a bad attack by aphides or brown rot on plums, for example, may cause an increased infestation by bark beetles. Therefore all dying and badly damaged trees or branches should be cut down and promptly burned.

**BARLEY.** Pearl barley is the grain deprived of husk and pellicle and rounded and polished by grinding. Pot or Scotch barley is more nutritious than pearl barley, being deprived of the outer husk only, and roughly ground.

Barley is valuable for thickening soups and broths, for making puddings, and for the preparation of barley-water. It contains no gluten, and therefore is not suitable for bread-making, except with a slight admixture of wheaten flour. It unites well with the oily matter extracted from meat in boiling. If soaked overnight in sufficient cold water to cover, it needs less time to cook.

For a nutritious barley stew, take  $1\frac{1}{2}$  lb. of boneless shin of beef or ox cheek. Wash and wipe this, then cut into large pieces and place it, in layers, in a saucepan, casserole or stewing jar, with two large sliced onions, some carrots, and 1 gill of soaked Scotch barley. On the top of the last layer arrange 1 lb. of washed, peeled, and thickly sliced potatoes. Season two quarts of cold water and pour this over the mixture until the saucepan is three-parts full. Then cover and stew slowly on the fire or in the oven until tender. Small suet dumplings and well-cooked cabbage should, be served with this dish. Mutton may take the place of beef, but the gravy will then be less rich.

**BARLEY CREAM SOUP.** Melt 2 oz. butter in a saucepan and stir smoothly into it 1 oz. flour; then add a pint white stock and stir it with a clean wooden spoon until boiling. Put into the mixture 1 oz. washed pearl barley, simmer till the latter is soft, which will take about  $1\frac{1}{2}$  hours, and rub all through a hair sieve. Rinse out the pan, pour back the sieved soup, and

simmer for 5 minutes.

Allow the mixture to cool for a few min., and then strain into it the beaten yolks of eggs and 2 gills milk or cream. Add seasoning and reheat the soup; it must not boil or the eggs will curdle. Serve in a hot tureen with fried croûtons. If no white stock is available use a mixture of half milk and half water, to which a small piece of onion has been added. Margarine may take the place of butter. Sufficient for about four persons.

**BARLEY MEAL.** A mixture of flour and barley meal is sometimes used for scones or home-made bread. Mix well 4 oz. each of flour and barley meal,  $\frac{1}{2}$  teaspoonful each of salt and carbonate of soda, and 1 teaspoonful of cream of tartar. Rub in lightly and finely 2 oz. of butter, and mix with about 1 gill of milk to as soft a dough as possible without making it actually sticky.

Having kneaded it lightly on a floured board, form into a thick round and cut across into four or eight pieces, taking care not to cut right through to the board. Place the round on a floured tin, brush over with milk to gloss, and bake in a quick oven for from 15 to 20 minutes. The scones should be broken (not cut) apart, and served hot, split and buttered. They can be baked on a hot, greased girdle if preferred. Sufficient for eight scones.

For barley meal cheese mix two heaped tablespoonfuls of barley meal with a little cold milk until smooth. Boil the rest of a pint of milk and stir in the barley meal. Cook for ten minutes, then add two tablespoonfuls grated cheese with some made mustard, and salt and pepper to season. Put the mixture into a pie-dish and brown in the oven.

**BARLEY SUGAR.** Put  $1\frac{1}{2}$  lb. of loaf sugar into an enamelled saucepan, add  $\frac{1}{2}$  pint of water and half the beaten white of an egg. Mix well together and then bring to the boil and skim carefully. When scum ceases to rise the sugar is clarified, but it is as well to strain through muslin. Put back in the pan and boil to the crack, i.e. so that a little dropped into cold water becomes hard and brittle. Remove from the fire, add a teaspoonful of lemon-juice, and after letting it stand for a minute or so, pour out on a greased dish. Before it sets hard, cut into strips and twist.

Barley sugar is one of the healthiest sweets for children, being rich in glucose, which counteracts any tendency towards rickets. Far better than cane sugar as a digestive, it is strongly recommended by doctors, and very cheap to buy or make.

**BARLEY WATER.** Wash 2 tablespoonfuls of pearl barley in cold water, put it into a saucepan with 2 pints of cold water, bring to the boil and boil gently till the liquid is reduced to 1 pint. Strain, and sweeten or salt according to taste. One cupful of this, added to one cupful of milk, hot or cold, makes a pleasant invalid drink, and for infants the barley water is used in the same proportion as water in their milk allowance.

For large quantities of barley water as a wholesome

drink make as above, adding to every pint, while hot, the juice of half a lemon and one tablespoonful of sugar. This beverage seems to be growing fashionable as a "soft drink" for teetotallers at parties, rivalling grape-fruit squash and tonic waters. Thin people, who want to put on weight should drink at least a quart a day. Barley water should be freshly made each day, and kept in a cool place.

To make Imperial Drink add 1 teaspoonful of cream of tartar to 1 pint barley water while hot. This is used in febrile conditions and to stimulate the action of the kidneys.

**Barm.** *See* Yeast.

**BAROMETER.** Mercury barometers for measuring weight or pressure of the atmosphere are not to be confused with the aneroid instrument, which arrives at the same result by totally different means. A barometer such as the Fitzroy consists of a large-bore glass tube about 3 ft. long, filled with mercury, and inverted into a vessel also containing mercury. This allows the mercury to descend a few inches, thus causing a vacuum at the top.

The surface of the mercury in the container is subject to atmospheric pressure. Hence, as the air pressure increases, the column of mercury is forced up the tube. Conversely, as the air pressure diminishes, the mercury column falls proportionally to the atmospheric pressure at the time. The average height of the top of the mercury column from the surface of the mercury in the vessel at the bottom is about 30 in. By arranging the tube so that the top of the mercury is visible it is possible to add a scale and take readings direct.

In general principle this system is used in the Fitzroy, Piesmic, Cistern, and Fortin barometers: the last mentioned is largely employed for observatory purposes. In other types a small float on the surface of the mercury is attached to a cord passed over a drum on an axle provided with a pointer, from which readings are taken on a suitably graduated scale.

Important points to remember with any mercurial barometer are to keep it always perpendicular and to hang it in a position where the temperature is equable, otherwise it will act as a thermometer.

*Barometer. Aneroid barometer shown in section. Explanatory details are given in the text.*

**Aneroid Barometer.** The aneroid differs from the

mercurial barometer in having no long glass column to get broken, nor any quicksilver to get lost. Also, it works anywhere and in any position. On the other hand, it depends on metal springs, and is, therefore, affected by changes of temperature, so that it requires to be checked from time to time by comparison with a good mercurial instrument in the neighbourhood or on about the same height above the level of the sea.

In the illustration, which is a section, *a* is a thin metal box with the top and bottom corrugated to make them more springy. This box is partly exhausted of air, so that the effect of the atmospheric pressure is to force the top and bottom inwards. A strong curved spring, *b*, is attached to the top of the box at one end and at the other to a fixed stand, *e*, and connected by the lever, *d*, to a bell-crank, *e*. The other end of this crank has another lever, *f*, attached; it joins a fine chain, *g*, which is wound round the spindle, *h*, of the pointer, *k*. A hair-spring, *l*, controls the movement of the spindle and keeps the chain taut.

The dotted lines show the movement in an exaggerated form. In the dotted line position the atmospheric pressure is high, and the box is compressed in consequence; lever *d* has been drawn down, the bell-crank pulled over, and the hair-spring has wound the pointer round several degrees on the dial in a clockwise direction. When the pressure falls the reverse action takes place, and the chain, *g*, pulls the pointer back.

**BARONESS PUDDING.** Take equal quantities of flour, suet and raisins;  $\frac{1}{2}$  lb. of each makes a good-sized pudding for four or five persons. Add a pinch of salt and make into a stiff dough with milk. Steam in a greased bowl covered with greased paper for three hours. Serve with jam or sugar.

**BARON OF BEEF.** A joint consisting of two sirloins left uncut at the backbone is called a baron of beef. This cut is now seldom used. *See* Beef; Sirloin.

**BARREL.** This is a cylindrical wooden vessel made of curved staves bound together with hoops and used for holding beer, tar, and other liquids. A barrel is also a measure of capacity, varying according to the liquid measured. A barrel of beer contains 36 imperial gallons, a barrel of oats equals 14 stone, and a barrel of tar equals 26  $\frac{1}{4}$  gallons.

*Barrel. Leaky barrel mended by tightening staves with wire.*

When they are no longer required for trade purposes, barrels can be utilised in various ways in or around the house. A port wine pipe set up on legs or on a small platform serves as a rainwater-butt. It

should be coated inside with tar, which is then set on fire and burned out. A second coating of tar is given, and after the exterior has been painted, the barrel is ready for use.

The charring and tar treatment preserves the wood from rotting. A draw-off tap near the bottom and overflow pipe at the top and a lid to exclude dust and dirt are desirable additions.

When barrels have been left lying about for some time the staves generally become slack; they can be tightened by driving the hoops further down the barrel, or by wiring them tightly. The wiring is done by twisting several turns of  $\frac{1}{16}$  in. diam. (16 gauge) galvanised wire round the barrel and tightening it up with a tourniquet. Secure the wire with clout nails, or by cutting a shallow groove for it to lie in, to prevent it shifting from its place.

To clean old barrels, wash and scrub them with caustic soda solution, or use one of the paint removers.

**Tapping a Barrel.** Barrels may be tapped by first setting the cask in such position that nothing will be lost during the process. Then remove the plug in the hole intended to receive the barrel tap. Wrap a piece of paper around the stem of the tap and drive it home tightly with a mallet. Set the cask in position with the tap to the bottom, drive the air release peg into the barrel, or preferably withdraw it if possible. The contents can then be drawn off by turning on the tap.

**BARREL: In Gas Fitting.** The trade name of barrel is given to wrought iron tubing used for gas and hot water pipes and similar purposes. Such tubes are made in three thicknesses or weights, according to the size of bore, and are butt-welded. The lightest and commonest class is used for gas fitting. Hot water pipe is stronger and of superior quality, and is usually tested to withstand a pressure of 300 lb per square inch. Steam barrel is superior to water barrel, and withstands 500 lb. per square inch.

There are many uses for such tube apart from their specific duties. Numerous fittings, such as angles, tees, and junctions, are available, and by their use a large number of articles can be produced by the home worker. Gas and steam barrel is measured by the bore or diameter of the hole. Thus  $\frac{1}{4}$  in. gas pipe has  $\frac{1}{4}$  in. diameter hole, and actually measures approximately  $\frac{3}{8}$  in. diameter on the outside. Gas barrel is connected by means of a screw thread cut on the exterior of the tube, two straight lengths being connected by a screwed socket or sleeve, screwed over the outside of the barrel. *See* Gas Pipe; Pipe; Tubing.

**BARRENWORT.** This is a hardy herbaceous perennial, equally attractive in leaf and bloom. The foliage, somewhat like that of a begonia, in autumn colours well; it gets dingy later, but should be left on through the winter to protect the buds. It is a spring-flowering plant, bearing yellow, white, blue, or violet flowers. The height of the different species varies from 6-18 in.

*Barrenwort, a hardy perennial somewhat like a begonia.*

The barrenworts grow best in shade, especially in cool, peaty soil, or in a mixture of peat and loam. They are very useful for shady rockeries, and will thrive under trees. Propagation is by division in spring, or by portions of the rhizomes which will form plants if put into gentle heat in spring.

**BARROW.** A barrow is an article used for conveying goods. The commonest form of it is that more usually known as a wheelbarrow, but there are also hand-barrows without wheels. *See* Wheelbarrow.

**BARTONIA.** Growing about 15 in. high, the bartonia is a hardy annual with deeply cut, toothed, greyish leaves and large bright yellow flowers showing a mass of prominent stamens resembling those of the wild dog-rose in shape. It thrives in ordinary soil, the seed being sown in September for spring flowering, or in spring for blooming in late summer. Pron. Bar-tony-er.

**BASEMENT.** A basement is the lowest floor of a building when it is situated below the ground level and when access to it is attained by steps outside or inside the building. The term half-basement is used when the ceilings on such a floor are above ground level.

There are various sanitary, hygienic, and other objections to basements, and modern houses are built without them. In large buildings, where mechanical ventilation can be installed, there is less objection to them.

The decoration of basement living rooms and flats requires careful consideration of wall treatments, artificial lighting and window curtains. Semi-glossy paints are helpful in pale, warm colours, avoiding dead white even for ceilings as uncomfortably harsh. Patterned papers should also generally be avoided, but a distinctive note can be given to plain wall surfaces by the use of colour for woodwork; thus a pale buff plastic paint may have coral enamel, a primrose yellow distemper, amber painted skirting and door. Mirrors can be used to advantage in dark rooms and give an effect of space. Wall lighting, which can be both brilliant and yet diffused, is the best substitute for daylight. Where possible reflectors may be placed outside windows. In the case of bay windows the inner sides of the bay may be panelled with looking glass.

Window curtains may be of light, bright surfaced materials. Pelmet, if used, must be designed not to obscure light. Curtain rods should extend on either side

beyond the window frames, so that curtains may be well drawn back. To hide out basement views somewhat, straight French net inner curtains with a light all-over pattern may be used completely to cover the windows. *See* Area; Cellar; Flat; Mirror; Window.

*Basement. Part of an ingenious and decorative conversion of a basement into a flat.*

### **BASIC SLAG.**

This is a valuable chemical manure, its worth depending on the percentage of

phosphate of lime which it contains. As influencing the availability of the phosphate, the fineness of grinding is extremely important. Basic slag is slow in action and must be applied in autumn. It is beneficial in fruit, flower and kitchen gardens. *See* Manure.

**BASIL.** Two species of this potherb are generally known, sweet and bush basil. They are nearly allied to the mint (*Mentha*) family and their scientific name is *Ocimum*. The sweet basil grows about 12 in. high, and is densely covered with small oval leaves. The little white flowers appear in early summer and are borne in long clusters. The bush basil grows about half the size, forming a roundish bush. Both plants are highly aromatic. They are annuals and are easily grown from seed in spring. They like a light, sandy, friable soil.

*Basil. Spray of sweet basil, an aromatic potherb.*

The tips of the leaves are used to impart their distinctive clove flavour to soups and salads, and are also used for seasoning. By cutting down one or two plants as soon as they come into bloom, and drying the leaves slowly in the shade, the leaves can be used in the winter. A form of bush basil is sometimes grown as a

pot-grown as a pot-plant for a greenhouse or window. It bears shining green leaves, and pale pink flowers. Pron. Baz'-il.

**Basil.** *See* Leather; Sheep-skin.

**BASIN.** Cooking basins are made in enamelled ware and aluminium as well as earthenware. The former have advantages, being light, unbreakable and easily cleaned.

Good quality enamel-ware is essential, as inferior enamel is liable to contain arsenic, easily, fragments of the coating getting mixed with the food.

To minimise the danger of chipping delicate china, glass, etc., when washing it, papier-mâché basins might be used with advantage. Clean them with a soft rag dipped in paraffin if marked and stained, and rinse well in hot water and dry. Mixing basins should be 11 or 12 in. across. These are useful sizes.

Pudding basins differ from the ordinary bowl, on account of the deep rolled rim intended to prevent the string used for tying on the pudding cloths from slipping upwards. These basins can be obtained in sizes from 3 to 12 in. across. Pudding basins with special covers obviate the need of pudding cloths. Spouted or lip-basins are handy, as milk, stock, etc., can be easily poured from them. *See Aluminium; Crockery; Enamel.*

## BASKET MAKING AND REPAIRING

How to Practise Simple Weaving with Osiers  
Other Varieties of Basket Work are described under  
Linen Basket; Raffia, etc.

Basket making may be carried out with the aid of a few simple tools, and although elaborate baskets require skill in manipulation simple work may be produced after learning a few of the methods of weaving the rods.

Most baskets are made with osiers worked up with the bark intact; others are made with rods from which the bark has been removed, and either left white or stained to a buff colour.

All osiers must be thoroughly soaked in water before use, in order to render them sufficiently pliable for bending. Round baskets may be made with no other tools than a knife and bodkin, but for square-sided work a screw-block is required to hold the stakes whilst weaving. A simple round basket embodies the principal methods of weaving, termed strokes. Such an example is shown, which can be used for marketing purposes. Short lengths of osier may be used; either the sizes known as luke and small in brown osier or tack and long small in white and buff will be suitable.

The bottom should be commenced by prearing six 12 in. lengths cut from the thick ends. For the first

stage these lengths must be tied together in two sets of three as shown in the illustration, but as there should be an uneven number of spokes, a whole rod should be used to provide the extra spoke, and also the material for binding the lengths together. The long rod will rest with its thick or butt end alongside one of the sets, and the remainder must be carried over and under the crossed lengths until it has been twice round.

The next stage commences the separation of the spokes, and the weaving of the rod is continued, first under and over each length until it is used up. Care must be taken to bend the spokes evenly and to work the weaving length as closely to the centre as possible. Having once singled out the spokes the succeeding work is quite straightforward, and only needs care in keeping the weaving rods close up as each round is finished. New rods are started two spokes back and left projecting about 1 in. beyond the top of a spoke, or the end may be pushed down alongside one of the spokes and then bent out. When a diameter of 9 in. is reached the end of the weaver should be cut off and pushed down alongside the nearest spoke, and the projecting ends of the spokes cut off close to the weaving.

The natural tendency in weaving will be to form a hollow tray, and this is just the formation required. The sides should now be formed by inserting the stakes, which are long lengths sharpened at the butt end, and pushed in alongside. It is still necessary to have an odd number of rods, so, as there are 13 spokes, 25 straight rods should be trimmed at the ends with a slicing cut called a slype. Each rod should be pushed down by the side of a spoke, a hole being prepared if necessary with the bodkin, and the single rod placed at the point where two spokes are closest together. The bottom must be placed flat on a table with the crown uppermost, and each spoke turned upright. If the osiers have been properly soaked, and the point of the knife is dug slightly into the angle of the bend this can be done readily enough. The tops should be gathered together and placed in a hoop, as shown.

The next stage is known as the upsett, three rods being worked round the stakes to stiffen them. Sharpen three rods and push the first alongside the single stake and the next two following. The three are now worked together, each one being carried in front of two spokes and behind the third, taking them in order, and continuing until they are used up. This should be done as tightly and closely as possible, working down on the corner in order to give a firm foundation to the succeeding work.

## Three Methods of Weaving

The quickest way of filling up the sides, known as slewing, consists of three or more rods worked in and out all the way up, new lengths being taken as required, and each length started with the top or thin end. The used end is left projecting on the inside and cut off later when the work is dry. The slewing should

be continued to a height of 5 in., and the rods worked out to leave the top level; if necessary short lengths of osier can be worked in in order to obtain the required level.

A band termed a wale has to be worked round the sides. Pick out four thin rods of medium length and, commencing with the tops, place them behind four stakes in order, and then carry them alternately in front of three and behind one, until the round has been completed and the commencing ends covered. The result of the work will be seen in the stiffening of the weaving. A single rod weaver should be worked, adding others to bring the sides up to the height of 8 in. This method of weaving is termed randing. The top should be left level, and if the weaving has been carefully done all the upright stakes will be equally spaced all round.

The sides are now ready for the border, which may be quite simple or full. The simple border is formed by bending each stake down in turn, and carrying the bent top in front of the first on the right, behind the next, and left outside the third, the ends being trimmed off a little beyond the stake they rest against.

For the full border, commence by laying down four spokes, the first behind the second, and left in front of the third; the second is taken behind the third and left behind the fourth, the third behind the fourth, and left behind the fifth. The fourth stake is taken behind the fifth together with the end of the first one laid down, the fifth stake is worked together with the second laid down, and so on until the complete round has been worked, the last four stakes being worked together with their corresponding ends underneath the bends of the first four. The projecting ends which are now on the outside of the border are trimmed off quite close to the border, when the work is dry.

The handle is formed from a stout length of rod, and bound in position with lengths of osier. A rod is cut to a length of 30 in., with both ends sharpened. One end is driven down through the border to a depth of 6 in. alongside of the stakes. The rest of the rod is carefully bent, and the other end driven through the border alongside a stake on the opposite side. The plain bow may be covered with a double spiral formed by driving the sharpened end of the rod each side of the handle. The rods should be wrapped round and the ends worked across and through under the border on the opposite side in each case.

The basket should be finished by cutting off all the projecting ends left inside, but as the rods shrink when dry, sufficient should be left to prevent the end slipping past the stake on which it rests.

**Basket Repairing.** The handles of clothes baskets are formed with two thoroughly soaked rods which are driven through the border alongside suitable stakes. The ends should be driven down as far as possible. Bend the rod on the left and pass the top under the border from the outside alongside the rod on the right and pull it right through to form a bow. Now twist the second rod on itself and carry it in the form of a spiral three times round the bow, carry it under and through the border and return to the commencing side and repeat. The end of the first rod can be treated in the

same way, and this is continued until the bow is filled up. The same method may be followed in re-covering a large bow handle when the covering is broken.

The bottom rim of both square and round baskets can be strengthened by driving in, alongside the upright stakes, a number of single stakes, endeavouring to get them as far through the weaving as possible. The upright ends are treated much in the same way as a border, each rod being carried down behind the next, in front of the one following, and left either behind the next or in front of the next but one. When the ends are cut off, the new rim will form a solid foundation to the old work.

**BASKET BALL.** Game played, especially by girls, on a stretch of ground between goals, which consist of a net shaped like a basket. It thus resembles net ball (q.v.).

**BASKET PLANTS.** The culture of plants in baskets is a great convenience to the amateur who possesses only a small greenhouse or conservatory. The baskets are usually made of galvanised wire, wood, or terracotta.

*Basket plants and methods of arranging them. 1. Basket placed on flower-pot for convenience in planting. 2. Section of portion of basket: A, moss lining; B, rough soil for base planting. 3. Side plants in finer soil, leaving space, A, for centre plant. 4. Section of basket with plants in position. 5. Correct method of watering by immersing basket in a tub.*

The number of kinds of plants available for basket culture is very great. The following may be named as suitable. Achimenes, asparagus fern, begonia, certain of the campanulas, buttercup oxalis, clianthus or glory pea, Cornish moneywort, fuchsia, ivy-leaved geranium, ivy-leaved groundsel, ivy-leaved toadflax, Cape cowslip, lobelia, mother of thousands, nasturtium, petunia, and thunbergia.

Wire baskets are best for ferns, and should be lined with moss. In hot weather the baskets should be dipped in soft water twice a day. Two parts fibrous loam, one part rough peat, one part leaf-mould, and sand make a suitable compost. The plants should be put into the baskets in spring. A well-grown plant—one, say, turned

out of a 5 in. pot—should be put in the centre, leaving the crown just above the top. An old plant should be divided into a dozen or more young plants, and these should be planted round the edge of the basket, as shown at 3 in the diagram above. Several kinds may be arranged in one basket, the small being inserted in the sides, the fronds pointing downwards. A large kind should occupy the centre. *See Flower Basket.*

**BASQUE.** That part of a bodice to which the waist is sometimes fitted, extending downwards from the waistline. A basque may be cut on circular lines, or it may consist of two straight pieces, one attached to the front and one to the back of the bodice, with openings at the side seams. *See Blouse.*

**BAS RELIEF.** The decoration of a modern house often includes some form of bas-relief in the frieze or ceiling of a room. The most common material is anaglypta, or one of the other variants of fibrous plaster. Modern fibrous plaster, which, with gypsum as a basis, sets into a hard cement, is quite durable enough for ordinary purposes.

The depth of the relief should depend upon the size and height of the room. In small rooms the relief should rarely exceed  $\frac{1}{2}$  in. to 1 in. in depth. *See Anaglypta; Moulding.*

**BASS: Cooking the Fish.** To bake, wash and clean one or two medium-sized fish, placing a little butter or dripping inside each, and seasoning to taste. Lay on a greased baking-tin, smear with more fat, and bake in a slow oven for a little less than half an hour, basting occasionally. Cut some potatoes into neat pieces, and when partly boiled put them into the baking-tin with the fish, and cook for 10 min. or so. When done, arrange the fish on a hot dish with the potatoes placed round and garnish with finely chopped parsley. If liked mustard sauce may be served separately.

Bass may also be stuffed. Take a fish weighing about 4 lb., wash and clean, and season it inside with salt, pepper and lemon juice. Then stuff with oyster forcemeat, sew the fish up, and lay it on a greased baking-tin, squeezing some more lemon juice over it, and placing a few thin slices of fat bacon on the top. Bake in a hot oven, basting occasionally with the fat. When cooked, place the fish on a hot dish and draw out the trussing thread. Sprinkle with parsley and cut lemon, serving with it tomato or any other suitable sauce separately. It is sufficient for seven or eight persons.

**BASS: A Useful Wood.** Bass or basswood comes from the lime, but more usually from the tulip tree of N. America. Alternative names are American whitewood, American poplar, tulip wood, and canary wood. It is a soft wood, usually light yellowish-green in colour, is obtainable in large sizes, and is often used instead of pine for furniture, panels, boxes, pianos, toys, and carving. Bass is as straight in grain and as free from knots as pine, and slightly harder. It takes stain

and polish well, the usual stains being ebony or walnut. *See Wood.*

**BASSET HOUND.** Originally a sporting dog, the basset hound is now kept more as a companion than for hunting hares. So far as head and body are concerned the basset is a full-sized hound, but it stands only 9 in. to 12 in. at the shoulder. The legs are so short that the deep chest almost brushes the massive fore-paws. The ears are very long.

The dog weighs from 40 lb. up to 45 lb.; the bitch rather less. There are two types of basset—the rough, with a harsh, profuse coat variable in colour, with a dense undercoat; and the smooth, with a short, fine, and glossy coat of black, white, and tan colour. It is good-tempered and affectionate. *See Distemper; Dog.*

*Basset Hound. Once a sporting dog. Specimen of the smooth-coated variety.*

**BASSOON.** An instrument of extensive compass, the bassoon possesses a beautiful tone, and is so useful in an orchestra that competent players are always in request. To fit the separate parts together, the reed is put into the narrow end of the crook, the broader end of which is inserted in the wing. The wing and the bass-joint are then placed side by side in the holes at the top of the double-joint, and finally the bell is put on. The instrument is held transversely across the person, sloping from the left shoulder to the right thigh. A strap round the neck takes the weight of the instrument, which lies in the hollow of the hands, the left being the higher of the two. The reed is taken into the mouth, but it must not come into contact with the teeth. The beginner will be wise to get at the outset a few lessons from an experienced person regarding the embouchure, the fingering, and other elementary points.

*Bassoon. A. Reed. B. Crook. C. Wing. D. Double Joint. E. Long Joint. F. Bell.*

A good instrument ought to last for many years, but this is conditional on scrupulous cleanliness. After use the interior (particularly of the wing) should have a soft rag passed through it. All tone holes should be kept free from dirt, again with a soft rag. Keep the joints clean, greasing them if necessary to prevent moisture working in and thus causing splitting. The crook should be occasionally washed in hot water. Should the blow hole become clogged, free it by using carefully a soft brush or a fine needle. Reeds also should be gently wiped and put in some warm place to dry after use. The instrument should be kept in a dry but not over-warm place, protected from dust.

**BAST.** This is the fibrous material used for tying up bunches of cut flowers, and also for keeping in hand wayward branches of straggling perennial plants. The fibre, which is very tough, is the dried and dissected stem of the hardy perennial *Scirpus*, allied to the bulrush and rush grass. *See Raffia.*

**BASTING: A Cookery Term.** A long basting spoon is used so that the oven door need not be opened wide enough to let in cold air. The juices out of the meat, etc., collecting in the baking-tin are allowed to drip from the spoon over the article that is cooking. This prevents burning and improves the flavour.

Basting ladles, being round, are convenient for dipping into baking-tins made with a well in one corner, in which the dripping is able to collect. *See Baking; Roasting.*

**BASTING: In Dressmaking.** Tacking employed to hold two thicknesses of material together before joining the seams. Begin with a knotted thread, the knot being on the top of the work so that the basting threads can afterwards be easily pulled out. Always bring the needle out  $\frac{1}{4}$  -  $\frac{1}{2}$  in. beyond where it is inserted, and make each stitch even. Finish off with two stitches on top of each other and leave an end of thread to avoid pulling the whole of the basting out by accident. *See Dressmaking.*

*Basting stitch showing how the needle should be inserted slantwise.*

#### THE BATH: HOW TO FIT AND CONNECT IT Installation Methods in Houses both Old and New

For Fittings and Arrangements see Bathroom; other

associated articles are Boiler; Enamelling; Geysers; Plumbing; Water Supply, etc.

Before fixing a bath in a house it is necessary to know exactly the location of the water supply, rain-water pipes, and gullies or drains required to take away the waste. If the room is in a basement, a waste-water gully must be available; if it is on the ground floor, then it is necessary to ascertain the difference in level between the floor of proposed bathroom and the level of the ground outside, and of the gully to be used for the bath waste. The waste pipe must have a continuous fall from the bath outlet to the gully, and this must not be less than 3 in. in 10 ft., and preferably more.

On upper floors it is customary to pass the waste into a rain-water head, or to fit a separate down pipe of cast-iron of at least 2 in. diameter, and having a head on the top and a shoe or bent nozzle at the bottom, in both cases delivering the waste water into an open-trapped gully. The local building by-laws may require certain arrangements of the pipes, particulars of which can be obtained from the district surveyor, but generally all require the overflow and waste pipes to discharge through the heads and into gullies in the open air and be easily visible.

In the great majority of houses the bath is made of cast-iron; the best kinds are covered with a vitreous enamel, giving the porcelain appearance so much liked, and a surface which will resist acids, enabling it to be easily cleaned and kept in sound condition. The bath should be fixed in such a way that every part, underneath, at the sides or ends, can be easily got at and cleaned.

Practically only two shapes of bath need be considered; these are known as the taper bath and the parallel, according to whether they narrow towards one end or not. Where sufficient room and adequate hot-water supply allows of the parallel bath, it is of great advantage, giving the highest comfort in use and a decidedly better appearance. The best size for a bath is 5 ft. 6 in. long, and the roll edge should be not less than 3 in.

The position of a bath in a room is of great importance. It should be quite clear of the walls at the sides and ends, so that there is no difficulty in being able to clean and dust all round it. It should also be raised from the floor with wooden supports, if the legs are not long enough, to permit of sweeping under it.

If a geyser is fitted a good ventilation pipe must be attached to carry the products of combustion to the outer air. A baffle should be fitted into the ventilation pipe to prevent a back draught into the room. All vent pipes, elbows, and the baffle must socket inwards, that is, towards the geyser.

*All geysers, of whatever type and however heated, are unsafe unless provided with a ventilation pipe.*

As to hot-water supply, baths hold from 30 to 60

gallons of water, and from 8 to 10 gallons of very hot water are needed for a hot bath. If an efficient system is already installed, this can be tapped to supply the bath, otherwise a geyser is the easiest and probably most efficient to instal, requiring only the one cold-water supply pipe, with a branch to the bath. *See Hot-Water Supply.*

The bath must be placed so that its foot is as near as possible to the wall through which the waste-pipe will be carried. Incidentally, this will facilitate the fitting of a geyser, if required, for it is essential that a ventilation pipe should be attached to a geyser (q.v.).

Careful consideration should be given to the run of the pipes. In the absence of a thoughtfully prepared plan there is likely to be unsightly confusion of them which will seriously militate against the tidiness of the bathroom's appearance and impede cleaning operations. The general aims should be to have them coming up from the floorboards closely under their points of termination, to keep them short and straight and neatly paralleled and right-angled wherever possible.

Since wiped lead joints are beyond the skill of the handyman it is suggested that light-gauge copper tubing with simple compression joints be employed.

The positioning of the junctions between the hand-basin and bath pipes is a point of obvious importance so far as the appearance of the lay-out is concerned. Further, unless the junction between the waste-pipes is well below the bottom of the bath, as shown in Fig. 1, the waste from the hand-basin may flow into the bath.

*Bath. Fig. 1. Positioning of junctions between basin and bath pipes. The main waste-pipe junction must be well below level of bath.*

The essential connexions for the waste and overflow pipes are shown in Fig. 2. As will be seen, the final outlet section is of lead and should be of not less than 1¼ in. inside diameter. To take this through the wall chip out the brickwork with a cold chisel (q.v.); it is

preferable to remove a brick that goes right through the wall from inside to outside. Pieces of brick and some strong cement should be employed to fill the gap.

If it is permissible to use a rainwater head, as shown in Fig. 2 (the L.C.C. and certain other authorities do not permit them to be used for waste discharge), fix the head to a two-inch cast-iron pipe, and run the pipe straight down to a gully-trap. Should there be a suitable rainwater head in a down pipe from the gutter close at hand, the lead pipe from the bath and basin can be taken direct to it.

*Bath. Fig. 2. Essential connexions for waste and overflow pipes, using outside rainwater head*

Most of the jointing can be carried out very easily by means of compression joints. When the pipes are cut to the required lengths with a hacksaw only a spanner of the required size is needed to fit these unions. However, it should be noted that special extension types of these simple devices are required when making connexions between the copper pipes and those of lead or iron.

When the bath is finally in position a test with a small quantity of water is advisable in order to determine that its natural flow is to the waste and that no residue is left. The bath itself will provide an incline, but in rare cases it may be found that there is an unevenness in the floor which offsets it. A correction can be made by inserting wedge-shaped pieces of wood under the supports at the head end.

It will be appreciated that these directions apply only to the installation of a single bath and hand-basin in a building. If added to an existing system special provision must be made for ventilating the trap and

waste-pipe.

**BATH BUN.** Take 1 lb. flour, 2 oz. margarine or butter,  $\frac{1}{4}$  oz. compressed yeast,  $\frac{1}{2}$  pint milk and water, 1 oz. sugar, 1 egg, pinch mixed spice, 1 oz. currants, 1 oz. sultanas and a little candied peel. Mix the yeast and sugar in a warm basin until it liquefies, then add the tepid milk and water and the egg well beaten up.

Put the flour into a warm basin and, making a hollow in the centre, pour in the yeast mixture and mix in well. Cover with a cloth and set to rise in a warm place for one hour. Melt the fat and beat this and the fruit in well, again setting the mixture in a warm place for an hour before shaping into buns and placing on a greased baking-sheet. Leave them for 20 minutes, then bake in a hot oven for 10 to 15 minutes. Just before taking the buns out brush them over with a glaze made of sugar and water, and garnish with candied sugar.

**BATH CHAIR.** Unless the working parts of a bath chair, particularly the wheels, tires and axles, are kept in good order, a great deal of effort will be wasted in overcoming unnecessary friction. The wheel hub, axle, and spring are the points that need attention in most bath chairs. Supposing the chair to have been out of use for some time, the following points should be specially noted:

*Bath Chair. Diagram illustrating correct method of making a joint in a wired-on solid tire.*

The chair or body if of wicker work should be well brushed and cleaned. The cushions or squabs must be cleaned, and re-covered if need be, or loose covers of chintz or other material can be made without much trouble. A coach-built body, upholstered in leather or leather-cloth, can be cleaned up with a mixture of beeswax, turpentine and paraffin, or prepared wax can be used for the purpose. The coach body should be properly washed, allowed to dry thoroughly, and polished.

The chair should now be supported on boxes or otherwise and the wheels removed. With the back wheels this is done by unscrewing the dust-cap, removing the split-pin, nut, and washer and withdrawing the wheel. On some machines a ball-bearing hub is used similar to that on a bicycle, and can be treated as such. Most bath chair wheels are fitted

with solid wired-on tires generally circular in cross section. If those on the wheels are badly worn they may be replaced by new tires. *See* diagram; also the article on Perambulator.

Clean the bearings and hubs with paraffin, and thoroughly lubricate with cycle lubricating oil. Replace the wheels. The front wheel generally rides on a spindle between the jaws of the front fork; it is removed by unscrewing the nuts and springing the forks open to allow the wheel to drop out. The steering head and arm should be looked to, cleaned and lubricated. The springs must now be cleaned and lubricated. If only one leaf is used for the springs it will only necessitate cleaning and oiling the supports, but if two or more leaves are used the best thing to do is to lift up the body; this will separate the spring leaves, when oil can be squirted between them with the aid of a small oilcan with long spout, all surplus oil being wiped off. *See* Tire.

**BATH CHAP.** When bought uncooked a cured or pickled pig's cheek requires soaking for several hours before putting into a saucepan with warm water to cover, and brought to the boil, afterwards being allowed to simmer slowly until tender. To dish, remove the skin and cover the meat with browned breadcrumbs. *See* Bacon.

**BATHING.** Open-air bathing combines the tonic effect of immersion of the body in cold water with vigorous exercise of many muscles. In those who are unaccustomed to it over-fatigue and excessive chilling of the body may easily be induced, perhaps to be followed by fainting, which is the most serious danger in this sport. When a person is seized with a cramp it is possible to turn on the back and float, but the swimmer who faints will sink.

It is not advisable to bathe after a full meal nor when one is fasting. The best time is about an hour after breakfast, and if bathing is indulged in before breakfast a little food should be taken first.

The first swim of the season should be a short one. On coming out of the water there should be no dawdling in dressing, and a sheltered spot should be chosen for the purpose. A short run will help to remove the stiffness, and if necessary produce a glow. Those who remain chilled and blue in spite of this should discontinue bathing.

**BATHING DRESS.** The regulation bathing dress or swimming suit is worn by both men and women. Other styles, governed by fashion for women only, can be made from paper patterns to be obtained through any fashion journal, while regulation swimming suits can be purchased cheaply.

**BATHING SHOES.** Shoes in which to walk over the shingle to the water's edge can be made at home. Buy a pair of thin cork soles of the same size as the shoes generally worn and also a pair of straw soles one

size larger. Cut two pieces of canvas or proofed material for the top of the shoe and two pieces of jap silk in the shape of a flat iron, and measuring  $4\frac{1}{2}$  in. across and  $5\frac{1}{2}$  in. long. Place the right sides of one piece of material and one piece of jap silk together, and sew along the straight edges. Turn the right side out, place over the toe-part of the smaller sole, turn the edges over to the under side, and sew firmly, forming the toe of the shoe. Now place this sole on one of the straw soles, and with crochet cotton sew the two firmly together, using a buttonhole stitch. Ribbon sandal straps of required length can be sewn on.

*Bathing Tent. How to make a tent consisting of a wooden framework to be covered with canvas.*

**BATHING TENT.** The framing shown above for a bathing tent is designed to stand considerable wear

and yet be quite portable. Front and side elevations and plan are given in the diagrams. The main uprights are  $1\frac{1}{2}$  in. square. The bottom framework is composed of two 4 ft. 3 in. lengths of 2-in. by  $1\frac{1}{2}$ -in. material, into which two 3 ft. 9 in. lengths of  $1\frac{1}{2}$ -in. material are tenoned.

The uprights are halved into the 2-in. pieces, and the floor boards are nailed or screwed on to fillets nailed on the inside as shown at A. The top frame is screwed to the uprights, as at B, projecting pieces of iron wire or stout wire nails being driven in to provide a means of fixing the top. The struts are all of  $1\frac{1}{4}$  in. by  $1\frac{1}{8}$  in. wood, to which lengths of thin iron bar are attached with screws, the tops being shown at C and the bottoms at D.

Ordinary bolts and nuts should be used to attach the struts to the uprights and the bottom frame. The seat is placed on a bracket, halved at the corners and attached to the uprights, and the top is composed of two lengths of iron bar riveted together in the centre, and fitting on the top of the uprights through holes in the ends.

One length of canvas is attached to the sides and a separate piece cut out and shaped to go over the top. Tapes are the best means of securing the canvas to the framing, and also to close the opening. Give the whole of the woodwork and iron several coats of oil paint.

## THE BATHROOM AND ITS FITTINGS

### Hints and Suggestions for the Modern Home

The Technical Aspects of the Subject are dealt with under Bath; Boiler; Geyser, etc.; the Health Aspects in the article immediately following. See also Plate, page 128.

Colour is attractive in bathrooms. Even if white baths and fittings are retained, though these are to be had in almost every shade bright colour is chosen for decorative schemes. Floorings in mosaic, marbled rubber, cork-tiling and linoleums; curtain materials of oiled or rubberised silk, terry towelling and American cloths, tilings for dado and wall, panels of vitrolite, slate, or nicolite for sides of bath, etc., and of glass for ceiling, bath mats and towels—all can be carried out in harmonious colours. When it is a case of doing up a bathroom in a rented dwelling, brightly painted woodwork and steam-resisting enamel will remove a dingy appearance, and with simple accessories not involving much expense.

*Bathroom made entirely of glass. The use of black and one colour gives a beautiful effect. (Photo from Jas. Clark & Son, Ltd.)*

A bathroom entirely of glass, as illustrated, is highly decorative in black and a colour. Another scheme can be carried out in polished and enamelled slate for walls, and for the sides of a built-in bath, with capping and skirting in a contrasting colour.

Slate can also be obtained in panels with a marbled effect and used for dado and bath, with a rubber flooring to tone. To modernise a bathroom in an old house much can be done with attention to details such as electric fitting, new curtains and colour. A simple scheme, with white porcelain bath, white tiled dado, a colour-contrast in painted walls and ceiling and red cork-tiling for floor, is shown in the bottom photograph below.

*Modern design bathroom with marble bath, paper imitating green marble and sycamore table with glass top.*

Besides the bath, an important requisite is a pedestal lavatory basin of glazed porcelain, with hot and cold water taps. The one illustrated has an easy-to-clean mirror above, without frame but with bevelled edges. The curtains are of rubberised silk. Taps, like other fittings, should be nickel-plated. They require no polishing, only wiping with a clean cloth. If there is no hot-water supply laid on to the basin, it is possible to obtain a bath geyser which has taps on either side, and if the lavatory basin is placed beyond the head of the bath the same geyser may serve both.

*Bathroom. Scheme with white porcelain bath, white tiled dado and coloured walls and floor. (Courtesy of Country Life)*

Above the lavatory basin may be one or two glass shelves, resting on nickel-plated fittings to hold various requisites. Towel-rails should be nickel-plated for choice. It is necessary to provide pegs on the door to hang dressing-gowns, etc

The bath itself should be provided either with hanging baskets, or a rack, nickel-plated, for holding sponge and soap. A crossway seat is useful for persons who are old or weak.

Bathrooms are difficult to keep neat unless every member of the household using the room puts his or her belongings away tidily. As the basin or the bath must be flushed out after each use, it is well to provide, hanging in a convenient place, a suitable swab. Where the bathroom fittings are as described, the daily cleaning is reduced to a minimum, as nothing but a swab for the bath and another for the floor, and a dry cloth and a soft cloth for wiping the nickel fittings, is required. Where there are wooden fittings and an enamelled bath the process is more tiresome, as scrubbing and a weekly cleaning with some dry soap are necessary, and the wood must be kept polished. If unsuitable to be left constantly open, the bathroom window should be fitted with a ventilating pane.

**BATHS: Hygienic and Medical.** For a warm bath the temperature of the water should be between 98° F. (about body temperature) and about 103° F. A hot bath should be two or three degrees higher. Such a bath induces increased perspiration and opens the pores of the skin. It is, therefore, usually best taken at night to avoid exposure, but if this is unavoidable it should be followed immediately by a cold sponge and then a brisk rub down with a rough towel. If a hot bath is prolonged beyond ten minutes it is apt to be depressing.

A warm bath at about 100° F. is very useful in the case of shock following large burns about the body, and especially in children it is a form of first-aid which can be quickly employed. This should be done also in the case of convulsions of children, and in the collapse following infantile cholera or any severe diarrhoea.

The temperature of the tepid bath is about 90° F. The cold bath varies from anything just above freezing point to ordinary tap temperature. A cold bath should never be taken when the body is chilled. People with vigorous circulations find that a cold bath taken immediately after jumping out of bed in the morning gives a feeling of exhilaration and health. After a momentary chilling a feeling of warmth comes over the body.

#### When Cold Baths are Inadvisable

Some people do not have this reaction, but remain blue and cold after their dip, and should discontinue it. They may find that they are able to stand a cold sponging, especially if they stand in warm water, or they may have to content themselves with cold sponging of the neck and shoulders. The benefit of the cold bath is due to the shock of the cold water on the skin, and if the water is cold enough to produce this,

## BATHROOM: TASTEFUL SIMPLICITY IN MODERN DESIGNS FOR HOUSES OF ALL TYPES

Above. Porcelain, glass, mirrors, rubber flooring; workmanlike lines, restful, cleanly shades of green or pale colour—these are the features of up-to-date bathrooms. Left, design for a house of superior class; notice the plate-glass shower-screen. In this and the neatly-arranged centre model the walls are lined with "Vitrolite" panels. In the simple arrangement, right, blue-green marbled and black glass is used. (Architects: Stanley Hall, Easton & Robertson, F.F.R.I.B.A., and Alan B. Stamford, A.R.I.B.A.)

Left, the glass lining is black with silvered roughcast on the left, and primrose on the right. The difficulty of an "acute" corner is

corner is overcome with surprising effect. Above right, a fairly conventional bathroom and separate lavatory.

Left, specially shaped bath and three-fold mirror over basin. (Ideal Boilers and Radiators Ltd.)

say 40° below body temperature, there is no necessity to overdo it in the winter time.

Spartan temerity may be another name for foolhardiness. The cold bath should never last longer than two minutes, and as it is not sufficient to keep the body healthily clean, a warm bath with plenty of soaping should be taken in addition at least once a week.

Mustard baths, made by adding a tablespoonful of mustard to a footbath of very hot water, are sometimes used to check oncoming colds. The patient soaks the feet in the water for five minutes, while the rest of the body is enveloped in blankets.

As a rule, infants should have a bath night and morning, and older children a thorough bath once a day.

*A thermometer should always be used in preparing an infant's bath, to avoid the risk of the infant being scalded by someone forgetting to add cold water.*

The bath water should be brought to the required temperature, about 100°, by pouring cold water into the bath and then adding boiling water until the thermometer shows that figure.

**BATTEN.** In the timber yard batten is the term used for unplanned wood of the following scantlings: 1 in. by  $\frac{3}{4}$  in., 2 in. by  $\frac{3}{4}$  in., 3 in. by  $\frac{3}{4}$  in. The 1 in. by  $\frac{3}{4}$  in. batten is chiefly used for tiling, but the 2 in. by  $\frac{3}{4}$  in. has a multitude of uses. It is employed for tiling, joist plates, partition bases, framing for attachment of patent wall linings, for shelf supports, light cupboard framework, for making mouldings, architraves, and picture rails, and for brackets. *See also* Amateur Theatricals.

**BATTER.** There are various recipes for making batter. It can be made as follows: Take 4 oz. flour,  $\frac{1}{2}$  pint milk, 1 egg and a saltspoonful of salt. If the flour is at all lumpy, pass through a wire sieve, or let it fall through the fingers into a good-sized basin. Having mixed in the salt, make a hole in the centre of the flour, beat the egg till frothy and add to it half the milk. Pour in about four tablespoonfuls of this mixture, and with a wooden spoon stir in a little of the flour, drawing it into the centre pool from the sides. When this centre pool is about as thick as rich cream, add more milk and egg, and work in more flour, always keeping a pool of smoothly mixed batter in the centre. Go on adding the mixed egg and milk until all is used, by which time all the flour should have been drawn in.

Next beat the batter well with a spoon, until the top of the mixture is well bubbled. Stir in the remaining milk, and put the batter aside to stand, thus softening the starch grains in the flour by soaking. No more beating must be done after the last half of the milk has been stirred in. Stand the batter for half an hour, after which it is ready for use. *See* Apple Fritters; Pancake; Toad-in-the-Hole; Yorkshire Pudding.

*Battery. Diagrams showing the arrangement of three dry cells in one case, as used in a pocket flash-lamp battery.*

## BATTERY.

Electric primary batteries are pieces of apparatus for transforming chemical energy into electric energy. The forms most usually found in the home are dry batteries, such as are used in pocket flash-lamps, and Leclanché batteries for bell work. A battery consists of two or more primary cells connected according to the voltage or pressure required.

A primary cell consists of a liquid known as the electrolyte and two metals called elements or electrodes. The action depends on the decomposition of the electrolyte and the effect of the liquid on the electrodes. When a cell is at work the electrolyte attacks one of the electrodes very vigorously. This is termed the positive element or anode, the other element being known as the negative or cathode.

The flow of current in the connecting wires outside the cell will be from the negative element to the positive, hence the negative element becomes the starting point of the current to the circuit. This is called the positive pole or terminal and is painted red or distinguished by the + sign. The other element becomes the negative pole, is painted black, and distinguished

by the — sign. It is these poles that are referred to in all wiring diagrams, and not the elements of the battery.

A dry cell consists of a zinc pot, open at the top, which constitutes one element, and a carbon rod or plate surrounded by the electrolyte in paste containing sal-ammoniac, peroxide of manganese, powdered carbon, chloride of zinc, glycerine, and water.

The ordinary dry cell has a voltage of about  $1\frac{1}{2}$  volts. By connecting several cells in series, i.e. the carbon of one to the zinc of the next, the voltage of each is added together, hence three cells in series yield  $4\frac{1}{2}$  volts. The quantity of electric current available depends on the size of the cell, and is called the amperage. The quantity cannot be increased by series connexions, but only by parallel connexions, that is, by joining zinc to zinc, and carbon to carbon. It is imperative to remember this basic principle when dealing with any form of primary battery.

Of wet batteries the Leclanché is the most extensively used for electric bell work. It consists of a glass jar, usually square. The positive element is a round zinc rod, the negative element a plate of carbon.

The latter is contained in an inner pot made of porous earthenware, the carbon plate being packed in tightly with black oxide of manganese and powdered carbon. The electrolyte is a solution of sal-ammoniac in water, about 2 oz. of the former to 1 pint of water. The solution should about two-thirds fill the jar when the porous pot and zinc rod are in place.

*Battery. Three Leclanché porous pot cells connected together in series to form a battery for an electric bell circuit.*

It is of importance to clean the zinc rods occasionally by washing them in strong soda water, also to renew the electrolyte if the battery becomes feeble. See that the electrolyte does not creep over the outer edge of the glass jar. If it does, wipe the jar clean and give it a coat of grease around the rim, where it is painted black. See also that the terminal nuts are clean and free from deposit. *See Accumulator; Bells, Electric; etc.*

**BAY.** The bay or sweet bay (*Laurus nobilis*) is an evergreen tree with aromatic leaves. It is frequently known as Poet's Laurel. It is not perfectly hardy, and ought to have a sheltered place. Sandy loam, well drained, suits it.

A bouquet garni for flavouring soup is generally composed of parsley, bay leaf and thyme.

**BAY RUM.** Originally imported from the West Indies, bay rum owes its distinctive odour to oil of bay, obtained from the leaves of *Myrcia acris*, the leaves of which are distilled with white rum. It is made as follows: Jamaica rum 8 oz., spirit of wine 32 oz., distilled water 24 oz., oil of bay  $\frac{1}{2}$  oz. Shake together and after seven days filter through blotting paper. This toilet water is a fragrant hair tonic and is also used to relieve headaches.

**BAY WINDOW: Its Fittings.** The decorative possibilities of a room are often improved by this form of recessed window. The bay space may be used for a writing-table or dressing-chest and furnished with a window seat.

The window requires a cornice to hide the rod on which the curtains are hung. The rod itself should be curved so as to allow of the curtains being completely drawn. If the curtains are of silk or any thin material a second rod with a frilled valance may replace the cornice. If the curtains are of velvet or any heavy material the cornice should be fitted with a flat shaped pelmet. This may be cut in curves or in angular design and may be embroidered or edged with trimming to make a good upper part to the window scheme. Still another method is to provide the windows with casement curtains and to put the rod for the heavier full-length curtains straight across the inside line of the recess formed by the window, so that when they are drawn the recess is shut off.

*Bay window fitted with a wooden seat having a locker in the centre. Working diagrams are given below and explained in the text.*

**Window Seat with Locker.** We give here a suggestion for fitting up the interior of a bay window about 4 ft. in width. The details shown will apply equally to any

recess up to 6 ft. wide. A seat with return ends is shown, together with a locker in centre, the front of which is made to fall. American whitewood or pine, if available, will answer all requirements. A part plan of the seat is given, showing the intersection of the return end, and also part plan of under-framing.

*Bay Window. Interesting treatment involving the use of casement curtains and the same material for pelmet, outer curtains and the seat cushion.*

A start may be made by cutting the battens or rails A which will fix the height of the seat. It must be decided at this point whether the seat will be cushioned or not, making allowance for the thickness of cushion (if any). Roughly speaking (within limits), the shallower the seat the higher it may be. In the present instance the seat is 12 in. deep only, and may, therefore, be made 1 ft. 6 in. high and even 1 ft. 8 in. without discomfort. The rail A might be of 3 in. by 1 in. material to be nailed to the uprights of the bay. In positions where these uprights do not show, the rails may be screwed to an existing wainscot, or suitable lengths of 2 in. by 2 in. material may be erected to afford a bearing at the limits of the seat. An additional bearing is obtained upon the locker sides B, which can be 1 in. less than the finished depth of seat.

In erecting these sides, lengths of 2 in. by 2 in. wood are first nailed to the floor at C, and the sides nailed to these. At the top, two lengths of 2 in. by 1 in. are shown, cut in flush to the top edges of both sides B and rails A and nailed, which should afford a firm structure for further procedure. The pieces C are cut back sufficiently to take the piece E, which butts between the locker sides, to which it is nailed, in addition to being

fixed to blocks behind, which are nailed to the floor. When this piece is in position it will form a rail for hanging the locker fall to, both being 1 in. thick. The fall should thus close easily flush between the locker sides and bed on to the rail D, which serves as a stop to prevent it pushing in. This fall is made of boards tongued together and glued up, the panel effect being formed by lengths of mould or  $\frac{1}{4}$  in. bead, glued and panel-pinned on.

For the sake of finish, a length of thin material ( $\frac{1}{4}$  in. or  $\frac{3}{8}$  in.) is nailed in front of E, to finish  $\frac{1}{8}$  in. from outer edge of each end, and have its edges rounded off at top and ends. The front supports or cheeks, F, can also be fixed by blocks to the floor, as indicated by dotted line, cut to set back so as to be practically out of sight, and the further fixing can be by means of dowelling, or slot-screwing to uprights. Width can be 1 in. less than seat, and if the front edge is shaped back to not less than 9 in. the effect will be improved. In dealing with the seat the returns can be put together as shown, and tongued. The front edges and outer corners will be best rounded off, and in fitting it should be notched to intersect with posts and any other projections, so that it fits close up to the recess walls when being nailed down. Where there is available space, a sloping back about 1 ft. 6 in. high or so is comfortable and also looks well. *See Curtain; Pelmet.*

**BAZAAR.** Summer is the best time for the home bazaar or sale of work if refreshments and the actual sale can be arranged in the garden, keeping the side shows indoors.

The goods offered for sale should depend somewhat on the people likely to attend. Home-made confectionery will probably be greatly in demand for the sweet stall, and some of the chocolate firms supply goods at reduced terms for charitable enterprises. Home-made jams, pickles, cakes and bottled fruits will always sell at a reasonable price.

Needlework is a less certain quantity. It should take the form of either beautiful household linen and decorative articles set out in attractive colour schemes, or of novelties likely to be in demand for gifts.

The arrangements for tea should be put in the hands of an experienced person under the organizer. The supplies must be ample, and appetisingly set out. Tea can be one of the most profitable branches of the bazaar, if most of the cakes are given by friends.

The side show is an unfailing source of profit. If possible a series of short concerts, dialogues and entertainments should be arranged at intervals throughout the afternoon and evening. It is better to keep the price of the tickets low, say sixpence and threepence. In these concerts a judicious mixture of local and imported talent is good. A palmist or clairvoyante always helps to bring in money. Other attractions are fish ponds, miniature golf, and competitions such as weight-guessing.

**BEACH WRAP.** Useful wraps to wear over a bathing suit are easily made at home from gaily

coloured and patterned terry towelling. Fashions vary, yearly, and designs can be obtained from a good pattern service.

### BEADS AND THEIR DECORATIVE USES

#### How to Carry out Designs on Canvas, in Crochet and Knitting, and on the Loom

Other suggestions for the use of Beads are given under Embroidery; Lampshade; Tassel, etc.

Bead work may be divided into five classes: needle and thread bead work (on canvas or on the thread only); crochet bead work; knitted bead work; loom bead work, and novelty bead work. The fashions come and go, but by one of these methods bead-bags, bead-embroideries, necklets, bracelets, flowers, etc., can be made.

A special loom bead can be bought for the finest work in this class. There are wooden millinery beads, Venetian necklet and flower beads, rondles, a flat glass disc for threading between beads to lengthen a necklet, appliqués, tubes for dress-trimming, large glass beads and long bugles, diamanté, imitation cord, jade, etc.; beads of papier mâché, of cork, of leather and of metal. Most of the small glass or crystal beads, and also tiny metal beads are sold in hanks.

Most of the metal beads have fairly large holes and can easily be threaded with a No. 9 or 10 bead needle. These needles run in sizes from 8 to 16, and have elongated eyes which allow the passing of a thicker thread, although the actual needle is finer than the finest darning needle. For necklet threading, special cards of silk in white and colours are sold with a threading wire attaching to one end. The sizes range from 4 to 8, the lower number being the finest.

Little cards of necklet wire in gold and silver colours, medium size only, are sold for threading heavy beads.

*Bead. Fig. 1. Design for a bag on canvas worked in beads.*

In Fig. 1 a design for working on canvas is shown. Designs can be bought ready stamped on canvas, but an ordinary transfer can be used, with two-thread canvas, that is, two threads going both ways of the canvas and producing a square mesh. When buying the beads, get a size that will just cover the mesh, so that the canvas will not show afterwards. The beads should not be too large

or the work will not set flat.

*Fig.2 Portion of canvas enlarged in order to show how the pattern is followed. The work is done in rows from left to right.*

This work is done in rows from left to right. Join the thread on the wrongs side, then bring up the needle at the left-hand lower corner of the mesh. Thread a bead and pass the needle down through the upper right-hand corner and up again through the mesh right underneath, making a stitch like the first half of a cross stitch with a bead resting on it. The work can be done in coloured sections, if desired. (See Fig. 2, with the needle in position.) When the end of the row is reached, pass the needle and thread through the meshes just under the beads to get back to the left-hand side. The alternative is to fasten off at the end of each row, as you must begin the following one at the left-hand side. The pattern must be followed in each row. Follow the colours and the outline for the shape of the bag, as marked on the canvas.

Bags and purses can be made by this method of bead-work. For square or oblong bags work in rounds like a stocking, beginning on a ring of chain, the size according to the width of bag required, and working on the inside with beads on the side away from the worker. Another method is to work the two sides of a bag in circles and afterwards work a straight strip, which will act as a gusset, and give more holding capacity to the bag.

#### Crochet Bead-Work for Bags

Before beginning the bead-work, procure the metal top and carry out the bead-work to fit. First unwind the thread to be used, passing it on an empty reel, and during this process slip the thumb and forefinger of the right hand along the thread to feel for knots. This is important, as a knot too big to pass through the beads means entirely re-threading, as they must be pushed down as the work proceeds. Sylko No. 8 may be used with a No. 10 bead needle and a No. 3 steel crochet hook. When all the beads on the thread have been used, cut the thread and pass the necessary beads on the new thread, then tie the latter very securely against the last bead, leaving a piece long enough to secure at the back afterwards.

*Bead. Fig. 3. How to crochet beads in circles.*

The method for the circular bag is as follows: Make 4 chain stitches and join into a ring with a slip-stitch to the first stitch.

**1ST ROUND:** \* Work 1 double-crochet into the ring, but after inserting the hook into the stitch push a bead close up to the hook, so that when finishing the double crochet the bead is encircled and secured in position; repeat from \* 5 times more.

**2ND ROUND:** 2 double-crochet into each stitch all round, always working in a bead as before, and taking up the back loop of the stitch below, throughout the work.

*Fig. 4. A fine early example of beadwork. A small knitted bag of coloured glass beads.*

*Fig. 5. Example of 18th century English beadwork. A watch pocket, one of a pair, embroidered on a net ground.*

Now work alternate rounds, on the first one putting 2 double-crochet into 1 every alternate stitch, and 1 double-crochet into the intervening stitch, to make an increase round, and on the second round work one double-crochet into each stitch. Mark the first stitch with coloured cotton to facilitate counting stitches. By repeating these two rounds a circle of any size can be made, but do not allow it to flute; this is remedied by working fewer increase stitches on a round. Pressing with a hot iron and damp cloth will remedy curling. When the piece is big enough work two or three rows of double - crochet without beads, the size of the bag top, which fits the holes at the top for sewing.

*Fig. 6. A watch-guard of beads threaded together.*

*English, early 19th century.*

*(Photos Courtesy of Victoria & Albert Museum)*

Fig. 7 shows bead work on plain knitting. Thread the beads on the silk, then decide whether a plain bag or one that will be gathered on the mount is required, so that enough stitches are allowed when casting on.

*Fig. 7. Beadwork applied in stripes to plain knitting for a bag.*

For a striped bag, cast on any number of stitches divisible by 6 and 3 over for edge stitches, which are knitted plain. Knit two rows plain without beads. 3rd row: Slip 1, knit 1, \* put the needle in the next stitch in position for plain knitting, then push up a bead against the last stitch and finish knitting the next stitch; repeat from \* to the end, and knit plain the last stitch without a bead. Now knit the next row without beads. If threaded correctly, you should now have 3 beads of the same colour to begin each row, so keeping the stripes intact. If knitting a pattern the beads should be carefully threaded in the right order before beginning to work. Any cross-stitch pattern can be copied in crochet, knitting, or loom bead work.

**Loom Bead Work.** The loom is a simple wooden device made in three sizes. The medium loom, 11 ½ by 7 ½ in., is used chiefly for necklets, purses, and bags. On this size a bag 7 in. wide can be made (Fig. 6), but it is best to work wide designs in strips, taking 20 to 40 beads according to size and join the strips together afterwards by threading in and out of the bead on the edge of the strips. Get extra long bead needles for wide designs. Any cross-stitch or tapestry design can be followed and the beads, without previous threading, are taken up each row according to pattern.

Ordinary strong linen thread or silk twist can be used. First prepare the warp threads, allowing some inches over the length of the intended article. Cut the threads in separate lengths, allowing one more thread than there are beads for ordinary flat weaving, as with a bag. The loom is placed with the spool end farthest away from the worker, Fig. 6.

*Bead. Fig. 6. Bead loom in position for working, with necklet in progress.*

#### How to Set the Warp

To set the warp, tie all the threads together on one end, and secure on one of the nails on the spool at the top of the loom. Then place the threads in rotation on the notches of the first bridge, and carry this thread down to the corresponding notch on the lower bridge. When all the warp threads are set, draw them down firmly, pass the ends through one of the holes at end of loom and push in the little peg to keep these threads quite taut; then wind the remaining length of thread round the end of the loom and pegs.

Take the weaving thread, which can be the same kind as the warp thread, thread it into the needle, and tie at the top of the first left-hand warp thread. Thread the full number of beads for the first row, pass the needle from left to right under the warp threads, and push the beads up in position between each warp. Where there are too many beads to keep on the needle let them slip down the thread, push them in position and hold under the warp threads with the forefinger of the left hand, Fig. 7. The beads should be pushed well up between the threads so that the latter do not come up over the needle when passing back.

Take the needle in the right hand, and pass it back from right to left through all the beads, taking care that the needle keeps above the warp threads to the end of the row, Fig. 8. Draw the thread up firmly. The passing of the thread under and over the work makes a selvedge on both edges. When the loom is full wind the work round the spool away from you, but leave a little of the work to project over the top bridge, as the threads can now only be pressed down the notches of the lower bridge. If they were passed down the upper bridge a gap would result in the work. Secure the ends firmly round the pegs again before beginning to weave. At the left-hand side of the spool there are three holes,

into one of which a loose nail is passed to keep the spool in position when working, and so keep the warp threads taut; they must not be allowed to slacken in the working.

*Fig. 7. First position: beads pushed up at back and held with forefinger.*

*Fig. 8. Second position: needle passed back through beads above warp threads.*

Embroidery is often enriched by bead outlining, as also are tapestry and paisley designs. Novelty beadwork includes necklaces, flowers, and various methods of decoration in vogue utilising beads, such as fringes and tassels for fancy work and dress.

**BEADING.** This is used for making fancy seams to connect two edges of material, and is an imitation of hemstitching. Beading can be bought by the yard under the name of veining. *See Hemstitch.*

**BEADING.** Although often used to describe any kind of moulding, the bead is, strictly speaking, a half-round moulding. These can be seen in almost any house. Thus the staff bead which holds the bottom sash of the window in position is shaped as in Fig. 1, and the parting bead which divides the two sashes as in Fig. 2. Fig. 3 shows the section of a bead used to break up the

the surface of flat panels, etc., while the centre bead, Fig. 4, is a dado or chair rail bead. Fig. 5 is the common half-round beading. Beads are often used to break the joints between various parts of work, such as on the edge of matched boarding, the panels of some kinds of doors, around door frames, to fix the glass in bookcases, shop fittings etc.

*Beading. Principal patterns of beading used in house building.*

**BEAD PLANT.** This popular plant has graceful feather-shaped leaves, and the flowers of different varieties are blue, white, or pink in colour. Usual greenhouse soil suits them, and they require to be kept moist and warm. They are propagated by means of cuttings taken in spring.

**BEAKER.** These are either vessels used for measuring liquids or large drinking cups. The former, made of glass, are used by chemists and marked with the various quantities. The latter are of interest as antiques, and valued by collectors. *See Glass.*

**BEAM.** In any building a beam is a piece of timber fixed and supported at each end, and itself supporting more or less weight. It follows, therefore, that the beam as a rule is placed edgewise, or, in other words, the depth when in position is greater than the width. Beams are called by particular names, according to the purposes which they serve. That which supports the joists of a floor is a girder or binder, over a window opening it is a lintel, when supporting the middle parts of long rafters it is a purl.

**BEANS: How to Grow.** Bean plants may produce very poor crops in dry seasons unless measures are adopted for resisting drought, blight, and the attacks of birds and insects. Ground that lacks lime naturally must be improved by liming, and shallow soils require a generous quantity of decayed vegetable matter or farmyard manure, placed well below the surface.

It is not necessary to use much stable manure in a garden that has been well cultivated for many years, but in dry soils some wet decayed material should be put in a trench about the width of a spade blade and about 18 in. deep. Over the manure replace several inches of earth, which should be well broken up with the rake. Upon the surface spread wood ash liberally, or a lesser quantity of sulphate of potash, and place the beans upon the compost.

**Broad Beans.** These may be sown 4 in. deep and about 9 in. apart, the first sowing being made in November,

except in very cold districts and exposed positions. Seville longpods or the early mazagan may be sown in November.

The second sowing may be made in February, the third three weeks later, and the last in the fourth week of April. One pint of beans is sufficient to sow a row about 70 ft. long. As soon as the plants are 2 in. high powder the ground on both sides of the row with soot or wood ashes, hoe thoroughly, and draw a little soil up to the beans. Beans should be hoed once in ten days, and slightly earthed up after hoeing. If the weather is very dry, water heavily once, and mulch with any available litter, covering it well with dry earth. Before the blossom sets, nip out the top blooms to check the breeding of black aphides, and burn them at once.

*Beans: methods of sowing and staking. 1. Runner beans in drill. 2. Section of deep drill for runners. 3. Broad beans in shallow drill.*

*Beans. Fig. 4. Staking straight row.*

**Scarlet Runners.** These may be sown as directed for broad beans. They must not be sown in the south until late in April, and in the north in May. It is well to make a second sowing about the first week in June. In light soil, sow in a trench and leave the earth slightly banked up on both sides. Hoe frequently along the rows and among the plants, and dress occasionally with soot or wood ash.

In prolonged dry weather it will be necessary to drench the bean row with water once a week, and the leaves may be sprayed with a syringe two or three times a week. Growth should be checked when the runners are about 7 ft. high, by nipping off the top shoot. A mulch of manure or litter should be applied in a drought after a heavy soaking of water. When flowers appear weak, liquid manure may be given once in 10

days. Always stir the soil with the hoe after watering, unless the rows are mulched when the beans are young.

Dwarf or French beans should be sown late in April, and about once a fortnight till the end of June. Sow in trenches and treat as for runner beans.

Beans. Fig. 5. Fence of sticks and string.

Beans. Fig. 6. Strings stretched between horizontal wires.

**Beans as Food.** A combination of beans, potatoes and butter with a green vegetable will supply all the elements necessary for a complete meal containing everything which health demands.

Haricot and brown or dried beans make a nourishing soup. French beans, runner beans, and broad beans are excellent as vegetables and in salads, while all the varieties of dried bean make savoury supper dishes in combination with tomato sauce, onion, cheese and other flavourings. Beans tinned with pork and tomato sauce are useful for an emergency supper dish.

Dried beans, though not so palatable as fresh ones, make a nourishing dish when properly cooked. Soak the beans for 12 hours in cold water. After this rinse well in several waters and leave for two days in a basin set in a damp, cool place, where the air can circulate freely. Then put this basin in a larger one with a little water in it, and cover the whole with a damp cloth. Within 12 hours it will be noticed that the beans are beginning to sprout, and they are then ready for cooking. Usually dried beans require boiling for about 45 min., though young haricot beans will cook in less than 30. Beans, like all other pulse foods, have in them a valuable form of anti-scurvy vitamins, and these are apparently non-existent until the beans germinate.

**BEAN CAPER.** Bean capers are the flower-buds of a small tree of the genus *Zygophyllum*, sometimes used as substitutes for the true caper. Gather the buds on a dry day, lay them on a paper out in the sun for a few hours, and turn into wide-mouthed bottles or jars. Boil one pint good vinegar with  $\frac{1}{2}$  oz. salt and 6

peppercorns, for five minutes. When the liquid is cold, strain this vinegar on to the capers and cork down tightly. They can be used in about a week's time, but will be better if they are kept for three months or a little more. *See* Caper.

**BEAN CUTTER.** A handy machine which performs the cutting of French beans and scarlet runners with rapidity, thus saving time and labour. Most of these machines also slice other vegetables, oranges for marmalade, etc., a special grooved attachment being supplied for the cutting of beans. The machine should be kept clean and dry, and receive an occasional drop of lubricating oil.

**BEAN WEEVIL.** The name is applied to several species of small beetles which attack beans and peas, but it belongs properly to *Sitones lineatus*. The wing cases of this tiny grey-brown weevil are streaked with white lines and the head drawn out into a broad snout. The female deposits her eggs in the newly formed pod, and the young larvae feed in the seeds.

Similar destruction is wrought by two species of *Bruchus* (*B. rufimanus* and *B. pisi*), the first frequently found in the grub stage when green peas are being shelled. The young plants may be protected by sprinkling them with soot or fine road dust. Bean seeds should be examined before sowing, and any that have been attacked by the pest should be picked out and destroyed.

**BEAR BERRY.** This is the popular name applied to trailing heath-like plants belonging to the genus *Arctostaphylos*. They are useful for the moist side of the rock garden, and the best sort, *A. Uvaursi*, has pink flowers in early summer and red berries in the autumn. The bear berry needs only the culture given to ordinary rock plants. *See* Rock Garden.

**Beard Tongue.** *See* Pentstemon.

**BEARING.** A bearing is any support for a rotatable shaft or similar driving part of a machine. In its simplest form it is a plain hole in the part that forms the support for a cylindrical shaft. In the journal bearing the load acts at right angles to the axis of the shaft, and includes such examples as the bearings of a mangle and the axle of a railway carriage. In the thrust bearing the load or pressure acts parallel to the axis.

The two great enemies of a bearing are the ingress of grit and dirt and the absence of a suitable lubricant. Small or delicate instruments such as typewriters and sewing-machines should have their bearings cleaned with a small brush dipped in paraffin, and then be well oiled with light-grade oil. Heavier machines such as washing machines, mangles, chaff cutters, lathes and small machinery generally need a heavier-bodied oil, known as light machine oil.

The oil must be present between the two working surfaces, and any excess outside the bearing should be

wiped off, as an oily exterior only attracts and retains dust. Adjustments are made in many different ways; the point to bear in mind is that the bearing should allow of free and easy movement of the shaft, but should prevent any shake or slackness. *See* Ball Bearings; Big End; Front Axle; Live Axle, etc.

**BEATRICE STOVE.** The name is applied to a particular variety of oil-heating stove burning paraffin oil. The heating elements are the wick and the tall, oval-shaped chimney or body, the vessel to be heated being placed upon the platform at the top of the stove. The oil is contained in a cast-iron vessel forming the base of the stove. These stoves are made with one or more burners. Success with these stoves demands scrupulous cleanliness, attention to the wick and the use of a good oil. *See* Lamp.

**BEAUMONTAGE:** Hard Stopping. This is used in the home for filling small holes, repairing damaged veneer, and similar purposes on all kinds of furniture.

It is made by dissolving a lump of resin, about the size of a large walnut, in a gill of common orange shellac, and adding a piece of beeswax about half the size of a walnut. This must be melted in an iron pot or tin can, either in the oven or on the top of a stove; only gentle heat is needed, and the mixture must not be allowed to boil. Before heating, a suitable colouring pigment must be added (about a teaspoonful) in powder form. By suitable blending almost any colour can be made to match the work to be repaired. The mixture is made into sticks by pouring some of it on to a wooden board, laying it in a line, and rolling with another board. The boards should be warmed, as the stopping hardens rapidly.

To use the material, it is melted into the hole or over the damaged places by means of a rod of hot iron. Do not have the iron too hot, or the wood will be scorched and blistered. Press the mixture well down into the hole, and leave a little of it above and around the damaged part. When dry and hard the surplus is removed with a chisel, knife, and fine or old sandpaper.

**BEAUMONTIQUE.** In certain classes of cabinet and joinery work an adhesive known as beaumontique is employed. It is composed of equal parts of litharge, white lead and whiting, worked into a stiff paste with boiled oil.

## BEAUTY AND BEAUTY CULTURE

General Rules and Modern Methods for the Improvement of Personal Health and Appearance  
Information on Special Aspects will be found under  
Ankle; Complexion; Diet; Figure; Hand, etc.

Want of daylight, fresh air, and exercise, improper diet and laziness are beauty's enemies. Five minutes devoted daily to the following simple exercises will improve the circulation and the digestive organs and strengthen the body.

(1) Stand with feet slightly apart, head thrown back, and bring both hands so that the backs come under the chin, fingers pointing forward, elbows close to ribs. Send hands up and out in front, as in the breast-stroke in swimming, then separate them gradually, sweeping them back and down as far as they will go. Then draw elbows up to the sides again. With these arm movements goes a trunk and leg part. Crouch low and bring the hands under the chin as described. While rising to an upright position, finishing on the tips of the toes, send the hands out in front, as described. Then beginning to crouch again, send the hands back and down, bringing them once more under the chin when quite crouched. Repeat six times. This exercise keeps the body supple and expands the chest.

(2) For reducing the waist, lie on the floor, arms stretched straight above the head. Bend the knees up towards the chest and roll over to the left side so that they rest on the floor. Roll them over to the right side and repeat this movement from side to side, feeling the turn coming from the waist.

(3) For reducing the stomach, lie flat on the floor with the hands clasped behind the head and feet under some heavy obstacle. Then sit up without raising the feet.

(4) A good hip reducing exercise is to lie face down on the floor, elbows out and chin resting on back of hands. Raise the right leg upward as far as you can, knee straight and toe pointed. At the same time raise the head up and back from the floor. Work the two movements rhythmically, Up-down, Up-down, giving a thrust upward with your head and leg on every up beat. Repeat eight times with the right leg, and then with the left. Then do alternate right and left for sixteen counts. Be sure to keep elbows on the floor all the time.

(5) The following is a good exercise for reducing the buttocks, and should be done regularly: Sit on the floor with legs stretched out in front of you, palms of hands flat on the floor each side of you. Raise feet from the floor and propel yourself round the room with your hands, taking care to keep the feet from touching the floor. This produces a rolling effect which wears away the superfluous flesh.

(6) To combine stretching with strengthening the whole spine, lie on back, with arms at sides. Slowly raise arms, while inhaling deeply, and extend beyond head till fingers touch floor. Stretch the whole body and begin to exhale slowly as arms return to sides. Begin another inhalation as body rises to sitting posture, taking care to let head follow shoulders and not come up first with a jerk. Then in slow continuous movement touch the toes with both hands. Do not bend knees. Exhale while returning to first position, relax whole body and repeat exercise.

The benefit to be derived from outdoor sports besides muscular development is the natural promotion of perspiration, thus eliminating poison from the system. In order to obtain full advantage from such activity of the pores, on returning home rub the body

briskly with a flesh glove and take a tepid bath.

*Beauty Culture. Fig. 1. Correct position half-way through exercise 6 as described in the text.*

*Beauty. Fig. 2. Hair brushing is more effective in the morning than at night.*

*Beauty. Fig. 3. Brush mascara on the eyelashes with upward strokes.*

*Fig. 4. An excellent figure-reducing exercise described in the text (No. 3 page 137).*

Care of teeth cannot be too much insisted on. In themselves they are an important point of beauty or the reverse, and proper mastication is essential to good digestion. Regular visits to the dentist and brushing the teeth night and morning should not be neglected.

Diet is the next factor to be considered. Too great restriction in the case of normally healthy people is not to be encouraged. Plenty of green vegetables fresh salads and sound ripe fruit supply the important natural salts, which keep the blood healthy, and therefore help to secure a good complexion.

An excess of foods containing starch, sugar or fats should be avoided when there is a tendency to put on flesh. For older people the mistake of drastic measures for reduction is that after youth the skin loses elasticity and when the flesh under it is reduced the stretched skin bags and wrinkles. Scragginess, which comes from malnutrition caused by indigestion, together with the flaccid sagging of the muscles caused by lack of healthful exercise, is equally to be guarded against.

### **Injurious Effects of Stimulants**

Alcohol has a coarsening effect on the texture of the

skin. Also coffee, tea, or cocoa must not be indulged in to excess; the first two stimulants often causing indigestion, with flushing or sallowness as a result, and the latter overheating and liver clogging. Roughness, blotchiness and redness of the skin are usually caused by acidity. In addition to the elimination of poisonous acid by perspiration and avoiding sugary and starchy foods and acid fruits such as currants, strawberries, plums, etc., the habit of frequently sipping a glass of water before meals and at night should be cultivated—an internal bath, cleansing the system of many impurities. Constipation should never be allowed, but drugs should only be taken on a doctor's advice, as promiscuous dosing may be harmful.

Eating between meals is a mistake. The digestive organs require a rest. Constant chewing of sweets spoils the shape of the mouth, and over-smoking is detrimental to clear eyes. There are other bad habits to be avoided or corrected. In walking, too short or too long a stop is tiring and throws out the balance of the body. A stride should suit the length of leg; there should be a free swing from the hips without wobbling, and steadiness of the shoulders. When standing an incorrect attitude is to thrust one hip outwards and distribute the weight of the body unevenly. A bad habit in sitting is to flop down so that the end of the spine, instead of supporting the body correctly, is curved under. As this, if continued for any length of time at a sedentary occupation, causes a strain on the internal organs, backache, a stoop and restricted breathing, it is most important to practise sitting upright, the base of the spine touching the back of a chair and the head in line with the body. When resting it is better to lie down flat than to loll in an easy chair. Screwing up the eyes is sometimes imitative, and should be checked; where caused by eyestrain, glasses should be worn.

Hair should be combed out at night, but vigorous brushing has a more beneficial effect when the body is not tired (Fig. 2). If the hair begins to come out a good tonic should be used. Dandruff must be prevented; it is impossible to have beautiful hair without a clean scalp. Most hair, if properly brushed, has sufficient gloss without using brilliantine.

Cosmetics have a place in beauty culture, their use being to preserve, whiten, smooth and brace the skin. To keep the contour of the face and the elasticity of the skin a simple form of massage may be gone through daily, after the physical exercises in the morning, as the muscles relax during sleep and want keying up. Having spread a little skin food or cold cream over the face, place the fingers of both hands on the cheekbones, the thumbs meeting under the chin, and with firm pressure pass them upwards to the fingers on each side, repeating the movement for about two minutes. Next place the tips of the fingers on the points of the jaw and work them firmly upwards past the corners of the mouth to the base of the nose.

Repeat this movement for about a minute. Then tap in a small quantity of cream round the eyes, using the third finger of each hand very lightly and working

from the inner corner of the eye outwards for a minute, and for another minute, having closed the eyes, very gently pass a finger along each eyelid, continuing the movement outwards to the edge of the hair. The whole process takes five minutes. After the massage the face should be bathed with a good astringent lotion.

Allowing five minutes for the extra hair brushing, five minutes for the physical exercises, and five minutes for the facial massage, it will be seen that beauty culture demands only one quarter of an hour each morning. Soaking daily in a hot bath enervates instead of braces the muscles. A quick warm bath, using a long-handled bath brush and followed by a cold sponge, keeps the skin in good condition. On alternate nights cold cream and an astringent complexion milk, such as a cucumber and benzoin preparation, should be applied. The first should be lightly rubbed and tapped in with the third finger, thus avoiding the danger of stretching the skin, and any superfluous cream wiped off; the second should be dabbed on with cotton-wool and allowed to dry in, thus alternately feeding and toning up the skin. The neck should be treated with the same preparations. Before applying these at night, the skin should be cleansed with a pure soap and hot water.

Make-up is somewhat a question of fashion, but should also be one for the individual, emphasising good points and glossing over bad, not a meaningless routine of cosmetics. Artificial colour may be unnecessary, because by following hygienic rules, sallowness and the whiteness of anaemia will be corrected. The clear, healthy pallor that is natural to some complexions is a beauty and should not be rouged.

When colour is used the shade must be chosen to suit the skin, the smallest quantity being applied lightly to the upper cheek-bones with absorbent wool if a powder, or with the tip of the finger if cream or liquid, and the face powdered afterwards. With regard to the lips, lipstick should tone with rouge or harmonise with natural colour.

#### For Eyelashes and the Skin

Castor oil used every-night, applied by a camel-hair brush, has a darkening and strengthening effect on lashes and eyebrows.

Mascara should be brushed on lightly with an upward movement, and eyeshadow should tone with the colour of the eyes as nearly as possible. This should be applied to the edges of the lids nearest the lashes and smoothed upwards and outwards (Fig. 3).

Sensitive skins may develop a rash from washing in hard water, and then it is better to use a good cleansing cream or milk, with a mild astringent to remove the grease.

It is most important to select the right creams, soap and powder for the individual skin; once these have been discovered they should be adhered to. Cheap powders clog the pores and produce blackheads—a silk-sifted pure rice powder delicately tinted to tone with the natural skin is the safest and most becoming.

Sound sleep in a well-ventilated room is most important. It is one of the best beauty specialists in the

world. When late hours have to be kept at night, if possible make up arrears in the daytime.

**BEAVER.** A fine greyish-brown fur used for winter coats and expensive for trimmings. Though light in weight beaver has great durability and a beautiful quality which easily distinguishes it from its imitations.

A silk beaver for hats has been largely ousted by velour. *See Fur; Velour.*

**BEAVER BOARD.** A Canadian product named beaver board is used for the covering of internal partitions and similar purposes. It is composed of wood fibre worked by a patented process, and resulting in a five-ply board approximately  $\frac{1}{4}$  in. thick. It is clean and pleasant to handle, is made in a range of convenient sizes, and obtainable from any good builders' merchants. *See Partition.*

**Bed Bug.** This is a variety of the insect known as the bug (q.v.).

**BED CRADLE.** A cage made of metal hoops and long wooden or metal struts is used under the name of a bed cradle in cases of illness to raise the bedclothes off the patient. This is necessary in fractures of the lower limbs, as the weight of the bedclothes may displace the foot. The apparatus can be used to give a hot air or vapour bath or to suspend an icebag for the relief of pain in appendicitis. In case of an emergency, a three-legged stool, a strong cardboard box with ends cut arch-shaped, or a child's hoop cut in two pieces, crossed and screwed together, make excellent cradles.

**BEDDING.** Too much importance cannot be attached to proper bedding, when it is remembered how vital sound sleep is to health and the amount of time spent in bed. The best kind of foundation is a good spring mattress. This may be either of the box spring variety or the ordinary spring with a stuffed overlay, or the wire spring mattress.

When an overlay mattress is used on box or spring it should be sent to be cleaned and remade periodically. Unless this is done every few years it is impossible for a stuffed mattress to be hygienic or comfortable, as the stuffing becomes matted and consequently lumpy. A good mattress will last for many years with occasional re-covering if cleaned and restuffed.

The wire spring type of mattress consists of a series of springs sewn into pockets and placed inside a cover. Over the springs a padding of hair or felt is laid, obviating the necessity of an overlay and keeping the full resilience of the springs. The mattress is then upholstered. There is no expense of upkeep with such a mattress, as it is fitted with vents for airing; the bedding is automatically kept fresh and does not absorb or retain any perspiration from the body. Loose

washing covers for top mattresses and box springs are desirable and save the mattresses.

The pores of the skin are most active during sleep, and for this reason the thorough airing of bedding and bedclothes is essential, and the temptation to make the beds immediately their occupants rise in the morning should be resisted. The mattress itself should be turned every other day from end to end, and on alternate days from side to side, so that each part in turn bears the extra weight. It ought to be taken into the garden and exposed to sun and air at regular intervals. All blankets must be regularly shaken and, if possible, put out at intervals in the sun. *See* Bedstead; Blanket; Bolster; Box Mattress; Eiderdown; Mattress; Pillow.

**BEDDING: In the Garden.** The flower gardener always arranges for his principal floral features to be displayed in the position where he can best enjoy them. The suburban or villa amateur cannot generally have his best floral effects beside the approach to his front door or under his front windows, but the country gardener can make such a provision.

In laying out beds the curved plan is preferred by many, especially where there is a lawn with a curved line. Rectangular beds economise working, and are more easily kept trim. The size of the beds ought to bear some relation to the width of the walk and the area of the lawn, where there is one. Small beds are troublesome if there are many of them, but very large beds have practical drawbacks too. Extra care has to be taken in the planting, for every cultural process among the inner plants means getting on to the bed.

Neither bedding plants nor herbaceous perennials can give an unbroken display of bloom throughout the year, but it is possible to have colour by the utilisation of shrubs, especially those which are fairly small and compact, such as mezereon and other daphnes, azaleas, heaths, and kalmias.

Some evergreens are slow in growth and thrive in ordinary soil, notably some barberries, laurustinus, veronicas, box, selected cypresses and tree ivies. These would be long before they outgrew the accommodation of small beds. There are small, neat evergreens in abundance which keep the beds green till spring brings in the flowers. Some of the best spring subjects are primroses, polyanthus, auriculas, wallflowers, forget-me-nots, aubrietias, arabises, daisies, yellow perennial alyssum, and Brompton stocks.

Beautiful beds can be provided at no great cost. It is possible to buy most of the plants named in autumn, but it is far cheaper and more satisfactory to raise them at home. By purchasing seed quite early one may get the very finest strains for a small outlay. *See* Flower Garden; Primrose; Tulip; Wallflower, etc.

**Bedding Out.** While bedding simply means a rearrangement, bedding out implies the transference of plants of a half-hardy nature from the shelter of the greenhouse to the open bed in late spring or early summer.

**BEDFORD CORD.** The feature common to all fabrics known by this name is a raised tubular cord or rib running lengthwise. Woollen Bedford cords are one of the best materials for riding breeches. The material is intended for breeches, and made in trousering width (27 in.). It looks a little clumsy in coats, but officers' complete uniforms have been made from it. Cloths similar in weight and appearance are made also in cotton and are cheaper; they are not so warm, are more easily soiled, and less suitable for wet weather.

A lighter make of cotton Bedford is used for summer dresses and is sometimes called piqué, although in true piqués the tubular ribs run crosswise, not lengthwise of the pice. The better qualities make excellent coats and skirts, white or in light colours. They wash and wear well, and are especially suitable for sports wear. *See* Piqué.

**BEDLINGTON TERRIER.** An intelligent guardian of the house, entirely dependable with children, this dog stands in the front rank as a destroyer of rats and other vermin. But although affectionate where his owner's family is concerned, he is suspicious of strangers and jealous of his own kind. The Bedlington has a hard though rather woolly coat of dark blue, tan liver, or sandy. The head is narrow, with a long, tapering, sharp muzzle. The long, sharply pointed tail is only slightly curved. The back is very arched. The animal stands about 15 in. high, and weighs about 24 lb. *See* Dog.

*Bedlington Terrier. A good house dog and ratter.*

**BED-MAKING.** The bed should be stripped every morning, the mattress turned and the bedclothes left to air. The under-blanket is then laid smoothly on the mattress. The bottom sheet must be thoroughly tucked in all round, so that there is no possibility of rucking up. Top sheet and blankets are then put on one by one, and tucked in at the bottom. The top sheet is turned down over the blankets, the pillows put in place and the whole covered by the bedspread. The bedspread is removed at night and the down quilt put in place.

**Bed-Making for Invalids.** A feather bed should

never be used in cases of illness. A good hair mattress is best, but a straw one does very well, particularly in infectious cases, because the stuffing can be burned. Where the illness is likely to be prolonged it is bent to dispense with the under-blanket and to replace it by a mackintosh sheet. If the under-blanket is used it should be large enough to tuck well in all round so that it may be kept smooth and not cause bed sores. The lower sheet is then put on in the ordinary way, and on top of it a draw sheet may be placed. This is an old sheet, folded to a sufficient width to reach from the shoulder blades of the patient down to his knees, and laid across the bed. It is tucked in at each side beginning with the greater part on one side and only a small turning on the other. It is shifted along a little every day until the bulk of the tucking in is done on the opposite side from which it started. In cases where the under blanket is retained, a mackintosh sheet may be placed under the draw sheet.

*Bed-Making. Changing an invalid's sheet.  
Above, changing sheet from above downwards.  
Below, changing sheet from side to side.*

The upper clothes should be warm but light, and no heavy, airproof counterpane should be used. A ventilated down quilt is the best means of obtaining extra warmth, as its weight is insignificant. In some illnesses, e.g. acute rheumatism or nephritis, the patient is nursed between blankets, and no sheets are used.

When the bed has to be made it can be done quite simply without disturbing the patient. First loosen all the bedclothes. Then let two people stand one on each side of the bed and take hold of the under blanket or mackintosh sheet, pulling against each other until all wrinkles are smoothed out. The same is done with the under sheet. Raise the patient slightly under the shoulders and shake up the pillows. Then lay him down and make all tidy.

Sheets can be changed as follows: When a clean

top sheet is required, have it aired, warmed and ready. Remove the top blanket from the bed and lay it over the clean sheet. Then take sheet and blanket together and lay them on the bed, while a second person stands at the opposite side ready to assist. Loosen the soiled sheet and the remaining blankets on both sides. The second person then seizes these and draws them quickly away, while the first holds the clean sheet and blanket in position. The clean sheet is then tucked in.

### Methods of Changing the Under Sheet

There are two methods of changing the under sheet, according to the nature of the patient's illness. The more usual is to change it from side to side. Two people should assist, one on each side of the bed. First the bedclothes are loosened and the clean sheet, rolled lengthwise, is brought to the bedside. The soiled sheet is then rolled up until it reaches the patient, who should be lying on his right side, and the clean sheet is rolled along behind it. Thus the two sheets will be resting against the patient's back in two long rolls down the middle of the bed. The patient is then rolled gently back on to his other side, and the second person draws the soiled sheet from under him, following it by the clean sheet. Once it is clear of the patient it can be straightened out and tucked in. A draw sheet is changed in the same way.

If the patient has to be lifted, as in most surgical cases, the change is effected from top to bottom of the bed instead of from side to side, and the sheet rolled widthwise instead of lengthwise. In this case the sheets will be rolled down until they are under his shoulders. The second person then raises him under the shoulders sufficiently for the sheets to be passed on as far as his hips. These are then raised, and the sheets can be drawn down beneath his legs and the change completed.

It is even more important in winter than in summer to see that a patient's bed sheets are thoroughly aired and warm. When the invalid is not too ill to leave his bed during a change of linen, the best method is to fold back the upper sheets and blankets, and to iron the lower sheet backwards and forwards several times with a hot iron. When, as in cases of severe rheumatism, etc., it is necessary to make a hot pack, the bed is prepared by putting a mackintosh covered with a hot blanket on it. A large sheet is rolled up lengthways and wrung out in boiling water, a large towel being used as a wringer. The patient is turned on one side, the sheet, half unrolled, is placed alongside, and then he is rolled in the sheet. The blanket underneath is then turned over to cover the patient in the sheet, while another mackintosh and several more blankets are placed over him. *See Bedspread; Blanket Nursing; Sheet.*

**BED-PAN.** The bed-pan is a utensil which should be in every home. In many cases of even slight illness patients suffer harm from chills, strain of the heart,

etc., by getting out of bed. Before use, the bed-pan should be warmed and the margin covered with flannel. After use it should be emptied and cleansed as soon as possible. It is wise always to keep some disinfectant in it, such as Lysol or a carbolic solution.

**BED-REST.** A comfortable bed-rest is a necessity in many cases of illness. A chair placed upside down and covered with a large pillow can be used as a temporary substitute, but where the patient has to face a long convalescence, as after a broken leg, it is usually worth while to buy a proper bed-rest. It is essential to have one in some types of chronic heart disease, where the patient cannot breathe comfortably if lying down.

*Bed-rest. Easily made folding pattern. An explanation of the lettering is given in the text.*

**Making a Bed-Rest.** The figure shows a simply made folding bed-rest. The framework, A, is 27 in. by 21 in. and made of wood  $1\frac{1}{2}$  in. by  $\frac{3}{4}$  in. for the uprights, and  $1\frac{1}{4}$  in. by  $\frac{3}{4}$  in. for the rails, which are tenoned or dowed into the sides. The back is webbed as shown. The rack, B, has the notched rails 23 in. by  $1\frac{1}{2}$  in. by  $\frac{3}{4}$  in. and a stretcher rail  $1\frac{1}{4}$  in. by  $\frac{3}{4}$  in. tenoned or dowed. The supports, C, are  $1\frac{1}{2}$  in. by  $\frac{3}{4}$  in. by 15 in. and are joined by a stretcher rail  $1\frac{1}{4}$  in. by  $\frac{3}{4}$  in. B and C are hinged to A by iron bolts  $2\frac{1}{4}$  in. by  $\frac{1}{4}$  in. A washer should be placed between the two pieces of work. Pine, beech or American whitewood are suitable for making this article.

## THE BEDROOM: DESIGN AND DECORATION

Ideas that Produce Harmony and Hygiene in the Sleeping Room

For the Furniture of the Bedroom see Bedding; Bedstead; Dressing Table; Wardrobe, etc.; also Bed-making; Bed-Sitting Room; Colour Scheme, etc.

Exciting designs and colours are out of place in a sleeping room, where the effect should be restful; also, it is advisable to dispense with heavy hangings and furniture not easily moved and cleaned.

In a small house, where the bedrooms open off one landing or corridor, a pleasant scheme allows of individuality in the separate rooms, but is harmonious when the doors are open. Thus the pattern of a cretonne in one room repeats the colour-note of paint and carpet in another, and so on. Building a colour scheme up to the already chosen design of wall-paper or fabric for hangings is often a good way to start new

decorations.

The aspect of each room has also to be considered. An east room which will get the morning sunshine may be in cooler colours, and the same applies to a south room, but in a north room it is necessary to have walls which will suggest sunshine and reflect all the light there is. For a room facing north, or where, as in the case of many town houses, the sunlight is intercepted by other buildings, there is nothing better for the walls than the colour-range from cream to orange with clear yellows and discreet use of pinks; for a sunny south room, cool blues and greys, and in a west room mauves may be selected; but in case of bedrooms, individual taste should make itself felt and the room be characteristic of its occupant.

*Bedroom. Small room in Georgian style with sprigged chintz canopy bed.*

If wall-paper is used it should be of smooth surface so that dust can be removed. For the floor, parquet is always desirable, but ordinary boards can be made dustproof before staining by filling up the cracks. Linoleum is a clean floor covering, and easily swept and polished. Nothing more is required for the floor in a small room except mats which can be taken up and shaken. It is never advisable to have a carpet right up to the skirting.

The most important piece of furniture is the bed, and the best should be bought with the means at disposal. Bedspreads and day cushions can add to the colour of the room, in harmony with the curtains. In many houses hanging cupboards and cupboards with shelves are built into the walls, or built in flush with the wall, so that they form a kind of panelling.

The pedestal basin with hot and cold water is fitted into some houses, but the ordinary washstand is disappearing as a piece of furniture. A well fitted bathroom and a hall cloak room do away with the necessity of wash-hand stands in smaller houses.

For the larger bedroom a wardrobe which has a hanging cupboard on the one side, shelves on the other, and in the centre drawers and a cupboard may be chosen where there are no built-in fixtures. If space is limited a chest of drawers may be selected which will also serve as a dressing-table. A long mirror placed pannel-like between two windows, or elsewhere in a

**BEDROOMS AND BEDSTEADS: SOPHISTICATED YET RESTFUL MODERN DESIGNS**

good light, is a distinct addition to the room, as it catches and diffuses the light. It is of utmost importance to avoid overcrowding, but an armchair, small writing-table, and a couch are desirable additions, so that the occupant will be able to read, write, rest, study, or sew without disturbing or being disturbed by the rest of the household. In a small room, by the elimination of the washhand-stand, of the wardrobe in favour of the hanging cup-board, and of the dressing-table in favour of the bureau, there is usually space for a table and an easy chair, thus giving additional usefulness to the room as well as comfort.

*Bedroom. Modern treatment in a town flat. Improved lighting, including lamp at bedhead.*

*Bedroom. Modern treatment in a town flat. Wardrobes with doors at ends and small cupboards compose the bedhead. (Courtesy of Rowley Galleries).*

Well placed lighting is important for the mirror. Candle-lamps fixed to the dressing-table itself are convenient. A good reading-lamp is essential: either of the hook on to the end of the bed type, a pendant, or a standard. Ingenuity is shown in adapting the rest of the furniture to antiques. Where Jacobean chests are available the hangings and bedspread are of printed linens which reproduce the designs of the period. If the cost of a good modern copy of the Jacobean bed is too great, have a divan bed with legs and a head-board which suits the style of room. If the central piece of the room is a good eighteenth century chest or tallboy, a simple drop table with a reproduction of an eighteenth century mirror will serve as a dressing-table, and the window hangings may be in damask. For a room with painted furniture, hangings should emphasise colour and type of painted decoration. Placing furniture must depend upon the shape of the room. Fresh air is

indispensable. The window should be kept open and the register of the fireplace should also be open, but the head of the bed should not be directly between the fireplace and the window. The dressing-table must be placed so that the mirror is in a good light.

In daily cleaning the bed should be covered with a dust-sheet to protect it. The carpet can then be gone over with the sweeper and the surround with the soft polishing mop. If the room has only small mats these can be removed daily and shaken. The room must then be thoroughly dusted. Once a week it should be turned out. A vacuum cleaner is helpful for carpet and hangings. All woodwork has to be dusted, particular attention being paid to the tops of furniture, curtain-poles, blinds, pictures, etc., which are out of reach in the daily dusting. Marble and tiles are washed, mirrors and furniture polished, and small rugs beaten.

**The Invalid's Bedroom.** The ideal position for the bed is between door and window; failing that, it should be placed between door and fireplace. A single bed is more convenient, and for any long illness a necessity, as a double bed adds to the fatigue and difficulty of lifting the patient, changing of sheets, etc. An iron bedstead about 3 ft. wide and not too low is best. It should be devoid of valances or curtains, and stand away from the wall so that the air can get to it from all sides.

All furniture, except essentials, should be removed. The best covering for the floor is cork carpet or linoleum, because it can be wiped over every day with a cloth wrung out in disinfectant. Even bare boards are preferable to a fixed carpet, and the necessary warmth and quiet can be procured by placing mats on the floor.

The top of the window should never be shut, and it should be possible to have the bottom open, too, for long periods at a time. If this places the patient in a draught a screen can be put round the bed. For purposes of ventilation a fire should be kept in night and day, unless the weather is exceptionally hot: not only does it ensure the chimney being clear, but it makes the temperature of the room easier to regulate. This should be from 60° to 65° Fahr., and kept even.

Heavy window curtains are unhygienic, but gaily patterned washable ones help to make the room bright and cheerful. Too many pictures, or too elaborate a wallpaper, are trying to the eye, and inclined to worry a patient. Plenty of flowers (not too heavily scented) should be kept in the room and should be removed at night.

There should be a comfortable chair or couch which the patient can occupy while his bed is being made, or when he begins to sit up.

**BED-SITTING ROOM.** One of the chief considerations is space. Accommodation must be found for clothes without introducing ordinary bedroom furniture. An antique style dressing-chest or a flat-topped bureau are useful pieces with long wall mirror conveniently placed. Two large cupboards are shown in

the illustrations, which provide in the one hanging room for clothes and space for bed linen, and in the other a sink for washing up and places for cooking utensils, etc.

*Bed-Sitting Room. General view of the room which forms a complete flat. The cupboard on the left holds all domestic necessities, the one opposite all wearing apparel. The small gas cooker has a convenient shelf beneath.*

*The other side of the room above, showing the divan.*

A divan bed may be covered in cretonne or silk, the cover lined to give weight. The pillows have covers to match or contrast. A day-bed with narrow head and foot-pieces and two bolster cushions at either end during the day may be substituted for the divan. Another type of bed is the settee bed, which has railings on one side and at the head and foot, and wired springs with an upholstered mattress. The cover should be removable so that it can be washed.

There are hanging cupboards described as hall cupboards, which do not look out of place in a sitting-room. The best type of table is the gate-legged variety of the drop-table, the leaves of which let down when not required. A gas fire is desirable, and also a small cooking stove, as shown in the illustration, but if there is a coal fire it is useful to have a gas ring in addition. See Bachelor Flat.

**BED SORE.** The cause of bed sores is the weight of the body constantly falling on bony points not well protected by fat. The chief sites are the heels, ankles, elbows and the lower part of the back. Beginning with slight redness, the affected area soon turns a dusky purple, and the soft tissues slough out or the skin ulcerates, leaving an angry sore.

The nurse should be vigilant in her efforts to prevent a sore forming. The sheet must be kept smooth and dry, any soiling being quickly attended to. Every day the skin of the back and other susceptible parts, having been washed with soap and water and thoroughly dried, should be sponged with methylated spirit and dusted when dry with talcum powder. If possible the patient should at least occasionally change his position. The mattress should not be a feather one, and if necessary a water-bed should be procured. Good results have been obtained by dry-rubbing the back with soap till the surface is quite smooth. If the skin becomes reddened it should be painted with flexible collodion. If the condition progresses and a slough is separating, fomentations may be applied in order to assist this.

These fomentations are made by wringing out clean napkins in a very hot saturated solution of boracic acid and should be just large enough to cover the affected area. They should be applied every two hours, being covered with oiled silk and a bandage to prevent too rapid cooling. When the slough has separated, wash the ulcer frequently with an antiseptic lotion and apply an ointment. Either of the following would serve: resin ointment and balsam of Peru, an ounce of each, or camphor gr. x., zinc ointment to an ounce.

**BEDSPREAD.** The bedspread should be in relation to curtains and carpet. While there is nothing daintier than the linen embroidered bedspread enriched with fine needlework of all kinds or by coloured border and large central appliqué design, linen bedspreads are not always favoured because of the cost of laundering or suitable for the style of the room.

For period rooms a selection should be made from printed linens, silks or satins which are in the designs nearest to the period. Chinese lacquer demands the beautifully designed silks of China, and if these are unobtainable the decorator may fall back on black or gold satin if matching the curtains, and trimmed with Chinese embroideries.

For ordinary purposes artificial taffeta the colour of the walls may be selected with a bold embroidered design introducing colours of curtains, etc.; or a patterned soft cretonne or print may be edged with casement cloth of the prevailing colour, or printed cotton bedspreads may be bought to tone with the room. See Appliqué Needlework; Embroidery; Linen.

#### **BEDSTEADS: ANTIQUE AND MODERN TYPES** Their Choice, Construction and Repair

For the arrangement of the Bedstead see Bedroom; other associated headings are Bedding; Bed-Making; Divan; Mattress; Sheraton, etc.

The cheapest iron or brass bedsteads have the bars of head and foot placed transversely, but better types have the bars of the head and foot in a vertical position.

They may be obtained enamelled in black, in white, and in a variety of colours, or the brass may be lacquered. The best brass bedsteads have the minimum of decoration, and the uprights are square and not round in section. In cleaning these, only a soft polishing rag is necessary. Polishes of any kind should be used sparingly.

*Bedstead of English oak, dated 1593, with finely carved pillars detached from the framework of the bed. (Victoria and Albert Museum)*

A wooden bedstead, with upright bars at head and foot, is the commonest type of bed chosen to go with plain or fumed oak furniture. The pattern can also be obtained in mahogany and in painted wood. If the bed is to stand by the wall it should always be provided with castors.

The cheaper kind of beds in the two foregoing types are of combination design, i.e. the wire-spring is fixed to the frame of the bed itself, screws allowing the wire to be drawn taut. It is better to choose a bedstead with iron frame complete, but without the wire. The wire or box-spring can be bought and superimposed.

For lasting value there is nothing better than the wooden bed with solid headboard and footboard made of mahogany or walnut. Where a finely marked piece of wood is used, it is in itself sufficiently decorative. This bed is a variety of what is known as the French bed.

Period wooden bedsteads are copies of old designs. A Tudor bed in dark oak will have a low footboard and two low posts at the foot, or no footboard at all; a Jacobean dark oak bed will have the twisted posts to be found in Jacobean furniture with upright bars at the head and foot; or if the solid head and footboard are chosen it will possibly have some carving. These Jacobean bedsteads have added strength by a transverse beam placed below the footboard. Good beds in inlaid mahogany in the Sheraton style can be had either with solid head and foot or with a central panel and upright bars.

A cane-panel bedstead looks right with furniture of 18th and early 19th century design, or with the lighter types of French furniture. The four-poster is an interesting revival, though hardly the most practical. It can be had either with or without the canopy. It is not necessary to retain the hangings behind the headboard, though this is usual. Curtains must be fixed so that there is no great difficulty in taking them down to clean and replace. The hangings are narrow, so that they do not prevent a free passage of air, but are only for decorative purposes. For the older patterns draperies of costly stuffs are in keeping. Models with twisted posts have Jacobean printed linen, or genuine embroidered hangings and an embroidered bedspread

of the same pattern. For others hangings and bed-covers of silk or damask are chosen, and for the painted four-poster there is the blocked print.

*Bedstead. Example in walnut with cane panels, adapted from a seventeenth century model. (Photo from Heal & Son, Ltd.)*

All these beds are chosen for their decorative quality, and must be justified by choice of accessories. The Chinese four-poster, the most ornate of all, is made to accompany Chinese lacquered furniture in black, green or red.

The best model for a child's bedstead is one with half sides, which prevents all danger of falling out. These can be had in light and fumed oak, or in painted wood to suit the rest of the nursery fittings. In choosing a child's bed it is important to see that all the parts are solidly fixed, that the laths are solid, and cannot be displaced by the most energetic child.

A folding bedstead for the use of an emergency visitor is a useful addition to the household in a London flat or a country cottage. One wooden model, folding up on the concertina pattern, occupies a very small space when not in use, and the thin overlay can easily be stored in a cupboard. There are also several varieties of the military canvas folding-bed. These are provided with a stout canvas overall cover, and form a very useful part of the family holiday luggage.

For use in hot climates an iron or brass four-poster is the best type. No wood is used, as wood is accessible to ants and other insects. The high posts have the transverse rods connecting them fitted with secondary rods for the mosquito curtain, but these are not always used, as many people prefer the curtain to have no division between the canopy and the sides.

Between a wooden and a metal bedstead there is little to choose in the way of strength provided both are good models. The wooden bedstead has one possible point of weakness—where the iron angle-piece which connects the iron bed-rail with the wooden head and footboards is fixed by four screws into the wood. After years of hard service it is possible for these screws to become loose in the wood; it is then necessary to take the bedstead to pieces, plug the wood, and reset the screws. It is wise to count the cost of the spring and the

mattress before choosing the bedstead.

**Repairs and Renovations.** These are well within the capabilities of most amateurs, provided they exercise common sense and pay due regard to the nature of the work to be done to the damaged part, as this determines to some extent the method of repair.

**Four-Poster Bedstead.** The earliest English specimens are few in number, those which have come down from Elizabethan times being chiefly of Italian or Flemish make. They lost popularity in the 17th century, and remained out of favour until the time of Hepplewhite and Sheraton, who gave the type a lease of life that lasted well into the 19th century. Sheraton designed pieces are particularly graceful.

The majority of bedsteads of this type will be found to be more or less worm-eaten, and probably damaged. If the worm is still in the wood, it can be detected by the deposit of fine wood dust on the ground beside the part affected. It can be treated by injecting petrol into the worm holes by means of a very small syringe; a hypodermic syringe answers very well. Other effective methods are to steep the parts in turpentine or paraffin. The work is then cleaned and repolished, treating the worm holes with beaumontage (q.v.) or other filling.

The joints were frequently held together with a form of coach screw; this will probably no longer hold in the wood, so bore out the hole, plug it with a well-fitting wooden plug, well glued into place, and drill out a suitable size hole for the screw. If the original canvas mattress is badly torn, either replace it with new or carefully patch and stitch together all the torn places, and re-work the holes for the lacing, using a buttonhole stitch. Probably only the old framework will be retained and a box-spring mattress fixed to it. All that is needed are some extra battens at the head and foot or elsewhere to support the framework of the box-spring.

**Iron Bedstead.** The usual failings of iron bedsteads are chipping of the enamel, rusting and tarnishing of the ornamental brass knobs and other parts, and breakage of castors. The paint work is readily dealt with by filling the chipped places with hard stopping, after cleaning the metal, and re-enamelling the whole framework. If the brass work is badly tarnished, or covered with a kind of black growth of spots, it is best to remove the parts—generally by unscrewing them—then boil in strong soda water to remove the remnants of the old lacquer. Polish with very fine and old emery cloth (that known as blue black is the best), then polish thoroughly with good metal polish, wash in hot water and re-lacquer. A good effect is often obtained by bronzing the brasswork, say, to blue-grey, and enamelling the metal work in a contrasting colour.

Missing castors are difficult to replace, as they are often cast on. One method is to cut off the old castor with a hacksaw, and drill out the end of the tubular leg. Obtain a new castor of similar size to the others on the bedstead and mount this on a hardwood, or preferably

metal, plug that can be tightly driven into the hole of the leg. An alternative is to fix a tube to the castor, either by riveting or brazing (q.v.), and then fit the leg into the tube. A length of about 6 in. above the castor will serve the purpose.

All-brass bedsteads can be dealt with along the same lines, but the re-lacquering job is no easy one for an amateur, as the whole section must be done at one time and must be kept at proper temperature.

**Wooden Bedstead.** With the so-called sanitary iron fittings, wooden bedsteads sometimes give trouble by the failure of the screws holding the shoe or cast-iron fitment into which the side bars are fitted. The only remedies are to withdraw the old screws, plug the holes, glueing the plugs securely into place and fitting new screws. A drastic and effective remedy is to bolt the shoes on with coach bolts. The heads will, of course, be visible, but this need be no detriment.

*Bedstead. Modern design by Joseph Emberton, A.R.I.B.A. Twin bedsteads linked together by one large head board.*

Sometimes it is desirable to alter the colour of a bedstead so as to harmonise better with the scheme of decoration. When the bed is an enamelled one, the treatment is obvious—re-enamel it in the desired tint. Many bedsteads are made of oak, birch, or similar material and then stained and polished. Here the old colour can to a certain extent be removed with methylated spirit or turpentine. Follow this with a careful rubbing down with fine glass paper. Re-stain the wood with a good quality water stain of the desired colour (obtainable from an oil shop) and then re-polish, or even work up a gloss with a good grade of furniture polish.

**Making an Oak Bedstead.** The bedstead shown in Fig. 1 is intended for a room of moderate dimensions. It is a 3 ft. size, but the general character may be preserved in a 4 ft. 6 in. size, if a double bed is required, or a pair of 3 ft. bedsteads could be made to stand side by side as twin beds. Width, as stated, is 3 ft., but for a child's bedstead it is possible to get an iron frame with diamond mesh-wire spring combined 2 ft 3 in. wide. This hint might prove of service when space is

limited, the accommodation being sufficient for comfortable sleeping without much sacrifice in appearance with the low foot-end. The height is 2 ft 3 in., and may be as low as 1 ft. 10 in. for any special reason. The length of bed is governed by that of the separate iron angle sides or combined spring, whichever is fitted, the size usually supplied being 6 ft 4 in. Fig. 2 shows a type of dovetail iron socket used in conjunction with angle iron bearers to connect the head and foot of a wooden bedstead. The height of head end is 4 ft 3 in., giving a sufficient display of curtain.

*Bedstead. Fig. 1. Single oak bedstead, the making of which is described in the text*

*Fig. 2. Dovetail iron socket for angle iron bearers.*

*Bedstead. Fig. 3. Foot end. Fig. 4. Patterns which may be applied to the foot of the bedstead. Fig. 5. Head end, shown draped with a valance*

A start may be made with the foot end. The posts, allowing  $1\frac{1}{2}$  in. on for height of castors, will require two lengths of 2 ft 1 in. by 2 in. by 2 in., finished sizes being a shade under for a stout bed. It is possible to use wood 2 in. wide on face by  $1\frac{1}{2}$  in. thick, if this happens to be more accessible. For the former size the posts are square for their full length, but have the corners just nosed off. A  $\frac{1}{4}$  in. ovolo is intended to be worked down the outer angle, and this can be carved effectively with pip and-bean detail, or this ornamental portion can be obtained separately in long strips (about 10 ft.) from the woodworkers' sundries-man, ready for grooving into the corner of the posts, to be glued and fastened here and there by needle points. Castors are often omitted in a 3 ft size, in which case it should be remembered to allow the slight extra length for the posts.

The top rail (A, Fig. 3) is mortised and tenoned into

position, but is often dowelled, or might be dovetailed in. It looks well if the top edge is slightly rounded away, D-shape. This rail is shown  $2\frac{3}{4}$  in. wide, and should be at least  $1\frac{1}{4}$  in. thick. The foot-rail (B, Fig. 3) enters the posts with a couple of shouldered tenons, and is  $4\frac{1}{2}$  in. wide.

The inner uprights (C, Fig. 3) take two pieces 12 in. by  $6\frac{1}{2}$  in. by  $1\frac{1}{4}$  in., to include  $\frac{1}{2}$  in. tongues, entering top and bottom rails and uprights, and all three are grooved to receive the panel. The panel (D, Fig. 3) should be of  $\frac{5}{8}$  in. thickness, reduced at edges to enter the  $\frac{1}{2}$  in. or  $\frac{3}{8}$  in. grooving. A flat section of mould can then be mitred up to drop in on face and be glued and pinned.

This finishes the construction of the foot end, but if some relief is required the left-hand device at Fig. 4 might very well be introduced into the centre of panel. It is easily set out and cut from a piece of  $\frac{1}{8}$  in. thickness for the centre diamond, this being notched for the smaller diamonds out of  $\frac{1}{4}$  in. material to intersect. Size for the device to finish is 8 in. by 4 in., and in mounting care must be taken to get the extreme points level. The easiest way is to pencil in centre lines on the panel, and glue up the pieces over these, the final being by the addition of a few needle points. The right-hand device is an alternative. The centre device is cut from a piece of  $\frac{1}{4}$  in. material cleaned up, with a four circle and crossbar opening, and the corner shaped ogee to form a centre panel. This last device would be very suitable if the bed were made in dark mahogany.

The head posts (Fig. 5) are 2 in. by 2 in., and are shown with 4 in. by 4 in. moulded cappings stub-tenoned on. It will not be necessary to introduce the pip-and-bean mould on the angle of the posts as for the foot-end. The top rail (E) is  $3\frac{1}{2}$  in. wide, which will afford an opportunity of applying some relieving device in keeping with the foot-end. The mid rail (F) might be 2 ft 6 in., or a trifle higher; width is allowed 6 in.; thickness of both this and the top rail (E) should be 1 in. The lower stretcher rail (G) can be  $2\frac{1}{2}$  in. by 1 in., and can be fixed anywhere between 6 in. and 10 in., from lower end of posts.

The curtain rod (H, Fig. 5) can be of  $\frac{1}{2}$  in. brass tubing, and special fittings are obtainable in brass for a small sum from most furnishing firms.

Details are given in Figs. 6 and 7 of a 4 ft. 6 in. bedstead of straightforward design. The woodwork, as in the bedstead described above, consists only of the head and foot, which are joined by dovetail sockets and angle iron sides. The posts, which are finished off with a moulded capping, are  $2\frac{1}{2}$  in. by  $1\frac{1}{8}$  in., the rails are 1 in. thick, and the central splat  $\frac{1}{2}$  in. thick. The upright slats are 1 in. by  $\frac{1}{2}$  in. The top edges of the upper rails are finished with a moulding, as shown. The panel on the centre splat is formed with a small moulding, which may be pinned and glued.

The posts for the head are 4 ft. 3 in. high over all, including castor and capping. The latter is planted on, and has an ovolo moulding worked on its edges.

The height of the foot posts is 3 ft 8 in. over all. The extreme width of the end, measured over posts, is 4 ft. 6 in. The upper edge of the lower rail for the head end is 1 ft 9 in from the floor, that for the foot being 2 in. nearer the ground. These rails are 6 in. wide, and the top rails are 2½ in. wide. The central splat is 8 in. wide; the 1 in. vertical slats are in pairs, as shown, spaced so as to leave intervals of 5 in. The dovetail sockets are attached so as to bring the angle-iron sides 1 ft. 3 in. from the floor.

*Bedstead. Figs. 6 and 7. Simple design in oak, with working diagrams.*

This design can be readily adapted for a single bed. The overall height of the posts for both ends might be 3 ft, and the overall width of the ends from 2 ft 6 in. There would be a single pair of upright slats each side of the central splat. If a pair of twin bedsteads is made, the head ends might be taken a little higher than the foot.

**BED TABLE:** For Invalids. The bed table shown in Fig. 1 has a double advantage. The legs are hinged so that the article may be converted into an

ordinary tray. By means of a very simple contrivance (Fig. 2) the legs are held down firmly, so that the tray will stand flat on a table or sideboard. When the legs are unfolded for bed-table use the same arrangement provides for them being held rigid. A tray of this kind may be made in almost any wood. American white-wood, or even pine, will serve the purpose. For a stronger article oak may be used, or if a specially nice piece of furniture is wanted, mahogany may be taken.

*Bed Table. Fig. 1. Folding table for invalid use.*

The size suggested in Fig. 4 is a tray measuring 22 in. by 14 in. This might be reduced to 20 in. by 12 in., with proportionately shorter legs, if only a small tray were wanted; or could be increased to about 28 in. by 18 in. for a patient who was likely to do much writing in bed. The legs are shown, 8½ in. long, which places the table at a convenient height.

Fig. 1 shows the bed table ready for use. At Fig. 2 is given a view of the underside, one pair of legs being up, while the other two legs are shown folded with the spring lath holding them down. Fig. 3 shows the article when used as a tray, while the scale plan at Fig. 4 will be a guide for sizes. The remaining sketches show details of construction.

*Bed Table. Figs. 2-8. Working drawings by means of which the amateur woodworker can make it.*

The top may be in one piece, 22 in. by 14 in. The thickness for pine or American whitewood may finish  $\frac{3}{8}$  in., but if oak or mahogany is used,  $\frac{5}{16}$  will do. A good sound board of  $\frac{1}{4}$  in. 3-ply would serve the purpose for a light table. The front of tray may be gently curved inwards as shown.

To the underside of the top at each end are screwed two battens, which may be  $12\frac{1}{2}$  in. by 1 in. by  $\frac{1}{2}$  in. thick. These should be chamfered on the outer edge (Fig. 6) and at the ends, and each is held with four brass screws. A rail is required for the back and sides of tray. The height may be  $\frac{3}{4}$  in., with a finishing thickness of  $\frac{5}{16}$  in. At the corners the rail may be simply notched, as Fig. 5, D, or dovetailed, or mitred and keyed. The top edges should be gently rounded, and the front ends of the side rails neatly finished off, as in Figs. 1 and 3. The rails are screwed with fine screws passed in from below, this being done before the battens are fixed.

The legs are  $8\frac{1}{2}$  in. long and 1 in. square, and are shown tapered on two sides. The leg rails shown in Fig. 5 (A and B) are fixed with an angle bridge joint. They are  $1\frac{1}{4}$  in. wide by 1 in. thick. The outer side of each has a shallow piece cut away to take the spring lath when the legs are folded. This is shown in Fig. 2, and also at Fig. 5 C. The part thus cut off will be  $2\frac{1}{2}$  in. wide and  $\frac{3}{16}$  in. deep, and must be in the centre of the rail. The cut provides for the spring lath lying flush with the legs when the article is used as an ordinary tray, so that the tray lies quite flat when the legs are folded down. Each pair of legs is hinged to the underside of the tray as shown in Figs. 6 and 7. The perspective sketch (Fig. 2) and the plan (Fig. 4) will also assist the worker. Strong back-flap hinges,  $1\frac{1}{2}$  in. by 1 in., are used. They are so fixed that the legs, when up, will lie against the flat  $\frac{1}{2}$  in. edge of the batten. It is important to note this, as if the legs stood away from the batten, the hinges would gradually loosen.

The spring lath holds the legs secure both when up

and down. It is approximately  $17\frac{1}{2}$  in. long, but allowance should be made for a little adjustment when fitting. In width it may be  $2\frac{1}{2}$  in. or  $2\frac{3}{4}$  in., and in thickness  $\frac{3}{16}$  in. or  $\frac{1}{4}$  in. bare. If the table is made in pine or American whitewood, it will be desirable to use sycamore or ash, or any other wood which yields a good spring, for the lath. If oak or mahogany is in use, the same wood may be taken for the lath.

**BED-TICK.** For a feather bed and for pillows and bolsters an all-linen tick of a close weave should be chosen, and the sewing must be close and strong; otherwise feathers and down will escape when the outer covering is removed. For hair and wool mattresses it is safer to choose a stock pattern, as when mattresses are re-made there is usually a certain amount of shrinkage and new tick may have to be added. See Feather Bed; Mattress; Pillow; Ticking.

## BEEES AND BEE-KEEPING

### How the Amateur Apiarian May Secure Profitable Results

Instructions for making Beehives are given in page 159. See also Bee Pest; Beeswax; Honey, etc.

Bee-keeping is eminently suitable for smallholders, cottagers, and others with a limited area at their disposal. The prospective bee-keeper should begin with not more than a couple of stocks, increasing the number as he acquires experience. The following instructions on bee-keeping are based on information given in Bulletin No. 9 issued by the Ministry of Agriculture.

A stock resulting from a cross between the English, or so-called Black Bee, and the Italian, or Ligurian race, will probably be found the best; but on this point it would be well to take the advice of an experienced bee-master in one's own neighbourhood. A normal colony of bees consists of the queen, a large number of workers, which are rudimentary or undeveloped females, and a few male bees or drones. A swarm is a mass of bees, frequently numbering 20,000, with a queen. The first swarm from a hive is, as a rule, much larger than succeeding ones.

Bees thrive best when protected from frequent variations of heat and cold, and a steady temperature can only be maintained when the walls of the hive do not conduct heat. If they do this in summer the warm sunshine will soon make the interior of the hive excessively hot in the daytime. During the cool summer nights the reverse will be the case. In winter, when the temperature of the air outside is constantly lower than that inside, a steady loss of heat from the bee cluster occurs. This often results in the death of the bees from exposure and starvation, although ample food may be accessible.

A double-walled hive of sound pattern is that called the "W.B.C." Fig. 1 shows the arrangement of this hive, full instructions for constructing which are given

(Continued in page 152)

*BEDROOM: UPHOLSTERED IN SOFT-COLOURED VELVET*

*Restful shades of green and grey make this bedroom scheme peaceful and soothing. The walls are apple green, with a metallic grey edging: the ceiling is a paler shade of green. The furniture is in modern grey-wood, the upholstery and bedspreads of grey velvet. The colour scheme is accentuated by the mat, with its modernist design, against a background of plain grey carpet. A note of warmth is struck by the rich yellow cushion in the armchair.*

in the article Beehive. It consists of a floor board having four splayed legs, and a brood chamber containing ten frames with a division board. These frames hang by ears or lugs on a metal runner, so that there is a space of  $\frac{1}{4}$  in. between the end bar of the frame and the side of the hive. This is a bee space, and therefore left clear. Between the bottom bar and the floor board  $\frac{1}{2}$  in. space allows the bees free passage, and they are also able to clean out in comfort the dead and any dirt which accumulates. Their natural instinct teaches the bees to leave this space open, and they therefore do not build comb there.

To obtain combs of the right thickness for brood rearing, i.e.  $\frac{7}{8}$  in., metal ends are fitted on to the lugs of the frames; these are  $1\frac{1}{2}$  in. wide, so that when they are in position, and all the frames are pushed together until the metal ends touch each other, there is a space of  $1\frac{1}{2}$  in. from the centre of one comb to the centre of the next, allowing for  $\frac{7}{8}$  in. comb and a  $\frac{3}{8}$  in. passage between each comb to accommodate the bees when carrying out their work in the summer, and to cluster in during the winter.

To compel the bees to build their combs in the frames they are provided with comb foundation. This is pure beeswax, in sheets impressed with the base of the cells. By its use straight combs can be obtained in any desired position. To make the brood comb strong, wire is first stretched across the frame; a sheet of worker base foundation cut to fill the frame is then inserted into the saw-cut made in the top of the frame for this purpose, and a serrated grooved wheel, called a spur embedder, is then heated in the flame of a spirit lamp and run along the wire, thus melting the wax slightly in order that the wire may sink into it. This holds the foundation rigid, and when the comb is built the wire is right in the centre of it, and there is very little fear either of the comb dropping out if held in the wrong position, i. e. horizontally instead of vertically, or of the combs breaking down, should the hives be sent any distance. The combs in these frames are reserved for the rearing of young and the storage of winter food, and should not be touched for surplus honey.

### The Structure of the Chambers

A second chamber, or super as it is termed, contains shallow frames, the combs in which are used for the production of extracted or liquid honey. The third chamber is a section rack containing 21 sections (bottomless wooden boxes  $4\frac{1}{4}$  in. square by 2 in. wide) in which comb honey is produced. Each section holds about a pound of honey. Surrounding these chambers and the brood chamber there is an outer case which also carries the porch over the entrance; the size of the latter is registered by sliding doors. There are also lifts which fit on to the top of the outer case, and on one another to accommodate the supers during the honey season. A roof completes the structure. The hive should be stocked as early as possible in the spring. It may be populated in three ways: by purchasing a colony of bees, a nucleus, or a swarm. The first is the most expensive method, as the bees have already built the combs, are rearing broods and have stored a certain

amount of food. A nucleus consists of four combs, and under favourable conditions may be worked into a full colony in time to give a limited amount of surplus honey before the end of the season.

*Bee. Fig. 1. Section of double-walled W.B.C. Bee-hive. 1. Bee way. 2. Section. 3. Metal divider. 4. End following board. 5. Spring block. 6. End of shallow frame box. 7. Shallow frame. 8. Air space. 9. End of brood chamber. 10. Bee space between frames and hive side. 11. Brood frame. 12. Lifts. 13. Queen excluder. 14. Metal runner for frames. 15. Outer case. 16. Porch. 17. Alighting board. (By permission of the Ministry of Agriculture)*

The safest way for a beginner to start is with a first swarm (not a cast, or after-swarm). The most satisfactory method of purchasing a swarm is by weight. A swarm weighing 5 lb. should be obtained, if possible. After-swarms weigh about 2 lb. and have a virgin queen.

The swarming season varies somewhat in Britain, according to the weather. There has been, in a very early season, a swarm on the 19th of April, the earliest in a 40 years' experience in the south of England. As a general rule, however, the latter part of May is the busiest portion of the swarming season, extending as it does through June and into July. Most of the swarms issuing in July are casts or second swarms, and, except in the hands of an expert keeping many colonies, are of little use and should be returned to the parent colony.

When the box or skep containing the purchased swarm arrives, it must be placed in the shade near the hive the bees are to occupy. If the swarm is in a box, the box should be placed upside down and the screws fastening the lid taken out. The lid should then be wedged open at one end about  $\frac{1}{2}$  in. to allow the bees to fly. If the bottom is of perforated zinc it should be

covered with a sack to exclude the light, otherwise the bees may escape. If the swarm arrives in a skep, the cording and wrap should be removed, and the skep placed on a board with a stone under one edge in order to allow of flight and ventilation.

### How to Hive a New Swarm

The hive must be made ready before the arrival of the swarm, and should face southeast. An ideal situation is by the side of but not under a standard fruit tree. The legs of the stand should rest upon bricks to prevent them from rotting. The hive must be set perfectly level from side to side, with a downward inclination of about  $\frac{1}{2}$  in. towards the front. In the early evening the roof, lifts, and outer case should be removed. To prevent the bees ascending to the roof a thin quilt of ticking or unbleached calico is placed over the frames. The front of the brood chamber should be raised from the floor board about an inch by means of two wedges. A board the width of the alighting board should then be placed in front of and level with the latter, sloping down to the ground. Both boards are covered with a cloth hanging over the sides to the ground, to stop the bees from crawling underneath.

The skep or box is gently carried mouth downwards until it is just above the sloping board. With a smart jerk the bees are thrown out in front of the brood chamber, about 1 ft. away from the entrance, when they will at once begin to take possession of their new home. It is their natural inclination to run uphill. As they run in watch should be kept for the queen, to see that she enters safely. When all are in the wedges should be taken away and the front of the brood chamber gently lowered to its proper position. Any bees in danger of crushing should be brushed away with a feather.

The swarm will benefit greatly if it is fed for at least a week with warm, thin syrup, made by adding three-quarters of a pint of water to one pound of white cane sugar, and heating it over the fire until the sugar is dissolved. Add a teaspoonful of Bacterol to each pound of sugar. It is administered by means of the bottle feeder, Fig 2. Brown sugar must not be used. On the second day after hiving, the bees are closed by means of the division board on to the number of frames of foundation which they are able to cover.

*Fig. 2. A nine-holed bottle feeder.*

If the swarm has been obtained early in the season building up will proceed fairly rapidly until all the combs are completed, and brood rearing will be carried out on such a scale that the hive will become overcrowded with bees before the honey flow is over. If this is allowed to continue the bees will swarm.

Swarming can be prevented to a great extent. Remove the quilts and place a queen excluder in position over the brood frame tops. This is perforated with slots made so accurately to size that the workers can pass through, but not the queen. Thus honey, without intermingling of brood or pollen, is obtained in the super that is now put on. If it is a shallow frame super, the frames should be fitted with sheets of wired drone base foundations.

When the combs in the first super put on are drawn out, and about two-thirds of the whole are filled with honey (i. e. when the bees commence to seal over the honey in the middle of the central combs), the super should be lifted and a second one placed underneath it. When the honey flow commences to decline it is better to allow the bees to complete those supers already in situation than to give extra ones.

### Clearing the Supers

The bees are cleared from the supers by means of an escape, Fig. 4, which allows the bees to pass through a hole into a passageway in which there are two springs placed in a V-shaped position. This escape is fitted into a clearing board, Fig. 5, cleated so that it entirely covers the top of the brood chamber. The clearing board, with the escape in position, is placed in the evening under the super or supers which it is desired to remove. The only means of exit for the bees is from the wide ends of the springs in the escape, which are so finely adjusted that the bees can push them apart to pass out at the points, but are unable to return when the springs are closed.

*Bee. Fig. 3. Shallow frame super perforated with slots of a size to exclude the queen.*

*Fig. 4. Bee escape, the V-shaped springs only permitting egress.*

*Fig. 5. Clearing board fitted with bee escape.*

The honey in the shallow combs must be extracted as soon as it is removed from the hive, while still warm. The extractor, Fig. 6, is a tin cylinder with an inside cage revolving on a spindle when the handle is turned. The cage will accommodate either two combs, one on either side, or twelve sections, six on either side.

The first operation in extracting honey is to uncap the combs with a special knife or an ordinary sharp carving knife. A jug, the depth of the length of the knife blade, is filled with hot water and the knife inserted. If

a cold knife is used it will spoil the comb. The cappings are removed by cutting upwards from the bottom of the comb with a see-saw movement.

Two combs are placed in the cage and the cage is turned slowly. When a portion of the honey has been extracted from one side, the combs are reversed, and the other side treated in a similar manner. Extraction is completed by revolving the cage more rapidly. When the honey in the bottom of the extractor reaches the cage, it is drained off and strained through muslin into 28 lb. tins or other suitable vessels.

The wet combs are now given back to the bees to clean down. The clearing board is left in position over the colony, and the tin slide over the hole on the front side of the board is withdrawn so that the bees can pass freely up into and down out of the super. When the empty combs are quite dry, the tin slide is pushed back over the hole, so that the only exit for the bees is through the escape.

The most profitable system is to work for extracted honey. It takes from 10 to 20 lb. of honey to make 1 lb. of beeswax, so that when a section is sold the bee-keeper parts with a valuable asset in the form of wax.

At the close of the honey season the keeper should see that sufficient stores have been left in the body box for consumption by the bees throughout the winter. A knowledge of the amount or weight of stores can be gained by tilting the hive at the front; if it feels like lifting from 15 to 20 lb., there is a sufficiency; but if it feels light they must be fed until it does so feel. To feed them, place a piece of perforated zinc, 5 in. square, of a gauge similar to that used in a meat-safe, over the feed hole already made in the quilts. Fill a 3 lb. glass jam jar with syrup made as directed for the swarm, but using only half a pint of water to the pound of sugar. Cover the mouth of the jar with two thicknesses of muslin and invert it on the zinc.

*Bee. Fig. 6. Extractor for withdrawing honey from comb by rotation.*

*Fig. 7. Bee smoker with bellows.*

As the bees empty the jar, replenish it with syrup until they have had sufficient by weight. There will then be a perfect colony or stock to commence the next season. Should there be any doubt as to the sufficiency of the syrup to last through the winter, a cake of bee candy should be placed over the frames.

The chief attributes necessary for handling bees

successfully are a knowledge of the habits of the bee, firm but gentle movements, adequate protection of the manipulator and proper subjugation of the bees. The only protection necessary is a veil for the face. This can be made of black mosquito netting, with an elastic band top and bottom, fitting tightly round the crown of the hat and under the collar of the coat to prevent the ingress of the bees. Gloves should not be worn, as they conduce to clumsiness, which will irritate the bees.

Subjugation is carried out by frightening the bees. When frightened they gorge themselves with honey, and are not inclined to sting. One of two subjugators can be used—a smoker (Fig. 7) or a carbolic cloth. The former consists of a tin cylinder having a conical nozzle, open at the pointed end. This is fastened to a pair of bellows with a connexion between the two at the back. Ordinary thick brown paper, corrugated paper, or fustian is rolled into a cartridge, lighted, and placed in the furnace of the smoker, with lighted end downwards. When the bellows are worked a volume of smoke is emitted from the nozzle and can be driven in any direction. A carbolic cloth is made by sprinkling a piece of calico the size of the quilt with a solution of one part Calvert's No. 5 carbolic acid to two parts of water.

When manipulating it is inadvisable to stand in front of the hive. When handling or turning the combs, keep them vertical and not horizontal. Bright, warm weather should be chosen for manipulating bees, as they are then usually in a good temper.

### Economics of Bee-Keeping

The strength of a healthy colony depends on the vigour and laying power of the queen, who is at her best in her second season, and should be replaced in the third by a young one. The economy of a hive depends on: (1) the generation and keeping up of the warmth of the brood nest (by means of the heat evolved from the bodies of the clustering bees) to such a point as will stimulate the production of eggs and enable young bees to be reared; (2) the nursing of the larvae, and the cleansing of the cells, for the queen to lay in; (3) the collection of pollen, water and nectar for food; and (4) the building of storage combs and collection of nectar for future supplies of honey.

The aim of the bee-keeper is to keep his colonies strong. The crowded condition of the hive should be secured at the right time—i.e. at the honey flow. Honey is made from the nectar of flowers. Spring and early summer are the times when the honey crop is gathered. There is a period every year, varying in each district, when the supply of nectar is most abundant. This time, should be ascertained by the bee-keeper, who will then stimulate his colonies beforehand.

Bees are thirsty insects, and at the end of February a shallow pan half-filled with washed stones should be placed at a distance of four or five yards from the hives. This should be partly filled with water to which table salt has been added in the proportion of one teaspoonful to a pint. The tops of the stones should be left dry for the bees to alight on.

*Bee. Shaking a swarm from branch on which the bees have settled.*

**BEECH.** One of the chief uses of beech wood is for chairs. Most of the bent-wood variety are of beech, and so are the Windsor and other non-upholstered chairs. The frames of upholstered chairs and couches are

often of beech, if they are not of birch; also turned table legs and many other turned articles. Beech may be stained to resemble mahogany or walnut. It is used for tool handles and for mallets and planes; sometimes for wood-worker's benches and dowel rods; also for brushes, and rollers for wringing machines and mangles. Beech is a heavy wood with straight and close grain, light in colour, sometimes with a reddish tinge. *See Chair.*

## BEEF AND HOW TO COOK IT

### Helpful Information about the Joints and Tested Recipes for their Preparation

For general cooking methods see Baking; Boiling; Braising; Roasting; also specific cuts as Brisket; Sirloin; Steak, etc.

Grass-fed, short-horned cattle provide the best beef on the English market. Cow-beef is not so tender or well-flavoured, but is sold at a lower price. Chilled beef is superior to and a little more expensive than the frozen meat imported from abroad. It may require to be slowly thawed before being put in the oven, and is wholesome and tender if properly cooked.

If raw beef is pale pink or purple the animal has not been in good condition; a clear red indicates health. If the fat is streaky, giving the beef a marbled appearance, the animal has been in prime condition. The fat should be without brown spots or streaks of blood. The flesh should feel firm and elastic. There is no disagreeable odour from good meat. After keeping it at home for a day or so, washing with diluted vinegar will restore freshness. Meat that is in prime condition does not get watery on standing, nor lose much juice in the process of cooking.

### The Parts of Beef and Their Uses

The hind parts of a bullock are the most expensive. Sirloins and ribs are used for roasts: the rump gives the best steaks for broiling. The topside of the buttock is useful for roasting or gives good stewing steaks. The silverside or underside is usually salted and boiled, as is also the brisket, which is a cheap joint. The aitchbone (buttock) is cheap and used mostly for boiling. Flank of beef provides good steaks for pies. The leg and shin are used for soup and also for potted meat. Cow-heel makes a jelly as good as calves-foot jelly.

Oxtail is stewed or made into soup. Tripe is the ruminant stomach of the ox, and is easily digested. The heart, liver and kidneys are moderately digestible. The sweetbreads of an ox require long and careful cooking. The suet around the kidneys is specially good for the finest of cookery uses.

When a joint of meat is kept for a few days it should be wiped and hung up in a cool, dry place to which flies have no access. The undercut of a sirloin may be taken off and used separately for beef olives or fillets of beef, thus giving an extra hot dish out of the joint.

**Boiled Beef.** Choose a salted round, aitchbone, brisket, or silverside, and tie it into a shape convenient for carving. Put it into a pot with just enough water to cover—cold water if the beef is very salt, otherwise warm. Bring the water slowly to the boil, and then add two onions, several carrots (cut lengthwise into pieces), some sliced turnips, and some herbs. Let the beef simmer, but not actually boil. Make some small suet dumplings and boil with the beef. Allow 25 min. for each lb. the joint weighs and 25 min. over. Serve the beef on a hot dish, pouring over it a cupful of the water in which it was boiled. Garnish with vegetables and dumplings.

These are made with 6 oz. flour, 2 oz. suet, 1 small teaspoonful salt,  $\frac{1}{4}$  teaspoonful baking-powder, and a little water or milk. First the suet is chopped and mixed lightly with the flour, baking-powder, and salt; then all are bound together with the water, kneaded lightly and made up into soft balls of dough, which are cooked during the last 15 min. the meat is boiling. Serve at once, otherwise they turn heavy.

*Beef. Quarters marked off to show how they are cut for market. 1. Hind-quarter. A. Leg. B. Topside. B1. Underside. C. Aitchbone. D. Thick flank. E. Rump. F. Loin. G. Flank. Dotted lines show direction of cut on the other side. 2. Forequarter. A. Fore-rib. B. Brisket. C. Middle piece. D. Clod and Sticking. E. Shin.*

**Braised Beef.** A round of beef is the most suitable. Flour the meat lightly and brown in a saucepan in hot fat. Add a teacupful of hot stock, salt and pepper, a little mace or nutmeg, any sliced or chopped vegetables, 6 or 8 peppercorns, 2 cloves, and a little parsley. If no fresh celery is available, add a little celery seed and a teaspoonful of dried herbs in a muslin bag. Cover and cook gently till the meat is tender, laying a piece of greased paper over it to keep in the steam. A couple of Spanish onions, boiled for a few minutes and then quartered, may be added to the braise. Place the meat on a hot dish, strain off the liquid, arrange the vegetables in four heaps round the dish, and pour some of the gravy round, serving the rest separately.

**Roast Beef.** Ribs of beef are often boned and rolled before roasting. Rounds and aitchbones can only be roasted successfully if very tender. Put in a very hot oven and reduce heat after first 10 minutes. Give 20 minutes to each pound, and 20 minutes over. The roast should be served on a hot dish with pieces of Yorkshire pudding, horse radish sauce, and gravy separately served.

**Rolled Beef.** Procure a large steak cut from the topside of beef, weighing about 2 lb., and cut about 1½ in. thick. Wipe and flatten slightly by beating with a rolling-pin or a cutlet-bat dipped in cold water. Remove the skin from ½ lb. of raw pork sausages, mix the sausage meat with 2 oz. fresh white crumbs, 2 teaspoonfuls chopped parsley, a dust of powdered herbs, a little salt and pepper, and one well-beaten egg. Spread this forcemeat evenly over the beef, but not within ½ in. of the edges.

Roll up the beef, bind in shape with tape, put in a baking-tin with 2 oz. of beef dripping and a teacupful of water, and bake in a moderately hot oven for about 1¼ hours. Baste frequently, and if the dripping smokes, add more water. When cooked remove the tape, place the roll on a hot dish, and strain round it about ½ pint of hot tomato sauce. If liked, a veal forcemeat of crumbs, suet, and herbs can be used instead of the sausage filling.

**Stewed Beef.** Trim 2 or 3 lb. of meat, tie neatly, and lay in an earthenware dish. Then boil 1½ gills of vinegar together with 2 teaspoonfuls mixed of allspice, cloves, and mustard seed for 5 min. and pour over the beef. Leave in this marinade for 2 hours, and turn occasionally. Cut 4 oz. bacon into large cubes; melt 1 oz. of beef dripping in a saucepan, and fry the cubes lightly. When done, lay them on one side and put the beef into the hot fat, letting it brown well.

Lift the beef out of the pan putting in its place slices of onion. Fry these, and add 4 oz. of whole new carrots. Lay the beef on these vegetables, add 1 quart of stock, a small bunch of herbs, and a few spring onions. Cover the pan and simmer contents for two or more hours, until the meat becomes tender.

Meanwhile melt 1 oz. of beef dripping in another

pan, adding and carefully browning 2 oz. of flour. Colour and flavour will largely depend upon this. Strain and stir in gradually the stock from the beef, then boil, skim, and season this gravy.

**Beef à la mode.** This is a useful casserole dish. Take 1 lb. of steak, and place in a pan to brown with a little butter, flour, and some small onions. Add a glass of claret to a breakfastcupful of stock. Pour over the meat and add carrot, a little mixed herbs, pepper, salt, and the juice of half a lemon. Simmer slowly for two or three hours, adding boiling water if necessary. Serve the meat in the casserole with the onions and carrots and a little chopped parsley.

**Cold Beef.** Scraps of cold meat may be utilised to make beef cake. It can be ornamented by pressing into the thickly greased top and sides of the mould thinly cut rings of boiled macaroni or cooked peas, rings of cooked carrot, etc.

Take a plain round mould and thickly grease it inside. Melt 1 oz. of butter or dripping in a saucepan, add 2 teaspoonfuls of chopped onion and fry a light brown. Stir in ½ lb. finely minced cooked beef, 2 oz. fresh white crumbs, and 2 teaspoonfuls of chopped parsley. Mix these with one whole egg and one extra yolk, well beaten, and ½ gill of stock. Season and mix carefully.

Press the mixture, a little at a time if the mould is decorated, into the greased mould. Twist a piece of greased paper over the top and steam the cake for ½ an hour, or till firm in the centre. Remove the paper, slip the shape on to a hot dish, and strain over and round it a well-flavoured hot brown gravy.

**Beef Polantine.** This may be served either for breakfast or as a supper dish. Cut ½ lb. of cold roast beef into fine shreds. Have ready 1 gill of good brown gravy heated in a stewpan, add the meat to it, and allow to heat gently. Peel and thinly slice one Spanish onion and divide these slices into rings.

Dip each of these in slightly beaten white of egg or milk, then draw them through a little flour and fry them in smoking hot fat until they are a golden brown tint. Keep these hot, and in the same fat fry three small firm tomatoes cut round in halves. Put the meat and well-seasoned and thickened gravy in the centre of a hot dish, arrange the tomatoes round and heap the fried onions on the top of the meat. This is sufficient for 3 persons.

**Pickled Beef.** To dry-pickle remove any bones or unsuitable bits from about 5 or 6 lb of thin flank or topside. Rub well over with common salt and leave for 24 hours. Pound together in a mortar 1 lb of common salt, ¼ lb. of brown sugar, ½ oz. of saltpetre, and ½ teaspoonful of black pepper to a fine powder. Rub this mixture thoroughly into the beef, keeping it in an earthenware pan. Turn and rub every day, or at least 3

times a week. Continue this process for 8 days, or until sufficiently salted.

*Beef. Above. Joints cut from the fore-quarter, as shown marked off in page 142. 1. Fore-rib. 2. Clod and sticking. 3. Shin. 4. Brisket. 5. Middle piece.*

**BEEF GOULASH.** A Hungarian stew. Cut  $1\frac{1}{2}$  lb. of boneless beef into 1 in. cubes, also 3 oz. of streaky bacon. Put these into a stewpan or casserole with 2 oz. of chopped onion, and one small, fresh red chilli, or 2 dried cayenne pods. Add  $\frac{1}{2}$  pint of good stock, cover the pan, and simmer contents for one hour, or until the meat is tender.

Mix 2 teaspoonfuls of fine oatmeal with 1 gill of cream, and stir into the stew until it boils. Allow it to cook gently for another 10 min, then season carefully and serve in the casserole or poured out on a hot dish. Small pickled gherkins and wholemeal bread should accompany this dish, which will be sufficient for five to six persons.

**BEEF JELLY.** Prepared by cutting 4 lb. of good gravy beef into small pieces, laying them in a jar with a pint of cold water and a little salt. Cover tightly, stand in a pan three parts full of boiling water, and stew gently for eight hours. Then strain through a clean hair sieve, and remove every particle of fat the following day. A sheet or two of best leaf gelatine or a little isinglass can be used to stiffen the jelly.

**BEEF NOISETTES.** Select a good fillet of beef weighing  $1\frac{1}{2}$  lb. Trim off rough pieces and divide fillet into round slices not less than  $\frac{1}{2}$  in. thick. Melt  $1\frac{1}{2}$  oz. of beef dripping or butter in a frying-pan, lay in the noisettes, and fry them quickly for 8 to 10 min., taking care they are under rather than over-cooked. Arrange neatly in two rows on a bed of hot mashed potato or spinach, pressing the round pieces of beef down to hold in position. The next process is to strain round them some hot brown gravy and lay on them a small pat of maître d'hôtel butter.

To prepare this, work into 1 oz. of butter, 1 teaspoonful of finely-chopped parsley, 1 teaspoonful of lemon-juice, salt and cayenne to taste. When mixed, shape into a little flat pat, and allow it to become cold; just before serving place a small piece of it on each noisette.

**BEEF STEAK PUDDING.** Take 2 lb. of steak, wash quickly, dry and cut into pieces about an inch square. Mix together 3 teaspoonfuls flour and a good seasoning of salt and pepper; dip each piece of steak in this mixture.

From  $\frac{3}{4}$  lb. of suet pastry cut off about a third and put it on one side; this is for the lid. Grease a pudding-basin, line it with the pastry, then pack in the pieces or rolls of steak. When the basin is full, pour in enough water or stock to come half-way up. Wet edges of pastry, put on lid, and press the edges together. Scald a pudding-cloth and tie securely over the pudding, taking care to make a pleat in the middle of the cloth to allow room for the crust to swell.

Put the basin in a pan of fast-boiling water and boil from 2 to 3 hours. Serve in the basin with a clean napkin pinned neatly round it. *See Steak.*

**BEEF TEA.** When properly prepared beef tea may provide some of the nutritive materials of beef, but the common idea of its excellent food value is unfounded. It is always of less value than milk as food. The stimulating effect on the digestion and the bowels of the meat extractives which it contains is often

valuable. Beef tea must not be allowed to boil, or even become so hot that the albumen it contains coagulates, as this renders it less easy to assimilate.

*Beef. Above. Joints cut from the hind-quarter, as shown in page 155. 1. Flank. 2. Rump. 3. Silverside. 4. Loin. 5. Leg. 6. Topside. 7. Top-rump. 8. Aitchbone.*

Wash 1 lb. of lean beef and dry, cut in slices, and scrape these with a sharp knife. As each piece is scraped, lay it at once in a pint of cold water with  $\frac{1}{4}$  teaspoonful of salt and let it stand for half an hour. Then put the meat and water in an earthenware jar, tying a piece of thick paper over the top. Place the jar in a pan of boiling water on the fire and let the water simmer gently for  $3\frac{1}{2}$  hours, stirring occasionally. When cooked, strain out the meat, but do not use too fine a strainer, unless it is imperative that not a particle of solid matter is given. Season carefully with salt. If more convenient, the jar containing the beef tea can be put in a slow oven instead of in a pan of water. Serve with thin dry toast, unless the patient is restricted to a liquid diet.

Uncooked beef tea may be ordered in cases of extreme exhaustion. Usually only one or two teaspoonfuls are given at a time, as it is very strong. It should be prepared only in small quantities, as it will not keep.

Wash and wipe 3 oz. of fresh topside of beef, trimming off fat. Scrape the meat finely, and as it is scraped lay in a shallow dish with three large tablespoonfuls of cold water and a salt-spoonful of salt. Cover over and let it stand until the meat is almost white and the water deep red. Keep pressing the meat well. It will take an hour or more to soak sufficiently. When ready, pour through a piece of fine muslin, squeezing out all the juice.

For beef essence cut 2 lb. lean meat into small pieces, sprinkle with one teaspoonful salt, put into a covered dish with one tablespoonful water, and bake in a moderately hot oven for five or six hours. Serve a teaspoonful of the juice at a time, hot or cold.

**BEEF TEA CUSTARD.** A useful invalid dish. To make, beat one whole egg and one extra yolk lightly, but well together, without frothing. Heat  $\frac{1}{4}$  pint of beef tea, and pour gradually on to the egg and season. Strain the custard into well-buttered little moulds, twist a piece of buttered paper over the top of each, and steam slowly until firm. If cooked too fast they will be watery and full of holes. When sufficiently cooked, let them stand for a minute or two and then turn them out carefully.

**BEEFWOOD.** This wood, which is used by cabinet-makers, comes mainly from the various species of the Australian tree *Casuarina*. It is also obtained from the bully tree grown in Guiana. *See Wood.*

### BEEHIVE: CONSTRUCTION OF A MODERN TYPE Comprehensive Instructions for the Craftsman Beekeeper

For the Principles and Internal Arrangement of a W.B.C. Hive see the article Bee.

Modern beehives are of two main types, the Langstroth and the W.B.C. The former is an American invention dating from 1852, and an improved form is extensively used in Great Britain. The W.B.C. is a hive planned in 1890 by W. Broughton Carr, solely to meet the needs of British bee-keepers. Its internal arrangement is shown in the illustration under Bees and Bee-keeping on p. 139, and we give below all necessary instructions for making a hive of this type.

The hive is shown in perspective in Fig. 1. The outer case, including the roof, consists of three parts, and it is advisable to commence by first making the portion shown at Fig. 2.

*Beehive. Fig. 1.  
W.B.C. hive which  
can be made by the  
amateur woodworker*

*Fig. 2. Lower portion.*

*Fig. 3. Corner-lock joint.  
Fig. 4. Through-dovetailed joint.*

*Fig. 5. Details of slides. Fig. 6. Weather groove in porch.*

*Fig. 7. Upper portion  
of lift.*

*Fig. 8. Roof of case.*

*Fig. 9.  
Alternative  
method of  
making a roof.*

The construction may be by nailing the case together; if this is done, fine oval brads should be used, and the work should be skew-nailed so as to prevent the joints opening when exposed to the weather. Or, the construction may be by the combing or corner-lock joint (Fig. 3), and this would, of course, be glued and nailed at the joints. Thirdly, the worker could adopt the through-dovetailing method illustrated in Fig. 4.

The front and back boards of Fig. 2 are 19 1/4 in. long, 8 7/8 in. wide, and 1/2 in. thick: the sides, 19 in. by 8 7/8 in. of 5/8 in. material. The inside measurement, when fitted together, is 19 in. from front to rear and 18 in. across the front. A plinth 1 1/2 in. wide drops 3/4 in. below the edge of the case so as to fit around the floor board and carry off the wet. The two slides, A (Fig. 2), which enlarge or reduce the entrance, are 10 in. by 1 1/4

in. by  $\frac{1}{2}$  in.; these pieces pass through a rebated guide piece (B, Fig. 5), fitted below the porch. A is one of the slides.

The porch is  $4\frac{1}{2}$  in. wide, and a weather groove is worked along the edge (Fig. 6) to carry off the drip. This porch is supported at each end by two  $\frac{1}{2}$  in. brackets. The second portion of the outer case is a "lift"  $6\frac{1}{2}$  in. deep, the wood being the same thickness as the lower portion (Fig. 2). It is advisable to make this in duplicate. A sketch of this lift is given at Fig. 7, and the inset, lettered P, shows an enlarged end sketch of the plinth. The lift may be removed to reduce the height of the hive for winter, and a second lift may be added in the summer when necessary.

The roof is very simply formed with a view to lightness, and is thoroughly rainproof. Fig. 8 will make the main points in the construction quite plain. The front and back pieces are  $\frac{1}{2}$  in. thick,  $20\frac{3}{8}$  in. long,  $2\frac{1}{4}$  in. deep at the ends, rising to  $3\frac{1}{4}$  in. in the centre or ridge; the sides are of  $\frac{7}{8}$  in. wood  $20\frac{1}{8}$  in. long and  $2\frac{1}{4}$  in. deep. Along the lower edge of the side pieces a rebate is cut  $\frac{3}{8}$  in. by  $\frac{1}{2}$  in. deep. This allows the roof to slip over the upper portion of the outer case, and so dispenses with a plinth, whilst effectually keeping out the wet. The top of the roof is of  $\frac{1}{2}$  in. wood, each piece being 24 in. by 12 in. Where the parts meet at the centre the ridge piece (of 3 in. by  $\frac{7}{8}$  in. material) is cut on the underside to cover the joint as shown, so that no water can possibly get in. This roof portion should easily fit over the other; let there be no tightness anywhere so long as the bees cannot enter from the outside.

Some amateurs may prefer to use the type of roof shown at Fig. 9. By making the front and rear of the roof of the shape here shown, the necessity of working out a V-shaped recess under the ridge piece is removed. Suitable ventilation holes should be bored in the front and rear, and a small piece of fine wire gauze should be fitted behind the holes to keep out intruders.

The floor board may be made separate from the legs and supported by a distinct leg frame, or the floor may be built in combination with the splayed legs (Figs. 10 and 11). Beginning with the floor board, the boards forming it are  $\frac{1}{2}$  in. thick, tongued and grooved where joined, and nailed on to the stout battens  $2\frac{1}{2}$  in. deep by  $1\frac{1}{2}$  in. thick. Between the points at A it measures 20 in., and the width across is  $19\frac{1}{8}$  in. The sloping alighting board projects 7 in. beyond the point A. The form of the entrance, as seen in sketch, explains itself. It is  $15\frac{1}{2}$  in. long by  $\frac{1}{2}$  in. high. Fig. 2, of course, fits on to this floor portion.

The splayed legs (a single line plan diagram of which is shown at Fig. 10) are likely to cause some little difficulty to the amateur builder, and the following suggestions will considerably help him. Take a joiner's adjustable bevel and, with a protractor set the blade to 105 degrees, as shown at Fig. 12; then mark at the shoulder lines, as shown at Figs. 13 and 14. Cut the joint as shown, and it will be found that the portion

above the shoulder line fits closely into the corner of the frame, whilst the shouldered portion gives rigidity to the whole structure. The height from the floor proper to the top of the flooring boards of the hive may be about 12 in.

### Details of Body and Frame

The body box (Fig. 15) is  $15\frac{5}{8}$  in. by  $14\frac{1}{2}$  in. inside measurements. It holds ten standard frames and a division board (or dummy), along with two strips of thin wood  $\frac{3}{8}$  in. wide and  $16\frac{1}{2}$  in. long. The front and back boards are  $\frac{5}{8}$  in. thick,  $15\frac{5}{8}$  in. long by  $8\frac{1}{4}$  in. wide; side pieces,  $17\frac{1}{16}$  in. long, 9 in. wide and  $\frac{3}{8}$  in. thick. The strip of wood, D ( $16\frac{3}{8}$  in. by  $1\frac{3}{8}$  in. by  $\frac{1}{4}$  in.), nails on the outside to enclose the frame ends as shown. Prior to nailing on this strip, a piece of wood S ( $\frac{5}{8}$  in. by  $\frac{5}{8}$  in. full) is secured in position level with the top edge of the front and back boards, along which are nailed the tin angle-pieces forming the metal runners, whereon the frames (fitted with W.B.C. ends) work. Fig. 16 shows one end of a standard frame: the portion above A lies on the recess formed in the body box.

The shallow frame box (Fig. 18) is an exact counterpart of the body box with two exceptions: first, the depth is reduced to 3 in.; second, the front and back boards are only  $15\frac{5}{8}$  in. long. The capacity of this box is ten shallow frames  $5\frac{1}{2}$  in. deep with ordinary ends, and two thin slips of wood, or eight similar frames fitted with W.B.C. ends.

Beehive. Fig. 10. Leg frame with plan diagram.

Fig. 11. Flooring and alighting board nailed to frame.

Fig. 12. Joiner's adjustable bevel, set to 105°, for marking off splayed legs. Figs. 13 and 14. Two views of legs showing shoulder joints.

Fig. 15. Body box.

Fig. 16. Corner of standard frame.

Fig. 17. Housing joint for frame.

Fig. 18. Shallow frame box. Fig. 19. The eke placed beneath the shallow frame box.

The eke (Fig. 19) may be described as a slice 3 in. deep from the lower side of the body box (Fig. 15) and, beyond stating that the four slips of wood shown on the upper edge are for keeping it in position when fixed, the sketch explains itself. Fig. 17 is a sketch of the housing joint for constructing the frame, and due allowance must be made in the length of the front and rear pieces to fit this housing. The eke may be used for giving space below the combs in winter and, having served this purpose, by reversing and setting it above the frames in early spring it helps in tucking in additional

warm wrappings. Finally, when set below the shallow frame box (Fig. 18), it converts the latter into a full-sized brood chamber for standard frames.

Suitable timbers for the making of the hive are yellow pine and red deal, or a combination of the two woods. Where required, screws alone are used, and these are previously dipped in paint, the overlaps and plinths being screwed in their positions from the inside of the cases. Where the wood overlaps, it should have two coats of white lead and oil previously. The outside of the hive is generally painted middle green, the inside being left unpainted. The illustrations are taken from *The British Beekeepers' Practical Notebook*, Madgwick Houston & Co.

**BEE PEST: How to Counteract.** Also known by the name foul brood, this disease spreads so rapidly that, unless precautions are taken, a whole neighbourhood may become affected, and the chances of successful beekeeping therein will be seriously imperilled if not utterly destroyed. Two forms of foul brood have long been recognized as existing in Europe, a virulent or strong smelling and an odourless form. A third type, sour brood, has usually been found associated with the strong-smelling type.

When stocks are found to be weak and are working languidly, with little desire to fly and swarming little, foul brood may be suspected. If it is present, an examination of the combs will show cells containing dying or dead larvae, and others with their covers sunken or perforated.

Chilled brood must not be mistaken, as it very frequently is, for foul brood. The dead larvae of chilled brood turn first grey, and afterwards become nearly black, whereas in foul brood the larvae turn at first pale yellow and then brown, except in sour brood, when they turn from grey to yellow.

When the disease is discovered in a weak colony, the burning of bees, combs, frames and quilts together with a thorough disinfection of the hive, is the best course. The spores are then destroyed and the source of the infection removed.

If an affected colony be still strong, the bees may be preserved by making an artificial swarm into a skep or swarm box. The bees should be confined in the skep or box. They should be kept confined in a cool place, such as a cellar, for 48 hours without food, by which time all the honey they may have taken with them will have been consumed, and the diseased bees will have died. After the outside has been well painted with oil paint the hive will again be ready for use.

At the end of the period of starvation the bees should be hived into a movable comb hive in the same manner as a swarm. They are then fed for at least a week on syrup, to which as much naphthol beta as can be heaped on a threepenny piece has been added to every pound of white cane sugar used; the naphthol beta being dissolved in methylated spirit, sweet spirit of nitre, or whisky, and added to the syrup while warm

but not hot.

In the case of mild attacks disinfection or fumigation may be resorted to with success, hot soda water or sulphur being used.

These remedial measures are described in Bulletin No. 9, issued by the Ministry of Agriculture. Before attempting them it is advisable to consult an expert bee keeper. *See* Isle of Wight Disease, etc.

**BEER.** Beer is a fermented infusion of sugary substances with added bitters. At one time the sugary substance consisted of sugar derived from malted barley, and the bitters took the form of hops, but now sugar from other sources is used one of these being by the action of sulphuric acid on starch, and calumba chiretta, quassia, and other substances are used to give the bitter flavour. Notwithstanding these changes the beer may be perfectly wholesome, though many beer drinkers prefer to have the old brew when they can get it.

Beer is a food to a greater extent than other alcoholic liquor, mainly in virtue of the malt or sugar which it contains: but, as a general rule, it is taken as an agreeable form of bitter tonic to stimulate appetite and aid digestion: or it is taken to slake thirst. If taken with a meal it should be in moderate amount, as apart from the nature of a liquid, any large quantity taken during digestion dilutes the gastric juice and delays digestion.

During convalescence from acute illness, and in many cases of consumption, a glass of beer or stout makes a useful and agreeable tonic. Stout is often recommended to nursing mothers by their friends as a means of meeting the additional strain thrown upon them: but as a general rule it is much more satisfactory to leave alcoholic liquor alone, and rather to supplement the diet with extra milk. Stout and porter are beers to which colouring matter has been added. Formerly this was burnt malt, but now it may be caramel, molasses, or liquorice.

People who drink a lot of beer are apt to become stout, and gout and rheumatism may be other legacies of the habit. A beer-heart is one which has broken down under excessive strain, largely imposed upon it by the necessity of pumping through the blood-vessels of the body streams of blood swollen by inordinate beer drinking over a long period. Again the heavy drinker may produce permanent dilatation of his stomach, and chronic gastric catarrh may be a result of intemperate beer drinking.

One has always to be careful about the quality of the beer purveyed. A good beer should be clear, transparent, and reddish-brown in tint, and should not be soured. Beer is sometimes watered, and alum or sugar is added to produce a "head"; the beer goes bad very readily with an increase in its acid content. Such beer may upset the stomach in any quantity. During hot weather many people bring on sickness and diarrhoea by the combination of lager beer and fruit of some sort. There is always some common salt in beer, but in some samples this is materially increased, apparently with the object of creating thirst.

Beer becomes sour on standing in consequence of the growth in it of a minute fungus which converts the alcohol in the beer into acid. This acid is the one which is found in vinegar. If beer becomes dead—that is to say, only slightly sour—it can be restored by adding a teaspoonful of carbonate of soda to each gallon of beer, mixing well, and allowing to settle. The beer will recover a good deal of its sparkle and flavour by this means, but will have lost some of its potency.

If markedly sour the beer cannot be restored, but should be kept to make vinegar. This is done by allowing the beer to stand in contact with the air until souring has progressed to the required stage. The liquid that results may be used as vinegar after having been clarified by filtering through several thicknesses of muslin or through cotton-wool. *See* Ginger Beer; Lager Beer; Spruce Beer.

**BEE STING: How to Treat.** The constitutional effects of a bee sting may be severe, and are those of shock coldness of the body, faintness, etc. The sting should be searched for and removed. The best application is ammonia, but solutions of bicarbonate of soda, common salt, or permanganate of potash may be used. Where the sting is about the eye, mouth, or outer passage of the ear, ammonia would not be used. For the shock the patient is kept warm and stimulants given. If speedy relief is not obtained the doctor should be sent for. *See* Bite; Sting.

**BEESWAX.** Wax is not gathered by the worker bee, but is organically produced in her body from honey and pollen, by secretion beneath scales. When cleaning hives a box should be kept for the collection of all refuse and burr combs. The scrapings from the floor board during spring cleaning should be saved, for there is generally sufficient wax to make it worth the trouble of extraction. Wax can be obtained from old brood combs and the capping from extracting combs.

The following methods for extracting the wax are recommended by the Ministry of Agriculture (Bulletin No. 9); (1) The Solar wax extractor; (2) steam; (3) boiling water; or (4) the heat of the oven.

The solar wax extractor is really a miniature garden frame, with a double glazed and hinged light. Inside the frame is fitted with a metal tray which slopes down to a tin trough covered with wire gauze. The extractor is placed in a sunny position and the material to be treated is spread thinly over the bottom of the metal tray. The wax melts and runs into the trough being strained of impurities by means of the wire gauze covering.

The material to be extracted by methods (2) and (3) must be stored until required in an airtight tin for protection against the ravages of the wax moth. In the winter it can be melted over the kitchen fire by means of a Gerster wax extractor, an arrangement similar to a domestic steamer.

To extract wax by means of boiling water the material is tied in a bag made of porous fabric and

stood on laths of wood placed across the bottom of a copper or saucepan, so that the bag does not touch the bottom. The bag should be weighted with a stone, and water poured in until it flows above the bag. The water should then be boiled very gently. The melted wax will percolate through the bag and float on the water, and when cold it can be lifted off in a solid cake.

*Beeswax. Worker bee, enlarged to show scales where wax is secreted.*

The chief use of beeswax for domestic purposes is for floor and furniture polishes.

A floor polish is prepared by shredding yellow wax, 14 oz., and placing it overnight in spirit of turpentine, 32 oz. In the morning place the basin containing the above in a vessel of boiling water and stir until clear. Then remove the basin from the hot water and stir the polish occasionally until it is cold. Many accidents have happened in preparing floor polish through contact of the turpentine vapour with flame. By the above method no danger of fire need arise.

White wax, which is employed for cosmetics, cold cream, and ointments, consists of beeswax bleached by exposure to sunlight. The beeswax is melted and formed into ribbons by pouring it upon rollers partly immersed in water. *See Cold Cream; Cosmetic; Furniture Cream.*

**BEET.** Of the ordinary garden beet, *Beta vulgaris*, there are several species, but the only two other than the common kitchen-garden beet which are much cultivated are the spinach beet and the Chilian, the variegated form of which has extremely beautiful foliage and is much grown in flower gardens. There are both green-leaved and red-leaved varieties, and there are white-skinned as well as red-skinned roots.

Most of the beets are natives of Italy and other countries of Southern Europe, and are best if lifted from the ground and stored for winter use, instead of remaining in the soil.

There are two types of culinary root beet—the round and the long. The typical round beet is the turnip-rooted or Egyptian. The skin is dark red and the flesh crimson, but not so deep in colour as some of the long beets. It grows quickly, and consequently gardeners have come to use it for their early supplies storing only the long type. The flavour is excellent. Somewhat larger than the turnip-rooted, and yielding a heavier crop quite as soon, is the globe, in which the roots while quite as wide as the Egyptian, are deeper.

The flavour and colour are good.

Beet is usually offered for sale at shops in a cooked state. The reason for this is that the skin of the edible beet is very tender, and easily cut, scratched, or pierced. If such an accident happens in its raw state, the beet bleeds or loses its colouring matter, and, at the same time, its appearance and flavour. Hence the value of cooking the root as soon as possible after it has been lifted.

As a native of the seashores, beet appreciates a light, sandy soil, but it is not fastidious, and will succeed in the heaviest clay, provided the soil is made friable. It is raised from seed and thrives in most parts of Great Britain. Early sowing is not advisable for the long or parsnip-shaped beets, because, apart from the risk from frost, there is the danger of the roots becoming large and coarse. May is generally quite early enough, but in light dry soils sowing may be practised about mid April. The turnip-rooted and globe beets may be sown about a month earlier. As a further safeguard against coarseness it is usual to sow beet on ground which was manured for a fibrous-rooted crop the previous year. It may follow peas, beans and leeks.

The seed should be sown in drills drawn 15 in. apart and about 2 in. deep, rather less than more. It is well to sow a patch as a reserve, transplanting to the rows in showery weather as occasion may require. Then only hoeing and thinning will be needed until the crop is ready. Some like to sow the turnip or globe beet in July after early peas or potatoes, and useful roots are thereby secured. To store, fork beet lightly up in October, taking care not to pierce the taps, draw them out by hand, remove the tops, and lay them head to tail and tail to head in sand, covering with straw, bracken or litter to keep out frost. It is not the case that cutting off the tops necessarily leads to loss of sap and colour. As long as the leaves are ripe it does not matter whether they are cut off or twisted, if at least an inch of the stem of each leaf is left on the crown.

**Spinach and Seakale Beets.** Even the smallest of kitchen gardens is the better for a row or two of spinach beet, which grows to a height not including the flower-stem—of two feet or more in rich soil. The root is a parsnip-coloured tap. The seakale beet, which is the same plant as the silver beet, is even more vigorous than the spinach beet, from which it is distinguished by having broad, white midribs instead of somewhat narrow green ones. *See Beetroot.*

**BEET CARRION BEETLE.** The beetle which attacks the beet is flat-backed about half an inch in length, and of a blackish-brown colour, the wing-cases ridged in their length. The larva is a shiny black flat oval whose natural food is carrion, but in the absence of this it attacks the leaves of beet and mangold. The description applies to *Silpha opaca*, but a near ally, *Silpha atrata*, of blacker hue, is equally destructive.

*Beet Carrion Beetle, Silpha; right its larva, magnified*

The white eggs are laid in the ground in spring, and these soon hatching, the larvae are ready to attack the tender seedlings of the beet. When the leaves show signs of being eaten they should be examined carefully, and the insects picked off and destroyed. Stimulating chemical manures should be applied to give the plants a chance by rapid growth of outliving the injury. Where manures of animal origin are used these should be well worked into the ground in autumn, so as not to attract the beetle in spring.

**BEET FLY.** The grubs of *Pegomyia betae*, a small two-winged fly, known as the beet or mangold fly, feed upon the leaves of beet and mangold. The white eggs are laid in batches on the underside of the leaf, and if these are looked for in spring and early summer they may be destroyed by the pressure of finger and thumb. If allowed to hatch, the legless grubs eat the fleshy parts of the leaves, thereby impairing the health of the entire beet plant.

The application of artificial manure, by stimulating growth, may enable the plant to thrive, in spite of this set-back. If, however, some plants have had their leaves skeletonised, it is better to pull these up and destroy both plant and insects.

*Beet Fly, a dangerous pest to beets and mangolds; magnified.*

**BEETLE DESTRUCTION.** A beetle trap consists of a well into which beer or diluted treacle is put, and sloping ends which make the well accessible.

Attracted by the odour, the insects fall in and die. Phosphor paste spread on thin bread is a deadly lure. Store-room beetles of different kinds will be found on or in the food they attack.

In the case of furniture the problem is often difficult owing to the large size of the article attacked. If small, it may be subjected to a high temperature in the oven; but if large, corrosive sublimate dissolved in methylated spirit should be forced into the minute worm-holes with a fine syringe. If it runs over the surface it will spoil the polish.

*Beetle trap with delicately balanced plates that yield with the weight of the insect and drop it into a central well.*

Furs or feathers attacked by beetles may be treated by the hot oven process, but great care must be taken that the temperature is not so high as to scorch or singe the articles. Naphthaline in the wardrobe will keep the beetles away, but it may not kill those that have made their way therein.

**BEETROOT.** The root of the beet is rich in sugar. It must be boiled and left to get cold, and is then peeled, sliced, and served with vinegar, or used as an ingredient of salads. It is also served hot as a vegetable. Beetroots are usually already boiled when sold by the greengrocer, but if raw, wash before boiling. Do not touch the skin with a sharp instrument or the root loses its colour. Boil from one to two hours, according to age and size, adding a tablespoonful of salt. Press the skin with the fingers; if it begins to peel off the beet is ready. Drain well in a colander, and when cool remove the skin.

*Beetroot. Roots of the globe or turnip beet. (Photo, Sutton & Sons, Ltd).*

If to be served hot, peel at once on removing from water, slice and send to table covered with a dressing composed of a teaspoonful each of flour and mustard, and a piece of butter the size of a walnut, a teaspoonful of salad oil, and one tablespoonful of vinegar. This

dressing should be mixed with a little gravy, milk or cream, and boiled till it becomes as thick as melted butter or white sauce. *See Beet.*

*Beetroot. Roots of the long beet (Photo, Sutton & Sons, Ltd).*

**Beetroot Pickle.** Prepare a quart of malt vinegar for the pickle by boiling it with  $\frac{1}{2}$  oz. each of whole black peppers and allspice and grated horseradish, and then let it cool. Cook 4 large beetroots, peel and slice them, place in bottles, and pour the vinegar over. It is important to take care that the bottles are securely covered.

**BEGGAR-MY-NEIGHBOUR.** A simple card game for two people in which the pack is shuffled, and the dealer deals out the whole pack one at a time to himself and his opponent. The non-dealer has the lead, and he and his opponent turn up cards alternately. When certain cards are turned up by a player his opponent pays him as forfeit a certain number of cards. One card is paid if a jack is turned up, two for a queen, three for a king, and four for an ace. The cards are turned face up alternately by the players until one of the four forfeit cards appears, when payment begins.

If while turning up cards for paying a player reveals a jack, queen, king, or ace, he ceases paying, and his opponent in turn begins to pay the number of cards required as forfeit. When the whole packs of each player are played, the hands held by each are played out again, and the game is so continued until the cards are in the hands of one player.

**BEGONIA: How to Grow.** For foliage and bloom the begonia ranks among the best of greenhouse plants. The summer leafing or tuberous begonias are excellent for the cool greenhouse, or for bedding out during the warm months: the winter flowering or fibrous-rooted sorts are valuable under glass when the supply of blossom has become scarce.

The culture of the tuberous sorts is not difficult. An ordinary 15-inch box is big enough, with an inch of drainage material at the bottom and a layer of moss over it. The compost is one part leaf mould, one part loam and one peat with a dash of silver sand. Begonia seed is so tiny that a lot of it may be lost if any lumps are left on the surface. The box or pan should be immersed as far as the edge in a tub of water in order to soak the soil. Any excess of moisture should be allowed to drain away, and the seed carefully sprinkled on the surface. All that is then necessary is a covering of the finest silver sand. Another method adopted by some growers is to lay on a few flakes of clean moist moss instead.

Afterwards the box should be placed in a propagator or in an even temperature of 60°, and be covered with a sheet of glass and a piece of brown paper in December or January. When the tiny seedlings show they should be carefully shaded. In a month they will be ready for transplanting to other boxes. The seedlings should be kept thereafter in a moist atmosphere at as near 60° as possible. If they are to be grown in pots the next shift should be into a 3-inch pot. If intended for bedding they can be kept in boxes.

*Begonia. Waxy white flowers of a single variety of begonia in full bloom. (Photo, Sutton & Sons, Ltd.)*

#### Growing Begonias Out-of-Doors

Bedding plants should be carefully hardened. The beginning of May is usually the proper time to put the boxes in a cold frame. Begonias in beds should be well treated. The beds should be dug deeply and well raked over. It is advisable to add spent hotbed manure if available. The plants do best in semi-shade.

Many begonia lovers ignore seed and start with tubers purchased in winter or spring. In starting tubers into growth, lay them on a bed of fibre or in a box of leaf-mould in a moist position in an ordinary greenhouse temperature, where they can get at any rate half-light. All the little fibrous hairs should be carefully rubbed off.

The winter flowering begonias, of which Gloire de Lorraine and its forms are the principal sorts, are invaluable. Gloire de Lorraine is propagated by cuttings. The flowering period extends from October to February, and at its best the plant is a mass of beautiful bloom. After flowering it should be cut back and one or two plants put aside for young stock. New shoots appear after the pruning, and these, which should be removed with a heel of the old wood, form the cuttings. There are several winter varieties.

The rex begonia is grown for its foliage. Its leaves are large and ear-shaped; they are coloured in a great variety of ways, including remarkable combinations of silver greys, crimsons, and bronzes. Propagation is effected by means of the leaves. The best way is to cut half-way through the larger ribs and to pin the leaves

down upon the top of a pot or pan containing sandy loam and peat, just above the places where the incisions are made. In due course tiny plants will appear at the points of these incis-ions. Pron. Be-go'-ne-er.

**BELCHING.** Besides being common in certain types of indigestion belching occurs in hysteria and neurasthenia. The gas is not from fermenting food but consists of air which has been gulped down. All that may be necessary in the way of treatment is to limit the consumption of sweet or starchy foods. In hysterical cases half-teaspoonful doses of ammoniated tincture of valerian will generally suffice. *See* Flatulence; Indigestion.

**BELGIAN HARE.** This is a popular breed of rabbits. It is long in body, has large and prominent eyes, and in colour is red with black ticking. It attains a large size, can be easily reared, and is marketable at an early age. *See* Rabbit.

*Belgian Hare, a breed of rabbit used largely for table purposes.*

## BELLS: ELECTRIC & OTHER HOUSEHOLD TYPES

### A General Guide to their Installation and Repair

Electric Batteries for Bell work are described under Battery and Dry Battery; Appliances using Electric Bells under Alarm; Burglar Alarm; Fire Alarm, etc.

Bicycle bells are usually actuated by a lever and have a train of wheels and a rotating hammer that sounds the bell many times with once moving the lever, as shown in Fig. 1. Useful types of doorbell are those that have a press knob outside the door and a clockwork device within the bell itself, the hole mounted on the inside of the door, Fig. 2. By revolving the bell a spring is wound up, the action of the door

press being to release a catch and allow the spring to unwind. This by actuating a train of wheels and a rotating hammer causes it to ring while press is held.

*Bell. Fig. 1. Bicycle bell, showing rotating hammer.*

**Electric Bells.** An electric bell system consists of several distinct elements. These may be

classified as follows: (a) The source of the electricity to sound the bells. (b) The bells themselves. (c) The contacts or pushes. (d) Indicators to acquaint the person rung for with the whereabouts of the ringer. (e) The connecting link between all these elements, viz. the wiring system. So far as the source of power is concerned, this is usually obtained from a battery of dry cells or Leclanché batteries located in some convenient place, such as a dry cellar or the top of a cupboard.

*Bell. Fig. 2. Sectional view of doorbell actuated by a spring which is released by pressing a button.*

It is a true economy to begin by installing adequate battery power. The average small house of eight rooms will need a battery of three or four Leclanché cells. A large rambling building on three floors with a sub-basement may well need twice this number. Every yard of unnecessary wire in a circuit means so much current wasted, and any bad adjustment or faulty connexions will increase the resistance, and add to the demands upon the battery. The best place for a battery is somewhere near the centre of a system, as all the leads or connexions are then shorter, and current consumption is less.

For indoor use the wire generally used is No. 18 or 20 copper, india-rubber double cotton covered, and paraffined. It is known as No. 18 (or 20) I.R., D.C.C. This wire is usually tinned, to facilitate soldering and guard against oxidation. When measuring up for wire remember to allow for the corners and for waste. When ordering wire it is usual to purchase it in several different colours to assist in identifying the various leads. Twin wire consists of two separate fully insulated wires, enclosed in an outer covering of cotton. In this case one of the wires is usually identified by means of a coloured strand. Flexible wires are used for hanging pushes.

A method of fixing wires above ceilings is shown in Fig 4, insulated staples being used to fix the wires to the rafters. All joints in wires should be thoroughly well

made, as upon the closeness of their metallic contact will depend the excellence or otherwise of the system. Fig. 5 shows two methods. After the wires have been soldered the joint is covered with insulating tape (Fig. 6). This should extend for at least one inch each way on to the covering itself. Connexions to pushes and bells are generally made by means of a binding screw or terminal nut, as in Fig. 6.

*Bell. Fig. 3. Common type of electric bell. The lettering is explained in the text.*

The best bells are mounted on an iron frame independent of the wooden base, and provided with a dustproof cover. The type most frequently used is the trembling or vibrating bell illustrated in Fig. 3. It consists of an electro-magnet, A, fixed to an iron frame, B, provided with a soft iron vibrating armature, C, one end of which is fitted with a hammer. The other end is fixed to the frame by a spring, D, an extension of which carries a platinum contact. Fixed to the iron frame but insulated from it is a contact post, E, with an adjustable platinum-pointed contact screw.

When a press button is pushed, current flows from the battery, through the wires to one terminal of the bell, thence through the magnet coils, armature, contact screw and post to the other terminal and back to the battery. The circuit is thus complete, but as the current flows through the magnet coils it energises the core. This attracts the armature, causing it to move and strike a blow on the gong while at the same time the contact spring moves away from the screw and thus breaks the circuit. The current ceases flowing, the spring returns the armature to its starting point, when the contact screw again makes contact and closes the circuit. Owing to this continuous sequence of operations the bell continues to ring while the press is pushed. The contact points should be clean, and the screw adjusted so that the armature is free to vibrate. The armature should not touch the core. Usually this is prevented by a projecting stud of non-magnetic material on the core.

Continuous ringing bells are used in connexion with burglar and fire alarms. Their construction is similar to that of the vibrating bell, but with the addition of a catch on the armature, which engages with a lever to which is fixed a spring. This bell works as follows: First, the current flows as in the trembling bell, but as the armature moves it release lever, which falls against a second contact post. This closes the circuit through another wire to a third terminal, and thence to the

battery. The bell therefore continues to ring until the lever is again broken by resetting the lever.

Relays are necessary on long circuits, and many forms of indicator are improved by their addition. The apparatus comprises an electro-magnet with armature and contact screws. Its duty is to close a local circuit when actuated by a relatively weaker current flowing through the coils of its magnet.

*Bell. Figs. 4-6. Diagrams illustrating details of work in wiring an electric system.*

Bell pushes, pulls, and switches are made in various patterns and materials. Their purpose is the same, viz., to close or open a circuit at will. The contacts of a push consist of two metal plates fixed to the base; one flat, the other shaped like a pig's tail and sufficiently springy to lift itself clear of the flat or lower plate. The press button is held up by this springy contact. An improvement is the morse-key type of push (see Fig. 7).

*Bell. Fig. 7. Morse-key type of bell push. (Courtesy of General Electric. Co., Ltd)*

The pear push, mostly employed in bedrooms, consists of a pear-shaped handle suspended by twin flexible wires from a rosette on the wall or ceiling.

Switches are sometimes used in bell work to break a circuit or transfer it from one place to another.

A switch remains open or closed until it is again altered, whereas a pull or a push has to be held to keep the circuit closed.

With the aid of the foregoing notes the amateur should have little difficulty in tackling the installation of a new system or the repair or alteration of an existing one. The only real trouble is in knowing where and how to place the connecting wires or runs. For this purpose reference should be made to the different wiring diagrams, Fig. 8. In dealing with an existing system, either for purposes of addition, or to trace a fault, it will be necessary to find out the runs of the different circuits.

An ordinary vibrating bell may be employed to test the circuits. Any single circuit can be tested by localising it—attaching one end by a temporary wire to a battery and the other end to one terminal of the bell. A separate temporary wire connects the other battery terminal to the bell. Hence, the circuit being complete and closed, the bell should ring; if it does not, the fault will be somewhere in the circuit under test.

When dealing with a failure of the systems as a whole, suspect the battery or a broken wire. If one or more bells ring feebly and some not at all, then the battery is almost certainly run down. When only one bell fails, and the others are up to standard performance, look for trouble on the affected circuit. It will probably be found in the push, the adjustment of the contact screws of the bell or indicator, or a broken wire. The latter is, however, comparatively rare.

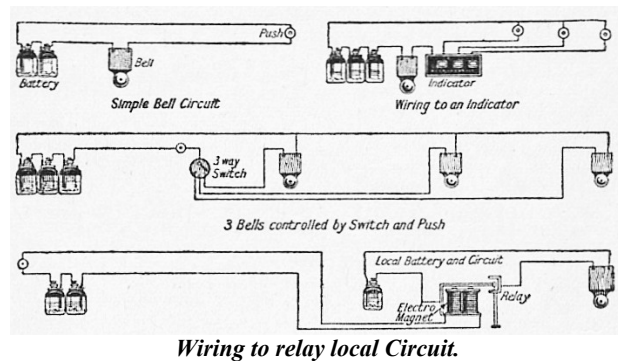

*Bell indicator with pendulum disk operated by an electro-magnet.*

**Bell Indicators.** In an electric bell system the indicator tells from which room a call has been received and so dispenses with separate bells. Indicator movements resolve themselves into two main classes—those that drop a shutter or move a disk and have to be reset every time the bell rings and those that swing like

a pendulum and do not require resetting.

A form of the pendulum variety is illustrated above. It consists of an electro-magnet fixed at one end to a metal frame. An arm on the frame lightly supports a pendulum armature from which is suspended a paper vane or disk. When the current flows through the magnet, the armature is attracted and set swinging and will continue to swing for some considerable time.

These indicators are generally mounted in a polished hardwood case with a glazed front, through which the paper vanes can be seen. This type of indicator seldom gives trouble; all that is needed to keep them in perfect order is to see that they are clean and that the wires and connections are sound.

*Bell. Fig. 8. Diagrams of simple electric bell systems which are easily installed.*

**BELLADONNA.** Both the leaves and the root of the deadly nightshade, or belladonna, are employed in medicine, the active principle being atropine. The liniment of belladonna often gives good results in neuralgia.

The symptoms of poisoning by belladonna, or deadly nightshade, are dryness of the mouth, impairment of swallowing and speech, thirst, dilatation of the pupils, dry skin, and frequently a scarlet rash, delirium, and unconsciousness. The best antidote is warm strong tea administered immediately. See Atropine Poisoning.

*Belladonna Lily. Cluster of the large delicately coloured flowers of the Amaryllis.*

**BELLADONNA LILY.** The popular name of belladonna lily is given to the Amaryllis, of which A. Belladonna bears rich deep pink or salmon-coloured flowers. It needs deep rich soil and the shelter of a southern aspect to thrive in counties north of the Thames. The bulbs should be planted in June and the

flowers appear, before the foliage, in August and September. The greenhouse or half-hardy species of the belladonna lily are known as *Hippeastrum* (q.v.).

**BELL CRANK.** A mechanical device for transmitting motion from one direction to another at an angle to it, usually a right angle. By suitable proportion of the arms a different stroke or pull is obtainable. The device is in extensive use on machinery, but derives its name from its application to domestic bells of the old spring-operated type.

**BELLEEK WARE.** While similar lustreware is manufactured in Glasgow, Staffordshire and the United States, the true Irish porcelain from the factory at Belleek on Lough Erne is easily distinguished by its characteristic mark, stencilled or stamped in colour, of the name with a device of a round tower, greyhound, harp and shamrock leaves.

For a quarter of a century after 1857 the factory turned out its best thin, eggshell type of parian ware, sometimes with an ivory glaze and a mother-of-pearl lustre. *See* China.

*Belleek Ware. Basin of genuine tinted porcelain made in the North of Ireland.*

Bell flower. *See* *Campanula*.

**BELL GAUGE.** Made of nickel-plated steel, and shaped as shown in the illustration, this is used for measuring knitting needles and crochet hooks. The latter should pass through easily and never be forced. For sizes 1 to 5 use the holes, but for sizes 6 to 24 inclusive use the slits leading into the holes, the holes in these particular sizes being intended to release the pins when gauged. *See* Crochet: Knitting.

*Bell Gauge for measuring knitting needles and crochet hooks.*

**BELL-GLASS.** A glass vessel, bell-shaped, with a knob at the top, this is made in various sizes, the mouth fitting into an earthenware saucer. Seeds sown in a pot and stood in the saucer under the glass will rapidly germinate and grow, owing to the close, moist atmosphere. Bell-glasses are also invaluable for forcing cuttings quickly to take root, or for growing seeds that need the protection of glass in their earlier stages. In the largest sizes—those which are used for the French system of intensive horticulture—the native word *cloches* is now so usually applied that it has become anglicised.

**BELL METAL.** The metallic alloy used in

bell-casting is generally composed of 78 p.c. copper and 22 p.c. tin. The material is expensive, but by its use alone can a good tone be obtained. Bell metal is occasionally used for very high-class cooking utensils, such as stewpans and kettles.

**BELLOWS.** In their simplest form bellows are elementary types of air compressor, adapted for blowing fires. The same principle is frequently applied to the bellows used for blowing the organ in a church or hall, to vocalise certain small toys, and to actuate part of the mechanism of a player piano. A concertina is another type of musical instrument embodying bellows to act as artificial lungs. Many cameras have bellows to exclude extraneous light rays from the lens and photographic plate. (*See* Camera).

Bellows are designed for single action, double action, or treble action, according to the number of stages through which the air is compressed. An example of the first is the domestic fireside bellows. Double-action bellows are largely used for small brazing and blacksmithing obs: a usual form operated by foot power.

**BELL'S PALSY.** Paralysis of the muscles of the face is known as Bell's palsy and is usually confined to one side of the face. The cause may be exposure to cold, as when a person sits at the open window of a railway carriage, or a blow in the region of the ear. It may also be brought about by diphtheria, meningitis or ear-troubles.

When due to cold, a mustard leaf should be applied behind the ear and the patient protected from further cold. If there is much pain 10 grains of aspirin may be given. Medical advice must be taken.

*Benares Ware. Simple engraved lota, a vessel employed in Hindu ritual. (Victoria & Albert Museum) (Indian Section.)*

**BENARES WARE.** The decorated brassware produced by Hindu artisans at Benares includes trays and salvers plates, tumblers, hookahs, gongs, and various forms of waterbottles and ewers. Especially graceful are the melon-shaped lotas, used for religious purposes. Cheap Benares ware has been produced for export, with shallow designs based on foreign requirements, such as jardinières and ash-trays. The inside of a piece of lemon rind rubbed hard on the surface and washed off with hot water will clean the article ready for polishing with a soft, dry cloth. Ordinary metal polish should never be applied. Good pieces, which should not be lacquered, may be cleaned with a mixture of sweet-oil and rottenstone, free from grit, rubbed in with a flannel, and finished off with soft

leather. *See* Brass.

### THE BENCH: FOR CARPENTER AND MECHANIC

See also Amateur Carpentry and the articles on Chisel,  
Hammer, Saw and other tools

The combined bench and cupboard shown in Fig. 1 is within the capabilities of any amateur. Convenient sizes are 3 ft. long, 1 ft. 9 in. wide on top, and 2 ft 9 in. high. The legs are 2 ft. 7 in. long, made from 2 in. x 2 in. deal, the cross-pieces of similar scantling mortised and tenoned into the legs. The back and ends are enclosed by  $\frac{3}{8}$  in match-lining, nailed in place, while the top is made from two pieces of 11 in. x 2 in. deal glued and pinned together and screwed in place with  $3\frac{1}{2}$  in. screws passing through the framework.

*Bench. Fig. 1. Combined bench and cupboard.*

The front is enclosed by two simple doors hung on 6 in. cross garnets and provided with a bolt. The floor is of match-lining; and the shelves and racks are cut from 6 in. x  $\frac{5}{8}$  in deal.

A few small drawers at the bottom accommodate screws, nails and other small parts. A backboard 4 in. wide and  $\frac{5}{8}$  in thick prevents the tools falling off at the back. A portable bench vice with a clamp fitting is very convenient; it is fixed up in a few moments, and when not wanted is accommodated within the cupboard. The various tools are supported on racks or shelves or hang from hooks, as may be most convenient.

The regulation joiner's bench, as a general rule, is made of beech wood or other hard material. The top fits into special slots, the cross rails being secured by long hardwood wedges. Two vices are fitted, one for ordinary use at the left hand end of the bench, the other, or tail vice, works longways of the bench and acts as a cramp for wide work. Square holes and the pegs provided to fit them enable work of widely varying widths to be held firmly. A tool-well prevents the tools getting in the way of the work, while a drawer holds others not needed at the moment. Convenient sizes for such a bench are: 6 ft. long, 2 ft. wide, 2 ft. 6 in. high,

legs 4 in. square, rails 3 in. x 2 in., top 3 in. thick. A portable carpenter's bench of a useful type is shown in the picture of a workshop on page 23. Such a bench may be purchased ready for use, or it is quite easily constructed.

Where a regular workshop is available it is frequently possible to build in a work bench. This is both economical and practical; stiffness and rigidity are assured, and for metal work it is preferable to the portable benches. One important item is to see that the bench stands fair and square on the floor: it must be accurately levelled, which may be done by means of suitable packing beneath the legs.

The construction of a mechanic's bench is illustrated in Fig. 2. A convenient height is 34 in., with a width of 30 in. and a length of 6 ft. The top is composed of oak or other hardwood 2 to 3 in. thick at the front, and 1 in. thick at the back.

The design of such a bench needs careful attention. The legs must be at least 3 in. square and very well framed up with diagonal cross braces and stout longitudinal members. The thick top may be bolted to the cross members, the bolt heads being sunk below the surface of the bench and the holes neatly plugged.

*Bench Stop. Left, wooden stop to insert in mortise. Right, rising metal stop controlled by screw.*

**BENCH STOP.** This is a hardwood or metal stop, fixed or adjustable, against which work is rested on the bench when planing, etc. In its simplest form it may be a wooden strip screwed to the bench top a short distance from one end, close to the front edge of the bench. Another kind of stop, made from a piece of hardwood about 4 in. long by 2 in. square, is mortised through the top of the bench about 2 in. from the edge. The stop fits tightly in the mortise, and is knocked upwards or downwards with a mallet to adjust its height above the bench. A face iron may be made by heating and flattening the end of a piece of 2 in. iron, and cutting serrations in its edge with a saw file. (*See illustration*).

Adjustable metal stops are made in various patterns, and are easily fitted to the bench top. In one type the stop piece is hinged at one end to its plate, and is raised or depressed by turning a large screw-head in the plate. In another type the stop rises and falls in a socket as the adjusting screw is turned.

**Bench. Fig. 1. Front elevation and end.**

**Fig. 1. Plan of framing.**

*Joints used. A, top rail, dovetail;  
B, cross rail, tenon;  
C, bottom rail, mitred tenon.*

**Bench. Fig. 2. Diagrams explaining the construction of a mechanic's bench.**

## BENT IRON WORK: SOME OF ITS USES

### A Process that Can Be Used to Beautify the Home

See further the entries on Lacquer; Piercing;  
Wrought Iron and other related subjects

Bent iron work is used for numerous household articles, including grilles, screens, lamps, stands for flower bowls and vases, wall brackets, photograph and picture frames, and other purposes. It varies in character from work done at a forge on red hot metal to that which is easily done cold by bending with pliers or with the fingers.

Bent iron work is often practised as a hobby by amateurs at home. Only a few tools are required, and the skill consists mainly in producing graceful curves, symmetrical proportions, suitable designs and secure unions of parts. The iron can be bought in coils, or strips of it can be cut with shears from sheet metal. Most of it is about the thickness of ordinary tin plate, and bends nearly as easily as the latter. Widths range from  $\frac{1}{8}$  in. to  $\frac{3}{8}$  in. In most articles there must be something in the form of a frame, or substantial element, to which the comparatively weak and slender ornamental work can be attached. The apparent endless variety is made up of a few elementary forms repeated continually. These are shown in Fig. 1. Besides these we get plain circles and ovals.

The strip of metal is cut with shears and then bent with pliers. Round-nose pliers are used for bending small curves, the unbent part being held with flat-nose pliers or with the fingers. Pliers are used to hold the strip securely and to bend a little at a time. They are moved along as required, and the workman judges by his eye when the curve is correct. Heavy, flat pliers are used afterwards to assist in taking out kinks and improving the curve.

Parts in contact are generally held together by clips (Figs. 2 and 3). These are made from the ordinary strip and pinched tight with pliers. Sometimes joints are riveted and sometimes soldered. Riveting is only practicable when the parts can be laid on an anvil for hammering the rivets. Holes for rivets are generally punched. In thick metal—that is, more than about  $\frac{1}{16}$  in.—drilling is the only way. In metal too thin to be countersunk the rivets used must be of the types shown in Fig. 4.

*Bent Iron Work. Figs. 1-6. Scrolls and joints used in the work. Figs. 7-13. Characteristic patterns for brackets, grilles, etc.*

Fig. 5 shows a rivet in place before it has been closed by hammering, the type of rivet shown being the cup-head or snaphead. The tool shown in Fig. 6 is used, in the same way as a punch, for imparting a neat convexity to the tail of the rivet, after the preliminary work has been done with the hammer only. A block with a similar concavity should be placed beneath the head of the rivet to keep it from flattening on the anvil.

Small bolts are occasionally used instead of rivets. For soldering, the surfaces must be cleaned and flux applied. They can then be coated with solder and pinched together with hot tongs, or bound with wire and heated by a flame, or pinched with pliers while the solder is running. Of all the above methods the clip is the most popular and the quickest.

*Figs. 14-15. Stand for a copper or china bowl.*

**Use of Twisted Strips.** Fig. 7 shows how strip can be twisted, either for appearance or to make it equally stiff each way. The ends are held with pliers or, preferably, one end is held in a vice and the other twisted with pliers. Fig. 8 shows chain made from strip iron. Fig. 9 shows examples of sheet metal ornaments. These are often of copper and, strictly, they are classed as repoussé rather than bent iron work.

Fig. 10 shows a wall bracket, the frame of which consists of stout iron rod. Fig. 11, made entirely of bent iron, is a stand made to suit a glass or china vase. Fig. 12 shows how the large areas of grilles and screens are filled in by a repetition of some simple pattern. Fig. 13 shows the same method applied to narrow borders.

For the floating flower bowl, shown in Fig. 14, a polished copper or brass bowl can be used, or one of brightly-coloured china. The combination of a flame-colour bowl with the dull black iron is very effective for table ornament. Make the foundation ring, A (of a size to suit the bowl), from stout iron, to which is attached the ornamental ironwork. The stand is made in two units, as shown in Fig. 15, each composed of three parts; these, when made up, are riveted to the foundation ring and form the four legs.

*Bent Iron Work. Figs. 16-18. Standard floor lamp and details of its construction.*

**Making a Standard Lamp.** A design for a floor lamp is shown in Fig. 16. First choose the lamp and make the top ring to suit it from  $\frac{3}{8}$  by  $\frac{3}{32}$  in. metal. Then cut a piece of gas barrel  $\frac{3}{4}$  in. outside diameter, and at the lower end fit a gas flange, screwing it on to the tube. The flange has to be cut away to form three arms (Fig. 17) and to these the bottom legs of  $1\frac{1}{4}$  by  $\frac{3}{16}$  in. iron are riveted or brazed. The long and continuous outer members, A, of  $\frac{3}{8}$  by  $\frac{3}{16}$  in. iron, and then the pieces B (Figs. 16 and 18) are bent and riveted in position. The inner ends of the latter are turned down into the bore of the upright pipe and secured by driving in a  $\frac{3}{16}$  in. Whitworth nut filed to fit as in Fig. 18. This part is completed with a rosette and ball head screw. The remainder of the decorative work is carried out in ordinary  $\frac{1}{4}$  in. strip iron, shaped

and clipped in place as shown in Fig. 16. The result is a handsome standard for an oil lamp. If desired, the design could be readily adapted to take an electric lamp, the fittings and shade carrier being purchased complete.

Bent iron is generally given a dull black finish. Dead black paint for iron can be obtained ready for use, or can be made by mixing drop black with turpentine and adding a small amount of gold size. Brass and copper ornaments should show their natural colour, but may be lacquered.

**BENZENE.** Also known as benzol, this is a colourless liquid distilled from coal tar. It is highly inflammable and requires careful handling. As a solvent of fats and oils, benzene is often used to remove grease stains from clothes and gloves, which it does without affecting the colour of the material. *See Stain.*

**BENZINE.** Similar to benzene as a grease solvent, benzine, which is obtained from petroleum, is cheaper and more widely used. Perfumed benzine is made by adding lavender oil 1 dr. to each pint of benzene. In using perfumed benzine the material should be laid on several folds of clean blotting paper, the stain covered with a few drops of the benzine, dusted with fuller's earth and pressed. *See Stain.*

**Benzoin.** *See Friar's Balsam.*

**Benzol.** *See Benzene.*

**BEQUEST.** The gift by will of anything except land is called a bequest and is the same thing as a legacy. When a specific article, e.g. "my watch," is bequeathed, the legatee is entitled to it subject to payment of debts, regardless of the fact that no one else gets anything. A general bequest is of a sum of money, e.g. "I give to John £100." If there are a number of such legacies, and the assets are not enough to pay them all in full, they should be reduced rateably. A residuary bequest is a legacy of what is left after paying specific and general bequests. *See Legacy; Will.*

**BERGAMOT.** When lightly rubbed the foliage of some bergamots diffuses an agreeable aroma. It is a hardy herbaceous perennial growing about 2 ft. high, and has square stems, hairy leaves and whorls of crimson flowers in summer. "Cambridge Scarlet" is the best variety. The sweet bergamot, an excellent plant for small herbaceous borders, thrives in any fairly fertile and friable garden soil. Propagation is by seed sown under glass in March, or outdoors a few weeks later; also by division in autumn or spring.

The only other species of note is the wild bergamot, a somewhat taller plant with purplish flowers, also having aromatic leaves.

The essential oil of the same name is obtained from a variety of orange, taking its name from the town of Bergamot. Its rind yields a very fragrant oil used in

high-class confectionery, liqueurs, and largely in perfumery. Bergamot is sold as an essence. Pron. Ber'-ger-mot.

*Bergamot.  
Flowers and  
leaves of the  
fragrant  
garden herb.*

**BEST MAN.** A relative or personal friend who accompanies the bridegroom to the church or wherever the ceremony is to take place. Previously he has seen that the necessary arrangements have been made and received instructions from the bridegroom as to what he wishes him to do. With the bridegroom he stands in position to receive the bride, and remains just behind the pair during the ceremony. At the right moment he hands the ring to the bridegroom and he accompanies the newly married pair to the vestry, where he usually signs the register.

If a reception follows the ceremony, the best man helps to attend to the comfort of the guests. The best man sees to the payment of the officials who have assisted at the marriage service — the clergyman or registrar, the organist and others that are necessary, and distributes gratuities. *See* Marriage; Wedding.

**BEVEL GEAR.** The use of bevel gears is for transmitting motion from one shaft to another when their centre lines are at an angle to one another. The teeth are cut radially and to an angle or bevel formed on the outer part of the face of the wheel, the angle and shape of the teeth being determined largely by the relative diameters of the pair of wheels. Two equal size bevel gears that are used to transmit motion at right angles are known as mitre wheels.

*Bevel Gear.  
Straight  
toothed bevel  
wheel and  
pinion.*

Familiar applications are the gears on egg whisks, hand drills, butter churns and some makes of window control gear. *See* Gear.

**BEVELLING.** It is chiefly in woodwork that bevelling is found; it means the production of surfaces which are neither at right angles nor parallel with each other. A box or tray with splayed or sloping sides and ends, or the body of a barrow, are instances where joints are bevelled to obtain the required shape of the article. In other cases an exterior surface may be bevelled in relation to other surfaces, e.g. the top edge of a plinth.

In furniture, edges are frequently chamfered, which means planing off the angles so that a narrow flat at the angle of 45° is formed. Parts meeting with a joint at 45°, such as the corners of picture-frames are said to be mitred. A sloping joint uniting pieces in the same plane is a scarfed or spliced joint. All come under the heading of bevelling.

As a general rule lines are marked on the work to show the exact extent of the required bevel, and the cutting tools work to these lines. In other cases appliances are used for guiding the tools. In sawing small pieces at an angle of 45° a mitre box or a mitre block may be used to guide the saw. For planing the angles two types of shooting boards are used. These may be for 45° only, or adjustable to any angle. One kind is used for planing long edges (Fig. 1), the other for short ends (Fig. 2). In both the plane is used lying on its side. It is slid backwards and forwards with the right hand, while the work is held in position with the left.

*Bevelling. Figs. 1-5. Diagrams illustrating methods of making edges in carpentry.*

A woodworker's bevel is used for marking lines (Fig. 3) and testing (Fig. 4). The bevel is adjustable to any angle, and is tightened by a screwdriver or by a wing-nut. Definite angles are obtained from a protractor, or by drawing a full-size view of that portion of the work on paper. Fig. 5 shows a type of bevel used chiefly by metal workers. Besides this there are bevels in combination with protractors.

**Beveren Rabbit.** This rabbit is largely bred for its pelt; there are two varieties, one slate blue, the other white. *See* Fur; Rabbit.

**BEZIQUE: For Beginners.** Bezique is a game of cards for two, three, or more players, and is played with two or more packs, one for each player, shuffled together. The packs do not contain the sixes, fives, fours, threes, or twos. The cards, in order of importance, are ace, ten, king, queen, knave, nine, eight, seven. For the sake of simplicity the game for two players will be described.

Two ordinary packs, with the noted cards removed, are thoroughly shuffled together and cut by the two opponents, the player cutting the higher card having the right to deal. The dealer deals out the cards, three to his opponent, three to himself, then two to his opponent, two to himself, and finally three to his opponent and three to himself. The 17th card is turned up for trumps, the remainder of the pack, face downwards, lying between the two players. If the turn-up happens to be a seven the dealer scores 10 points.

The game is 1,000 up, and the points scored are for the following combinations held by the players, and declared by them, i.e. placed face upwards on the table. The table gives the names of the declarations:

	Points
Bezique (queen of spades and knave of diamonds, or queen of clubs and knave of hearts, according to trumps)	40
Double bezique (both queens and both knaves)	500
Sequence (ace, ten, king, queen, knave of trumps)	250
Common marriage (king and queen of any suit save trumps)	20
Royal marriage (king and queen of trumps)	40
4 Aces	100
4 Kings	80
4 Queens	60
4 Knaves	40
Seven of trumps (turned up)	10
Playing seven of trumps	10
Exchanging seven of trumps for trump card	10
Winning of last trick	10
Each ace and ten in tricks of scoring player	10

The play is as follows: Each player looks at his hand, and the dealer leads a card which he thinks he is least likely to want for one of the combinations given in the table. His opponent need not take any trick, though if a ten or an ace is played he generally tries to do so, since such cards count towards his score at the end of the game. He may also wish to take a trick because he wishes to declare one of the combinations enumerated. He need not follow suit, and may take a trick by playing a higher card of the same suit or by trumping.

Whichever player takes the trick turns over the two cards, and then either declares any combination he may wish to do, or takes another card from the top of the pack. His opponent takes the next card, so that each player makes up his cards again to eight. One of the drawn cards may provide a card of a required combination, but a player cannot declare until he has won another trick. He must, too, declare anything before taking another card.

The trump card may be an important one, e.g. the

ace or ten, and a player may exchange it with the seven of trumps, if he holds that card, on winning a trick. Playing either seven of trumps in this way, or playing it on a trick, except when playing the last eight cards, entitles the player to score 10.

### When to Declare Bezique

Each declaration, as made, must be laid down face upwards on the table. Bezique is declared by placing the proper queen and knave on the table. The bezique queen and knave must be of opposite colour and neither may belong to the trump suit; i.e. bezique must either be queen of spades and knave of diamonds or queen of clubs and knave of hearts. Double bezique may be declared either by placing both queens and both knaves on the table, or by first declaring bezique and then afterwards adding the other two cards. But all four must be on the table at the same time to obtain the double bezique score. Should the bezique be declared and the cards afterwards played, the player may afterwards hold the second queen and knave, but he can only declare bezique with them and not double bezique. The same rule applies to all combinations, i.e. all the cards of that combination must be on the table at time of declaration.

Sequence consists of ace, ten, king, queen, and knave of trumps. The king and queen may be declared first (but not afterwards) as a royal marriage, and the other three cards added when convenient. In some forms of the game a royal courtship is allowed, scoring 20 points. This consists of the knave and queen of trumps.

### Use of Cards a Second Time

Cards once declared in a combination cannot be used again for a similar combination, as for a royal marriage. Such cards, however, may be used a second time in different combinations, e.g. the ace in sequence may be used to form one of four aces, the queen in bezique may be used with three other queens to give four queens, and so on.

The play goes on as described until the stock between the players is finished, and each player is left with eight cards. Though he may, by his very last card, complete a combination, he cannot now declare it. The last trick before the stock is finished counts 10 points to the winner, and in playing the last eight cards players must follow suit, if possible. If not, they are at liberty to trump. When the final card is played each player goes through the tricks he has won and counts the aces and tens he has in them, these being added to his score.

The following are a few hints on playing. First of all it will be found by a player that he often holds parts of one or more combinations. It will not be always possible to keep all the cards, and one or more cards of a wanted combination will have to be played on tricks. In such a case it is better to keep four kings and four queens than four aces. The two former sets can always be used for marriages and so increase the score.

It is not always advisable to declare or play valuable cards as early as possible. To play one of two kings of trumps before any declaration tells your opponent that you have both kings, and he will not trouble about getting sequence.

When the number of cards in the stock is becoming low, it is advisable to take as many tricks as possible and to declare everything at once, and not separately. That is, if you have sequence, declare it as a whole and lose the royal marriage score.

In three-handed bezique, played with three packs of cards, triple bezique may be scored, counting 1,500 points, and the game is often fixed at 2,000 up. With four-handed bezique, players may either play for themselves or act as partners, as at whist. In the latter case each player may declare when he or his partner has won a trick.

**BIB.** A baby's bib can be made from a double square of bath towelling bound with white tape, cutting a semicircle from the square to fit the baby's neck and attaching tie-on tapes. Bibs are also made of silk over a pad of cotton-wool quilted and lace-edged.

**BICARBONATE OF SODA.** In conjunction with cream of tartar, bicarbonate of soda is used in making baking-powder. It is also frequently employed in the making of scones, etc., in the proportion of about  $\frac{3}{4}$  teaspoonful to a teaspoonful of cream of tartar and 1 lb. of flour. For soda cakes it is used without the cream of tartar. If too much soda is used in a cake it will flavour it disagreeably and give it a yellow colour.

It is also valuable as a medicine, being given for indigestion in doses of ten to twenty grains, dissolved in water. It is also taken in the form of compressed tablets, known as soda mints, containing ginger and peppermint. Moistened with water and applied to the part, bicarbonate of soda relieves the pain from insect stings. *See Baking Powder; Soda Cake.*

### THE BICYCLE AND ITS MECHANISM

Care and Adjustment to Secure Good Running Order  
The articles on Ball Bearing; Brake; Chain; Coaster Hub; Three Speed Gear; Tire, and other parts of the Bicycle should be consulted. *See also Motor Cycle.*

Dealing first with the frame of the bicycle, the two parts requiring attention are the ball races in the steering head and the cup cones of the bottom bracket. To keep out any wet, the cones A (Fig. 1) are a press fit into their housings. These cones may be driven out from the inside and replaced with new. The cone B at the crown of the front forks is only a light press fit, so can be easily replaced. Ball races must not contain a full ring of balls; there must always be one short. The object is to allow freedom of movement for the balls.

When the head is complete, as shown at Fig. 1, tighten down the lock ring C just sufficient to stop all looseness, and no more. After seeing that the handlebars are the right height and square with the front wheel, tighten the nut D.

*Bicycle. Figs. 1-6. Diagrams illustrating some of the more important parts of the mechanism.*

With the bottom bracket (Fig. 2) the inner cones, A, are in most cases in one piece with the spindle, B, that carries the cranks. The outer races, C, are carried in the bottom bracket shell. In assembling, set the balls in the outer races with vaseline, and first screw the ball race on the chain sprocket side into its original position. This assures correct alinement of the chain over the sprockets. Next screw in the other outer ball race, finally locking by the means provided. When fitting the cranks on to the spindle, take particular note to fit the head of the cotter pins head to tail, i.e. if the head of the sprocket cotter is on top; the head of the other one must be underneath. If this is not observed the cranks will not be in line. When fitting new pedals it will be found that they are screwed into the crank, a left-hand thread being used for the sprocket-crank and a right-hand thread for the other.

The hubs of the wheels follow two distinct types. In one the adjustment is carried out by the cone, A, on the spindle (Fig. 3); in the other the outer race, B, is used as the means for adjustment (Fig. 4).

Where adjustment of the wheel bearings is by the former means (Fig. 3), it is advisable to leave the bearing very slightly slack; the thrust transmitted to the cones by the nuts that hold the wheel in place between the forks will take up the slack that was left.

Should the rims of the wheels be out of truth, remove the tire and tapes that cover the ends of the spokes. Then mount the wheel between the forks, turning the bicycle upside down so that it is supported on the handlebars and the seat, and give it a vigorous spin. Now hold a piece of chalk to the edge, allowing it to approach the spinning rim until it just catches the high

places. Stop the wheel, and with the nipple-key tighten all the spokes on the opposite side to the chalk marks, and slightly let down all the spokes on the same side as the chalk marks. Then wipe off all marks, and repeat the process until the rim runs true. When finished, the tone of all spokes should be nearly the same; but if there is a considerable difference, work at it until a fairly uniform note is achieved. After any adjustment to the spokes, file down any ends that may be protruding through the nipples.

If the machine is fitted with a free wheel it will probably be one of the two types shown in Figs. 5 and 6. To remove the free wheel from the hub of the wheel, first undo the lock-ring. Since this will have a left-hand thread, it must be turned in a Clockwise direction. Next, by means of the holes that will be found on the face of the free wheel, slack this off with a punch and a light hammer. In this case turn it in an anti-clockwise direction, as it has a right-hand thread. In most patterns a repair of the mechanism is impracticable.

Of the saddle there is little to be said, except that an occasional dressing applied on the under side with a leather preservative will help to keep it in good condition.

When adjusting the chain remember that there is sure to be a tight place during the complete travel of the chain's length round the sprockets; therefore, find this tight place and adjust accordingly, not too tight. Also note that the wheel is central between the bottom forks, otherwise the machine will not track properly, neither will the chain be in true alinement. Do not forget that, where fitted, the back brake, if of the bottom stay pattern will also need adjustment.

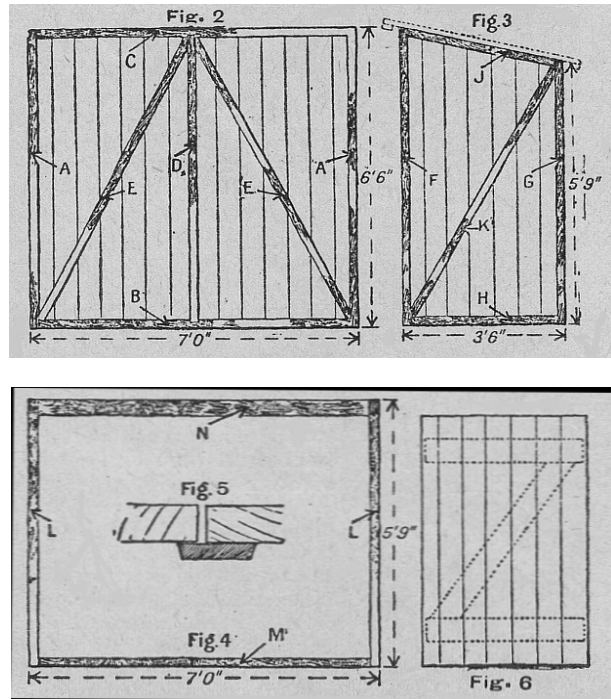

**BICYCLE SHED:** How to Make. A portable shed for two cycles, framed up in sections, is shown in Fig. 1. The front, back, ends, and roof are made up in separate parts, and are fixed together with bolts and nuts.

*Bicycle Shed. Fig. 1. Simple shed for making which instructions are given in de text.*

The framing should not be less than 2 in. square. That in the back (Fig. 2) consists of two end uprights, A, bottom rail, B, and top rail, C, which are half-

lapped and screwed together. There is an inner upright, D, which is notched into the top and bottom bars, and nailed in position; and the frame work is strengthened and kept rigid by the stays, E, which are fitted and nailed in position. The ends (Fig. 3) each consist of a back upright, F, front upright, G, bottom rail, H, and top rail, J, which are half-lapped and screwed together. The stays, K, are simply fitted and nailed in position.

*Figs. 2-6. Diagrams giving working details and dimensions. (By arrangement with Evans Bros. Ltd., London)*

The front framework consists of two end uprights, L, bottom rail, M, and top rail, N, which are half-lapped and screwed together. The top rail should be 4 in. deep, or it may sag when the roof is fixed. The bottom rail should be framed into the uprights so that the face of uprights projects 1 in. beyond face of rail. The ends and back are covered with  $\frac{3}{4}$  in. grooved and tongued match boards, fixed with the joints running from top to bottom. The boards on the ends should overhang  $\frac{3}{4}$  in. at the back edge to cover the edge of the boards on the back. The front and back sections fit between the end sections, to which they are fixed with bolts and nuts.

The roof should be of 1 in. match board, with the joints running from back to front, and overhanging 3 in. all round. The boards are held together with battens fixed across the under side. The roof is screwed on. A pair of doors are made from 1 in. matchboard battened together, as at Fig. 6, and hung with hinges. The left-hand door is fitted with bolts at the top and bottom, and the right-hand one with a lock, while a fillet is fixed on this door, to cover the joint, as at Fig. 5. The bottom of the shed is covered with 1 in. boards, resting on the bottom rails of framing. When complete give three coats of oil paint.

**BIENNIAL.** Most flower-garden biennials are distinguished by a single main stem, which branches freely above the root. True biennials start from seed one year, flower and seed the next, and then die. Most biennials seed freely and germinate surely, because at the season when they are sown, mid-May to mid-June, the ground is warm.

The following are the most useful hardy biennials. Some are not true biennials, but are best treated as such: Brompton stock, Canterbury bell, chimney bell-flower, foxglove, Iceland poppy, Indian pink, sweet rocket, sweet-william, wallflower, forget-me-not and honesty. *See* Annuals.

**Biffins.** These dried apples are similar to Normandy pippins (q.v.). *See* Dried Fruit.

**BIG BUD.** The pest known as big-bud is caused by the black currant mite. The plant which suffers most is the black currant.

In the black currant the developing buds are attacked and swell until they are almost globular in shape, and are about twice the size of the normal buds. As a rule the buds dry up and die in early summer. The natural result of this loss of buds is a progressive decrease in the crop, which may ultimately fail altogether.

*Big Bud. Its effect on a terminal bud of black currant.*

The disease is dealt with in Leaflet No. 27 of the Ministry of Agriculture. Badly affected bushes should be grubbed up and burnt. In gardens, attacked buds should be destroyed as soon as they can be detected, so as to kill the mites before the period of migration, which is from March to May. The best treatment is to use lime-sulphur on the bushes from early March to mid-May. Here is the mixture:

Slake 1 lb. of quicklime; add 1 lb. of flowers of sulphur and 1 gall. of water; heat and stir.

Boil the mixture for ten minutes, stirring all the time; allow it to cool and sediment to settle, then pour the liquid into a bottle, and cork it well.

For use, mix 1 pint with 12 gall. of water.

*See* Black Currant.

**BIG-END.** The big-end in an internal combustion engine is the larger of the two bearings at each end of the connecting-rod, the small-end or gudgeon-pin bearing being the one on which the piston is mounted. The big-end in its most common form is of the split type, and the bottom half, or cap, is bolted to the upper half, which is machined integral with the connecting-rod, by two or more bolts.

*Big-End bearing of type used for internal combustion engines.*

The illustration shows a bearing of common type. A is the connecting-rod with big-end housing drilled and countersunk at B to receive the bolts, C, that hold the cap, D, in position, also oil ways. These bolts are secured by a castellated nut and a split pin. The cap, D, is drilled centrally at the bottom, and fitted with a scoop for picking up oil to lubricate the bearing as it passes over the oil sump located in the crank case.

Between the cap and the upper half of the housing are placed two packing pieces E, known as shims. These are formed of a number of very thin sheets of brass, and are provided so that wear in the bearing may be taken up. The housing, F, called the brasses, is in two pieces and of phosphor-bronze, having a shoulder at each end to locate it in the main housing, and is machined rough on the inside and recessed, as shown, to receive the white metal lining. The white metal, G, is cast in, turned nearly the correct diameter and finally scraped a true fit to the crank pin.

Big-end bearings on motor-cycle engines are solid and not split, as in large engine practice. They are constructed with a phosphor-bronze bush, or with roller or ball bearings, roller bearings being most favoured. The usual construction of a motor-cycle crankshaft allows of the big-end being slipped off the crank-pin on parting the two fly-wheels that go to form the crankshaft.

**Repairs to Split Bearing.** To get at the big-end on the majority of engines fitted with the split type

bearing, it is only necessary to remove oil sump, thereby exposing all the connecting-rod big-ends to view. Dismantle the bearing requiring attention, and withdraw the connecting-rod with piston down past the crankshaft. This can be done on most modern engines; otherwise it will be necessary to take off the cylinders and withdraw it from the top.

To take up wear in a split type bearing proceed as follows: Thoroughly cleanse off all oil and dirt. Next remove one thickness only off each of the shims; then very thinly coat the crankshaft with a mixture of thin oil and blue mineral or red lead. Replace the housing en suite on the crankshaft and bolt up tight, giving each bolt a half-turn alternately to ensure keeping the pressure on each equal. The connecting-rod should now be given one complete turn (not more), then carefully dismount to avoid disturbing the marks that the blue coating has made on the high places on the white metal housing. These high places should now be very carefully scraped off with a proper scraper. Having done this, clean and remount the bearing, following exactly the same procedure, and continue until there is practically an even film left all over the faces of the white metal. Always bear in mind that any white metal removed from the unmarked surface means that an equal amount has to be scraped off the entire face to correct the error.

On finally cleaning and assembling remember that the connecting-rod must on no account be an easy fit, neither must it be too tight; if held horizontally with piston and gudgeon-pin in position, it should have a tendency to fall a little way only. This test can only be applied when the crankshaft is removed from the engine. *See Bearing; Motor Car; Motor Cycle; Piston.*

**BIGNONIA.** With brilliant flowers of varying colours the bignonia flourishes in the greenhouse, and is a good climber for roof, pillar, wall or trellis. Propagation is effected by cuttings in the autumn, and inserting them in sand under a bell-glass or a frame or in a propagator. Loam and half peat, with sand, form a suitable compost. They are better planted out in pots. Magnifica, crimson, and Tweediana, yellow, are suitable for the greenhouse. Capreolata, orange-red, may be grown against a sunny wall out of doors. Pron. Big-no'-ne-a.

**BILBERRY.** Growing wild in woods and moorlands, this fruit is also known as the blackberry in Scotland and the blueberry in America, and is much used for making jam and tarts by reason of its distinctive flavour.

Bilberries should be washed and picked over before cooking, and are then steamed in a jar placed in boiling water, allowing about 2 oz. sugar and 2 tablespoonfuls water to each lb. of fruit. With a short crust the berries make a delicious tart. For jam-making the fruit is preserved as in recipes for black currant (q. v.). This is essentially a home-made jam, and is not often to be obtained in the shops, the reason being that the demand far exceeds the supplies available. The bilberry leaves a

stain on table linen and light-coloured garments which is hard to remove unless treated immediately with cold. If the stain has dried, it is best to stretch the material across a basin, pour hot water over the affected parts and afterwards apply fresh lemon juice.

**BILIOUSNESS.** Eating too much rich indigestible food often results in a bilious headache, especially with those who suffer from indigestion. In normal conditions poisonous substances formed during digestion are rendered harmless by the liver before they reach the general blood stream, but in indigestion these substances may overwhelm the protective resources of the liver, and accordingly we have symptoms of poisoning in the shape of malaise, physical and mental, and sometimes pronounced headache, with or without vomiting. The latter is beneficial, as it rids the stomach of much of the disturbing material.

Bismuth salicylate in 10 grain doses three times a day or 10 grains each of bismuth carbonate and sodium bicarbonate will be useful. Two grains of calomel at bedtime and 2 drams of Epsom salts in half a glass of water on an empty stomach in the morning will assist in clearing the liver and intestines. Very little and simple food should be taken.

A sick headache is a different thing, though people who are subject to it may precipitate an attack through indiscretion in diet, it may follow overwork or worry or other cause. In this form eye trouble is not uncommon. Some people who require glasses have periodical headaches; a visit to an oculist obviates distress and the taking of a lot of medicine.

Bilious attacks in children are, as a rule, simply bouts of acute dyspepsia due to overeating or the eating of too rich or not quite fresh foods. The only treatment needed is a teaspoonful or so of castor oil and a starvation diet for twelve hours.

Sometimes what may be considered to be mild bilious attacks, occurring at intervals of a few months, with vomiting and more or less severe abdominal pain lasting for a day or two, may be mild, recurrent appendicitis.

*The greatest care should be taken here in prescribing purgatives, and if there is the slightest abdominal tenderness (particularly over the lower right abdominal area), the physician should be sent for.*

In some children there is an inherited incapacity of the liver which gives rise to repeated attacks of biliousness on the slightest occasion. These begin about the age of three or four years. A railway journey, a visit to the seaside, fatigue, a fit of anger or grief, paddling, or exposure to cold wind may, for example, be enough to bring on an attack of biliousness with vomiting.

Treatment consists in putting the patient to bed in a quiet, darkened room and giving no food whatever. A glass of hot water or ice sucked at intervals relieves the thirst. Hot fomentations or a hot bag will ease the pain.

As soon as the vomiting ceases, give the child two to four grains of grey powder, followed by a small dose of Carlsbad salts after six or eight hours. As soon as the aperient has acted, give some light nourishment, such as milk and soda-water, iced whey and jellies. Next day plain, ordinary diet may usually be resumed. Sodium carbonate, in 5 gr. doses, in milk before breakfast might be given to the patient for some days, and doses of Epsom or Carlsbad salts every three or four days. *See* Appendicitis; Diet; Indigestion.

**BILL:** Tradesman's Account. An account contains a list of the items purchased, with the price opposite each, and the total. This bill should be checked at once. If any mistake is discovered, the liability should be at once repudiated in writing, a copy of the letter being kept. An example of such a letter is the following:  
2 January, 1931.

"Dear Sir,—With reference to your account delivered this morning, I want to call your attention to two items, one of Dec. 2 and the other Dec. 15. I ordered the joints on that day myself at your shop, and paid cash across the counter. Please correct mistake in your books.

Yours truly,

ANNIE JAMES."

It is important to write at once. If nothing is done till the tradesman renders his statement to account rendered overwhelming evidence will be required in a court of law to prove the money not owing.

Where sums of money are paid at intervals on account, the tradesman can appropriate the payment to any of the items owing. The householder, on the other hand, can also appropriate it to any he likes, and he has the first choice. It neither party appropriates the money to a specific item, the payment is by law considered to be appropriated to the oldest of the items. This is important when considering the question of old accounts, which are irrecoverable after six years, unless something is paid on account, or some acknowledgement of indebtedness is made within six years before the action is begun.

It is not the case that if an incorrect bill is sent in by a tradesman, the debtor need not pay it. No one, except a solicitor, is ever bound to send a bill in at all, unless he expressly agreed to do so. If the bill is not correct, send or take the amount really due, and if the tradesman refuses to accept it, pay it into court with a plea of tender before action when sued. If it is the correct amount he will have to pay all the legal costs. *See* Accounts.

**BILLBERGIA.** This plant is sometimes grown in greenhouses in England. It possesses thick and fleshy leaves on a short stem, and bears large heads of blossoms in late autumn and winter.

Equal parts of loam and peat, with a little decayed manure and a sprinkling of sand, suit them. Suckers form at the base of mature plants, and these can be used for purposes of propagation. The best species are

*B. moreli*, blue and rose; *B. thyrsoides*, scarlet; and *B. vittata*, green, red, and violet. Pron. Bil-berjy-er.

**BILLHOOK.** In its various forms the billhook is a useful tool for wood-chopping, sharpening the ends of stakes, and cutting down bushes or brushwood. The short-handled handbills, however, are the most serviceable for chopping firewood.

*Billhook. Above, small bill with chopping blade. Below, hedging tool, which has a long handle.*

When cutting sticks, faggots, or kindling, the cut should be made at an angle to the stick, cutting from the thick end in the direction of the thin end, and not straight across. The same principle is applied when cutting growing timber; undergrowth is best cut with an upward slashing blow. The long-handled billhook is used for hedge cutting, or in places otherwise out of reach. A billhook needs a keen, sharp edge.

Most workers will find it best to hold the edge of the bill away from the body. The object of the hook part is to facilitate cutting growing timber.

**BILLIARD BALLS AND CUES.** The standard size for billiard balls is between 2 1/16 in. and 2 3/32 in., and they must be of equal size and weight. Ivory balls are used in British official championships, both amateur and professional, and are generally employed in first-class play. When buying a set of ivory balls, a fair price should be paid to get a well-seasoned set made of the right kind of ivory, and they should be bought 2 1/16 in. full, thus allowing for adjustment.

A new set of ivory balls ought to be kept in the billiard room for a week or two to get accustomed to the temperature before they are taken into play, and at first they should be just tapped lightly while playing a series of gentle strokes, a process which hardens the texture of the surface of the balls; it is well worth while to humour a set of new ivory balls for a month in this way before playing an ordinary game with them. Any chalk on the balls should be removed with a cloth.

They should not be handled any more than can be helped, and in particular the ivory ball should not be held in the hand while waiting to play. On a damp day especially the balls are all the better for an occasional rub while play is in progress.

Professionals know that it spoils ivory balls to

leave them in the pockets when play is finished, and are careful to place their set in a proper box lined with soft material. (See Fig. 4). Nor would they leave ivory balls on a window-sill exposed to cold and draughts, or on a mantelpiece when the heat of a fire would ruin them at once. This explains why a professional will have a good set of ivory balls in use for years.

Composition balls, which are not affected by changes of temperature, are cheaper and more lasting than ivory. They are much in favour where economy is the deciding factor, although they are not so pleasant to play with and do not throw quite the same angle as ivory. Their absolute truth is a strong point in their favour, their durability is another, and so is the fact that all sets of one make are alike, whereas ivory may differ very considerably. For snooker and other pool games requiring a large number of balls the low cost of composition is an important consideration.

Composition balls, however, need much more cleaning, as chalk marks and dirt of all kinds stick to them more easily. They should be washed in warm water, rubbed thoroughly clean and dry and then given as much polish as they will take from a perfectly dry cloth.

#### Size and Weight of Cues

Billiard cues of any weight or size are permitted by the rules of the game. In practice, weights vary from 14 to 18 oz., but size as regards the length of stock cues does not vary so much as it might. Many faults might be remedied if cues suitable for very short or very tall people were more readily obtainable. Cues under 15 oz. are seldom used, but the championship has been won by a player using an 18 oz. cue. Generally from 15 to 16½ oz will cover every requirement, and it is preferable to have a cue heavy rather than light. When it comes to judging a billiard cue, appearances are even more deceptive than usual. No matter how high the polish may be, anything whippy should be rejected at once, and wood twisted in the grain, especially towards the point of the cue where it slides over the bridge-hand, is another thing to guard against.

When play is over, the cue should be replaced in its case, as no cue will keep straight if it is left leaning against a wall. If the cue feels sticky as it slides over the bridge-hand, it should be rubbed briskly with a dry cloth or a sheet of paper, but not sandpaper. The use of sandpaper to remove temporary stickiness wears the wood away unevenly in a very short time, and renders the cue useless for real billiards. Sandpaper may be used with advantage on the leather tip of the cue. Constant play makes the tip hard and shiny, and if it is lightly rubbed against the grain of the leather with a piece of coarse glasspaper, or even a wood file, a constant source of miss-cues will be removed.

#### How to Tip a Billiard Cue

When tipping a cue, the first thing necessary is a flat true surface on which to lay the new tip. Useful little machines are sold which do this troublesome job

very neatly, but if it has to be done by hand it must be completed well and truly. Select a tip as nearly as possible a perfect fit, soak the adhesive wafer in hot water, adjust the tip firmly and accurately, and leave it to dry thoroughly. If proper care is taken, especially as regards selecting a tip which fits, there should be small need for trimming and filing. But if this has to be done, never allow the woodwork of the cue itself to be touched by file or sandpaper. The tip must be made to fit the cue, not the cue sandpapered to fit the tip. The tip of a cue should be large rather than small.

Besides the ordinary cue, there are the long-rest and the half-butt, which should be kept straight and well tipped. It is better to lay them on the floor under the table than to try to prop them up in a rack.

Cement for fastening the tips of billiard cues is made by soaking 1 oz. of isinglass in 2 oz. of water, and adding 1 oz. of glacial acetic acid, warming together until dissolved.

### THE BILLIARD ROOM AND ITS ACCESSORIES

#### General Information on Lighting, Heating and Equipment

The main requisites of the game are considered in the preceding article, Billiard Balls and Cues, and in that on Billiard Table, while the construction of some of the lesser accessories is dealt with here.

*Billiard Room. Fig. 1. Well lighted room in a private house. Note the strips of carpet and, right the raised seats for onlookers. (Bedford Lemere)*

The ideal billiard room is built on a ground floor with brick or concrete supports for the legs of the table and should be a substantial and well-lighted structure. A skylight for play during the day is the only perfect natural light, as a side-light which throws shadows as the balls lie on the table is most disconcerting. Ventilation is also helped by the skylight, parts of which should open to let out smoke and allow fresh air to enter; but an open sky-light should always be watched in case of rain.

Electric light is the best artificial illuminant, but gas mantles are quite good, though the wasteful naked flame should be avoided. Whatever light is used, the shades should be adjusted so that the full glare of the light cannot catch the eye of a player as he shapes at his

stroke. A well-arranged room in a private house is illustrated in Fig. 1.

The heating of the room requires careful attention, as both balls and table are very sensitive to changes of temperature, and the game is not pleasant to the players if the weather is cold and the heating insufficient. One of the many systems of heating by pipes radiators is far better than an open fire, which should be avoided on account of the glare, the dust and the impossibility of maintaining an equable temperature.

*Billiard Room. Fig. 2. Standard pattern marking board, with scorers sliding on brass strips.*

The space required for a full-sized table is rather more than 21 ft. by about 16 ft., which must be clear space after allowance has been made for settees. A little less is possible, but the measurements given allow a margin of comfort. The floor covering should be of woven material where the feet of the players tread on it. The marking board (Fig. 2) and cue-racks must be well made and kept in good order. Nothing is more annoying than a marking board which sticks, or cue-racks fitted with cheap clips which disfigure the cues with band-like marks.

But for every fortunate possessor of an ideal billiard-room there are many who cannot get absolutely the best of everything. The most usual shortcoming is lack of ground-floor accommodation, which generally means that a top light is impossible. When this is the case the upstairs room selected for the table must be strong and well built, for a billiard table is a heavy piece of furniture, and if it begins to settle down unevenly it is at once out of truth and useless.

Those who have to fit a table of less than standard size into an ordinary house will be well advised to make sure they have room enough to play properly. A small table in a room too small for it not worth having, and the same may be said of small tables which are set up without due regard to levelling. In an ordinary house, especially if fitted in an upstairs room, these small tables take time to settle down, and often require readjusting more than once before they can be depended upon. For the rest, everything which applies to the ideal room for a full-sized table is applicable to the small table; but when it comes to making the best of what must necessarily fall a good deal short of the ideal, the light is the last thing which should be allowed to suffer.

A badly lighted table, be it large or small, is an abomination, and there is no reason why the small table should suffer in this respect. Generally a top light is out

of the question, so that it is all the more important to arrange the best of artificial light, as all play will be dependent upon it, so far as seeing the balls well is concerned.

*Billiard Room. Fig. 3. Cue rack. Fig. 4. Padded box for billiard balls. Fig. 5. Sectional view of a clamp for a billiard cue.*

There are various styles of cue-racks and stands. The wall rack is simple to construct and quite efficient. It is conveniently made in two lengths, the one fitted with the slotted ledge (Fig. 3, A) above a rail, which is fitted with equally spaced spring clips and secured to the wall by brass-plates and screwing. The rail can be of  $\frac{3}{4}$  in. thickness and 4 in. or so wide, with the ends and under edges plain or moulded ovolo as preferred. The spring clips are purchasable from a good-class ironmonger in dozens, and merely require screwing into equally spaced positions. The shaped ledge above is screwed and glued on, and the clips are fixed on the centre line of each recess so that the cue lies evenly within it. Width of this ledge can be about 2 in. and its shaping a repeat such as Fig. 3 C.

The revolving cue-stand is specially suitable for some rooms, but as it is not likely that a player would undertake its construction we do not give details. These stands can often be obtained second-hand at low prices.

The amateur craftsman might, however, exercise his skill in the making of a box to take three balls, as illustrated at Fig. 4. Finished dimensions can be  $8\frac{1}{4}$  in. long,  $3\frac{1}{2}$  in. deep and  $2\frac{1}{4}$  in. high. The lower box portion can be  $1\frac{1}{2}$  in. high, and the workmanship is usually of the best. Sides, back, and front are carefully dovetailed together of  $\frac{1}{2}$  in. or  $\frac{3}{8}$  in. mahogany, and a

$\frac{1}{4}$  in. bottom rebated in. The lid is dovetailed together in similar fashion, and the top rebated in. A separate partitioned box is inset, made from  $\frac{3}{16}$  in. thickness, mitred together, and finished to project with bevelled edge about a full  $\frac{1}{4}$  in. above the box.

A cue cramp (Fig. 5) is an essential accessory of every billiard room. In action, the cue top is passed through the centre of cramp, and the cemented tip compressed into position by forcing down the stop upon it and securing it in position by pulling down the cramping ring over the cuts in the splayed end. In addition there is a hole to take a small length of file with which any unevenness of tip or adhesive is corrected. The file is holed at one end, and a length of brass chain secures it to the stop above.

## BILLIARDS: HOW THE GAME IS PLAYED

### The Strokes Explained and Illustrated

This work contains also articles on Pool, Pyramids and Snooker Pool

English billiards is played on a table measuring 12 ft. by 6 ft. The spot is  $12\frac{3}{4}$  in. from the top cushion, the middle spot is half-way across the table in line with the centres of the middle pockets, and the pyramid spot is equidistant between the middle or centre spot and top cushion. The table has six pockets, one at each corner and two in the middle of the longer sides. Those at the spot end are known as the top pockets; those at the balk end as bottom pockets.

The game is usually played by two to four players. Points are scored as follows: two for a cannon, i.e. when the playing ball strikes the other two balls; two for going into a pocket after hitting the white; and two for potting the white, i.e. driving it into a pocket. Three is the score for going in off the red or for potting the red. A miss counts one to the non-striker; three if the ball is sent into a pocket or off the table without striking a ball. The rules should be consulted for other examples of scoring. Each player or pair of players has his own ball, these being the two white ones, one being distinguished by a spot. Various ways of deciding who shall start first are in vogue. Beginning the game is known as breaking the balls.

A player can continue playing as long as he scores from every stroke, but as soon as he misses, his opponent takes his place. The total score made by a player without losing his turn is known as a break. If the cue-ball, when at rest, touches either of the other balls, the balls must be spotted and the striker continues his break. Fouls and their penalties are matters concerning which the rules should always be consulted.

### Importance of Correct Stance

A correct stance is of primary importance in billiard playing, but is difficult to define with exactitude, because players of varying height and physique have to play on a table which measures, from the floor to the cushion rail, from 2 ft. 9 in. to 2 ft.  $10\frac{1}{2}$  in. The safest guide to a reliable stance is to remember that absolute steadiness is the ideal in view. A cueman when standing

as he should to make his stroke is, above all things, firm and steady. Only his cue-arm, lissom and ready to propel his cue should be flexible and ready for the utmost nicety of movement.

Billiards. Fig. 1. Full-sized table, showing the lines and spots.

Billiards. Figs. 2 and 3. Two views of a good bridge, firm, but not rigid, as made by Tom Newman. (Photos, Wrightson)

As a general rule it will be found that by advancing the left leg and slightly bending the left knee, while the right leg is kept firm and straight, the foundation of a correct stance is assured. The upper part of the body should be bent forwards, the left arm thrown well out and the left hand arched to form a bridge over which the cue slides. The cue butt should be held without force or effort, always bearing in mind that the cue is to be swung at the ball, not pushed or thrust with a movement having continuous and appreciable power behind it.

To gain impetus for the swing, the cue must be drawn back—it is sometimes helpful to draw the cue back very slowly indeed—but when the swing forward is made it should be kept as flat as is consistent with freedom, and must be continued until the cue goes clean through the ball in the line of the stroke. "Let the cue do the work," is continually dinned into the ears of pupils by professional teachers of billiards, and is such excellent advice that no progress can be hoped for if it is ignored.

Face the balls when sighting a stroke, and always endeavour to have the cue-tip on a line taken from fairly between the eyes when the ball is struck by

swinging the cue at it. Never forget the swing—it is all important. In actual ball striking, the first thing to do is to learn to hit the cue-ball truly in its strikable centre. This is by no means an easy thing to do with consistent accuracy, but it must be done, and the best way to master it is by utilising the familiar one-ball stroke, played by placing the cue-ball on the centre-spot of the balk-line and playing it straight over the line of spots.

If struck truly in its centre, the ball should rebound straight to its starting-point. Mostly, however, it will show a tendency to return to the right, which proves that right-hand side is being imparted unintentionally, a fault which must be rectified. To eliminate any tendency to strike the ball above or below centre, it is a good plan to practise this stroke with the spot-ball, adjusting the spot for each stroke exactly where the cue-tip should impinge on the ball. This one-ball practice is admittedly tiresome, but it must be persevered with if real billiards is to be played.

The half-ball stroke with the resultant natural angle is the next step, and it is a very big one, towards aptitude at the game. The half-ball stroke is made by directing the centre of the cue-ball towards the extreme edge of the object-ball. It must be played with the least side on the cue-ball, without strength enough to force the stroke, and with free cueing to impart life and brisk forward rotation to the cue-ball.

There are four set positions usually demonstrated as showing the half-ball stroke and the natural angle, but in a strictly scientific sense the angles thus shown differ appreciably. In a practical play, however, it is indisputable that the hazards can be scored as described from the following positions.

Place the red ball on the centre-spot and the cue-ball  $7\frac{1}{2}$  in. from the centre-spot on the balk line (Fig. 5). Place the red ball on the pyramid spot and the cue-ball rather less than an inch inside either of the spots at the ends of the balk-line (Fig. 6). Place the red ball on the billiard spot and the cue-ball in line with the shoulder of the middle pocket (Fig. 7). Place the red ball on the billiard spot and the cue-ball in the centre of one of the top pocket openings or on a line a shade nearer the top cushion (Fig. 8). If the balls are placed as directed above, and a half-ball stroke played as shown in the diagrams (*see p. 170*), the losing hazard will always result, and if the strength is correct the red ball will travel as indicated by the dotted line in the diagram and stop in excellent position.

#### Half-Ball Shots the Key Strokes

These four strokes, for open billiards, may be called the key-strokes of the game. Any player who can handle them really well, especially Fig. 5, is well on the way towards cuemanship of no mean order. But unless they are mastered as well as opportunity permits, the making of difficult strokes at uncertain intervals, or even the making of them fairly frequently, will be of very little use. The player who has a sound working knowledge of the half-ball stroke knows what he is doing when he tackles any other stroke on the table. He has a reliable standard of comparison to work by, knowing as he does that a half-ball contact will produce

a given result; he can calculate what a contact thicker or finer than half-ball will give him as regards variations from the natural angle.

All this is done, it should be noted, without striking the cue-ball anywhere except in its centre, and it is altogether wrong to regard this as merely a preliminary step towards higher flights in the game. Plain ball striking is the backbone of all billiard playing, and no man can make a break of any size unless he has reasonable command of it. It is an all too common fallacy to imagine that screw and side are the things that really matter, and that the beautiful simplicity of plain ball striking is a mere rudimentary commonplace of no interest.

*Billiards. Fig. 4. Correct stance and grip of cue, demonstrated by Tom Newman (Photo, Wrightson)*

There are, of course, very many strokes which lie beyond the power of plain ball striking; then, and not till then, does the employment of side, top or screw become necessary and justifiable. Side is imparted by striking the cue-ball to the right or left of its centre, as the case may be, and is not so much a matter of striking the ball as far as possible to the right or left, as it is a question of neat and crisp cueing. When putting side on a ball the best results are obtained by keeping the cue-tip on a line struck fairly across the centre of the ball. It is a mistake to put top or bottom on the ball when imparting side, unless it is done purposely to combine side with either of these things.

The action of pure side is to take the ball away in the direction of the side imparted, excepting when a ball is moving rather slowly against the nap of the cloth, when the action of side is reversed. Side has a certain amount of effect on the course of a ball before another ball or cushion is struck, but the effect is much more apparent and decided after contact with a ball or cushion, especially if force is used when a ball is played at and the ball to ball contact is thick. In billiard parlance, mention is often made of running side, check side and pocket side. These definitions are apt to confuse the beginner unless clearly explained.

Place the red ball on the billiard spot, the cue-ball on the centre spot of the balk-line and the second-

*Billiards: the key strokes. Fig. 5. Standard half ball shot; cue-ball on balk line, object ball on middle spot. Fig. 6. Standard half ball shot; cue-ball on balk line, object ball on pyramid spot.*

*Fig. 7. Standard half ball shot; cue-ball in centre of top pocket opening, object ball on billiard spot. Fig. 8. Standard half ball shot; cue-ball at shoulder of middle pocket, object ball on billiard spot.*

object ball near the left balk pocket (Fig. 9).

If a smart half-ball is played on the right of the red with plenty of right-hand side on the cue-ball, it will be seen at once how this side helps the run of the ball off the cushions. If the same stroke is tried with left-hand side, the check action is at once apparent. With running side the cannon is scorable, but there is indeed a difference if the stroke is attempted with check side, which illustrates yet another important attribute of side. This is the effect it has after a side-laden ball impinges on a cushion. At normal pace, if a ball has no side on it, the angles of incidence and reflection are equal when it strikes a cushion and rebounds from it, but running side makes the angle off the cushion more

obtuse, wider, as it is called, while check side makes the angle more acute.

*Fig. 9. Half ball cannon; cue-ball on centre of balk line, object balls on billiard spot near left balk pocket.*

Screw may be defined as latent backward spin. It may bring the cue-ball back as much as 6 ft. or more after full contact with an object ball lying a foot or so away. When it is clearly understood that the ball must be made to spin backwards as it travels forward, much of the elusive difficulty of the screw stroke is eliminated. The manipulation of the stroke depends on keeping the cue as level as possible while striking freely and neatly well below the centre of the cue-ball and checking the cue with a sudden pinch of the fingers immediately after the ball is struck, not, as is often stated, at the same moment, for the cue must go through the ball, be it ever so little, to set up the requisite backward rotation. The weight of the stroke supplies the forward momentum, the cue-action and the low striking giving the screw effect.

Top is the direct opposite to screw, and is imparted by striking the cue-ball well above its centre. It is mainly useful when playing long follow-through cannons. In a modified sense, so far as striking the cue-ball slightly above its centre is concerned, top helps to impart life to certain strokes. It is, however, as well to avoid the use of top whenever possible, as it panders to inaccurate cueing.

Top may be used in conjunction with side, so may screw, and only experiment is of much use in demonstrating the multitude of effects thus to be obtained. But it cannot be too often repeated that plain ball billiards comes first, and that intricacies such as the combination of side and screw are to be avoided if possible. When employing side or screw it is advisable, as a general rule, to use as much of either as the cue-power of the individual can impart, obtaining any desired result by varying the strength of stroke and the ball-to-ball contact.

Drag means striking a ball low with the intention of preventing it from running untruly when it is desired

to play a long shot at slowish strength. The cueing is more free than is used for the screw stroke pure and simple, and the stroke, although difficult, is worth practising, especially if the table and balls are short of absolute perfection, as drag helps to minimise such defects. Stun is produced by holding the cue heavily when playing rather full on the object ball; the cue-ball is struck rather below its centre and can be made to stop dead, when the stroke is known as a stab shot, or it can be made to travel slowly to make a cannon or pocket, usually a cannon. The stun stroke is very useful when it is desired to send the first object-ball a long way and barely move the second object-ball, many pretty gathering cannons being made in this way.

Break-building can be summed up as the art of playing one easy stroke in such a manner that another easy one is left; in its highest forms, notably in top-of-the-table billiards, it depends upon a sense of touch and insight into the possibilities of the game which amount to a gift. In the ordinary way, however, much can be done if thought is taken before a stroke is made, thought directed towards computing where the balls will be when they stop, usually the last thing the novice troubles about!

Ivory balls of standard size and equal weight are presumed to be in use when playing the strokes mentioned in this article. If composition balls are used, it will be found that the positions will be apt to vary slightly.

**BILLIARD TABLE:** Its Care. Because of its bulk and size, a billiard table is apt to be regarded as a fixture which cannot very well come to any harm if left alone, or as something strong enough to stand any treatment short of wilful and malicious damage. The truth is that such a table requires constant attention to keep it in good playing condition, and, although far from fragile, is much more easily damaged than is commonly supposed. Slate, cloth, rubber, wood and a little metal are the raw materials which enter into the making of a billiard table. The nature of these substances differs widely, and to fashion and adjust them into a perfect and harmonious whole is no mean feat of craftsmanship. The cloth and cushions are the most sensitive parts. Damp and cold will ruin the best cushions, so will the player who never uses the rest, but insists on clambering on the table to reach a shot he cannot get at in the ordinary way.

The table should be brushed frequently, always with the nap of the cloth, and the brushing should be so thorough that the fibres of the brush dig well into the nap and fetch out the chalk and dust; a perfunctory brushing is very little use. If a cloth is brushed in this manner it does not want ironing half so often as is supposed, especially if a duster is wrapped round the brush and the table gone over again after the brushing is completed.

When ironing a billiard table the iron should be hot enough to iron linen, but it is too hot if it leaves the least trace of singeing on an old piece of white rag with which the face of the iron should be cleaned before it is allowed to touch the cloth. The iron should be

grasped firmly and run quickly up the centre of the table in a straight line with the nap of the cloth, and the operation completed by taking in successive swathes of cloth until the whole is covered, care being taken not to press the iron needlessly against the cushions, especially when ironing near the pocket openings. Above all, do not iron against the nap of the cloth; one such application of a really hot iron spoils the cloth entirely.

When a new cloth has been on for a little time it needs stretching and readjusting- always a job for an expert. This operation throws the original balk-line and spots out of place, and they have to be changed accordingly. Banging a ball on a spot is bad for both the ball and the cloth, and should be sternly discouraged.

*Billiard Table. Miniature table, the top of which can be replaced by leaves, thus making a dining table.  
(Photo, Thurston)*

**BILL OF SALE.** A bill of sale is a document whereby personal goods are transferred or else mortgaged, and is commonly used by people who wish to borrow money on their furniture. A mortgage bill of sale must be in a particular form and registered.

The creditor can only seize the goods for one (or more) of the following causes: (1) default in payment of principal or interest; (2) bankruptcy of the debtor; (3) if the debtor fraudulently removes the goods; (4) fails to produce his last receipt for rent; or (5) suffers an execution to be levied on the goods.

A mortgage bill of sale cannot be given for less than £30. It can only be given by the true owner of the chattels.

**BINDING:** How to Apply. Seam edges are sometimes finished with a special tape binding to neaten, and edges of garments are bound with braid, self-material, or a contrasting coloured fabric, as a decorative trimming. In other cases two edges or ends are bound together to secure them, e.g. the ends of a wire sewn to the outer edge of lampshade, etc., and set to a certain shape. Here the binding is done by lapping the ends of the wire a few inches, then twisting a strip of muslin round and round until both ends are hidden (Fig. 1), fastening off with a few stitches. Another method is to fold a long strip lengthwise, and to slip the wire up into the fold, then to sew along

within the edges.

*Binding. Diagrams showing how braid or other material should be applied for binding purposes.*

To bind seams, place the binding along the raw edge of the seam, so that half its width lies over the material and half extends beyond the raw edge; then hem or run the lapped edge of the binding down, after which turn the remaining or unattached edge over to the other side of the seam turning, and hem down (Fig. 2) so that the turning is sandwiched between. In using braid, sewing-silk of the same colour as the braid should be employed, and the running or hemming stitches should not be made tightly enough to indent the braid. If the braid is to be taken round a corner, it should be set in a mitre (Fig. 3), or if along a curve, the tiny cotton thread generally woven into each edge of the braid should be pulled up to make the requisite shape.

If a very narrow binding is required, another method is followed. The braid is set over the right side of garment, so that none of it extends beyond the edge, but so that the outer edge of braid comes level with garment edge, after which it is stitched on within these outer edges (Fig. 4). The remaining or unattached edge of braid is then turned over to the wrong side of garment and hemmed.

If the edge of a dress, etc., is to be bound with strips of self or contrasting coloured material, the strips must be cut off on the cross, and joined to the required length. The joins must come on the straight of the grain, so that the ends of the strips will be necessarily slantwise and the joins corresponding. To do the binding, follow the second method explained for braid binding, and illustrated in Fig. 4, though in this case, if any curve is to be bound, the strip, being cut on the cross, can be stretched to the desired shape, and need not be drawn up. In binding, carefully note that no part of the garment edge which comes on the cross is stretched in the process. After binding press well. *See Bookbinding.*

**BINDING COURSE.** In brickwork this is the name given to a row of bricks set across an inner and an outer course to bind them together. *See Bond; Brick; Building.*

**BINDWEED.** Two plants bear the name of bindweed or bearbind, *Calystegia sepium* and *Convolvulus arvensis*, and both are very pretty, but if once they get out of hand they become weeds of the worst type. The safest means of extirpation is to dig

them up by the roots, which usually extend for a considerable distance horizontally underground.

**BIRCH.** The silver birch, *Betula alba*, so called because of its shiny white bark, is a most graceful and ornamental tree that flourishes best in light soil. It is a beautiful lawn tree. Planting may be done from Nov. to March inclusive. The birch is raised from seed which is sown as soon as it is ripe or in spring.

**BIRCH: In Furniture Making.** The wood of the birch is one of the cheaper hard-woods, used for much the same purposes as beech. It is a light brown in colour, close-grained, sometimes with a figure similar to mahogany, and is often stained to resemble that wood. It is easy to work, and has a smooth surface with a rather lustrous appearance. It is used for bedroom furniture and frames of chairs and couches, turned articles, brush heads, casks and tubs, handrails, and dowel rod. Plywood is often made layers of birch, and in this form it is used for chair seats, vehicle bodies, as well as for panels for various purposes.

Birch dowel rod is sold at most hardware and general stores, and by timber dealers, in lengths of 3 ft. and upwards. Diameters are from 3/16 in. to 7/8 in., the most useful size being about 1/2 in. Cabinet-makers use it for dowelling the frames of chairs and other articles, as an alternative to making mortise and tenon joints. For this purpose it is used in short pieces usually not exceeding 3 in. or 4 in. long. *See Wood.*

**BIRCH TAR.** Tarry oil obtained from a birch, the *Betula alba*, and known as birch tar, is used as an application in skin diseases associated with itching, e.g. chilblains, eczema, or psoriasis. It should not be used if the skin is acutely inflamed and moist. A useful combination is birch tar, 1 dram; zinc oxide, 2 1/2 drams; vaseline, 5 drams. *See Chilblain.*

**BIRD BATH.** One of these shallow stone basins may be put in an open space in the garden to provide water for birds. Some are fashioned like miniature fishponds, about 2-3 ft. across and 2-3 in. deep, but a more useful kind stands on a pedestal, and the birds are thus protected from cats. One of these makes an effective centre for a small lawn. It is cheaper and less difficult to erect than a sundial, as it only needs to be kept full of fresh water. If the basin is a large one, it may have a raised stone in the centre as an additional perching ground for the birds.

*Bird Baths in stone, the above one a meditative cherub on its brink. (Sussex Gardens Ornaments)*

*Bird bath having a circlet of dancing pixies (J. Panichelli & Sons)*

**BIRD CAGE.** The designs and types of birdcages are innumerable, but they all naturally divide themselves into two types, viz. all-wire cages, with which must be grouped cages of light wood framing and open wirework all round, and box cages.

The danger of the all-wire cage lies chiefly in the fact that cold wind or draught can pass through it, and if this cage is placed in a window it becomes a death-trap for even the most hardy species of birds. This danger can be eliminated by placing the cage against a wall, and in such a position that no current of air can pass through it from end to end. If it must stand in a

window, then the only safe procedure is to surround it on three sides with clear glass. The screen must be the full height of the cage, and be placed between the cage and the window. Thus an all-wire cage can be made a safe habitation for all species of birds.

*Bird Cage. London breeding cage containing a separate compartment and rest for the birds on right.*

*(Courtesy of J.J. Thomas & Co., Ltd)*

The best cage is of the box type. Every cage, whether its materials be of wood or metal, should be fitted with a metal draw-tray for cleaning convenience, and the food receptacles ought to be so placed as to be easy of access both to the birds and their owner.

As to the size of the cage, it must be sufficient to allow the occupant to move about and perch without fraying or otherwise damaging its plumage. It must be large enough for the bird to turn about without bending its tail feathers, and the perches so placed that its head does not rub against the top of the cage or its tail come in contact with the floor of the cage. A small active, vivacious bird no larger than a wren often needs a larger cage than one four times its size. It is an indisputable fact that to put such a bird in a cage in

which it can merely hop and not move about freely is to rob it of any chance of a long or happy and contented life. Many species of birds become corpulent and fall into ill-health if they cannot take some wing exercise.

For canary fanciers both type and size of cage are regulated by the governing body of each variety. For other species the cages are invariably of the box-type, and the novice exhibitor had better leave himself in the hands of the cage-maker.

Of parrot cages there are three types—round, square, and rectangular. The rectangular is too

large

for the average room, and of the two former the square is the better, as a cage of 2 ft. sq. contains more space than one of 2 ft. diameter.

Cages should have a spring and autumn clean, when they need to be scalded with some insecticide solution, dried, distempered inside, and the exterior re-stained. *See* Aviary; Canary; Parrot.

**BIRD CHERRY.** This is a name sometimes given to ornamental flowering cherries. The botanical name of the tree is *Prunus padus*. A native of Britain as well as of Manchuria, it is a hardy, May-flowering tree, often attaining a height of forty to fifty feet. The flowers take the form of pendulous racemes six inches in length, and are white or pink.

The bird cherry thrives in ordinary loam, and is best grown as a specimen tree on a lawn, or grouped in park or woodland. It is rather too vigorous a subject for the ordinary garden.

*Bird Cherry. Sprays of hanging blooms of the ornamental flowering cherry.*

**BIRDLIME.** Made in Japan from the bark of the holly, birdlime is the chief ingredient in fly-papers and fly-strings, and is also used for spreading on boards to trap mice and rats. Artificial birdlime for the same purposes is made by melting together boiled linseed oil, 6 oz.; gum thus, 1 oz.; and castor oil, 2 oz. This is applied, while still warm, by means of a stiff brush. *See* Fly-paper.

**BIRD LOUSE.** Bird lice are unrelated to the true lice, and are more of the nature of scavengers, feeding upon scurf, skin secretions, hair and feathers. They are small, flat, wingless insects of the order Platyptera, and have mandibles armed with sharp teeth. They affect domestic poultry and pigeons chiefly. The eggs are attached securely to the hairs or feathers. Where they cause annoyance to pets, finely powdered sulphur or insect powder should be blown into the plumage.

**BIRD SCARER.** The scarer shown in Fig. 1 is driven by a windmill, which revolves a rod, and causes two metal plates to clap together. The post and arm, Fig. 2, are 1½ in. square, half-lapped and screwed

together, the post being pointed for fixing in the ground. The windmill is attached to a hardwood rod, Fig. 3, which is  $13\frac{1}{2}$  in. long over all by  $\frac{1}{2}$  in. diameter, working through a hole in the post bored in the position shown at Fig. 2. The stock of the windmill, Fig. 4, is 3 in. in diameter by  $1\frac{1}{2}$  in. thick, with a  $\frac{1}{2}$  in. hole in the centre to fit the rod.

Fig. 2

Fig. 1

Fig. 3

*Bird Scarer. Diagrams showing how to make an apparatus worked by wind.*

Fig. 8

The six sails Fig. 5, are 6 in. long by 3 in. wide at the ends, tapering to  $\frac{1}{2}$  in., by about  $\frac{1}{3}$  in. thick. They are fitted to dowels, Fig. 6, 2 in. long by  $\frac{1}{2}$  in. diameter, having slots 1 in. long to receive the sails, and bored 1 in. into the stock. This method of fixing the sails allows of their being easily set on the angle to catch the wind from whichever direction it may happen to be blowing.

Two round fixing blocks, Fig. 7, are required to adjust the rod to its correct working bearing in the post. The blocks are  $1\frac{1}{2}$  in. in diameter by 1 in. thick, having  $\frac{1}{2}$  in. holes in the centre to fit the rod, while a small hole bored from the circumference to the centre admits of a small pin being driven through and into the rod when the blocks are finally adjusted. The metal plates are 4 in. by 2 in. by about  $\frac{1}{16}$  in. thick. The plate on the arm is attached with two wire staples, while that on the rod is fixed by making a saw cut in the rod and driving two small screws, as illustrated in the diagram, Fig. 8. See Scarcrow.

**BIRD SEED.** The principal seeds used as food for cage birds are canary, flax, hemp, millet and rape. The first named is the flattened yellow seed of canary grass; flax or linseed is also compressed, but smaller and brown in colour, and produced by the common flax. Millet is the round, hard seed of *Sorghum vulgare*, the guinea corn; hemp, the large, roundish grey seed of *Cannabis sativa*; and rape is the dark shot-like seed of a variety of the turnip. To these may be added the seed spikes of the plantain obtainable from any plot of waste ground; and for the larger birds tares, Indian corn, and the seeds of sunflower. Seedheads of thistles are appreciated by some finches, who pick the seeds from the thistle heads with avidity. *See* Aviary; Canary, Parrot.

**BIRDS' EGGS.** In making a collection of birds' eggs the first thing to do is to acquire some practice in the handling and preparation of the specimens, in order to avoid spoiling them and thus taking eggs wastefully.

The easiest and simplest way to blow an egg is to make a hole in each end with a pin and then blow out the contents with one's mouth. This method may be tried on the common eggs till one is sure of holding the egg so judiciously as to escape breakage. A drill and blowpipe should then be got from a dealer in natural history requisites, and some eggs blown by the proper method of making a neat round hole in the centre of one side, and expelling the contents through this alone. In both methods a pin should be inserted to break up the yolk before the blowing process is begun. If an egg is hard-set, the embryo bird should be snipped to pieces with a pair of fine scissors, and the bits withdrawn with a pair of fine-pointed forceps, but the taking of such eggs should be avoided wherever possible.

When cleared, the eggs should be thoroughly washed out with water injected by means of a fountain-pen filler or similar instrument; care should be taken to avoid wetting the egg more than can be helped. After washing out, the hole or holes in the egg should be closed by gumming a tiny disk of paper over the opening; the egg is now ready for the cabinet, and should on no account be varnished. Neither should the eggs be gummed on a card or strung on strings, as is sometimes done. The eggs of some water-birds have a chalky coating, and this should not be scraped off.

For keeping eggs till one has a cabinet ready, chip pill-boxes bedded with any soft material will do; each egg should be marked with a number with a fine pen and marking ink, and the numbers should be entered in a notebook with the name and any other particulars opposite. For exhibition in a proper cabinet, the best bedding is black cotton-wool; the name labels can be gummed on to the edges of the partitions. Ducks' eggs should be bedded on a little of the down with which the bird lines the nest, since this down differs according to the species of duck, and is a considerable help to

identification.

### Identification of Birds' Eggs

Practice in the blowing of large eggs like these should be obtained with the eggs of ordinary ducks and of fowls. In the case of large eggs it is often only convenient to exhibit one, and indeed to take only one egg from a nest is a good rule in the case of most birds. It is the taking of the whole set, and the accumulation of numerous sets of the same species, regardless of its scarcity, that has brought egg-collecting into disrepute.

In order to be sure of the name of an egg one must not take it till one has seen the birds, or one of the birds, to which the nest belongs. As often as not an egg cannot be identified apart from its producer by a beginner, and even the expert may be unable to distinguish between the eggs of some species. This is most often the case when the birds are nearly related; thus, the eggs of the various tits are often very hard to distinguish.

Sometimes the eggs of quite different birds may be alike, as in the case of the sedge-warbler and the yellow wagtail. In this case, however, the nest is some help, for that of the sedge-warbler is constructed in the bushes, while the yellow wagtail's is a rough affair built on the ground among the grass.

The thrush's nest is very characteristic with its plain hard lining of mud-plaster; but though the bright blue eggs, with their few and distinct black spots, are very different from those laid by any other bird which nests here, they are not always true to type, and in rare cases may be marked with brown instead of black, or even be plain blue altogether.

The thrush and robin are the two birds most likely to be found breeding early in the year, but, generally speaking, it is not of much use to look for eggs till March, and the great months for eggs are April, May, and June. After that, although many birds breed a second or even a third time in the year, the supply of eggs rapidly falls off.

Before setting out to search for eggs one should find out which birds are protected by law, and the particular regulations applying in the locality.

It is a mistake to think that one will always find the nests in the most out-of-the-way places; birds often nest in a frequented spot, and in a wood, for instance, the nests are more likely to be found along the pathways than right in the depths of the thicket. Birds which build in holes are often careless of observation, and less inclined to secrecy than those which build among the boughs and twigs.

Birds which build high up are also less secretive than those which build low down, and the hardest of all nests to find are those of birds which nest on the ground.

In searching for nests which require climbing to reach them, it is always best for two people to go together. Assistance may be required, and someone will thus be at hand in case of an accident. The eggs of many cliff-building sea birds, indeed, are not to be got by any ordinary amateur, and must be obtained from men who make it their special business to collect them.

## BIRDS' EGGS: A CABINET FOR COLLECTORS

### How to Make a Compact Set of Airtight Drawers

The woodworking enthusiast who is also a naturalist will readily adapt this design to other collections, such as Butterflies. Information about similar hobbies will be found under Flowers; Shells, etc.

The cabinet shown in the diagrams in this and the next page measures 3 ft.  $\frac{1}{2}$  in. wide by 1 ft.  $6\frac{1}{2}$  in deep over the carcass. The total height is 3 ft. 2 in. There are 30 drawers. The cabinet is adaptable, with little alteration, to the needs of the collector of butterflies or other natural history objects.

*Birds' Egg Cabinet. Figs. 1-7. Front and end elevation and sectional and other details of construction.*

The cabinet is of solid mahogany throughout, with veneered door panels and end panels. For the drawers, which call for most careful and exact workmanship, a perfectly sound and well-seasoned hardwood is essential. The cabinet has no ornamental features. The top is moulded and the ends (like the doors) are panelled. In Figs. 1 and 2 are shown respectively the front and end elevation, whilst 3 shows a front view with the doors removed.

The carcass consists of two  $\frac{3}{8}$  in. framed ends (for section see Fig. 7, A), to which the  $\frac{5}{8}$  in. carcass top and bottom are dovetailed (Fig. 4). The ends are rebated to take the framed back. The  $\frac{3}{4}$  in. central

gable is fixed by grooving to the top and bottom. Half-way up are the stiffening shelves (solid shelves, not merely rails),  $\frac{3}{8}$  in. or  $\frac{1}{2}$  in. thick, grooved to the middle and end gables. In each case the grooves will be stopped back a little from the front to mask the joints.

The top is shown in Fig. 5 and 6. It is  $1\frac{3}{8}$  in. deep, made up of a solid  $\frac{1}{2}$  in. top and a moulded and mitred  $\frac{7}{8}$  in. by 2 in. slip below.

The base is dovetailed together, and faced up with  $\frac{1}{4}$  in. lengths. Stout angle blocks are glued and screwed on to take circular toes  $3\frac{1}{2}$  in. in diameter by in. thick, which are screwed on from below. The base mould is shown in Fig. 5.

The doors are framed up of  $2\frac{5}{8}$  in. by  $\frac{7}{8}$  in. stiles and rails, sections being shown at Figs. 5 and 6. The panels are  $\frac{5}{16}$  in., and it will be seen that the doors open right over the gables, so that access to the drawers is easy. The rails are shouldered and tenoned as indicated by dotted lines at Fig. 4. The astragal is shown at A and B, Fig. 5. Note should be taken of the section at A, and also of the detail at B, which indicates the stopped bead at the ends. The ends of the cabinet are framed and panelled to appear like the doors. As, however, the inside faces have to be fitted with narrow fillets on which the drawers run, the panels are flush with the stiles and rails at the back, as Fig. 7, A.

At Fig. 7 is also shown a sketch of the fillets. A reference to Figs. 8 and 10 will show that grooves are run in the drawer sides to engage on the fillets, and as the comfort of using such a cabinet depends largely on the easy running of the drawers, there must be absolute accuracy in the fixing of these fillets.

Their positions should be accurately marked, and, for preference, shallow grooves should be run in the gables to receive them. In the case of the present cabinet the drawer grooves are  $\frac{3}{16}$  in. by  $\frac{3}{16}$  in., and thus the fillets will project  $\frac{3}{16}$  in. by  $\frac{3}{16}$  in. to engage with the grooves. If bedded in the gables they may be cut  $\frac{5}{16}$  in. wide by  $\frac{3}{16}$  in. deep. Of course, fillets are fixed to both faces of the central gable as well as to the ends, and all are stopped back about  $1\frac{1}{4}$  in. to correspond with the drawer grooves.

The back is framed in the manner indicated at Fig. 4. The necessary brass fittings consist of two pairs of strong brass butts, two flush bolts for left-hand door, lock, and two drop handles.

The drawers are so constructed as to be virtually airtight. Everything depends first, on accuracy in setting out, and secondly, on exactness in construction. The drawers are 17 in. wide, 16 in. from front to back (not including knobs), and 2 in. deep outside. A part side view is given in Fig. 8, sections in Figs. 9 and 10, a part top view in Fig. 11, and details of the disinfectant reservoir in Fig. 12. The drawer in reality is a box with a framed lift-up glass top. There is no space between the drawers. There is a scratched bead, which will be seen in the sections, Figs. 8 and 9. The drawers, by means of their side grooves, run on the fillets already described, and the lift-up glass tops are hidden by the fronts when the drawers are shut. The details and

sections here given are drawn half size.

The drawer fronts (Fig. 9) are 17 in. long, 2 in. deep, and  $\frac{5}{8}$  in. thick. On the top, at A, a tiny V-groove is run, and at B there is a flat bead, both of these features being simply finishing touches. If Fig. 8 is examined in conjunction with Fig. 9, it will be observed that the lift-up top comes flush with the top of the drawer front.

### How the Cabinet is Kept Airtight

The inside of the front is rebated to receive the top, a rounded fillet, C, being carefully worked right along to engage with a corresponding groove, E, run in the top frame. These rounded fillets keep the top practically airtight when on, and must be neatly mitred at the ornors. About  $\frac{1}{8}$  in. from the lower end a groove is run to take the  $\frac{3}{16}$  in. bottom of drawer. The fronts are dovetailed to the sides as in Fig. 8. The drawer sides are shown here as if  $\frac{3}{8}$  in. thick, but, in the actual cabinet under consideration they are only  $\frac{5}{16}$  in. They are slightly narrower in width than the fronts, as the top comes right down upon them. Fig. 10 shows a section through the sides. The top edge is finished with a rounded bead exactly similar to that on the front; in this case, however, it is easier to work as there is no rebate.

*Birds' Egg Cabinet.*

*Fig. 8. Part of drawer side.*

*Fig. 9. Section of drawer showing air-excluding lift-up top.*

The groove by means of which the drawer slides is shown at F in the section, Fig. 10. The groove, which may be  $\frac{3}{16}$  in. wide by  $\frac{3}{16}$  in. deep, runs to the back of the drawer, but is stopped  $\frac{5}{8}$  in. from the front. The greatest care must be taken to set out these grooves accurately, and to cut them clean and sharp. The slightest error will cause the drawer to stick, and if force is required to open or close it the gable fillets will soon wear. Like the front, the sides will be grooved in order to take the drawer bottom. Two thumb-slots (shown in Fig. 8) are worked to the top edge of each side, so that pressure with the finger may be exercised on the lift-up lid to remove it. A section is shown. The back is shown in section in Fig. 9. It also may be  $\frac{3}{8}$  in. thick, with rounded fillet, C. It is dove-tailed to the sides as indicated in Fig. 8. The bottom may be  $\frac{3}{16}$  in. thick, of sound wood. It is slid from the back into the grooves cut in sides and front to receive it. To the back it is firmly bradded to prevent its working loose.

Fig. 10. Section through drawer side. Fig. 11. Part of lift-up top, with detail of corner. All half scale.

In Fig. 3 the two middle drawers are shown slightly deeper than the others. The actual drawers are no deeper, but the front is taken down half an inch to hide the edge of the stiffening shelf, which is set back about  $\frac{1}{4}$  in. from the front edge of the gable-ends and centre partition.

Fig. 12. Details of the disinfectant reservoir which is placed in the front side of drawer.

All drawers, with their lids, should be numbered, so that each may be kept in its proper place. Preferably, the numbers of the drawers should be stamped on the top edge of drawer front and on the under front edge of lid frame.

The lift-up top is a frame which fits closely on the drawer. It is shown (in section) separately in Fig. 9 and in position in Fig. 10. It engages in three distinct ways: first, the front edge of frame fits into the rebate cut in the drawer front; secondly, the groove, E, fits on the rounded fillet, C; and thirdly, the projecting bead, D, fits exactly within the four sides of the drawer.

The frame sides are only  $\frac{1}{2}$  in. wide by  $\frac{3}{8}$  in. thick. Thus the wood used must be in perfect condition. The inner top edge is slightly chamfered, and the lower edge is run with a U-shaped groove, E, to fit the rounded fillet, C, formed on the drawer sides, front and back. A rebate is cut to receive a pane of medium heavy sheet glass, and the frame is mitred at the corners and keyed as shown in the inset sketch at Fig. 11. (The mitre key is also shown in Fig. 8.) The glass, which must fit closely, is held by a fine bead, D, which projects as shown to fit inside the drawer. This bead must be securely glued in.

**BIRTH.** The birth of every child, whether born alive or still-born, must be registered at the local registry within 42 days in England and 21 days in Scotland. A child must be registered by the father (if the child is legitimate) or the mother; failing them by the occupier of the house where the child is born, or by any person present at the birth. The father may register an illegitimate child- and give it his own name. The cost of a birth certificate is 2s 6d. In the case of a foundling information must be given to the registrar. The name may be altered within 12 months (Scotland, 6 months) of the registration. See

Baby, Childbirth.

**BIRTHDAY.** Most people think that a person born on the 30th of June, 1900, would come of age on the 30th of June, 1921. The person in question comes of age on the 29th of June, 1921, because that is the day on which he actually completes 21 years. And as the law takes no notice, as a rule, of fractions of a day, it does not matter at what hour on the 30th of June, 1900, he was born. He is 21 and of full age at the very first moment of the 29th of June, 1921.

**BIRTHMARK.** Angiomata, naevi, or port wine marks are masses of dilated blood-vessels slightly raised on the skin, scalp, lips, etc. Moles may be flat, but are usually somewhat raised above the skin. Common sites are at the side of the nose or on the cheek on the line between the angle of the mouth and the opening of the ear.

The treatment is best left to a doctor, as some of the conditions require excision, liquid air, or electrolysis, while others are treated by radium and carbonic acid snow. It is never safe to irritate moles by the use of caustics or otherwise.

**BISCUIT:** How to Make at Home. All flat bread that is baked until it is crisp may be called biscuit, but as a rule the word is used for the two principal sorts, referred to as soft and hard biscuits. The soft variety is easier to make at home. To ensure crispness the dough should be thin. It is difficult to keep it of equal thickness, so have two strips made of hardwood that does not readily warp—say, mahogany—and when the rolling of the sheet of dough is nearly finished, the two strips of wood are placed one on each side of the sheet, and near enough together to support the ends of the rolling-pin. The pieces of wood are made of a thickness the biscuits are intended to be—about  $\frac{1}{6}$ - $\frac{1}{8}$  in. The whole sheet is then easily kept of one thickness, and the biscuits are not so readily burned.

Rich biscuits need no aerating agents; they are made short with butter or other fat, and bound together with eggs. Those with less shortening, and made into dough with milk, have usually chemical aerating agents mixed with the flour, or self-raising flour may be used. Biscuits should be baked on a shelf near the top of the oven, so that they may colour.

A rolling-pin about  $1\frac{1}{2}$  in. in diameter, 16 in. long, and the same thickness throughout, is better than the ordinary kitchen roller with handles. A variety of cutters can be made from oval and oblong mustard and other tins; all that is necessary is to pierce a hole in the bottom to let in air. A soft broad brush (should be kept for washing over with a glaze of egg added to twice its volume of milk. A fork serves for pricking, or a little docker, with the spikes equidistant.

**Wholemeal Biscuits.** Into 1¼ lb. medium fine wholemeal mix, ¼ oz. bicarbonate of soda and ½ oz. cream of tartar. Rub into this 4 oz. good margarine, or half margarine and half butter. The meal is then placed in a basin, and at once mixed into dough with about ½ pint milk, in which 4 oz. sugar has been dissolved. The dough should be stiff and yet easy to handle. Turn on to a board dusted with meal, and roll out in sheets 1/6 in. thick. Use only a small piece of dough each time. The baking-sheets require no grease, nor do the biscuits need pricking. They bake in a hot oven in about 12 min. and if cooked should feel hard when pressed.

By using half the amount of flour, ¾ lb. medium oatmeal, and more milk, oatmeal biscuits could be made from the same recipe.

**Short Biscuits.** Sift ½ lb. flour — all ordinary flour or half ground rice or cornflour — and rub into it 4 oz. butter or margarine. Mix in 2 oz. white sugar, turn out the whole on a floured board, and mould to a paste. When well worked together so that it does not crumble, roll out thinly and cut into fancy shapes. Put a piece of almond, angelica, cherry or candied peel on the top, and bake in a slow oven until lightly browned. Do not attempt to remove from tin until cold.

**BISCUIT WARE.** The term denotes pottery which has been fired without or before being glazed. It includes unglazed stoneware, black Egyptian, terracotta, and Wedgwood jasper. China collectors prize certain famous and beautiful biscuit groups made at Sèvres, as well as those modelled in the Derby factory especially between 1790 and 1810.

These figures, which have the feel of new clay tobacco-pipes, sometimes with a slight translucent glaze, include groups suggested by Angelica Kauffmann's drawings, rustic figures and scenes, Derby medallion portraits of British generals and admirals, besides small round or oval plaques of Bristol make. After the best period the secret of making biscuit ware was lost, and a long interval intervened before Parian ware took its place.

Pieces ought to be dusted with clean cloths, and washed in clean water, otherwise the unglazed surface may become smeared or discoloured. *See China.*

**BISMUTH.** The various compounds of bismuth have an antiseptic, astringent, and sedative action. Those most commonly used in medicine are bismuth oxide, bismuth car-bonate, bismuth subnitrate, bismuth salicylate, the dose of each being 5-20 grains; the liquor of bismuth, dose ½-1 dram; and the compound bismuth lozenges. All these are used in irritable and inflamed states of the stomach and bowels, and relieve the pain, vomiting, and diarrhoea.

Bismuth carbonate is perhaps the best of the preparations, as it relieves acidity. For indigestion, a useful combination is bismuth carbonate, grains 10; magnesium carbonate, grains 20; and bicarbonate of

soda, grains 20. This can be taken in milk or in soda-water, three times a day, half an hour after meals.

**BISQUE SOUP.** A shredded onion and a piece of cucumber are fried in a tablespoonful of butter and added to a quart of fish stock, the whole being seasoned with salt and pepper and cooked until the vegetables are tender. Then the yolks of two eggs are beaten into ¼ pint cream and added. The soup should not be allowed to boil, but stirred thoroughly until it thickens, when it is ready to serve flavoured with anchovy sauce. *See Soup.*

**BIT: For Driving.** A bit is the mouthpiece of a bridle carried by the horse in its mouth so that the driver may cause it to obey his will. It is usually of metal, and both the cheek straps and the reins are attached to it. A curb bit has a curb chain instead of a bar, and gives the driver a strong leverage by enabling him to compress the horse's mouth. A snaffle bit is joined in the centre, and is usually provided with check pieces so that the reins may not go into the horse's mouth. *See Driving; Harness; Reins.*

**BIT: For Wood and Metal.** Small steel cutting tools or bits are used for boring wood or metal; they are rotated by means of the brace or stock, into which their square-tapered ends are fitted. Of many patterns designed to suit all kinds of boring work the most useful are the following:

*Bit. Figs. 1-8. Bits of patterns in common use. Figs. 9 and 10. Expansion bit and extra routing cutter for obtaining large diameters.*

Auger bits, Fig. 1, for deep boring, are made with a long shank, a twist, and a head. The latter has two spurs which define the size of the hole, two cutters which remove the wood and place it so that the twist draws it up, and a screw which draws the bit into the wood. Sizes range from 3/16 to 1¼ in.

Centre bits, Fig. 2, for shallow boring are made with a central prong, a spur and a cutter which acts as a lifter or lip to carry off the shaving. They are made from  $\frac{1}{4}$  in. to  $1\frac{1}{2}$  in. in diameter.

Countersink bits are employed for boring conical depressions to allow screw-heads to be turned in flush. There are three kinds in ordinary use. The flat bit, Fig. 3, having two inclined edges ground to opposite angles, is mainly used for iron and for enlarging the holes in hinges, etc. The rosehead bit, Fig. 4, is for brass, but is useful for hardwood; it has a conical head with edges which may be sharpened on a stone. The snail-head, Fig. 5, for soft woods, is conical, with one side cutter.

Nose bits, Fig. 6, are for end grain; they are hollow in the shank, with a centreing projection at the point, and range from  $\frac{1}{4}$  in. to  $\frac{1}{2}$  in. in diameter. Shell bits are similar in shape, but have a plain rounded end. They are handy for cross-grain boring where deep holes are required. Spoon bits, also similar in form, have a pointed end.

Twist or gimlet bits, Fig. 7, are for hardwoods; they have a gimlet point and are cut on the curved sides of the shank. They are difficult to sharpen. Sizes range from  $\frac{1}{32}$  in. to  $\frac{3}{8}$  in.

Turnscrew or screwdriver bits, Fig. 8, are used in those cases where a large number of screws have to be driven.

Expansive or expanding bits are intended for boring shallow holes up to about 3 in. in diameter. They have a fixed screw-head and an adjustable spur and cutter. In Figs. 9 and 10 are shown Clarke's patent expansion bit and the extra routing cutter for obtaining large diameters.

A type of bit having practically no centre point is Forstner's auger bit, a splendid tool for boring away the groundwork for carved panels, etc. Bits should be kept either in a wooden stand, with the shanks fitting in a tapered hole, or in a canvas or baize roll. Soldering bits are described under the heading soldering. *See* Brace; Drill; Soldering.

**BITE: Of an Animal.** A bite is likely to produce a poisoned wound, or, at any rate, should always be treated as such. Bleeding should be encouraged for a short time, unless it is too free, and the wound should be washed out with an antiseptic lotion, such as saturated solution of boracic acid, carbolic acid lotion (1 in 60), or a solution of permanganate of potash. If the bite is a severe one, as by a horse, the treatment will have to include that for shock— warmth and stimulants, hot coffee, spirits in water, or a teaspoonful of sal volatile in water.

In the case of a dog bite a ligature should be fastened on the limb (if the bite occurs on one), and this is done by tying a handkerchief round the limb, passing a piece of stick through it, and twisting the ligature tight. This can be left on for half an hour if necessary. Immediately the ligature is applied, or at once in bites on other parts, the wound should be sucked. There is no risk in doing this if the lips and mouth are free from abrasions. The mouth should be rinsed out with water

or spirits after the operation is completed. A piece of boracic lint or a clean rag wrung out of boracic or carbolic solution is then applied. The doctor will have been sent for, of course, and may decide on further measures. The anxiety in dog bite is whether or not the animal is suffering from hydrophobia, though, of course, one may be bitten by other animals or even by human beings suffering from hydrophobia. Therefore the dog should not be destroyed until sufficient observation of its condition can be made.

In Great Britain the only snake whose bite need be considered is the adder or viper, and the bite is rarely dangerous except in the case of children and debilitated persons.

Where insect bites or stings have occurred the sting or stings should be searched for and treatment applied as given under Bee Sting. *See* Adder Bite; Bee Sting; Frost-bite; Hydrophobia; Sting.

**BITTER ALMOND.** The skins are rough and indigestible, so they should always be removed by blanching. Bitter almonds contain a substance called amygdalin, one element of which is prussic acid. Therefore, though useful for pounding with sweet almonds, or as a flavouring, they should be used in moderation. *See* Almond.

**Bitter Apple.** *See* Colocynth.

**BITTER PIT.** The name is given to a disease of ripening apples, apparently not caused directly by fungus or insects, but physiological and due to some weakness in the tree. It is so named from depressions in the skin of the fruit, which correspond with brown spots in the underlying flesh. The tissues of the apple are stored with starch, which during the ripening process is changed into sugar. In fruit suffering from bitter pit it is found that the starch of the brown spots remains unchanged and bitter to the taste, whilst the surrounding white flesh has become sugary. At present no cure is indicated, but the trouble is less likely to occur if the trees are lightly pruned and planted in well cultivated and adequately drained land. *See* Apple.

**BITTERS.** Various kinds of bitters, including Angostura, Khoosh, orange, and peach, are made by cordial compounders, and taken with sherry, gin, etc., as an appetiser. Bitters can also be made at home. One recipe requires a bottle of orange wine, a quarter of proof spirit, and 2 oz. of bitter orange peel. The latter should be steeped in the spirits for a week or 10 days, and then run off. The spirits are then mixed with the wine, and the bitters are made.

**BLACK: The Dye.** There is not one black, but many, and dyers of fabrics are able to offer several

shades of black, more or less blue, full or reddish.

Comparison of blacks should be made not merely by looking downwards at the samples but by holding the patterns up to the light at eye-level, when the difference of tone is much more apparent. Blacks of the same shade look different when they are dyed upon a shiny or a matt surface.

There should be no difficulty in obtaining permanent blacks, such as will not turn rusty in wear. On cottons the fastest black is an aniline dye.

Linen dyes black with difficulty, but silks, natural and artificial, are satisfactory. Professional garment dyers have the means of making a better job than can be turned out at home, but faded blacks can be improved by re-dyeing with home dyes.

**BLACK-AND-TAN.** This neat-looking, short-coated terrier, also known as the Manchester terrier, is a good house-dog. Quiet and alert, he is always ready for a romp with the children. He is, moreover, a good ratter.

*Black-and-tan Terrier. Specimen of the miniature variety of this short-coated breed of dog.*

The head is long and wedge-shaped, with tapering jaws, small bright eyes and a black nose. Jet-black is the predominant colour, picked out sharply here and there with rich tan. The muzzle, lower jaw and throat, a spot on each cheek and over each eye should be tan; so should the front legs below the knees, but the hind legs should have tan on their inner side only. The same colour marks the under side of the tail, the vent, and there is a touch of it on each side of the chest. The weight varies from 10 lb. to 20 lb., but there is also a toy race which does not exceed 7 lb. *See Dog ; Terrier.*

**Black Beetle.** This is an incorrect name commonly applied to the cockroach, which is not a beetle. *See Cockroach.*

**BLACKBERRY.** The cultivated varieties of blackberry are rarely superior to the best of the wild brambles in flavour, but they produce much larger fruit, ripening in September and October. The parsley-leaved blackberry is one of the best for gardens. The best of the newer ones are Edward Langley, Pollards, Best of All, and Himalayan Giant. All flourish in ordinary soil that has been dug and manured. The latest novelty is a white blackberry which was found growing wild in Bedfordshire and is available for cultivation in gardens.

Blackberries are readily propagated by pegging down the tops of canes, for roots are thrown out freely, and when they are abundant the tips can be cut away and the parent liberated. They succeed on arches, trellises and frameworks of stout stakes.

The principal difficulty is to get the plants established, and severe pruning is required. It should begin with the planting, and

consists in cutting whatever canes the plants may be carrying close to the ground. The canes will bear a large number of strong laterals if they are stopped when they have grown to about half their normal height, say, 3 ft. The laterals may be pinched at the foot. This treatment dwarfs the plants, which may be convenient in some gardens, and as a rule it gives very good crops of fruit. After the first year pruning is done as soon as the fruits are gathered by cutting out the old canes. *See Apple; Bottling.*

#### **BLACKBERRY AND APPLE JELLY.**

Stalk and examine 4 lb. ripe blackberries and turn them into the preserving pan with 1 ½ lb. of apples, washed and cut in slices, but not peeled and cored.

Then pour into the pan ½ pint water and the juice of one lemon. Boil until the apples are soft, then strain off the juice through a jelly bag. Rinse out the pan, measure the juice back into it, and add 1 lb. white sugar to every pint of juice. Boil it steadily until it will jelly firmly when tested on a plate. Pour the liquid into dry, warmed jars and tie them down at once. Should the blackberries be poor and what is termed bulley, use double the amount of apples and only ¾ lb. sugar to each pint of juice. *See Apple.*

**BLACKBERRY AND APPLE PIE.** For every pound of blackberries used to make this covered tart take ½ lb. apples, 3 tablespoonfuls sugar, and a breakfastcupful water. Fill a pie-dish with the fruit and sugar in layers, taking care that the fruit is on the top. An inverted egg-cup should be stood in the centre. Then pour in the water and cover the dish with a short crust. Bake the pie in a moderate oven for about ¾ hour. One lb. blackberries will be enough for 4-6 persons.

**BLACKBERRY CREAM.** Put 1 lb. of blackberries in a saucepan with ¼ lb. sugar, the thinly peeled rind of a lemon, and 2 or 3 apples peeled and sliced. Stew slowly until the fruit is soft, stirring frequently; then rub the mixture through a hair sieve. Dissolve ¾ oz. gelatine in 2 tablespoonfuls of water, and strain it into the juice. When the latter is lukewarm, stir in ½ pint of whipped cream, and pour it into a wet mould. When the mixture has been allowed to set in a cool place, it can be served with jelly.

**BLACKBERRY JAM.** Although it is often made without apple, even a little of the latter is an improvement to blackberry jam. Peel, core and slice 1 ½ lb. of apples, and put them in the preserving-pan with a gill of water and 4 lb. of white sugar. Stew the apples until soft, stirring frequently with a wooden spoon, and adding more water, if necessary.

When soft, add 4 lb. of stalked blackberries, and boil steadily until some of the jam sets when tested. Remove scum during the boiling. Turn out jam when finished into dry, heated jars, and tie them down at once. *See Apple; Jam.*

**BLACK CAP PUDDING.** One beaten-up egg to  $\frac{1}{4}$  lb. of flour and a pinch of salt is the proportion for the batter, half a pint of milk being added to bring it to the right consistency. The batter is heated and stirred. A mould having been thickly greased, 1 oz. of cleaned currants are sprinkled into it, then the batter is poured in and the mould covered with greased paper and allowed to steam for an hour and a half. *See Batter.*

*Black Cap Pudding. A wholesome steamed batter capped with currants.*

**BLACKCOCK.** This game bird, in season from the middle of August to the end of November, is usually roasted and is excellent and economical. The female bird is known as grey hen. They should be hung and kept for a few days after shooting. After plucking and cleaning the bird, wipe it inside and out with a damp cloth; washing spoils the flavour. It should be trussed as a chicken. Roast for about an hour in a moderate oven, basting it frequently. Dish on a slice of buttered toast with bread sauce, gravy and fried breadcrumbs served separately. *See Game.*

**BLACK CURRANT.** Of all currants the black are the richest in flavour. They have none of the extreme acidity of the red, but have a rich almost vinous taste. The plants thrive best in heavy, retentive soil, and are most healthy and productive when throwing up an abundance of suckers from the base. Whatever the soil, large pieces of young wood may be selected for cuttings, and planted for most of their depth, 5 to 6 ft. apart, in autumn, with all their buds left on. They should become profitable in their third year and be at their best in the seventh year from the insertion of the cutting.

The rooted cutting is shortened to about 9 in. at the end of the next season's growth in order to increase the number of main branches. No summer pruning is needed, and the winter pruning merely consists in cutting out parts of the old branches in order to make room for young ones. The young wood that is produced from the plant in one season bears fruit the next.

**Currant Diseases.** One of the most serious is that termed nettlehead, or reversion. The bushes may revert by degrees. The leaves become elongated and narrow, assuming the nettlehead form; there is change in the flowers, and fruit production almost entirely ceases. May and June are the best months to detect the disease, which can only be done by carefully inspecting the bushes.

Methods are recommended for dealing with reversion in Leaflet No. 277 of the Ministry of Agriculture. The plantation should be examined systematically, if

possible twice a year, at blossoming time and again in May or June. Reverted bushes should be marked, and after the crop has been gathered they should be grubbed up and burnt. Care should be taken to propagate only from sound stock. Since the disease is conveyed by the big bud mite, keeping down this pest will reduce the incidence of the reversion disease. The surest method of detecting reversion is to count the veins running from each side of the midrib in the terminal lobe of the leaf; if there are fewer than five veins, reversion may be suspected. *See Big Bud; Bottling; Magpie Moth; Red Currant; White Currant.*

**BLACK CURRANT GIN.** Made from 1 quart of black currants,  $1\frac{1}{2}$  lb. of Demerara sugar, and  $1\frac{1}{2}$  quarts of gin. All that is necessary is to put these ingredients into a stone jar and shake them occasionally. This drink improves with keeping.

**BLACK CURRANT JAM.** A little less than a pound of sugar is sufficient for 1 lb. of black currants, it should be added to the fruit in the preserving-pan, and the whole allowed to stand for some time. Then the sugar and fruit are brought slowly to the boil, being thoroughly stirred so that they do not stick to the pan. About 35 minutes' boiling should be sufficient, but the only safe test is to place a little in a saucer and stand it at an open window to see whether it will jelly when cold. The covering of the jam should be done whilst it is quite hot. *See Jam.*

**BLACK CURRANT JELLY.** Simmer the currants in an earthenware jar placed in boiling water until all juice is extracted and then strain through muslin. With a pound of sugar to each pint, the juice is boiled until it sets firmly when dropped on a plate. It is then poured into jars and covered at once.

**Black Currant Mite.** This is the name of the insect which causes the disease known as Big Bud (q.v.).

**BLACK CURRANT PUDDING.** The ingredients are:  $\frac{1}{2}$  lb. of flour, 5 oz. of suet,  $1\frac{1}{2}$  lb. of black currants and 2 tablespoonfuls of brown sugar. The suet is chopped and mixed with the flour, which is then made with water into a soft but not sticky paste. A quarter of the suet crust should be now cut off and put aside for the top of the pudding, the remainder being rolled out about  $\frac{1}{2}$  in. thick on a floured board. Line a greased pudding basin with this pastry, then put in the currants, with the sugar and about a gill and a half of water. The small piece of pastry for the top is rolled out and pressed on to the basin (a little water being used to make the two edges adhere) and then covered with greased paper. A floured pudding cloth is tied over top of basin and the pudding boiled in fast-boiling water for about  $2\frac{1}{2}$  hours. It should be served with cream. This will be sufficient for 4-6 persons.

**BLACK DOLPHIN.** Collier, black fly and black dolphin are names applied by gardeners to the aphid that settles on the terminal shoot of broad beans. Similar in form and habits to the aphid that troubles the rose-grower, the black dolphin is rendered distinct by its sooty hue, delicate pale legs and antennae, and a long fine beak which is thrust into the cuticle of the plant whose juices are sucked through it. It exists through the winter in the egg-stage on some perennial weed such as dock. The eggs hatch in April, and the wingless young colliers settle upon the new vegetation. These are nearly all females, which produce living young, and the multiplication of these pests goes on indefinitely.

As soon as the pest appears the tops of all affected bean plants should be nipped off, dropped into a tin and emptied on the kitchen fire. Where this course is not possible owing to their having been allowed to spread, the plants should be syringed with an insecticide or with strong soap-suds free from soda, washing off the soap with clean water within twelve hours. Broad beans which are sown in November suffer much less damage from this pest than spring-sown plants.

**BLACK DRAUGHT.** This name is given to a strong aperient containing Epsom salts, liquorice, spirit of sal volatile, and senna. The usual dose is 1½ oz. taken early in the morning. The previous evening a blue pill (5 grains) is taken, the combination being a common remedy for such ailments as congestion of the liver or biliousness.

**BLACK EYE.** This is an effusion of blood under the loose skin over and around the lids. It is due to a blow. As the tissues beneath the skin in this region are very lax, considerable subcutaneous bleeding takes place, and this accounts for the discoloration, which at first is dark purple and then passes through brown and green to yellow. Apply cold compresses made of folded flannel or lint, sufficient to cover the area, wrung out of iced water, and applied as continuously as possible for a few hours. An older remedy is the application of a piece of raw beef.

When swelling has subsided the removal of the discoloration can be hastened by compresses soaked in spirit lotion, methylated spirit, one teaspoonful, water up to two tablespoonfuls, and covered over by gutta-percha tissue, the whole being held in position by a bandage. Several times a day a little vaseline should be smeared over the eyelids, which are then gently massaged. *See Eye.*

**BLACKHEAD: How to Cure.** Blackhead or comedo is a little white or yellowish elevation of the skin with a black centre and is often associated with common acne, which is a chronic skin disease characterised by pimples, blotches, blackheads, and a greasy skin on the chin, forehead, shoulders, and back. It is commonest in young people at the change from childhood to adult life. The hard pimples with

little black dots in their centre are the tiny skin glands which have become choked with secretion which has undergone degeneration. Later these little red mounds become pustular and discharge. New crops of pimples and blackheads succeed each other, the affection often persisting for years.

The parts affected should be washed thoroughly night and morning with soap and warm water. After this, mop the parts for five minutes with water as hot as can be borne. Then press out with the finger-nail, guarded by a thin silk handkerchief, or with a comedo-extractor (which any chemist can supply), as many of the blackheads as possible. At bedtime apply the following lotion with a little cotton-wool, and allow it to remain on all night:

Precipitated sulphur	1 part
Rose water	24 parts
Lime water	24 „

If this causes irritation apply cold cream until irritation disappears and then use an ointment of salicylic acid, sulphur (10 grains each) and zinc oxide (60 grains) with soft paraffin (to make 1 oz.), resuming the lotion later.

The diet should be very plain with ample fresh and stewed fruits and green salads. Fatty foods, pastry and sweets should be avoided. An excellent aid to clearing the skin is to drink 8 glasses of water, two at a time, between meals.

Where the pimples tend to become full of matter, ¼ grain doses of sulphide of calcium taken four times a day often have a drying-up effect on the spots.

For the anaemia and constipation so frequently noted in acne the following prescription is recommended:

Sulphate of iron	16 grains
Sulphate of magnesium	1 ounce
Dilute sulphuric acid	1 teaspfl.
Peppermint water (enough to make)	4 ounces

Take a tablespoonful of the above prescription in a wineglassful of water, at least half an hour before taking breakfast.

**BLACKING.** For preserving and polishing black leather boots, various dressings mostly depend upon the use in their manufacture of a form of charcoal made from bones, known as ivory black or bone black. The first recipe makes a liquid blacking.

Mix 8 oz. of ivory black with 1 oz. of sperm oil so that a smooth paste results, then add 6 oz. treacle mixed with an equal quantity of good malt vinegar. Stir these well together, and add gradually 1 oz. (by weight) sulphuric acid. Effervescence and heat result, and when the effervescence has subsided, add 16 oz. vinegar, and bottle the blacking whilst still warm.

For use on calf leather boots, the recipe of a polish which is waterproof is:

Carnauba wax, 10 oz.; beeswax, 3 oz.; stearin, 1

oz.; shredded and melted together in a tin saucepan. When melted, remove from the fire and add spirit of turpentine, 45 oz.; with which aniline black,  $\frac{1}{2}$  oz., and ivory black, 2 oz., have been previously mixed. The paste should then be made smooth by rubbing in a mortar.

If the paste is required for brown leather boots, phosphine and bismarck brown, 2 dr. of each, are added in place of the aniline black and ivory black.

Boot varnish is made as follows, and applied with a small sponge:

Dissolve 20 dr. blue-black aniline dye and 31 dr. bismarck brown aniline dye in a gallon spirit to form the "mother-liquid dye." Then mix 2 pt. of this with 1 gall, spirit, and camphor, 11 oz., Venice turpentine, 16 oz., shellac, 36 oz.; finally adding 2 pt. benzine with which has been mixed 3 oz. castor oil and  $1\frac{1}{2}$  oz. linseed oil. *See Boot.*

**BLACK JAPAN.** A compound of asphalt, boiled oil, and turpentine is used as a varnish for metals under the name of black Japan. Brunswick black is a similar article; when imparting a dull surface it goes by the name of Berlin black.

**BLACK ROT.** Nearly all the cultivated plants belonging to the cabbage family are liable to be attacked by this disease. In Britain it is most frequent in kale, cabbage, and cauliflower. A characteristic feature is the appearance of dark or blackened veins in the foliage, which turns pale or yellow, the veins sometimes standing out so clearly as to appear like a black network. When the affected leaves and stalks are cut across, the veins or vascular bundles appear as dark points, and when the stem is thus examined a characteristic black ring of wood is present.

*Black Rot. Its effect on a cabbage stalk, here shown in sections. (By permission of the Ministry of Agriculture)*

When young plants are thus attacked they may survive for some considerable time, but remain stunted and unhealthy. In the case of cabbage and cauliflower, no head is formed, and in turnips and radishes the root fails to develop properly. In severe cases all the leaves may fall off and the plant remain merely as a long stem with a few deformed leaves at the apex; in other cases a head which is apparently sound is found to be diseased inside. Plants are attacked at all ages. Infection usually takes place through the parts above ground and generally by way of the leaves. Slugs and caterpillars

are carriers of the disease.

Another source of infection is contaminated seed, which may produce infected seedlings. Contaminated manure or soil in which diseased cabbages have been grown is a source of danger. A small amount of infected soil may ruin the bed, and if there is any doubt such soil should either be rejected or sterilised. Diseased plants should always be burned. They should never be buried, thrown on the manure heap, or given to pigs, chickens or other animals. Where the disease has existed no cabbages should be grown on the land for five years. Leaflet 68 issued by the Ministry of Agriculture deals with this disease, and gives information about methods of disinfecting the soil.

**BLACK SCAB.** This is the name of two diseases, one affecting apples and pears, the other potatoes. The first shows itself in the form of black specks and spots, which spread into large discoloured patches. The fruit, leaves, and twigs may all be affected. In bad cases the fruit cracks. In drier years it is rarely so severe as in wet ones. The best treatment is, in winter, to prune out all diseased and unhealthy-looking shoots, and to spray with Bordeaux mixture (q.v.) or lime-sulphur, just before the flower-buds open, and again as soon as the petals have fallen.

In potatoes black scab (wart disease) appears to be a disease of the tuber only. The first sign is a series of warts in the eyes, which develop into black crinkled masses. The affected tuber rots, and a dark fluid of offensive odour oozes out. The disease may not affect potatoes in store during the winter, but may show itself at the eyes when the sprouts begin to push. Every tuber affected and the haulms should be burnt. No seed from the affected stock should be planted, even if part of the crop appears to be clean.

It is perfectly easy to prevent potatoes being damaged by this disease by planting only varieties which are immune to its attacks, e.g. Witch Hill, Arran Comrade, Abundance, Great Scot, Majestic, and The Bishop. *See Apple; Pear; Potato.*

**BLADDER PLUM.** The malformation and distortion of the young fruit of the plum-tree, known as bladder plum, is caused by a minute fungus, *Ascomyces pruni*, which is perennial in the tree affected and in spring spreads into the tissues of the new shoots. The plums attacked are distinguished by their larger size, pointed ends, hollowness, and the skin having a bloom upon it due to the threads of the fungus bursting through; they soon turn yellow and shrivel. It has been suggested that the twigs bearing these bladder plums should be cut well back and destroyed; but it is probable that the fungus runs through most of the tree. *See Plum.*

**BLANCHING.** Calf's head, calf's foot, sheep's and lamb's trotters, veal and lamb sweetbread and brains are all blanched before cooking. They are first

placed under a tap of running water in order to rid them of blood, and then put in a pan of cold water, and brought slowly to the boil. They are allowed to boil for from 15 to 20 min., with the exception of veal sweetbread and brains, which should only be allowed to boil for 10 min., and lamb's sweetbread, which must not be allowed to boil at all. The water is then drawn off and the meat cooled before cooking.

Celery, artichokes, endives, turnips and small onions which have been kept for some time may be blanched before cooking. They are scalded, and then cooled by steeping in cold water until just warm, when they should be placed on a sieve ready for use. *See Almond; Calf's Head, etc.*

**BLANCMANGE.** Blend two heaped tablespoonfuls of cornflour with a little cold milk, till it is like smooth, thick cream. Boil the rest of a pint of milk, with a piece of lemon rind to flavour, and add about two tablespoonfuls of sugar, stirring till the sugar is quite dissolved. Remove the lemon and pour the hot, sweetened milk over the cornflour paste, stirring all the time, as in making starch. Put the mixture back in the pan and boil gently for five minutes, still stirring continuously. Then pour into a wetted mould and allow to stand in a cold place for several hours before turning out.

*Blancmange. Sweet cornflour blancmange flavoured with orange and coloured with cochineal.*

If a few drops of cochineal are stirred in before taking it off the fire, the blancmange will be pink. A little vanilla essence or almond flavouring may be used instead of the lemon. A large tablespoonful of grated chocolate may be added to the above recipe when blending the cornflour and milk, and the blancmange served with whipped cream.

When in season, stewed raspberries yield sufficient juice to make a delicious blancmange. Cook this as for ordinary blancmange, using the syrup of the raspberries as liquid, and serve with whole raspberries.

A more elaborate blancmange is made by pouring the cornflour mixture over several layers of fruit placed in the bottom of a mould. Glace cherries, bananas, and tinned pineapple will make a good foundation. When the mould is half full, add another thick layer of mixed fruit and fill to the top with blancmange. The first layer must be nearly cold before the second is added.

**BLANKET.** Roughly divided into four types,

blankets are of (1) a loose cellular weave, (2) Witney, (3) cloth, and (4) Scotch diagonal twill. The first of these are expensive, loosely woven to admit free passage of air, very light, but of the finest wool to ensure warmth; made in colours and satin bound.

The hairy pile of the Witney blanket is scratched or teased out of the body of the article, and the fabric is weakened to that extent. The better qualities are made with long wool, and the loss can be afforded, but the lowest qualities are less satisfactory, because there is too little foundation left, and the pile comes away in wear and washing. Witney blankets are warm when new, but become in effect cloth blankets when their pile has been lost. Cloth blankets are made of shorter wool and their surface is slightly raised, but not by wire brushes, and their wear is dependent upon quality. There are both all-wool and union blankets, and the best qualities of union (i.e. wool and cotton) are to be preferred to the cheapest all-wool varieties. Scotch blankets are made of strong wool, and wear well.

Blankets are sold per pair, of dimensions which should be stated in inches, and calculated to fit respectively single or double beds. It is advisable to see that a good overlap of half a yard per side is left.

In any blankets it is essentially desirable to have a maximum of warmth to a minimum of weight. The fine wools are warm without being heavy, but are much more expensive than the hairy wools. The finest wools are used for blankets for babies' cots, and there are also camel-hair blankets in colours and satin bound to be obtained in all sizes. Jacquard dyed blankets are not so practical, where colour is liked, as those plainly dyed.

Moth does not attack unwashed new blankets, thanks to the sulphur fumes with which they are bleached. Washed blankets attract moths, as the softness makes them ideal for laying their eggs. When stored it is advisable to wrap each pair separately in newspapers and place in a chest or trunk with a tight-fitting lid.

Washing blankets demands special care, and plenty of water, hot, but not too hot for the hand to bear. When the articles have been wetted through, a mild soap should be added. A good flake soap of guaranteed suitability in washing woollens may be used and dissolved before use. The quantity should be sufficient to produce a quick lather to be poured in and the blankets left to steep before beginning to dolly them or to plunge by hand. Blankets must never be rubbed in washing. When a large part of the dirt has been removed, the blankets should be given a second wash. The water should be wrung out either by hand or by mangle, and the blankets should have two washings in lukewarm water to remove all vestiges of soap.

A yellow tinge may be corrected by adding a little blue to the washing water. They can be whitened a little by prolonged exposure to sunlight, which is also the best way to dry them. In washing blankets the aim is not merely to cleanse, but if possible to improve

them by turning them out in fresh, light, spongy condition, and the method of drying is all-important. The housewife has to use lines or stretch the blanket on the grass, and in either event it is advisable to turn the article about frequently. A sunny day with a good wind should be chosen.

Old blankets are useful for ironing-table pads, or, cut to shape and blanket-stitched, for table underlays to prevent the spoiling of polished table tops by hot dishes. Odd pieces of blanket afford good scouring cloths for washing floors and similar work. *See* Bedding.

**Blanket Cloth.** A heavy woollen fabric used chiefly for coloured and white sports coats.

**BLANQUETTE.** A form of veal stew, for which the ingredients are 2 lb. breast of veal, 2 onions, 2 cloves, 2 carrots, a bunch of herbs, salt, pepper, 1 oz. flour, 1 egg, and 1 tablespoonful chopped parsley. The meat must first be freed from skin, fat and gristle and cut into small pieces  $\frac{1}{4}$  in. thick. These are put into a saucepan and as much warm stock or water poured over them as will cover them, generally about a pint, then brought to the boil and skimmed. The onions are peeled and a clove put in each; the carrots are scraped and cut up, and the herbs tied up. All are then put into the pan, seasoned, covered, and allowed to simmer gently for one hour.

Take out pieces of meat and strain gravy. Mix flour with a little cold water, stir into gravy and bring to the boil, stirring all the time. Simmer for five minutes, then cool slightly and add the yolk of an egg well beaten. Put pieces of veal into a small pan, strain gravy over and heat through; on no account let it boil. Pour out on a dish, and garnish with parsley, and the blanquette is ready for the table.

**BLAUD'S PILL.** A favourite preparation of iron, Blaud's pill is chiefly used in anaemia, especially in those types where there is a great deficiency of haemoglobin, the red colouring matter in the blood. Each five-grain pill contains one grain of carbonate of iron, the dose being one to three pills. To be of use the pills must be freshly made.

**BLAZER.** An unlined jacket resembling a cardigan with three pockets, but with collar of the step variety, a blazer may be used for ordinary sports wear by boys or girls. Blazers for schools, colleges, and universities have their special colours, as also have those of many clubs.

**BLEACHING.** The articles calling for treatment are mainly white cottons and linens, sometimes woollens and, less frequently, silk. Cottons and linens are best bought fully bleached. Unbleached cottons and linens are dingy in colour, as the raw material carries with it impurities of a waxy or gummy nature. These discolorations disappear gradually in wear and washing and the article assumes a whiter appearance; the

whitening process is assisted by drying the washing in the open air, and preferably in a good breeze. Country and sea air are better than town air for the purpose of this natural bleaching.

It is wrong to boil linens in washing soda, although cottons may be treated in that way to whiten. Soda disintegrates the linen fibre and causes it to come away as short fluff. A good mild soap should be used in washing linen and well rinsed out. If linen is ironed with soap still left in it, or if linen after washing is stored above a hot cylinder, a yellow tinge is caused which may call for bleaching. This colour can generally be removed by careful re-washing with repeated rinsings, followed by open-air bleaching. The article should be spread on the grass and periodically moistened. The continual wetting and drying has much to do with the removal of the colour.

### How Cotton Fabrics are Bleached

When cotton is bleached by professional bleachers from its natural colour to a full white it is boiled in clear lime water and washed; treated with weak acid and washed; boiled with caustic soda and washed; steeped from 2 to 4 hours in clear solution of chloride of lime; boiled for 12 hours and washed; left in weak acid again for 3 or 4 hours and washed: finally it is rinsed and blued. To attempt the process at home without the necessary plant would lead to damage to the fabric. If chloride of lime, i.e. bleaching powder, is used at all the solution should be made three days in advance and the mixture should be stirred up or shaken in a large jar repeatedly at intervals. Only the clear liquor must be taken and about 1 lb. of the powder should be used to a gallon of water. The cottons should be fully washed and rinsed before they are put to steep in the bleaching fluid. The action of the bleaching powder is hastened if the cottons are previously rinsed in water acidulated very slightly with sulphuric acid. When taken out it is important to rinse them well in water to which washing soda has been added. They must be well rinsed again and then dried.

Bleaching powder should not be used on woollens. It dissolves wool if left for a sufficient time, and in any case makes it harsh. Necessity to bleach woollens chiefly arises when repeated or careless washings have turned what should be white flannel or white knitted goods to a yellow tone. To whiten these a solution of 1 lb. soap and 3 lb. ammonia to 5 gal. water may be used. The action is slow, and the articles may have to be left some days.

A more expensive method of bleaching is applicable to cottons, linens, woollens, and silks. It involves the use of peroxide of hydrogen. A solution should be made in an earthenware vessel of one part of commercial peroxide of hydrogen to ten parts of water and a few drops of ammonia, sufficient to make the mixture slightly alkaline. The articles should be put to steep wholly under water, or stained portions will result. The vessel should be covered against light, which interferes with the result. After half an hour

or so, when the articles have been thoroughly penetrated, they should be squeezed semi-dry and hung in a draught to dry. The bleaching takes place while the articles are drying and only if the atmosphere is cool enough. The operation cannot be done if the air is warmer than 68° F., and the peroxide must be new. A good white can be obtained with peroxide without danger to delicate goods, but pains must be taken to wash it out afterwards.

Lace needs to be treated with special care during the bleaching process. For this use a very weak solution of chloride of lime and water, just sufficient of the former to give the water a faint smell. This provides an effective bleach which, in addition to its remarkable whitening properties, does not injure the lace. Another simple way of bleaching lace which has become discoloured is to press it gently with a warm iron and then sew in a clean linen bag. The latter is left to soak in olive oil for a whole day and night, and afterwards boiled in a lathery mixture of soap and water. When the boiling has continued for  $\frac{1}{4}$  hour or 20 min., rinse the bag thoroughly in slightly starched water and then take out the lace. The latter should be stretched out to dry. *See Cotton; Straw; Wool, etc.*

**BLEACHING POWDER.** By passing chlorine gas over layers of slaked lime, a pungent smelling white powder is obtained which is used for bleaching purposes, and is also employed a disinfectant. A liquid form is made by slaking the powder with water, about 2 oz. to the pint. When used as a bleach for clothes, a tablespoonful of the powder is added to a copperful of clothes.

It is useful also for removing mildew stains from linen. For bleaching engravings, a tablespoonful of the clear liquid is mixed with a pint of water and the engraving soaked in the liquid. It is necessary afterwards to remove all traces of the bleaching liquid by soaking the engraving in several changes of clean water, as any trace of chlorine left in the paper would in time cause deterioration.

**BLEACHING SOAP.** The chemical generally employed in these is perborate of sodium, a salt which releases oxygen on contact with water. Oxygen plays an important part in open-air bleaching, and when the bleaching soaps are used, the wash-tub does work that is ordinarily done during open-air drying. Bleaching soaps present one means of increasing the whiteness of articles which cannot be exposed for long.

**BLECHNUM.** This is a family of vigorous hardy and greenhouse ferns. *B. brasiliense* and *B. glandulosum* are grown under glass in a compost of peat, loam and sand, and need abundant supplies of water from spring till autumn, but do with less during the cold months. *Blechnum spicant*, the hard fern, grows wild in Britain; it is dwarf and evergreen. There are many varieties of this fern. Pron. Blek'num.

**BLEEDING.** Haemorrhage, or bleeding, may be external, as from a wound, or it may be internal. It may occur from arteries, veins, or capillaries, the small vessels which unite arteries to veins. Blood from the arteries is bright red, and comes in spurts, the direction of these being away from the heart. Blood from the veins is of a dusky red or a purple hue, and flows in a steady stream. Blood from the capillary vessels is redder than venous blood, and it oozes out of the surface of the wound. Of the three forms bleeding from an artery is the most serious. Vein bleeding can nearly always be stopped by pressure. Bleeding from capillaries is slight.

*Bleeding.* 1. Place for compressing common carotid artery. 2. Pressure to arrest bleeding from subclavian artery. 3. Pressure applied to subclavian artery by means of key handle. 4. Pressure applied to superficial temporal artery. 5. Compressing occipital artery behind ear. 6. Facial artery pressed against lower border of jaw. 7. Forced flexion of elbow joint to arrest bleeding from arm. 8. Pressure on brachial artery. 9. Bleeding from sole arrested by pressure on posterior tibial artery. 10. Compressing femoral artery.

Haemorrhage in certain parts of the body is given specific names. Cerebral haemorrhage (one of the causes of apoplexy) occurs from an artery in the brain; haemoptysis from the lungs; haematemesis, the stomach; haematuria, in the kidneys or urinary passages; epistaxis, from the nose.

In wounds of the hand, arm, foot, leg, or other parts, the simplest plan to stop bleeding is to press the

fingers on the wound; or, if that is unavailing, then to apply pressure to the main artery. In bleeding of the forearm, one method of putting pressure on the brachial artery is to place a pad in the hollow of the elbow and bend the arm. Bleeding from the leg may be controlled by placing a pad in the hollow of the knee and bending the leg.

In the case of the thigh, the femoral artery is compressed against the bone in the middle of the groin. When the bleeding is from the neck, pressure is applied to the carotid artery, a little below and on the outer side of Adam's apple. In bleeding from the nose a cold cloth on the nape of the neck and another on the forehead are often effectual.

Another method of stopping bleeding is by the application of an improvised tourniquet. *See Tourniquet.*

In capillary bleeding over a large surface one may employ styptics such as tannin, perchloride of iron, gallic acid, turpentine, or alum; but very hot and very cold water often prove effectual. In internal bleeding, indicated by excessive pallor and a thready pulse, send for the doctor and meanwhile keep the patient perfectly still.

*Bleeding Heart. Foliage and arching sprays of drooping pink flowers.*

**BLEEDING HEART.** *Dicentra* or *dielytra*, popularly termed Bleeding Heart, is a herbaceous perennial, hardy except in the most exposed situations, and makes a bush nearly 3 ft. high. The pink flowers are borne on long arching stems, and are nearly an inch across, heart shaped, and particularly graceful in effect.

**BLENDING.** Indian or Ceylon teas are frequently blended with China tea, the strong coarse flavour of the Indian product being mellowed by the subtler and more delicate flavour of the China tea.

No fixed rules as regards proportions can be laid down, but the following would make a good blended tea: take 1 lb. coarse Indian tea,  $\frac{1}{2}$  lb. of China tea,  $\frac{1}{4}$  lb. of Assam, with  $\frac{1}{4}$  lb. of broken Pekoe.

Butter and margarine can be blended in the home, but such a mixture is not so good for children as genuine butter. The mixing may be done on a pastry board, the butter and margarine being worked together with the aid of wooden butter pats, or they may be melted together in a basin and then thoroughly

stirred whilst cooling. *See Adulteration; Coffee; Tea; Tobacco, etc.*

**BLIND: Their Training.** Each local authority is obliged by law to provide suitable education for the blind children in its area from the age of five years. The parents should get into touch with that body in good time, so that the child is able to begin his schooling as soon as the age of five is reached.

When a person loses his sight in middle life, his friends should seek the assistance of the county education authority, for it is the duty of that body to see that blind persons receive such occupational training as will fit them to earn their own living. During training a maintenance grant can be obtained. Do what is possible to banish self-commiseration from the patient.

If blindness comes on in advanced age, the same principle of keeping alive in the patient's life as many interests as possible should be followed. His friends should get in touch with the nearest Home Teaching Society, which will send a visitor to teach Braille. A blind person unable to follow his employment can obtain an old age pension at 50. *See Braille; Pension.*

**BLINDS.** Blinds are out of fashion owing to the use of practical long and casement curtains; and also of pelmets or valances to finish the window scheme. Owing to these the lace edging of sitting-room or trimmed blinds is no longer required, and in town houses obscures the daylight when the blinds are only partially drawn up to show this decoration at the top of the window. For kitchen and back premises dark green blinds are best as they only require dusting and can be kept clean if sponged or wiped with a damp cloth. Even here oiled silk or American cloth is being used for casement curtains. Another substitute is the latticed outside shutter, which with easements open gives a sufficiently darkened room for sleep with a regulated supply of air.

Where holland or linen blinds are washed at home, the best plan is to unstitch the hems before putting them in the water. Then, if the material stretches, it may be cut to fit the roller and sewn up again, with little or no trouble, while, if it shrinks, the roller may be cut to fit the blind.

**Fitting and Repair.** Apart from Venetian blinds, almost all blinds in use are mounted upon rollers, upon which the material forming the blind is wound. The first thing to see about is that this roller is horizontal; if it is not, the blind will not roll up flat, but will creep over to one side.

When putting up a new blind a string can be stretched tightly between two thin nails driven into the framework of the window, the string occupying the place where the roller is to be fitted. This string should be tested with a spirit level and adjusted until it is horizontal. The simplest arrangement of mechanism

consists of two metal supports providing bearings for a plain wooden roller, with suitable pins in the ends to act as an axle. At one side of the roller is a V-shaped pulley wheel around which passes a stout string or cord, joined at the ends to make it continuous, tension being brought upon this cord by an adjustable wheel mounted in a metal framework known as a blind rack. Some of these racks have a ratchet arrangement; others a screwed rod and milled nut for adjustment. Racks of all patterns are fixed to the window frame by means of screws.

Points to watch are that the roller can revolve truly and freely; that the cord is sufficiently thick to grip the pulley; and that the wheel on the blind rack rotates easily. Cord tends to stretch, and needs continual attention if the blind is to function properly.

The renewal of the blind cord is done by winding the blind up to the top and removing the old cord and threading a new one through the hole in the lever, turning it once or twice round the spool and then through a hole in the roller end provided for the purpose. A knot is then tied in the cord, and this prevents it from pulling out of the hole.

Automatic or spring blinds are made with a hollow roller, into which is fitted a coiled spring. One end has an automatic ratchet action. With these blinds no cords or controls are necessary. The blind is merely pulled down as far as needed. Another form of spring blind has a hollow roller, in which a spring is located at one end of the roller, also a ratchet with a spring-pressed lever pawl. This type is good for general domestic use. *See Sun Blind; Venetian Blind; for other treatment of windows, see Casement, Curtain, etc.*

**BLISTER:** How to Treat. A blister is an accumulation of fluid beneath the superficial layers of the skin occurring in skin diseases, burns, from the use of vesicants, and as a result of chafing and pressure. The last variety is usually found on the hands and feet. When much walking has to be done, the feet should be washed with a solution of alum or with methylated spirit or weak formalin. The feet and the insides of the socks can then be dry rubbed with a soap or a smooth dusting powder applied. If blisters form they should be pricked with a clean needle and covered over with boracic ointment on a rag, fastened on smoothly. Blisters which occur on the hands are dealt with in the same way. *See Foot; Hand; Skin.*

**BLOATER.** These herrings, which are cured at Yarmouth and other seaports, are usually grilled or fried. The head is removed, and the bloater may either be cooked as it is or split open, the backbone and roe removed, the roe being cooked separately. In the latter case, to fry the fish, heat a little dripping or lard in a frying-pan until a faint blue smoke arises, then drop in the fish, inside down. When browned turn it over. To grill, lay it, inside up, on a heated, greased gridiron and turn when brown. Another method of treating bloaters is to place two, insides together, on a gridiron and broil them over a clear fire. In all these cases the

fish will take about 7 min. to cook thoroughly. They are best served very hot. *See Herring; Roe.*

**BLOATER PASTE.** For a savoury paste, grilled bloaters have more flavour than those cooked ill water. Cook one dozen large bloaters about 10 min. or till the skin and bones come away easily. When free from these, pound the flesh finely with about half its weight in butter.

Rub with a wooden spoon through a fine wire sieve; season with cayenne and powdered mace to taste, and press it into small dry pots, leaving a space of  $\frac{1}{4}$  in. on the top of each. To make air-tight, pour in melted mutton fat, and leave till they are set hard. Mutton fat being harder than beef is less likely to crack across or melt.

**BLOODHOUND.** Easily trained for police work and often so used, this dog, in spite of his bulk and manifest strength, is gentle and obedient. He is an affectionate companion, and a trusty custodian of any property.

*Bloodhound. Specimen of the breed famed for keen scent and used for hunting and police work.*

A solemn-looking dog, standing a little over 2 ft. and weighing about 110 lb., he varies in colour from black-and-tan to red-and-tan or tawny, with perhaps a little white on the broad chest, the feet and tip of tail. The narrow head is long in proportion to the length of body, with folds of loose skin, especially over the forehead. The eyes are deeply set, and the long, thin ears hang straight down in soft folds. The forelegs are straight and large-boned, the feet large and strong. The long, tapering tail is carried high with a moderate curve. *See Dog.*

**BLOOD POISONING.** Three distinct conditions are comprised under the name of blood poisoning. When the blood absorbs only the poison produced by disease germs, the resulting condition is termed septicaemia; if the germs as well as the poison

are circulating in the blood, septicaemia results. In pyaemia the germs are carried by the blood to various parts of the body and cause multiple abscesses to break out.

The chief symptoms of mild sapraemia are headache and fever; in septicaemia there are shivering, pains in back and limbs, hot and cold sweats, and high fever. Septicaemia is usually due to the introduction of pus-producing organisms through a puncture, e.g. a pricked finger.

*When shivering and fever follow the slightest wound, no time should be lost in sending for professional aid, as both septicaemia and pyaemia may require surgical treatment.*

**BLOODSTAINS.** To remove bloodstains from silk or wool, these should be washed with water and rubbed with soap liniment. For cotton and linen goods use solution of chlorinated lime (bleaching powder), and wash out the solution with clean water. Where the stain is old-standing it is sometimes necessary to employ pepsin.

**Blossom Wilt.** As this pest attacks apples, particularly certain varieties, it is generally known as apple blossom wilt.

**BLOTCH.** This may consist of pimples, discoloured areas of the skin, or small groups of pustules, and may occur in connexion with skin diseases or eruptions. A blotchy face is not uncommon in constipation. A laxative should be taken, as cascara tablets or sulphur at night, or Epsom or Carlsbad salts first thing in the morning. Sugar, sugary foods and pastries should be left out of the diet, though fats need not be reduced. It is probable that in most cases more open-air exercise is needed. In washing, too coarse a soap must not be used, and if the water is hard add a little borax.

The following ointment will be found useful:

Oxide of zinc powder	1 dram
Precipitated sulphur	10 gr.
Salicylic acid	10 gr.
Concentrated camphor water	10 minims
Lanolin	1 oz.

*See Blackhead; Pimple.*

**BLOTTER.** To make the simplest kind fold and stitch about six sheets of strong blotting paper, the size of an exercise book or larger, into a cover of stout coloured paper. This may be quickly ornamented by stencilling (q.v.). Alternatively, make a cover of two sheets of cardboard, fastened together by a strip of linen, glued securely down one side of each. To this linen stitch the blotting paper, and the book is ready to slip into a loose cover.

For an embroidered blotter cover, take  $\frac{3}{4}$  yard of silk, linen or other plain material, with the same

quantity of lining silk,  $1\frac{1}{4}$  yards narrow galon and a piece of cardboard, 18 by  $11\frac{1}{2}$  in.

Cut an oblong in the covering material and also in the lining measuring 19 by  $12\frac{1}{2}$  in. Fold the material in half, across, and in the middle of one half draw or transfer the pattern selected for embroidery or appliqué work. Decoration must be done before the blotter is made up.

Half an inch has been allowed for turnings and the cover and lining must be seamed along three sides; the cardboard is then slipped in, the fourth seam closed and the inside of the blotter is finished off all round with galon. The blotting paper is attached by means of a tinsel cord to which a tassel may be added.

Blotters may be covered with brocade or shot taffeta edged with tinsel galon and finished with a heavy silk and beaded tassel, arranged to hang over the edge of the writing table.

A leather cover can be made with no other tool than an embroidery needle. An oblong piece of dark sheepskin is needed, large enough for the back and front cover to be in one piece. One inch extra should be left all round for turnings and an inch for the fold at the back. A pattern should then be designed in the centre of the front, and outlined in coloured fine cord stitched down, or couched, with sewing silk all round its edges and across it, as desired. The rest of the design can be filled in with coloured beads.

Two pieces of stiff cardboard are then needed, as mounts for the back and front. Cover them with soft interlining (domette is the best) and lay in place on the leather. Turn an inch of the leather down over the mount and fasten it securely by means of long stitches from top to bottom and from side to side. Cover these stitches with interlining, and then slipstitch in a silk lining of a colour to match the design. Such a blotter is suitable for dining-room or study. Colours should be in harmony with the decorative scheme of the room.

A blotting pad is simple to make. Across each corner of a large piece of very stiff cardboard fasten a strip of American leather or suède, about  $2\frac{1}{2}$  - 3 in. wide, glueing the ends round underneath the board. Several thicknesses of blotting paper the same size as the cardboard can then be secured on it, by slipping each corner under one of the triangles so formed. Blotting paper can be obtained in nearly all colours to match covers or corners.

Blotters can also be obtained made in the form of a semicircle of wood, with a handle fastened into a thin piece of wood which fits, and is screwed down, on to the flat side. The blotting paper is placed on the curved part, the ends being slipped under the handle to keep it secure. *See Leather Work; Writing Table.*

**BLOTTING PAPER.** Besides its obvious use, blotting paper is effective in removing grease from clothing. Heat an iron, lay a pad of blotting paper over the grease-spot, and pass the iron over it, allowing sufficient time for the heat to penetrate. When the

blotting paper is removed it will be found to have absorbed the grease.

A filter for water can be improvised with a piece of clean white blotting paper cut in a circle, according to the size of the vessel into which the water is to be filtered, and folded into three, to make funnel-shaped, and inserted into the bottle or jug. For pressing and keeping flowers blotting paper is used owing to its absorbent quality.

**BLOUSE.** What may be termed the two classical styles of blouse are seldom quite out of fashion in some form. The first of these is the tailored shirt blouse to the waist, and the second the Russian overblouse or tunic, belted, fastening down the side-front and pouched at the back.

Most fashion journals illustrate styles of blouses that are in vogue, and it is quite easy for the home worker to select a pattern and adapt it to her own requirements.

**BLOW-FLY.** This is a large, stout-bodied, two-winged fly of a steel blue colour, whose presence indoors is made known usually by a loud buzzing noise.

*Blow-fly eggs.*

*Highly magnified head of a bluebottle, showing its relatively large eyes.*

*Fully grown blow-fly.*

The blow-fly or bluebottle lays its 500 to 1,000 white eggs in batches on such joints of meat as it can reach, cooked or raw. These eggs hatch in the course of a few hours, and white, legless maggots or gentles issue from them. In spite of the absence of jaws or any cutting apparatus, these apparently helpless creatures are able to break down the firm muscular material of the meat and use it for their own sustenance. This they accomplish by pouring out a fluid from the mouth which rapidly dissolves the firm flesh and reduces it to a condition in which the gentles can absorb it. A few days of continuous feeding bring the maggot to its full size, and it changes into the pupal form within the

larval skin, which hardens and turns dark red. About a week later the pupa skin splits to release the perfect blow-fly.

Blow-flies are not bred in ordinary dwellings; they come in from without. Great care should be taken, therefore, to prevent their access to any flesh foods. The larder window must be kept open for ventilation, but it should be covered securely by a sheet of wire gauze. Should the female fly have deposited batches of eggs, these should be at once cut out and the joint washed with a solution of boracic acid.

Besides the bluebottle described, there is another blow-fly of similar habits. It lacks the blue tint and instead is black, but owing to the disposition of the delicate hairs with which it is clothed, it appears to be chequered with black and grey, and the forebody appears to be striped. Its eyes are red.

**BLOW LAMP.** Plumbers, gas-fitters and electricians use the blow lamp to cut and make up connexions, painters to blister old paint so that it may be easily scraped off. The instrument consists of a strong body of sheet steel or brass, A, capable of holding from a quarter of a pint, in the small sizes, to two pints or more in the larger ones, of petrol, paraffin, or kerosene. The spirit is forced through a nozzle in a very fine annular jet into a special Bunsen type burner, B, either by means of compressed air or by warming the body of the lamp. As the spirit passes through the burner it is more or less completely vaporised by heat from the walls of the burner, which become very hot, and at the same time draws air in with it. The result is a very hot, strong flame. The diagram shows a form for burning paraffin oil, in which an air pump, C, is used. There is a groove, G, running round the base of the burner, in which a little methylated spirit is placed and lighted when starting the lamp, to give a preliminary heating. D is the filling cap, E a relief valve to reduce pressure when needed, and F, the handle.

*Diagram of a blow lamp, showing how the appliance acts.*

*Blow lamp in use for removing old paint.*

A few strokes of the small air pump, forming part of the lamp, develop the necessary pressure to force out the jet of oil, and, once started, the heat of the burning flame is usually sufficient to keep the lamp going, though a stroke or two of the pump may be given when needed.

**BLOW PIPE.** The many forms of the blow pipe in use, from the simple bent tube to elaborate appliances, are divisible into two classes: those blown by the mouth, and those operated by mechanical means, which may be merely a special form of bellows. The object in all cases is the same, namely, to supply an extra amount supply an extra amount of oxygen, either as oxygen or as air, to a flame or jet of burning liquid or gaseous fuel, or a mass of solid fuel, to increase the intensity of its heat.

*Blow pipe. Figs. 1-4. Forms of pipe employed for different purposes.*

The simplest form is shown in Fig. 1, and consists of a piece of metal tube bent and tapering to a point; air is blown through this from the wide end by the mouth. Fig. 2 shows a mouth blow pipe with a connexion at A to a source of gas, and Fig. 3 shows an injector blow pipe to be blown by bellows.

In using the common blow pipe, some skill and practice are needed to maintain a steady stream of air from the mouth. The blast is to be kept up by utilising the muscles of the cheeks, breathing being carried on through the nostrils alone.

The introduction of the jet of air from the blow pipe into the body of the flame, as shown in Fig. 4, gives rise to a double combustion. The outside of the large, shaded, hollow cone is burning with the aid of the external air; the inside with the aid of the forced jet of air from the blow pipe. In consequence, the shaded cone part acquires a very high temperature, more than sufficient to soften a bar of iron, or an iron tube to bend it, to solder any common article, or to weld two pieces of iron together. *See Bunsen Burner.*

**BLUE:** The Colour. For laundry use, blue consists of indigo, prussian blue, or ultramarine, in solid or liquid form. It is used in the rinsing water for white clothes, to neutralise any yellow tint after washing. It is also, for the same reason, used to rinse white hair. The solid blue sold in various shapes and in small bags consists of a mixture of 10 parts of ultramarine, 10 parts of bicarbonate of soda, 3 parts of liquid glucose. These ingredients are ground together in a mill until a stiff paste results. From this various

shaped cubes or cylinders are cut, which are afterwards dried. On account of the presence of bicarbonate of soda the blue is a remedy in cases of wasp sting. For this purpose the blue bag is moistened and dabbed on the stung part.

Liquid blue, which is often preferred to solid blue for laundry purposes, is made by mixing prussian blue, 4 oz., and tartaric acid,  $\frac{1}{2}$  oz., with one gallon of hot water, and stirring occasionally with a wooden stirrer for twelve hours. Then strain through a woollen cloth. Another method is to dissolve 1 p.c. of aniline blue in water, the advantage of this variety being the absence of acid. *See Colour.*

**BLUE BELL.** The wild hyacinth that flowers in the woods in spring is popularly known as the bluebell. It improves with cultivation if grown in cool shady places with a moist soil. The bulbs are best planted deeply (6 in. deep is not too much), and when suited will send up an abundance of deep blue spikes year after year. There are many varieties, some bearing pale blue, some white, flowers. *See Harebell; Hyacinth; Scilla.*

**Bluebottle.** *See Blow-fly.*

**BLUE FLY.** This name is given to one of the many aphides pests which infest gardens and plants. It attacks roses and other subjects growing under glass. The best treatment is by nicotine fumigation, assisted by sprayings of soft soap and paraffin emulsion. *See Rose.*

**Blue Gum.** *See Eucalyptus.*

**BLUE MOULD.** Starting from minute spores, this appears as a small white speck, which spreads gradually over the surface of the food until a large area is covered, the older parts of the growth being blue or greenish-blue in colour.

It is really a plant which grows best on a moist surface. Jams, preserves, bread, flour, condensed milk, fruit and cheese are amongst the articles on which the mould may grow. In the production of certain cheeses, such as Gorgonzola, blue mould helps to produce the typical appearance and flavour of the cheese.

To prevent the occurrence of blue mould where it is destructive, food should be kept covered and in a dry place, and food tins should have well-fitting lids. Oiled paper should be put on jam while still hot from boiling to keep out the air; or a little melted paraffin wax poured on to the surface of the jam as soon as it has set. *See Cheese.*

**BLUE OINTMENT.** Named from its colour, this ointment is prepared by rubbing together metallic mercury and benzoated lard. A small proportion of suet is added to stiffen the ointment. It is employed in

skin diseases, chronic inflammations, and enlargements of the glands, also for killing parasites. It is better to use it in a diluted form (one part of the strong ointment with two parts of lard) to avoid the risk of salivation.

**BLUE PILL.** An old-established remedy for liver complaints is the blue pill, followed next morning by a black draught (q.v.) or saline. It is a blue mass, consisting of metallic mercury rubbed for a long time with confection of roses and powdered liquorice root. The dose is from four to eight grains.

**BLUE PRINT.** A kind of photograph of bright blue colour, known as a blue print, is made by printing from a negative on to a special paper which may be bought as ferro-prussiate or cyanotype.

To make a print, a sheet is laid with the yellowish coated side in contact with the negative in a printing frame and exposure made to bright daylight until, on opening one half of the frame, it is seen that a greyish-blue picture is visible. The picture must appear much darker than it is required to be when finished; and the shadow parts should have a semi-metallic, choked-up appearance.

When it is judged that exposure has been sufficient, the print is simply soaked in clean water, when it quickly becomes of bright blue colour, showing all details. It is washed for a few minutes in water and left to dry by hanging up at a little distance from a fire.

Blue print paper is very largely used for making copies of engineers' plans or drawings, etc. When exposed to light behind an original of this kind it will yield an excellent copy in white lines on a blue ground. *See Dark Room; Developing.*

**BLUE STONE.** Sulphate of copper crystals is so named. It is most popularly known as an application for exuberant granulations, or proud flesh, and it stimulates the healing of sluggish sores. The crystals may be rubbed on or used as a solution in water. Copper sulphate is a speedy emetic in narcotic and phosphorus poisoning, in a dose of 5 to 10 grains, but the doctor should administer it. It is recommended for styas as a one p.c. solution, applied every half-hour after the affected eyelashes have been pulled out.

Chronic poisoning produces a green line along the gums. In poisonous doses it acts as an irritant. After the use of an emetic, white of egg and milk should be given, and followed up by drinks of barley water and thin arrowroot. Fomentations may be applied to the abdomen to relieve pain. *See Poisoning.*

**BOARD:** Varieties and Uses. A board as generally understood means a plank or piece of wood relatively long in proportion to its breadth and thickness. In the timber trade a board is reckoned as 1 in. thick, and most hardwoods, whitewood, walnuts, etc., are sold by board measure, at per foot super. If the material measured 2 in. thick, then the price at 6d. per foot super would be 1s., because there are two layers, as it were, each worth 6d.

*Square Edge Board*

*Tongued and Grooved Flooring*

*V. Jointed Matchboard*

*V. Jointed and Beaded Matchboard*

*Sawn Weatherboard*

*Rebated Weatherboard*

*Matched Weatherboard*

*Board. Sections of standard prepared board used in building.*

For general indoor use, and many outdoor jobs as well, the ordinary wood, known as yellow or red deals, answers very well. Such deal is sold in planks, that is, 11 by 3 in.; deals, that is, 9 by 3 in.; battens, that is, 7 by 2 ½ in. From pieces of timber of these basic sizes all smaller sizes are of timber cut.

The term prepared boards means that the edges and one flat surface have been machined or planed smooth by machinery. A rough board is one that has been left by the saw. Shelving boards are cut 9 in., 10 in., or 11 in. wide, and ¾ in., 1 in. or 1 ¼ in. thick. They are planed on face and two edges, and sold by the lineal foot or per foot run.

Matchboard is made in several thicknesses and widths; it is planed on one side, and machined on each edge. The sections illustrated are the ones most generally used. Weather-boarding is made in two general forms—the ordinary tapered or feather-edge board, and the rebated, which presents a flat surface on the interior and the familiar appearance on the exterior. A matchedweatherboard is also made; this is tongued and grooved and machined, as shown in the diagram. Matchboard and weatherboard are sold by the square, that is, 100 nominal square feet.

For the average indoor use ordinary square-edge planed boards can be purchased from stock at most timber yards in 3 in., 4 in., 5 in., 6 in., 7 in. or 9 in. widths and ½ in., ¾ in., 1 in., and 1 ¼ in. thick. Flooring is usually stocked in ¾ in., 1 in. and 1 ¼ in. thicknesses, 1 in. being that most generally in request.

Matchboard is made in ½ in., 5/8 in., ¾ in., and 1 in. thicknesses, and 4 ¼ in., 5 in. and 6 in. widths. The quoted thicknesses of boards are always nominal, being derived from the deal or plank from which the material is cut. Thus a ½ in. board will only measure a full ⅜ in. actual thickness, and a board nominally 6 in. wide will only hold up to 5 ⅞ or possibly 5 ¾ in. if planed on both edges.

When using boards for shelving it is important to

see that the thickness is adequate for the space to be spanned by the board. In general a 9 in. by  $\frac{3}{4}$  in. board will only span 2 ft. without sagging, under normal loading. The special uses of manufactured boards are dealt with in a plate on the previous page. *See Floor: Matchboard, etc.*

**BOARDING HOUSE.** In towns or at the seaside boarding houses resemble private hotels, and differ from furnished apartments in the fact that the guests take their meals in the same room and share a general sitting-room, in which a piano and comfortable chairs and couches are usually provided. In large cities boarding houses seldom provide more than two meals a day, breakfast and dinner, except on Sunday, when all meals are provided. The terms for room and meals are inclusive. At seaside boarding-houses lunch and afternoon tea are usually provided at an inclusive charge. City boarding houses charge much the same all the year round, but the boarding- houses at watering places, which have no winter season, increase their tariff during the summer season. This culminates in August, which is, as a rule, the most expensive month in which to seek holiday accommodation.

A boarding house keeper, as distinct from a lodging house keeper, has no right to detain a boarder's luggage for an unpaid bill. On the other hand, she is not liable for the safety of the boarder's luggage or belongings, unless she is guilty of negligence. In a case where a servant was taken on who was a convicted thief, the boarding house keeper was held guilty of negligence, because she engaged the servant without any inquiry, and under such circumstances that she might have known the sort of servant she was engaging. So that, when the servant stole from the boarders, the boarding house keeper was held liable. *See Holiday; Lodgings.*

**BOARD WAGES.** A servant who is engaged in the usual way, that is, at a wage, with the mistress to provide food and drink, cannot be compelled to accept board wages, but if the mistress does not provide the food and drink the servant is entitled to provide them herself and can claim the cost from the mistress. In England, if a mistress dismisses a servant with a month's wages in lieu of notice, she only pays ordinary and not board wages. In Scotland she must pay a month's board wages, to compensate the servant for the board she could have had during the month. *See Servant.*

## BOAT: THE MAKING OF A MODEL

### Fascinating Work for the Amateur

The reader should consult also the articles on Aeroplane; Engine and other Models; also Soldering; Woodworking. A companion article is the one on Yacht.

The making of a good working model boat is a fascinating occupation for the amateur. In this article full instructions are given for making (a) a model cross-

channel steamer of modern type, and (b) a fast electrically propelled model speed-boat.

*Boat. Fig. 1. Model cross-channel steamer which can be made by the amateur. Fig. 2. Sheer plan and deck plan.*

*Figs. 3-5. Drawings giving form of hull at the three critical points indicated on plans above.*

In the construction of the steamer (Figs. 1 to 5) commence by making the hull from a solid block of sound pine or deal, free from knots. This block when finished must measure 24 in. long, 3 in. wide, and 3 in. deep. If a larger boat is required the drawings can be enlarged in proportion.

The hull can be shaped as follows. Plane the wood block smooth and flat on all four sides, and draw a centre line along the top and bottom faces. Square off the three section lines, A, B, C (Fig. 2), on all sides of the block. Mark on the upper and lower faces of the block the deck line, and on the sides of the block mark the sheer line or profile. Now saw away the surplus wood nearly to these lines thus producing a boat-shaped block.

To ensure getting the hull the correct shape, cut three cardboard moulds, shaped as shown in Figs. 3-5. Apply these from time to time to their corresponding section lines while the work of shaping goes on. This is best done with the aid of chisels and gouges, working from the middle towards the ends until all three moulds fit properly, their upper edges flush with the upper part of the block. Mark off the sheer-line and cut this to shape. Then hollow out with gouges and chisels the interior of the hull, taking care not to run the tools through to the outside. Cut a deck from a piece of yellow pine  $\frac{3}{32}$  in. thick, and fix it temporarily with a couple of fine brads.

To complete the hull, cut a recess  $\frac{1}{4}$  in. wide into the bottom of the hull on the outside and fill it with lead. Then cut away the middle part of the deck, so that the whole of the superstructure can be lifted off to get at the machinery. The superstructure and bridge are made from  $\frac{3}{32}$  in. pine or cigar-box wood. The

captain's cabin is cut from mahogany, and the windows and doors drawn on it with Indian ink, and coloured with water-colour paints. The railings are made from model stanchions and floral binding wire secured with solder.

The funnels are made of tin-plate, the stays being floral binding wire soldered in place as shown. The top of the funnel is beaded over, and a wire ring soldered beneath it. The two hatch covers and the skylights are cut from mahogany. A cigar-box offers useful material for this kind of work.

The lifeboats are carved from solid yellow pine blocks, fitted with seats, and mounted on flat pieces or chocks secured to the deck with glue. The davits are made from brass wire,  $\frac{3}{32}$  in. diameter, flattened at the ends and drilled to receive a hook, blocks, and falls.

The rudder is cut from sheet tin or zinc, soldered to a brass wire  $\frac{3}{32}$  in. diameter; this passes through a brass tube let into the stern. The rudder post is afterwards bent over at right-angles to form a tiller. The end is bent over so that it presses on the notched brass quadrant screwed inside the hull; the friction holds the rudder in position.

The propeller shaft and stern tube shown in Fig. 2 are best purchased ready for use, as are the ventilators. Additional fittings can be represented if desired, as shown in the illustrations. The hull should now be painted inside and out in any desired colours, and the various parts assembled in place as in Fig. 2.

The drawings which are here given show a steam engine and boiler that can be purchased at a moderate price from Bassett-Lowke, Ltd. Northampton, and capable of running the boat for over a quarter of an hour; alternatively a clockwork motor can be purchased at any model shop, but will only run the boat for a minute or two. A special type of electric boat motor, known as the Nautilus, if energised with a small 6-volt accumulator, is suitable for this boat, and should run it for 20 min. or so on one charge.

**Making an Electric Speed-boat.** The hull for this boat, 24 in. long (Fig. 6), is of sheet zinc; it has almost a flat bottom, and tapers off at the bows to a sharp, thin cutwater. When the loading is suitably distributed (i.e. the greater proportion of the weight at the stern) the bow lifts and skims the surface in true speed-boat fashion. The hull is fashioned from a flat piece of zinc, which is bent up and joined at the front to form the bows. The stern is finished off with an outwardly sloping transom, this being, of course, a separate piece of zinc. The spray hood extends back from the bows for about half the boat's length, and gives an attractive outline to the craft. The height at the stern is 3 in., and at the bows just double. The width of the cockpit where the spray hood ends is  $\frac{5}{8}$  in., tapering off to 4 in. at the stern.

The amateur who does not care to tackle the job of making such a hull can procure one from Whitneys, 129 City Road, London, E.C., who supply the power plant here illustrated and described. The hulls are made 24, 30 and 36 inches long, and also in the metre

size. We will assume that the 24-in. hull has been made or purchased. A permanent-magnet motor to suit this size will run from a dry battery (Ever Ready No. 126), or a special low-built light-weight accumulator may be purchased. This, while costing three times as much as the dry battery, has the advantage that it can be re-charged quite cheaply. Fig. 7 shows the motor with propeller shaft, stern tube and three-bladed propeller.

*Boat. Model Electric Speed-boat. Fig. 6. Hull which is made of zinc. Fig. 7. Accumulator. Fig. 8. Motor with propeller shaft, stern tube and three-bladed propeller. Fig. 9. Larger power plant suitable for 36 in. hull.*

The motor shaft has a projecting pin which engages with the forked end of the propeller shaft and so acts as a driver. The motor frame is already set at an angle, so that when it is screwed down by its lugs to a wooden base made to fit the floor of the hull, the shaft will be inclined approximately at the correct angle to line up with the propeller shaft. The stern tube, through which the latter protrudes, must be soldered into a hole carefully made in the hull. The propeller shaft is supported further by a simple bracket made from a strip of brass bent up and soldered to the hull. The inner end of the stern tube is provided with a stuffing gland to exclude water. The tube may rest on a block fixed to the wooden base, and may be secured by a brass or zinc strap passing over the tube and screwed to the base. A clip for the dry battery or accumulator should be fixed at the stern.

A wooden dashboard may be fitted just under the mouth of the hood, and a simple switch on this will start or stop the machinery. The rudder is made from sheet zinc or brass, and soldered to a brass post. The post passes up through a brass tube soldered to the hull and protruding through the deck. The rudder is held in place, when set, by a lock nut. Fig. 8 shows a larger motor for a 36-in. hull. Two 4-volt accumulators in parallel are needed for this set. The motor is mounted parallel with the floor of the hull, and is connected to the inclined propeller shaft by a flexible spring coupling.

**Bobbinet.** Machine-made plain net made with extra stout cotton and suitable for window curtains. *See* Lace.

**BOBBIN LACE.** Lace hand-made, not with the needle, nor by knitting nor embroidery, but by twisting and plaiting threads into a pattern, is known as bobbin lace. Other names for the same kinds are pillow ace and bone lace (now obsolete). A design is drawn in pencil upon cardboard and points are inked and then pricked to show where the gimp must be made. A tracing of this draft is made on parchment, and this is fastened down upon the lace-making pillow. Solid-headed pins are then inserted at the pricked holes.

The bobbins from whence the name comes are wood or bone, and carry the thread. Two threads are tied together, and they, with their bobbins, hang upon the pin. The lace-maker deftly throws one bobbin over another, using the pins as the key to the design.

**BOCCONIA.** The plume poppy or bocconia is a fine herbaceous perennial plant, growing 6 to 8 ft. high, with glaucous leaves and long plumes of buff-coloured flowers. It loves a deep, moist, substantial soil, and thrives in well-tilled clay. It is effective if a small clump of it is grown in an isolated position as a form of lawn decoration. Propagation is by division in autumn or spring under glass, and by pieces of root laid in shallow boxes of gritty soil in a frame in spring. Pron. Bok-coney-er.

**BODKIN.** A thick needle with a blunt end and a wide eye for threading elastic or ribbons through slots or lace, etc. A good substitute is an ordinary safety-pin, which also has the advantage of not becoming unthreaded in the middle of a hem.

**BODY BRUSH.** In best makes bristle only is used, the knots are wire-drawn, and the backs screwed on as with good clothes brushes. The handles, which are lengthy for convenience and straight or bent to suit various tastes, are usually made of beech or similar hardwood.

Cheap fibre mixing brushes, which are harsh, or pure bristle of white and grey, can be had of any required stiffness. They should not be left lying on their backs in a sodden condition when not in use, but hung or propped up to drain and dry. Occasional rinsing in hot water to which a little ammonia or antiseptic preparation has been added will tend to keep them wholesome. *See* Brush.

**BOETTGER WARE.** Genuine pieces of the jasper-like stoneware in dark red, which was produced by the inventor of Dresden china early in the 18th century, are rare. They may bear imitations of Chinese marks, or the famous crossed-swords device, or be unmarked. Unglazed red ware of German make has been faked up and passed off as Boettger.

The various styles include half-busts or figures with the drapery beautifully polished in a lathe, sprigged teapots, beakers and candelabra, besides vases with lacquered or enamelled designs. All these form effective ornaments for the living-room, but do not mix well with more delicate work, such as Chinese floral pieces or old decorated white china.

**BOG: In Gardening.** An artificial bog is a piece of moist ground, natural or prepared, in which may be grown water-loving plants which do not actually require a pond or stream. These bogs are usually made of concrete or Portland cement basins, about 1 ft. in depth, and filled with peat and loam. The bog is kept wet by means of a drip from natural or artificial sources.

Most of the ferns make good bog plants, and other popular specimens are the sundew or *drosera*, hardy lady's slippers, side-saddle flowers or *sarracenias*, butterwort or *pinguicula*, marsh marigolds, and Japanese primroses. *See* Water Garden.

**BOG BEAN.** This interesting aquatic plant is sometimes found by the edges of streams and pools. It is called *Menyanthes trifoliata*, and is also known as the buck bean. It is herbaceous and flowers in early summer, the flowers being bell-shaped, white inside, and streaked with red outside. The flowers are borne on stems which float on the surface of the water.

The bog bean is easily propagated by taking short lengths of the stems and pegging them down with carnation pegs to the moist ground or bottom of the water, until they throw out roots. *See* Water Garden.

*Bog Bean, a plant for the water garden.*

**BOG OAK.** This is the name given to oak found buried in peat bogs which centuries of immersion have turned to a deep black colour. It has applications in cabinet-making. In various parts of Ireland where deposits of bog oak are found a considerable industry exists in carving and fashioning this material into curios for souvenirs.

**BOIL: How to Treat.** A boil is caused by a germ finding its way into the skin either into a hair follicle or elsewhere, there setting up inflammation. A cause may be any temporary falling off in the patient's health, but the general health may be apparently good.

Over-eating, especially of rich foods, is a cause of boils. The patient should keep for a few days to a light diet and avoid alcohol. Boiled Spanish onions are beneficial. The boil should be sponged several times a day with a solution of one part carbolic acid to 20 parts water. If it is about the nostrils or in the ear, medical treatment is necessary, and a physician should be consulted.

Impaired nutrition through under-feeding may cause boils in young children. The diet should be carefully looked to in such cases. Chemical food will be a good tonic. The skin all round the affected area should be washed every day with saturated boracic acid solution, and the following ointment is then applied: boracic acid powder, one dram; vaseline, one ounce.

More sunlight and more hours spent out of doors will also help greatly to build up the general health, and if a change of air is possible it may be the best thing. *See Gumboil.*

**BOILER:** For Hot Water Supply. The development and successful use of any hot water boiler depends upon an appreciation of the fact that water rises when it gets hot. It is easy to see, therefore, that in an enclosed boiler the water will tend to rise as it gets hot. If a regular supply of cold water be introduced through a pipe at the bottom, and another pipe be taken from the top of the boiler, the hot water will rise up this pipe, and the heated water can be stored up in a tank at any convenient spot in the house above the level of the boiler. The storage tank is connected by a second pipe to the bottom of the boiler. The pipe that the hot water goes up is known as the flow pipe, the other as the return pipe, and both should be  $1\frac{1}{4}$  in. diameter.

*Boiler. Fig. 1. Type largely used in kitcheners, and shown in position in Fig. 2 (right) by dotted lines.*

A boiler of this type (Fig. 1) is generally placed at the back of the kitchener, as indicated in Fig. 2. The direct heat of the kitchen fire is about three times the value of the due heat at the sides and back of the boiler, so that the most efficient boilers are those nearest to the direct heat of the fire.

Many of the troubles of boilers are caused by the assumption that they are self cleansing. The water, however, unless it is "soft" and free from lime, must be regularly drained off, the stove itself taken apart sufficiently to give access to the boiler, and the

manhole or clearing plug located and unscrewed. When the manhole is opened and the water remaining in the system escapes, a can should be placed to catch as much of the water as possible, and an old sack or two used to soak up the remainder. After the boiler has been emptied, the scale or fur is removed by scraping it out with a metal chisel or a piece of hoop iron.

*Boiler. Fig. 3. Independent boiler which produces a constant supply of hot water. Fig. 4. (Right) Boiler which will supply hot bath water and may also be connected with two small radiators or a towel rail. (Smith & Wellstood, Ltd., and National Radiator Company, Ltd.)*

When a boiler is heavily coated with fur the coating acts as a screen or insulator between the water and the heat from the fire. It also prevents the water from coming in contact with the metal of the boiler. Contact is necessary to prevent the iron from burning away, and this is most likely to happen where the deposit is thickest and the heat is greatest, just at the crown of the arch forming the flue beneath the boiler. After scrupulously cleaning the boiler, wash it out thoroughly and replace the manhole covers, well bedding them down with red lead, putty, and a piece of stout string coiled around and pressed down into the bed before replacing the cover, which must be screwed up tightly.

*Smoke outlet*

*Boiler. Fig. 5. Sectional diagram of a dome-top boiler. A. water inlet; B. grate level below which is a water way, C; D. mud hole; E. hot water outlet; F. fire door; G. feed door.*

**Independent Boilers.** The home installation of a new hot water system is most conveniently carried out by the amateur if the independent type is chosen. These, being self-contained, can be placed in any part of the

building on the ground floor, or in the basement, provided they are not nearer than 18 in. to any woodwork and that any requirements of local authorities or fire insurance companies are complied with. The boiler should stand on a good solid bed of concrete (q.v.) or other fireproof material. The outlet flue is generally made of cast or wrought iron in the form of a stove pipe. The water supply and the flow and return pipes should be of iron, except in certain districts where the water is very soft, in which case copper or lead pipes will have to be used.

In summer, gas or electric heaters are advantageous; but in general coke or anthracite boilers are best. The one in Fig. 3 will burn anthracite, broken coke, or coal, and consume all combustible household rubbish. The boiler shown in Fig. 4 is intended to supply hot water for the bath. It is generally possible also to heat one or two small radiators with a boiler of this kind, but a different type is required for a proper central heating system.

In addition to those illustrated there are many other excellent makes. Boilers of this kind are fitted with a hot plate on which kettles and saucepans can be kept hot. They have dampers fitted in the stove pipe and over the air inlets beneath the furnace door. These are closed to retard the rate at which the fire burns; by making it up and adjusting the dampers the fire will remain alight all night, thus providing a constant supply of hot water.

Boilers intended for hot water supply only are frequently placed in the cellar or in a basement. The sectional diagram (Fig. 5) shows such a boiler. It can be connected to an existing hot water pipe system and thus relieve the kitchen; but provision must be made for the removal of the boiler in the kitchen. The old flow and return pipe used in conjunction with the kitchen will, of course, be disconnected from the old boiler and connected to the new one. *See Anthracite; Central Heating; Hot Water Supply; Radiator; Range.*

**BOILING: Of Food.** Boiling is used for three distinct purposes. The first of these is to retain nutriment and flavour within the food, by preventing the escape of juices into the liquid, e.g. boiled meat or fish. This object is gained by placing the food into boiling liquid, and by a preliminary process of actual boiling for about 10 min. the albumen is hardened and seals up the nutritive and flavouring juices. The heat must then be sharply lowered, or the albumen all through the meat, poultry, etc., is also hardened, and the food made tough and tasteless. To prevent any possibility of this, casserole cookery, a slow process which ensures the retention of the natural juices, is often preferred for such foods.

The second object of boiling is to impart flavour and nutriment to the liquid, e.g. meat and bone soups and broths. To accomplish this result, the materials are placed in cold liquid, and allowed to soak for a time before heat is applied slowly till boiling point is reached. Boiling is continued till the ingredients have

yielded their nourishment.

Boiling is employed thirdly to give part of the nutriment and flavour to the liquid, and partly to retain it in the meat, etc., e.g. stewed chicken, Irish stew. This effect is produced by placing the food in cold water, and quickly heating it to boiling point, keeping it at that temperature for about five minutes and then lowering the heat to simmering point.

Boiling for the entire time of cooking is required for bone and meat soups; all green and most other vegetables; all boiled puddings, all starchy foods, e.g. flour in sauces; and for rice, macaroni, etc.

It should be noted that once the surface of liquid bubbles briskly, no amount of fuel will make it any hotter. The only result of furious boiling is that fuel and food are wasted.

Water in which meat, vegetables, rice, macaroni, etc., have been boiled should be used for stocks, soups, and sauces. *See Beef; Chicken; Cookery; Pudding, etc.*

**Bokhara Rug.** *See Rug*

**BOLECTION MOULDING.** In building work bolection moulding finds a place largely in the ing work bolection moulding finds a place largely in the panels of doors. Such mouldings rise above the face of the framing and are rebated over the edges, forming a narrow projecting ledge between frame and curved part of the moulding. *See Moulding.*

**BOLERO.** A very short jacket with open fronts, the lower edge terminating some inches above the waist. It periodically returns to everyday fashion, and is employed for Spanish or gipsy fancy dress being worn over a white blouse.

**BOLSTER.** Usually round in shape, it may be stuffed with feathers or with white horsehair. A variety for use with the large, square pillow is the wedge bolster. This is about 20 in. from back to front, deep at the back, the height about 5 in., and sloping to the front, where it is as thin as possible.

Upholstered like a mattress, a bolster should have a permanent under-cover, and a cover which is changed regularly in the same way as a pillow-slip. *See Cushion; Pillow.*

**BOLT.** For doors, cupboards, and similar purposes, bolts are made in hundreds of different sizes and styles. They have one object in common- to secure a movable part to some other part usually immovable. Essential considerations are security, efficiency, and neat appearance.

A few of the more useful types of bolt are illustrated, their principal uses being as follows:

Common japanned tower bolts (Fig. 3) are made in several sizes, from 4 in. to 12 in. long, and are used for outhouse doors and general purposes. They frequently shoot into a plain hole drilled in the doorpost.

*Bolt. Figs. 1-6. Various patterns of door bolts in common use. See text.*

Brass barrel bolts (Fig. 4) are made in sizes from 2 in. to 24 in. long for internal work, and are screwed flat on the door. Flush bolts (Fig. 6) are generally made in brass, with a sunk slide, in many sizes and widths, from 3 in. long by  $\frac{1}{2}$  in. wide to 24 in. long by  $1\frac{1}{2}$  in. wide. They are fixed to the edge of a door, and embedded by cutting a recess, and are frequently used on the one side of a double door.

Blind bolts (Fig. 1) are made straight or necked, and extensively used on cabinet work, for doors of small cupboards, etc. They screw flat on to the door, and may shoot into a hole, through a brass plate, or into a socket.

Monkey-tail bolts (Fig. 5) are largely used for warehouse and garage doors. They are mostly about  $\frac{3}{4}$  in. square, 12 in. and upwards in length. Padlock bolts (Fig. 2) are sometimes used on the outside of storehouse or shed doors, the bolt being locked to a staple with a padlock. Such bolts are usually galvanized to resist rusting.

Bolts seldom give trouble, the only things likely to affect them being the shrinkage or warping of the door, or the wear of the hinges, allowing the door to settle. This generally necessitates the removal of the staple or socket, plugging the old holes, and rescrewing.

Bolts fitted with stamped metal sockets sometimes work stiffly. They are generally corrected by holding a heavy hammer beneath the barrel and striking a few sharp blows with a light hammer on the upper part of the barrel or socket. This stretches the metal somewhat and makes more room for the bolt. The bolt should be shot into the socket while doing this, as it then presses on the tight spot; the jarring due to the hammer blows

is transmitted to these tight spots, and they are thus stretched. See Latch; Lock, etc.

**BOLT AND NUT : How to Use.** In the general meaning of the word a bolt consists of a circular rod of metal having a solid head formed on one end, and screwed or threaded at the other end to receive the nut. The pieces to be held, or bolted together, are thus clamped between the head of the bolt and the nut.

*Bolt and Nut. Various types commonly used in engineering.*

Bolts are made in a wide variety of forms, sizes, and shapes, adapted to various purposes. The forms of the screw thread and its pitch, or number of turns to the inch of length, vary according to certain standards.

The ordinary black ironmonger's bolt with hexagonal head is used in all houses. The hole for it to pass through must be slightly larger in diameter than the nominal diameter of the bolt, as it is not machined to exact size.

British standard fine-threaded bolts, known as B.S.F. bright bolts, are extensively employed on automobile and aircraft work. This is a very strong bolt made of high tensile steel.

Engineers' bright bolts are machined all over, and hold up very closely to size. Made with hexagonal head from superior grades of mild steel, they should always be used on machinery or any job where strength is a consideration.

Coach bolts, which are much used for bungalow work and poultry houses, have a rounded head and square portion on the shank immediately beneath the head to prevent the bolt turning round.

Eye bolts are so named because the head is formed as an eye or ring. Generally screwed Whitworth and made in the black and bright qualities, they are very useful for attaching a hook or fastening a line.

Hook bolts are serviceable when circumstances prohibit an ordinary bolt, as when temporarily bolting a plate to a girder.

T-head bolts are extensively employed on machine tools for bolting castings or other work to a faceplate or saddle.

Rag bolts are adapted to secure machinery to a concrete foundation, being inserted before running in the concrete.

Small bolts which are used for clockwork and model making are made in sizes from  $\frac{1}{16}$  in. to  $\frac{1}{4}$  in. diameter, and are variously threaded. Model threads

are 40 t.p.i. (threads per inch). Whitworth model sizes are 40 and 60 t.p.i. B.A. threads are used on small-size bolts especially for scientific instrument work.

For all-round household work the regular black, hexagon-head bolts, or the coach bolts,  $\frac{1}{4}$  in.,  $\frac{5}{16}$  in.,  $\frac{3}{8}$  in., or  $\frac{1}{2}$  in. diameter, and of appropriate length, will be found the most suitable and convenient. The length of a bolt is measured from under the head to the end of the shank. The diameter is the diameter of the threaded portion or shank. A coach bolt is driven home into wood with a hammer blow. The square part should be a tight driving fit into the wood. An ordinary bolt is screwed for only a part of its length, the usual length of thread being roughly three times the diameter. When a bolt is wanted with a thread all the way from the head to the end, it is known as a screw and should be purchased as a screw or set as a screw and should be purchased as a screw or set screw.

**BOMBAY DUCK.** A fish obtained in Indian waters, and exported from Bombay either in a dried and salted condition or in tins. Bombay ducks are usually crisped in a brisk oven for a few minutes, and served with curries. To powder these dried fish, crisp in the oven without burning, pound finely, and put through a strainer. *See* Curry.

**Bonbon.** This word is used for certain large sweetmeats. *See* Cracker; Sweets.

**BOND:** In Brickwork. Bond is the name given to any arrangement of bricks so that the vertical joints in one row or course do not come exactly over or under a vertical joint in the next course. To ensure a satisfactory bond, the bricks must be uniformly arranged, have as few bats or partial bricks as possible, and the vertical joints or perpends in every other course must be above each other.

Several kinds of bond are in general use, the principal of these being known as English, Flemish, garden-wall, and herring-bone. The ordinary dwelling-house is usually built with English or Flemish bond. The names apply to certain recognized ways of arranging the bricks in the one brick or 9 in. thick wall, and the one and half brick or  $13\frac{1}{2}$  in. thick wall. *See* Bricklaying.

**BONE.** Grouped together as the skeleton, the bones of the human body form the framework upon which all the tissues depend. Bones are composed of chalky substance (carbonate and phosphate of lime) together with fibrous tissue. In youth the fibrous tissue preponderates and the bones are elastic to a large extent, whereas in old age mineral salts make up the bulk of the bones. Children's bones, therefore, tend to bend and yield under pressure, whereas the chalky bones of old age are brittle and break easily.

Inflammation may occur in the periosteum (the tough membrane that covers the bone), the bone, the bone marrow, or in all three. It may follow an open wound

or be due to microbes brought by the blood, more especially after an injury. Hence superficial bones, like the shin or bone in the neighbourhood of joints, are specially liable. The inflammation may be acute or chronic. If the bone is denuded of periosteum the portion laid bare is likely to die.

Children who are run down, or who have some source of infection about them, such as a sore throat, are occasionally liable, after a slight injury perhaps, to a virulent and dangerous infection of the bone marrow of a long bone. The child looks very ill, highly fevered, perhaps somewhat delirious, and screams if some part of the bone, say, the lower end of a femur, is touched.

The importance of remembering this condition is that it is sometimes mistaken for acute rheumatism, and valuable time is lost. Dragging at the arms of small children is a cause of inflammation at the growing ends of the bones. The treatment of these conditions is surgical. *See* Arm; Fracture; Leg, etc.

**BONE BLACK.** A form of charcoal, prepared by heating bones at a high temperature in iron vessels from which air has been excluded. It is employed for bleaching sugar and also in the manufacture of blacking. The best kind, ivory-black, is made from waste ivory. In this variety the charcoal is in a very fine state of division.

**BONE MEAL.** This contains about 45 p.c. of calcium phosphate with about 5 p.c. of nitrogen. It is a useful fertiliser to apply to plants which are coming into full growth in the ordinary heated or intermediary house. It is a valuable stimulant, and is practically inodorous.

Bone meal is largely used, on account of the phosphates it contains, to promote growth in young chickens. It is often confused with green cut bone, from which it differs materially, the latter possessing a high nutritive value, and bone meal little, if any. *See* Chicken; Fertiliser; Poultry.

**BONES: Use in Cooking.** Clean, fresh bones contain a large amount of gelatinous matter, but this can only be extracted by quick and long boiling. It is quite easy to know when bones have yielded all nutritive and gelatinous elements, as they have then a spongy, perforated appearance and are of no further use.

Bone stock is a foundation for various soups. Poultry and game bones, which must not be the least high, and ham and bacon bones are especially valuable as flavourers. To make stock, wash 2 lb. of bones, removing the fat and marrow. Saw or chop into short pieces, and put in a saucepan with 2 quarts of cold water and a teaspoonful of salt.

Heat slowly until they boil, and remove any scum. Add 2 oz. each of cleaned and scraped carrot and onion cut in quarters. Do not peel the onion, as the skin will add colour and flavour. Boil the whole steadily for 4 hours, strain into a basin and leave until cold. The hard white fat that forms on the

top may be saved for dripping, for use with vegetables, etc.

For devilled bones select those with sufficient meat to afford a meal. Sirloin of beef bones or those from a roast saddle, or blade-bone from a shoulder of mutton are best. Mix together 2 teaspoonfuls of French and one of English made mustard, a teaspoonful of shopped chutney,  $\frac{1}{2}$  teaspoonful of strained lemon juice, with salt and cayenne to taste. Work all these into 1 oz. of butter. Spread and work this mixture well over and into the meat on the bones, and dust with a few browned crumbs. Place on a baking tin in a sharp oven until thoroughly hot, or they may be broiled. Serve at once with any of the melted mixture poured over them, and garnish with tufts of prepared and seasoned cress.

Marrow bones contain nutriment and make a savoury or lunch dish. Select large, fresh bones and have them sawn through if more than 3-4 in. long. Cover the end of each bone with a little stiff paste made of flour and water only, to prevent the escape and wasting of the marrow during cooking. Tie each in a cloth and boil from  $1\frac{1}{2}$  to 2 hours. Take out of the pan, remove cloths and paste, pin a clean napkin round each bone or half bone and send to table upright on a hot dish, with dry, crisp toast in a toast-rack. A long marrow spoon is used to extract the marrow.

**BONING: Joints and Poultry.** Some joints of beef, mutton and veal, e.g. breast of mutton, brisket and aitchbone of beef, and shoulder of veal, and also, on occasions, fowls, ducks and other birds, are boned before they are cooked, to lessen carving difficulty.

If a boning knife is not available, a sharp-pointed kitchen knife may be used, and should be slipped with a clean cut to the bone. Do not include in the joint any pieces of gristle, etc., that might be left on the bone.

The secret of successful boning is to cut the meat as little as possible. In some cases, e.g. a shoulder of veal, the hole left by the bone can be filled with forcemeat. Such meats as pig's head and calf's head, and also sometimes breast of mutton, etc., are boiled whole until the bones readily leave the meat.

Fowls, turkeys and ducks may be boned and their original shapes retained, if so desired. To bone and shape a turkey, take one that is plucked and drawn, cut off the neck and loosen the skin from round it, pushing it well back. When the wishbone is exposed, detach it carefully from wings and breastbone. Divide the joints of the wings and clear them. The breastbone has next to be freed; detach the most prominent part carefully.

Roll back the meat over the part unboned, keeping the knife close against the bones. Detach the legs at the joints, and, after a little further work, the entire skeleton will come away. Then wash and dry the turkey. To bone the legs, the knife is worked gently round the bone, the thigh bone being removed whole. Continue until about half the drumstick is exposed, and then saw it off, leaving a little bit of the bone in to help to give the prepared turkey a more natural appearance. The small end bones of the wings are also left. For a galantine the end bones of the wings and legs are

removed.

Turn back the meat the right way out. Fill the legs and wings with forcemeat, pressed tightly in until they resume their former shape. The trunk may be stuffed with forcemeat, or tilled with a cooked ox-tongue, the bend of it lying where the prominent part of the breastbone should be. The spaces left are stuffed with as much forcemeat as the turkey will hold. Work the turkey with the fingers until it has nearly regained its shape, tie securely in a buttered cloth, and it is ready for boiling.

A fowl boned in a similar way could be stuffed with sausage meat, the spaces being filled with mushroom, bacon, or other stuffing. Ducks are stuffed with sage and onion. To bone a bird that has already been cleaned, slit it down the back, and work round it from there. The back can afterwards be drawn together.

Our illustrations show how a chicken can be boned. In Fig. 1 it is represented as ready dressed, but an untrussed bird is dealt with in precisely the same manner. When trussed, remove the skewers and strings, reserving the liver, gizzard, extreme ends of the wings, and the feet up to the first joint.

To bone the chicken (Fig. 2), it should be held up on end supported by the left hand. Commence by turning the skin of the neck back over the breast and back until the shoulder bones of the wings are laid bare. Divide each joint as in the photograph and scrape the bones of the wings quite clean, removing the wing bones from the carcass.

*Boning a Fowl.*

1. The bird ready dressed for boning.

2. Skin of neck turned back to lay the shoulder bones bare.

The flesh of the body must now be removed carefully and cleanly with the boning knife down towards the thighs, and must be scraped off the breast bone without breaking the skin (Fig. 3). Divide the thigh joint as shown, scrape the bones quite clean,

breaking them at the joints, and remove them also.

### 3. *Dividing the thigh joints.*

### 4. *Removing flesh from breast-bone.*

5. *Flesh spread over with stuffing of hard-boiled eggs, bacon, sausage-meat and mushrooms, before being rolled up for cooking.*

Now proceed, as shown in Fig. 4, to remove the flesh entirely from the carcass. Cut off the "parson's nose," turn inwards the flesh of the wings and legs, and trim off the rough edges of the neck.

Arrange the flesh evenly over the surface of the chicken. Spread carefully 1 lb. of sausage meat flavoured with  $\frac{1}{4}$  lb. of chopped mushrooms, 3 oz. of bacon, cut in fingers, and a hard-boiled egg, sliced. Arrange it as shown (Fig. 5) and roll it up neatly, but do not sew the edges together. Tie it in a cloth like a roly-poly pudding, and it is ready for cooking.

The finished dish is shown in Fig. 6. Remove the cloth, rinse it out in hot water, and tie the chicken up in it, tightly shaping it. The bird should then be pressed between two dishes and allowed to cool. *See Beef; Breast; Chicken; Fillet; Garnish; Stuffing.*

6. *The finished dish as garnished for serving.*

**BONNET: Of Motor Car.** The bonnet's seating, both on the dash and the radiator, is threaded through holes with a strip of some soft material. Should this be hard, which is more than likely, through the ingress of oil and dirt, replace with new.

A frequent cause of noise is due to the bonnet butting up against the seatings, thus giving the impression that it is too long. This is seldom the case, the fault usually being in the radiator, the holding bolts of which have become loose, allowing the radiator to vibrate. These should be tightened.

Where a top centre hinge is employed see that it is firmly secured at each end. Finally, a little very thin oil worked into the hinges will cure a lot of puzzling noises; the same applying to bonnet fastenings. *See Motor Car.*

## BOOKBINDING FOR THE AMATEUR

### How to Repair and Rebind One's Books

The article on this subject is one of a group that describes hobbies which can be taken up with advantage by the amateur. See *Leather Work*

Simple bookbinding may be done at home with a few tools and appliances, and the handy man can improvise or make for himself many of those required. The tools needed are as follows:

1 laying press	1 sewing frame and keys
1 pair backing boards	1 backing hammer
1 pair cutting boards	1 paring knife
1 pair pressing boards	1 bone folder
1 pair pressing tins	1 knocking down iron

To these may be added others likely to be in the amateur's tool box, i.e. a small tenon saw, a square, and a glue pot. A paste-pot will be needed also. The bookbinder uses a small "tub" for this purpose (Fig. 8), a rectangular wooden box having fixed across it at one end a wooden strip on which to rub out surplus paste from the brush. Glue and paste brushes should be the proper ones made for the purpose. They can be obtained, together with other requirements of the amateur bookbinder, from the firms which specialise in these goods.

Since the cutting of book edges presents some difficulty to the amateur, and is done by machinery in a fraction of the time taken by the old-fashioned

method, it is suggested that the local bookbinder be asked to trim the edges of any books which require this treatment. If this course is adopted the amateur will not need the tool called a plough, which is used, in conjunction with the laying press (Fig. 8), to cut book edges by hand.

*Bookbinding. Fig. 1. New end papers, A and B, tipped on to the first section. Fig. 2. Making a new case; A and C, boards; B, strip of manilla paper.*

*Bookbinding. Fig. 3. Section showing book being backed.*

*Fig. 4. Backing board*

*Fig. 5. Cutting board*

*Fig. 6. Book after backing.*

*Fig. 7. How book is rounded.*

We will commence with a cloth bound book which

has come out of its cover, and is otherwise in fairly good order. Dealing first with the cover, remove any loose portions of the end papers and any hard glue adhering to the back. If the corners have been telescoped they can be carefully hammered out flat. The back of the case may be repaired with pieces of binding cloth of the same sort and colour as the original. Should the back be damaged beyond repair, a new back may be made from a strip of cloth. The new back must be cut wide enough to allow an overlap on each side, which is glued and pressed between the edge of the old cover and the board. The edge of the old cover fabric must be rubbed down with a bone folder to make a close joint, and the case can then be put aside in a press, or under a weighted board, to dry. An old copying press, often to be picked up cheaply, would be very useful to the worker.

A new case is easily made, the old one serving as a gauge for size. If the old boards are usable, the measurements of the case should be observed before stripping, and a piece of binder's cloth cut to the size, allowing an overlap all round for turning in. If new boards are necessary, strawboard of the appropriate thickness should be obtained and carefully cut to size with a sharp knife and a metal straight-edge. A piece of stiff paper is glued to the back, leaving a space between the boards and paper strip. Fig. 2 will make this clear.

The cloth is glued out and left for a minute, when the left-hand board, A, is placed on it, leaving the correct margin for turn-in. The manilla strip, B, is then placed on the cloth, and finally the right-hand board, C. The positions might be marked on the cloth by pencil lines before glueing. Turn in the edges, rubbing the cloth down with the folder. It will be noted that the point of the board comes a little within the diagonal edge of the cloth, just leaving a little cloth to form a fold when the edges are turned over the board. The cover is then turned right side up and the whole surface rubbed down well with the folder. If the glue is hot and in proper condition there will be a smooth surface and no bubbles.

The book itself must now be dealt with. New end papers will be needed, and perhaps the strip of mull which held the back to the covers has come away. The mull may be pulled off and replaced by another strip, but if the sections are loose or some of the stitches are broken, this must be attended to first. The sections of a book are sewn through the fold from the centre, each section being also caught to the next. Ordinary books are machine sewn, the better-class work being sewn to tapes or cords. The methods adopted for hand-sewing books are shown in Figs. 9 and 10. The latter explains the process of sewing on tapes.

Make new end papers by cutting a sheet of stout white paper twice the size of the book page and folding it in the middle (Fig. 1, A, B). This is pasted at the fold and tipped on to the first section of the book. The end papers for the final section are made and fixed in a similar way. Any torn leaves in the book

may be mended with paper resembling that of the original. The old end leaves will furnish paper for patching or mending, and gummed transparent mending paper may be utilised. Loose plates should be tipped with paste and carefully replaced.

*Bookbinding. Fig. 8. Laying press, showing plough for cutting book edges; (above), paste tub.*

*Bookbinding. Fig. 9. Sewing press, showing the method of sewing on cords. Path of needles indicated by dotted line.*

*Bookbinding. Fig. 10. Sewing on tapes; path of needle shown by dotted line. Fig. 12. Method of overcasting single leaves.*

After any loose sections have been dealt with, and new end papers attached, the back should be glued up. Place the book in the press between boards, and work thin glue well into the back. When the glue is dry, but not hard, the book may be rounded. Fig. 7 shows how this is done. Place the book flat on the bench, front edge towards you. With the four fingers of the left hand stretched across the side and the thumb pressed into the front edge, pull the thumb and fingers towards each other, at the same time hammering the back of the book towards you. Turn the book over and repeat the hammering. This will force the sections forward on each side, and the book will now be perfectly flat with a round back, instead of being wedge-shaped with a flat back as when first sewn (Fig. 11). The threads used for sewing do not now fall exactly over one another, and the increased thickness or sewing swell is thus reduced (Fig. 10). (These illustrations show a book which has been sewn on cords. In good class work the ends of the cords are laced through holes in the boards of the cover. The cloth or leather cover is then made on the book itself.)

Place the book between backing boards in the laying press back outwards. The top of the backing boards should be about the same distance away from the back

edge of the book as the thickness of the cover boards (Fig. 3). Screw up tightly and hammer outwards from the centre to form a groove into which the cover boards will fit. Care must be taken to keep the round true, as near as possible the third of a circle (Fig. 6).

If the back of the book was in fairly good order it will not have been necessary to re-sew sections or to round and back the book. Glue up the back and line it with stout paper, rubbing down the lining after a while with a folder. When dry, glue up again and place on the back a strip of mull about 1½ in. wider than the back, leaving unglued the overlapping portion, which is pasted down to the covers when casing in the book. The book is then placed aside to dry.

*Fig. 11. Book sewn on cords, showing catch stitch between sections: Left, after sewing; right, back rounded.*

To insert the book into its cover, the front end paper, together with the overlapping portion of the strip of mull, should be evenly coated with thick paste and the book laid carefully on to the cover, seeing that the "squares" (margins) are equal on head, tail and fore-edge. Next paste the other (back) end leaf, which will now be uppermost, and leave it for a minute. Then hold the book with the right hand between its leaves, and bring the cover over on to the book with the left hand, watching meanwhile to see that the margins are even and equal to those of the front cover. The book must be placed between pressing boards and left overnight in the press. The back of the book should protrude from between the boards and the edges of the latter should be close up to the backing ridge.

The title of the book could be printed, typewritten, or neatly written on a paper label, this being pasted on to the back of the cover. If gilt lettering is wanted the local bookbinder would title the book for a small charge. Fig. 12 shows a method of over-sewing single leaves to form a section. In the illustration of a sewing frame (Fig. 9) a section is shown being sewn to cords, a method adopted for better-class work.

## BOOKCASES AND BOOKSHELVES

### Fittings to Make or Buy for House or Flat

Here is shown how accommodation for the books of the household can be provided at small cost. For information on the Carpentry details involved see Cabinet Making; Joint; Mortise; Tenon; Wood, etc.

The shape and size of a bookcase must vary according to the space available for its accommodation. Those most usual in houses of moderate dimensions are made to fit the recesses on each side of a fireplace, or to rest against a wall. They should have the advantage of light, without the disadvantages of strong sunlight or

appreciable heat from coal or gas fire or hot-water pipes. The golden rule is to make the bookcase for the books. Any ornament should be of the simplest kind, and the shelves should be movable, so that the books can be placed upon them according to their size.

Sectional bookcases on the unit system are useful in this respect, and possess the advantage of being easily moved and added to. On the other hand, their appearance is not so decorative for a drawing-room or in association with period furniture as shelves well placed in niches or recesses, or bookcases of the Chippendale style (q.v.). Space saving is so necessary in many homes that bookshelves are often added to built-in corner seats, above the padded backs; or low bookcases form separate and yet composite parts of a divan sofa, made in three sections, with upholstered centre and the two-shelfed bookcases at either end, painted to suit the woodwork of the room or made in oak, walnut or mahogany.

The total height of the bookcase shown in Fig. 1 is 4 ft. 3 in., the width 2 ft. 10 in., and the depth 10½ in. The bookcase portion has three spaces, and will hold from 60 to 70 volumes of crown 8vo or demy 8vo size. For a living-room bookcase oak will look best, or American whitewood will serve if it is stained to the colour of one of the hardwoods.

The ends, Fig. 2 (A), may finish ⅞ in. thick. The upper part is cut back with a simple shaping, and the lower parts may be shaped as indicated if the cabinet is not to stand in a recess. Both ends are dovetail-grooved to take the cupboard top and bottom, the grooves being stopped about ¾ in. from the front edge in order that the joint will be hidden. The back edges may be rebated for the upper and lower backs.

The cupboard bottom (B) and top (C), like the ends, should finish ⅞ in. thick. They are dovetail-housed to the ends, and the front edges will be cut back to correspond with the stopped grooves. At front the edges are flush with those of the ends. The back (D) is indicated as three-ply, but may be matched or framed according to the use to which the cupboard portion is to be put. The shaped rail (E) below the cupboard bottom stands back about 3/16 in. It may be doweled on, or glued with angle blocks behind.

The upper shelf (F) is shaped as shown in the plan, and is plain housed to the ends. If the upper back (G) is made in two parts the shelf may be cut ½ in. wider than shown, in order that it may go right to the back. The small brackets (R) stand in ¼ in., and are fixed with small glued blocks.

On the section the upper back (G) is shown in one piece. If preferred, it may be in two parts, the upper portion being doweled to the shelf (F). If in one piece, or if jointed (the joint coming behind the shelf), ½ in. wood may be used, in this case, H is a ¼ in. pilaster, planted on, and J J are two moulded slips, 1½ in. wide by ¼ in. thick, planted on to form a kind of plinth. If it is preferred to have the upper back divided, the wide portion between the shelves might be (a) framed up with a long mirror, or (b) framed to form two panels as indicated, or (c) it might be a solid board with a small

mould (S) pinned on to form panels. The ends, which are 5½ in. wide at the top, are rounded off to the section shown.

The doors (M and N) should not be made till the carcass is otherwise complete. They are framed up of stiles and rails 2 in. by ⅞ in. and are shown without a mould. The astragal (O) should be quite plain if the doors are made to the section shown. Inside shelves (P)

	Long in.	Wide in.	Thick in.
2 ends (A) .. .. .	51	11	7 1/8
Cupboard bottom (B) .. .. .	33	10 1/2	7 1/8

are ¾ in. thick, and may be hung on fillets or on studs.

In the cutting list given above the lengths and widths allow for joints and paring, but all thicknesses are net. If the upper back (G) is cut in two pieces, the lower one will be 10 in. wide and the upper one 2½ in. (*See also page 219*)

**Making a Set of Bookshelves.** A set of bookshelves which are suitable for a narrow recess at the side of a fireplace; or the return corner of a room at the window end, is shown in Fig. 3. The addition of a small cupboard below adds to its usefulness. Additional wide shelves may replace this, if desired. If other furniture has to be matched, oak or other hardwood may be used, but for ordinary purposes American whitewood will do.

The cutting list is as follows, lengths given allowing for joints, but all thicknesses are net.

	Long ft. in.	Wide in.	Thick in.
2 uprights .. .. .	6 2	8	7 1/2
2 extensions for ditto .. .. .	2 7	3	7 1/2
Top .. .. .	2 9	9 1/2	7 1/2
Cupboard top .. .. .	2 5	11	7 1/2
Cupboard bottom .. .. .	2 5	11	7 1/2
Cupboard shelf .. .. .	2 5	10	7 1/2
4 shelves .. .. .	2 5	8	7 1/2
2 rails .. .. .	2 5	2	7 1/2
4 door stiles .. .. .	1 6 1/2	2	7 1/2
4 door rails .. .. .	1 3	2	7 1/2
2 door panels .. .. .	1 3	11	1 1/4

Back (matched) about 15 ft. super.

The sizes given on the scale drawings in Fig. 4 are necessarily suggestive. A carcass width of 2 ft. 6 in. is useful for the narrow recess, but this could be slightly

(Continued in page 221)

## BOOK CASE

Right. Fig. 2. Front elevation, section and plan, below.

Bookcase. Below. Figs. 3 and 4. Set of shelves with cupboard which can be made by the amateur woodworker.

increased or reduced to suit requirements.

The uprights (about 6 ft. 2 in. long) are 8 in. in width, but widened by glue-jointing to 11 in. for the lower part. The added portions are shaped at the top, and at the extreme top of the uprights a little piece is glued on to give a break. The uprights should be dovetail-housed to the top, shown 9½ in. wide.

The cupboard bottom and top and the top shelf should be dovetail-housed to the uprights, the housing being stopped in each case to mask the joint. The other shelves may be housed, or fitted on fillets or secured in position with bookcase pins. The shaped rails below the bookcase top and the cupboard bottom may be glued on with angle blocks behind. The doors are framed of material 2 in. wide by ¾ in. thick, with or without a mould. The inside cupboard shelf, fixed or adjustable, will act as a door-stop.

When shelves have to be fitted into a recess, and no screws or nails may be driven into the wall, a good plan is to provide two uprights of flat board as wide as the shelves, one for each side, or alternatively two narrow uprights, about 3 in. by 1 in., for 9 in. wide shelves, for each end. If the shelves are not to be adjustable for distance apart, it only remains to cut grooves in the uprights at the desired levels. An alternative method, avoiding the need of wedging between the wall and the upright, is to cut two or more shelves so that they have projecting ends that pass through slots cut in the uprights for that purpose. These are then secured with wedges driven through slots in the projecting ends of the shelves.

*Bookcase. Fig. 5. Light hanging shelves.*

Fig. 5 shows a hanging bookshelf. The shaped part of the ends shown in the elevation is cut out with a bow saw and carefully cleaned up to a smooth finish. The ends are then marked out, and the dovetail grooves cut so as to receive the ends of the shelves, which are cut as at C (Fig. 6).

The front and ends of the cornice board should have their edges moulded, as shown at A or B. The moulding at A is worked with a moulding plane, but those who do not possess a suitable tool could easily cut the moulding shown at B, which would be almost as effective. The shape cut at B would be worked as follows: Mark the

work as deeply as possible with a cutting gauge, and plane roughly to shape with a jack plane; then work away the square or fillet with a tenon saw and chisel, pare up, and glasspaper to a finish. It will greatly facilitate the working of the moulding if the glasspaper is wrapped round a small piece of wood about 2¼ in. long by 1 in. by 1 in.; there will then be little or no tendency to rub the flat or chamfered portion of the moulding out of shape.

*Fig. 7. Slotted strip for adjustable shelving. Fig. 8. Strip, with supporting studs. Fig. 9. Bracket used with this system. (Hill & Cozens, Ltd.,)*

Assemble the parts as follows: Glue to the grooves which are cut in the ends, and fix in the three shelves; glue, nail, and screw the cornice board, and allow the glue to harden; cut the shaped piece, and glue and screw it to the cornice board. If the screws be put in from the top of the cornice, the method of fixing in the shaping will be concealed from view. Three coats of suitably coloured enamel will make a good finish.

Ends, shelves and cornice board are of canary wood, ¾ in. thick; they should be kept as thick as possible but planed out of winding. The shaping, also of canary wood, ¾ in. thick, is screwed in position from top of cornice board with 3 screws, 1½ in. long by 10 or 8 gauge. The cornice board is fastened to the ends with 4 screws 2 in. by 10 gauge and 4 oval nails, 2 in. long. To fix the bookshelf to the wall, 3 brass ear plates are required; 2 ear plates are fastened to the cornice board and 1 to the centre of the bottom shelf.

*Bookcase built up on the unit system from boxes with and without doors, made by Venesta, Ltd.*

**Movable Shelves and Portable Shelving.** When a large number of books is to be provided for, and perhaps the whole side of a room will be taken up with the shelving, the system described below is suitable. The sides and any intermediate uprights are  $1\frac{1}{4}$  in. by 8 in. or 9 in. boards, and the shelves are 1 in. thick. Oak is very suitable for the purpose. A pair of uprights are connected by a base at the bottom and a cornice at the top, these being of the length selected for the shelves. Angle brackets and screws are used to fasten them to the uprights. Slotted brackets can be obtained which permit the removal of the base or cornice by just slacking off the screws, which need not be entirely unscrewed. Two grooves are ploughed in each upright to take narrow metal strips (Fig. 7) pierced with rectangular holes about an inch apart. The strip lies in the groove flush with the face of the wood, and is secured by screws. The shelves are supported on steel studs which fit into the holes in the strip. The strips are sold in lengths of 6 ft., but can be had in special lengths at a little extra cost. Iron brackets from 2 in. to 6 in. wide are also made for use with the bookcase strip (Fig. 9). In making up shelving on this system it is imperative that the strips on each of the uprights should be the same height from the floor line. Intermediate uprights will be grooved and fitted with iron strips on both faces, since they support two sets of shelves.

*Bookcase. Set of shelves, so constructed that each shelf can be adjusted to the height of the volumes it is intended to bear. (Courtesy of Country Life, Ltd.)*

**BOOK COVER.** Spread the book open on a piece of material, holland, linen, brocade, silk, etc. Mark where the edges come, and cut a rectangle, leaving 1 in. for the turnings at top and bottom, and nearly the width of the cover extra at each side. Turn these side-pieces over the cover boards, and shut the book to make sure there is enough play for the back. Then remove from the book and stitch down the loose side-pieces at top and bottom. Also turn in a narrow hem along their loose edges, and along the unstitched part of the top and bottom.

Turn the cover the other way out, and slip the cover boards of the book into it. The title can be written on the cover in coloured Mandarin ink, or embroidered, if of silk or brocade, but this must be done before it is put over the book.

A temporary cover can be made of stout brown paper cut out similarly to the cloth cover described

above.

**BOOK ENDS.** These are more decorative for a few books on occasional or writing table in living-room or bedroom than the ordinary book rest, as they may be obtained in brightly-coloured pottery, tinted plaster, marbles, painted and lacquered wood and heavy glass. Weighted wooden ends are covered in embroidery on canvas and in raffia work. *See Pottery; Raffia.*

**Book Keeping.** This is not widely employed in the household, but there the keeping of accounts is desirable. *See Accounts.*

**BOOK MARKER.** The simplest is a piece of ribbon, a little longer than the book itself, glued to that part of the binding where the pages are stitched together. A metal clip marker combines a page cutter, or a separate ribbon marker may be weighted either end with a tiny metal figure or animal.

**BOOK PLATE.** A printed label which can be pasted inside the cover of a book to mark its ownership, a book plate may be specially designed and an elaborate production blazoned with coat of arms or some fanciful design, or a simple form with the owner's name. The earliest existing examples date from the early 16th century, and these, as well as fine specimens of workmanship of the 17th and 18th centuries, are collected by some people as a hobby.

**BOOK REST: How to Make.** A book rest or book rack differs essentially from a bookcase or bookshelf in that it is mainly used for holding books which are constantly in use. It is generally designed so that the books are tilted at a convenient angle for quick selection.

*Book Rest. Fig. 1. Tilted book rest suitable for a study table or writing-desk. Fig. 2. Front aspect.*

*Fig. 3. End of book rest inlaid with black and white check pattern.*

*Fig. 4. How the shape of the ends may be transferred: the squares indicated represent each half inch.*

The book rack shown in Fig. 1, which is made with two ends, a back and a bottom, could be carried out in

oak, in which case the ends may be inlaid with a black and white pattern, as shown at Figs. 1 and 3. If this plan is adopted, the rack should be fumed fairly dark and waxed, and the inlay could be ebony and holly. Mahogany and walnut are also suitable woods.

The ends, which are  $6\frac{1}{2}$  in. wide by 6 in. high, are cut from  $\frac{1}{2}$  in. material with the grain running from top to bottom. The shape may easily be transferred from Fig. 4, if the squares indicated in the illustration represent each  $\frac{1}{2}$  in. The back and bottom should be 1 ft.  $5\frac{1}{2}$  in. long, the former being 6 in. wide, and the latter 4 in., while a thickness of  $\frac{1}{4}$  in. will be found sufficient. The back and bottom are simply housed  $\frac{1}{4}$  in. into the ends in the positions indicated at Fig. 4. The joints are cut to fit fairly tight, and are glued.

*Book Table in polished oak. It has shelves on every side and is admirable for the lounge.*

**BOOK TABLE.** This space-saving piece of furniture takes the place of a revolving bookcase, having shelves on every side to accommodate books and periodicals in use, and

is also a convenient occasional table. It has the advantage of being solidly made and perfectly steady for a reading lamp or tray of glasses, etc. See illustration above.

## **BOOTS: USEFUL HINTS ON CHOOSING**

### **How to Recognize Good Footwear and to Preserve it in Use**

Related articles are those on Boot Polish; Boot Repairing; and Leather. See also Brown Boots

When buying a pair of boots, to the casual eye the cheaper boot, nicely treed up, well stretched to take out all creases, and then carefully polished, will not present much difference from one at perhaps double the price; but close inspection will reveal the greater smoothness or velvety feel of the grain if of a high grade box-calf, which will be found to give greater satisfaction in wear, and to retain its appearance longer than the cheaper boot made from a lower quality coarser skin, or

perhaps from box-hide, which can usually be recognized by the absence of grain marking, and the harsher surface when the hand is passed over it, making it more liable to crack in wear. The higher grade box-calf has distinct grain markings and is beautifully supple.

The finish of the boot should also be regarded, the neatness of the closing of the uppers, the exact regularity of the stitching to the vamp or golosh, the perfect insertion and alinement of the eyelets, and, above all, the quality of the leather of which the tongue is made and the way it is attached to the inside of the opening. A cheap boot often reveals itself in the tongue, being of very poor, rough stuff carelessly fastened into the inside of the front.

The lining of the boot should be examined, and, whether of linen or leather, this should fit without wrinkles. Then the fingers should be passed down towards the toe. If there is a crease in the toe, where the lining has been badly lasted, and this is quite a common fault in a cheap boot or shoe, it will cause constant trouble in wear from the first day. The looseness of the lining will form a hard ridge, which will rub blisters across the toes. At the heel, the fit of the stiffener inside should be noted. If on passing the fingers downward the edge of the stiffener is plainly to be felt, then it can usually be anticipated that the friction of the wearer's heel will rub a hole in the back lining very quickly, and a blistered heel will probably result.

If all these points are satisfactory and the boot fits closely to the foot when the wearer stands up and puts his weight upon it, without painful compression of the big-toe joint or cramping of the toes, then, whether the boots are cheap or expensive, it may safely be assumed that comfortable wear will result, and as much durability as the purchaser has a right to expect.

In buying patent leather shoes it is well to choose the best, although even the best patent-colt or patent-calf cannot be relied upon to wear without cracking in spite of many attempts to produce a patent leather that will not crack; but cheap patent, which is often not leather at all, but American cloth, is certain to become cracked in wear and quickly to lose its smart appearance. It is all the more important, therefore, to see that the finish of the inside of the shoe is all that it ought to be.

Owing to the hard enamel surface patent shoes will not stretch in the least degree. They are also airtight. When the foot becomes warm and swollen there is no possibility of the shoe stretching, and thus the hot foot, prevented from swelling, becomes cramped and still hotter through lack of ventilation which ordinary leather affords.

A glacé kid boot is sometimes made with a patent leather cap, and to preserve the surface of the patent this cap is rendered unbreakable with a toe-puff or case of hard leather, stiffened canvas, or compressed fibre inside. This looks smart at first, but in wear the flexible glacé has a tendency to crease in the same place

every time the foot is bent, exactly where the stiff toe-cap finishes, and very quickly an unsightly crack develops.

### Leather which is Waterproof

In regard to the soles, it is difficult to tell the quality of leather used, as the leather is scraped, and what is called fake applied to it, either black or brown. This applies to vegetable tanned leather. Chrome tanned sole leather can be distinguished as it is always left in its natural green colour. This leather is absolutely waterproof, and in the best tannages is far more durable in wear than even the best quality oakbark-tanned. While chrome is watertight, it is also airtight, and is not recommended if the wearer has hot feet.

It will be found the truest economy to have two or three pairs of boots in use at the same time. After being worn for a day, the boots should be placed on a pair of trees. If wet, they should not, in any circumstances, be placed near a fire, but should be laid on their sides in a dry place, and not with the sole to the floor, so that the wet sole can dry in the air. When boots have been thoroughly soaked, an excellent plan for drying them before putting on the trees is to fill them with sawdust that has been well dried. This absorbs any moisture that may have soaked through; and if the sawdust is tightly packed, it swells as it absorbs the moisture and keeps the uppers nicely stretched as they dry. When the boots are dry the sawdust can be shaken out, and after being dried in the oven, this can be kept for further use.

The boots should then be placed on the trees and well polished. The uppers of wax-calf or kip should be treated with dubbin in wet weather, and chrome uppers can be treated with a dressing of glycerine. This will help to resist the damp, or if it is not applied until after the wet boots have been dried, will keep them supple. Before being polished, either with wax polish or other suitable blacking, according to the character of the upper leather, the surface grease should be carefully wiped off or a good shine will not be obtained. Wet soles will be found to dry hard and present a shrivelled appearance. An application of glycerine well rubbed in will not only restore the nature of the leather, but will render the soles more watertight when again worn, and prolong their life.

A hot water pipe has ruined more good boots than the wearers have ever dreamed of, the subsequent rapid deterioration of the boot being attributed to poor quality leather or faulty workmanship. Leather scorches and perishes if subjected to heat. The damage is not noticed at the time; but when the boots are again worn, the perished brittle leather cracks and crumbles away.

### How to Determine the Fit

The fit of the boot is determined across the joint over the crown and the arch of the instep and the heel. From the joint backward the boot should fit snugly like a well-fitting glove, but there must be plenty of room for the toes. There must be no looseness in the heel, but

this will be kept quite snug by the fit of the joint. There can be no greater mistake than to have the toes fitted. The ideal is close heel, well-fitting joint and instep, and leave the toes plenty of room to look after themselves. In walking the weight of the body is put on to the foot, and is transferred to the toes as the heel leaves the ground. If there is no room for the toes to spread naturally under this transference of weight, the result is cramp, discomfort, and pain, with eventual corns and foot trouble generally.

Leather improves with keeping, and it is a good plan to buy boots several months before they are worn. They should be stored in a dry cupboard and occasionally cleaned. A little vaseline round the edges of the soles from time to time will add to the durability. A varnish dressing which produces a shine without rubbing or brushing is injurious to the leather. Polish cannot penetrate when applied over such a varnish, and polish, which helps to preserve the leather, cannot do so unless it penetrates it. When shoes are varnished it makes them impervious to the perspiration of the foot, which is absorbed into the leather itself and gradually rots it.

Chrome upper boots or shoes (box-calf, willow-calf, dull chrome, glaze kid) should never be cleaned when damp. The best makes of polish only should be used. Vegetable tanned uppers, wax calf, waxed kip or split, such as farm boots, etc., may be kept soft by rubbing in nightly dubbin, neat's-foot oil, or tallow.

**BOOT BRUSH.** Owing to the improvements effected in leather polishing preparations the old method of boot-cleaning has in many homes completely disappeared; but for preparatory cleaning from dust or mud the boot or shoe brush is still a necessity. Pure bristle is the cheapest outlay. If fibre is used in a mixture it will soon break, and horse-hair will not last so long in hard wear. The butt or root end of the bristle supplies what is needed for the reliable hard brush, and the bright, needle-like stiffness of these knots should be looked for. They can also be obtained with a row of knots set in the end of the stock to brush out the welts. For blacking with oil or water blacking, or applying polish, a softer quality is required.

The polishing brush should be of medium stiffness where blacking is used, and a softer one will give the right finish after applying polish. *See* Blacking; Boot; Boot Rack; Brown Boots; Brush.

**BOOT BRUSH BOX.** For those who use both black and brown boots the box shown in Fig. 1 will prove serviceable. The sizes given are approximate for an average size brush and pad, and the usual small tins of polish.

*Boot Brush Box. Box holding cleaning apparatus for both black and brown boots.*

The partitions provide for brushes in the centre, and black or brown polish and pad on either side. The sides can be housed and nailed and the holes stopped; or, in a rougher fashion, the parts can be nailed together.

*Boot Brush Box. Details showing how the box, with its partitions, is made.*

The partitions can be of  $\frac{1}{4}$  in. thickness, being plain-grooved into position, as indicated at Fig. 2. These parts should be secured in position with just a touch of glue. The grooves are squared and the sides cut with the tenon saw, the core being removed with a  $\frac{1}{4}$  in. chisel.

The bottom is best cut  $\frac{1}{2}$  in. longer and wider than the sides of the box, so that the edges, when the bottom is screwed on, can project  $\frac{1}{4}$  in. on all sides, to be neatly rounded off for finish. A brass handle is screwed on for lifting purposes. This side of the box can be  $\frac{3}{4}$  in. or  $\frac{7}{8}$  in. in thickness, using a 4 in. handle and  $1\frac{1}{4}$  in. screws, entered well home. U-shaped openings in the sides of partitions fronting the small wells will facilitate the removal of the paste boxes.

**BOOTEES:** How to Knit. In choosing wool for a baby's bootees be sure it is of good quality, well shrunk, and soft in texture. They will often be in the wash, so cheap wool is a mistake, and they must not be made too small, or they will stop circulation instead of assisting it. In using wool or ribbon ties, be sure they are not pulled too tight.

The following pattern is simple in plain knitting, and two needles only are used till just at the finish. The materials required are 1 oz. of well-shrunk 4-ply fingering in white, pink, or blue, three knitting-needles, No. 10, and 1 yd. of narrow ribbon. The ribbing may be continued nearer the ankle by working an additional 8 rows with 30 rows plain knitting.

Cast on 40 stitches. Rib knit 2, purl 2 for 16 rows; then work 38 rows in plain knitting. For the next row—the 55th—knit 2, wool forward, knit 2 together to make a row of holes, and repeat this till the end of the row. Knit 2 rows in plain knitting. Then begin the instep of the foot as follows: Knit 14, then knit backwards and forwards on the next 12 stitches for 34 rows. Break off the wool (fastening the end firmly) and

leave these stitches on a needle or safety-pin.

*Bootee knitted according to the directions given in this article.*

Begin again with the 14 stitches on the left of the ankle, picking up the 17 stitches along the side of the instep piece just finished, and 6 of the stitches left on the safety-pin. Take another needle and knit on the other 6 stitches across the toe, the 17 stitches on the other side of the instep, and the 14, stitches at the ankle. Knit backwards and forwards, using the three needles for 14 rows, without shaping. Then work 6 rows, decreasing once at the beginning and end of each needle. Cast off.

Sew up the seam neatly, threading the ribbon through the holes at the ankle. *See Baby.*

**BOOT LACE.** East India kip provides the leather for laces used with heavy boots. Mohair laces are usually a mixture of wool and cotton. The leather buckle lace worn with golf and other sporting shoes consists of a thin strap of leather inserted through the eyelets of the shoe, and fastened by means of a nickel, or other metal buckle instead of being tied.

**BOOT POLISH.** Wax polishes are coloured with aniline dyes, black or brown as required. The surface obtained on the boot must not be sticky, hence a very hard wax, known as carnauba wax, is employed.

The wax is boiled with borax or soda to form an emulsion, and this is mixed with a hot solution of soap coloured with nigrosin (an aniline black). Boot dressings in liquid form, used for ladies' kid shoes, contain shellac, which has been dissolved in borax or soda solution. If soap is added a dull finish is given in place of the gloss of the plain shellac dressing. *See Blacking; Boot.*

**BOOT RACK.** A folding rack is shown in Fig. 1. It is made with a back and two folding frames, and in the size shown is capable of holding eight pairs of ladies' or six pairs of gentlemen's boots. If a larger rack is desired the length of the rail may be extended or height of rack increased. To make it, 4 ft. 6 in. of 3 in. by  $\frac{3}{4}$  in., 10 ft. 6 in. of  $1\frac{1}{2}$  in. by  $\frac{3}{4}$  in., and 8 ft. 1 in. of  $\frac{3}{4}$  in. round material must be arranged for. The 3 in. material is cut into two 2 ft. 3 in. lengths, the  $1\frac{1}{2}$  in. into three 2 ft. 2 in., and four 1 ft., and the  $\frac{3}{4}$  in. into four 2 ft.  $\frac{1}{4}$  in. lengths.

For the back take the two 2 ft. 3 in. lengths of 3 in. material for the sides, and the three 2 ft. 2 in. lengths of  $1\frac{1}{2}$  in. for the rails. Dovetail the two front rails into the front edges of the sides, and the back rail into the

back edges, in the positions at Fig. 2. The ends of the sides are shaped as at Fig. 3, and hanging holes are bored.

The two folding frames are exactly similar. For each take two of the 1 ft. by 1½ in. pieces for the sides, and two of the round pieces for the rails. The frames are made to the dimensions shown at Fig. 4 by shouldering down the ends of the rails to ½ in. diameter, for a length of ¾ in., and boring holes in the sides into which the shouldered portions of the rails may fit.

The frames are fitted to the back with rivets or round head screws, as at Figs. 3 and 6. The frames when extended rest on the edges of the front rails of the back, as at Fig. 3. A coat of stain or varnish will be necessary as a finish.

**Fig. 1.** *Boot Rack. Fig. 1. Useful rack made to fold against the wall when not in use. Figs. 2-6. Diagrams showing details of construction.*

(By arrangement with Evans Bros., London)

## BOOT REPAIRING IN THE HOME

### Essential Processes Simply Described

Readers may usefully turn to the preceding article on Boot, in which hints are given on the selection and care of footwear. See also Clog.

Most boots and shoes in ordinary wear today are either welted, where the outer sole is stitched through the edge to a welt sewn round the edge of the upper, or machine-sewn, where the outer sole is sewn through to the inside of the boot by stitches going right through the sole substance. The outer soles may also be attached by riveting, by thin wire screws or, less frequently nowadays, by wooden pegs. Of these, all may be repaired by riveting on a new sole, although in the case of welted boots it is preferable that it should be stitched

on. With machine-sewn boots, a sewn sole makes a better repair, but it is quite adaptable for riveted repairs, as described in this article, the only method practicable for the average home worker.

**Fig. 1.** *Boot Repairing. Figs. 1-9. Illustrations of the various stages of soleing and heeling a pair of boots, the correct method of doing which is described in the accompanying article.*

*Boot Repairing. Figs. 10-15. Concluding stages in soleing and heeling a pair of boots, showing how the heels and soles should be finished off with a rasp and sandpaper and finally burnished.*

The essential tools are a shoemaker's hammer, with one head; a couple of shoemaker's knives, one ground right down to a small triangular blade, which will be found the most handy for cutting off the worn sole of a welted or sewn boot; a shoemaker's rasp, rounded on one side and with a flat file surface on the other; a straight awl, sandpaper (No. 1½), a glazing iron, the most convenient shape to use being the combination iron. Also shoemaker's ink, heelball, and the indispensable rivet. The rivets will be of the length most suited to the job in hand, and should be preferably brass, except in cases where a double row of rivets is fixed to take wear, when iron should be used.

An iron foot or last is necessary. This can either be attached to a shaft in an iron socket fixed to a bench, or, where repairing is only an occasional job, an iron foot fixed in a wooden stick or "leg" resting on the floor may be used. Several sizes of iron feet will be required for men's, women's, and children's boots, and these will be interchangeable in the same wooden leg.

Leather can be purchased ready shaped up in soles

and top-pieces, or it can be bought by the piece. Select a piece with even, smooth grain and equal substance. The flesh side should not be loose, but should be firm and hard. If a pattern of the sole to be replaced is taken in paper (Fig. 1), this can easily be applied to the piece of leather chosen and waste avoided.

The pattern is made by placing a piece of newspaper flat on the sole of one of the boots with the edge across the waist where the graft is to be, and passing the file side of the rasp downwards round the edge of the sole, leaving the exact shape of the sole filed out. In cutting the soles from the piece of leather, take care to turn the pattern over when cutting the second sole. Temper the leather by steeping it in a pan of cold water for 5 or 10 min. Then take it out, bending and twisting it in the fingers until the superfluous surface moisture is absorbed and the leather is mellow.

When the leather is fairly dry but still moist and plastic, place it grain downwards on the lap-iron—an old flat-iron minus the handle—held on the knees, and strike it firmly and evenly with the flat head of the hammer, commencing in the middle and working out to the edges. The strokes should not be too vigorous or the fibres will be crushed. This hammering makes the leather tougher and closes up the pores, making it more waterproof and more durable in wear.

Now take the boot to be repaired, and, after damping the bottom and placing on the foot, take off the old sole. The little pointed knife is inserted in the joint at about the spot where the new sole will join the old, and the stitches cut through to the corresponding point on the other side. In Fig. 2 a machine-sewn boot is shown, and the same method will apply to ripping a welted boot. If the old boot has a nailed sole, the toe should be prized up by inserting a screwdriver or blunt old chisel and the toe end of the sole seized in the nippers and levered back, the middle sole being held down firmly with the other hand meanwhile. The old sole should be cut off across the joint with a slanting cut, leaving a longer length of waistline on the old sole on the inside than on the out (Fig. 3).

### Repairing the Middle Sole

Before proceeding further the middle sole should be made good. If the boot is worn so badly that part of the middle sole has been worn through, a thin patch should be placed over the worn spot with a couple of short rivets tapped in to keep it in place. Boots should never be allowed to wear through the middle sole before being repaired. It may be found that in ripping a riveted sole the middle sole has been pulled away from the inner sole. This should be knocked down and half a dozen rivets put in. These should be just long enough to penetrate the inner sole and burr over on the iron foot, but not long enough to turn over appreciably. They should be hammered well home.

Having made all secure, take the new sole and, placing it in position on the stripped bottom, with the back of the knife mark a line across the old waist where the groove or skived hollow for the end of the

new sole is to start. (Fig. 4). Skive out on the old waist from this line, tapering towards the joint cut (Fig. 5). Now skive off on the flesh side of the waist end of the new sole, tapering towards the joint, but not too finely or sufficient substance will not be left to hold the waist rivets securely (Fig. 6). Place the new sole in position and, holding firmly, make a row of holes from side to side near the joint, but not too near. The first rivet is knocked in on the side (Fig. 7), and the row of rivets is now finished across the waist.

After nailing the waist, press the fingers across sole, hammer from waist to toe, and, holding down firmly, drive in a rivet in the centre of the fore part quite near the toe. The new sole should now be lying snug on the middle sole, and the edges of the sole should be pared close, care being taken not to cut the edge of the middle sole.

A line is now drawn about  $\frac{3}{8}$  in. from the outer edge all round the sole. This can be done with the thumbnail, using the first finger as a guide on the edge of the sole. Now with the awl make the holes for the rivets at equal distances all round, not too far apart, taking care to hold the awl perfectly upright.

When some degree of expertness is attained in driving the rivets, the hole-pricking may be dispensed with, the rivet being pressed into the leather (which should be still sufficiently moist and plastic to enable this to be done) with the left hand, as if placing in the hole made by the awl, and then one smart tap should drive it home. After the whole row has been completed, the edge of the sole should be well hammered all round in order to drive the rivets home.

Before finishing the edge, the heel may be taken in hand. The corner of the top piece should be prized up and seized with the nippers, and the top piece pulled off, the boot being held firmly on the foot with the left hand. The second lift should never be allowed to get worn through, as a worn-over heel destroys the shape and appearance of the boot, in addition to putting an undue strain upon the boot upper at the heel. But if the second lift is worn, then a cut should be made across the heel, so that the worn part can be prized off and a new half-lift nailed on (Figs. 8 and 9).

Trim off and, after taking out any protruding nails or hammering down, rivet on the top piece. To secure this,  $\frac{3}{4}$  in. rivets should be used, and then a double row of shorter rivets to take the tread (Fig. 10).

Sole and heel are now ready to be finished off. The first process, supposing the edges to have been closely trimmed up with the knife, is rasping. This is effected with the round side of the rasp, and gives the edge a slightly hollowed shape (Fig. 11), which is accentuated with the round edge of the buffing knife (Fig. 12).

The heads of the rivets on the sole should be rubbed over with the flat side of the rasp. If it is desired to finish the joint in a workman-like manner, the upstanding edge of the new sole can be skived off with the knife, the surface at the joint rasped, and then the whole surface of the sole can be buffed and finished off with sandpaper.

The edges of the sole are now finished off with

sandpaper and inked. When this is dry we proceed to the operation of setting the edge or polishing. For this the combination iron will be found most convenient. Fig. 13 shows this tool with its different faces, A, B, C. First the inked edge, having been allowed to dry, is ironed, and then a thin coating of heelball is applied, and the iron, warmed up but not made too hot, distributes the heelball evenly over the surface. Firm, even pressure with a quick motion will produce a smooth, shiny surface, and then, to finish off, the superfluous heelball is taken off, and a final polish applied with a piece of cloth, which is folded across the thumb. Figs. 14 and 15 illustrate the method of holding the iron, and show the different edges that are employed for sole and heel.

**BOOT SCRAPER.** A boot scraper saves dirt and mud being brought into the house, and one similar to that shown in Fig. 1 can easily be made. The scraper is constructed with a wooden framework consisting of two sides and a bottom bar, and is fitted with a scraping-iron at the top.

The side bars of the framework are  $10\frac{3}{4}$  in. long by 2 in. wide by 1 in. thick, and slots  $\frac{3}{16}$  in. wide are cut  $1\frac{1}{2}$  in. in from the top ends. The bottom bar is 12 in. long by 2 in. wide by 1 in. thick. Notches 1 in. wide by  $\frac{1}{4}$  in. deep are cut in the upper face of the bottom bar to receive the bottom ends of the side bars.

The scraping iron should be 12 in. long by 2 in. wide by  $\frac{3}{16}$  in. thick; the top corners are rounded, and  $\frac{3}{16}$  in. holes are bored at the ends. The iron fits into the slots at the top ends of the side bars, and is fixed with  $\frac{3}{16}$  in. rivets, which pass through the bars and iron.

*Boot Scraper. Figs. 1 and 2. Simple scraper and method of fixing it.*

Before fixing, at least three coats of good oil paint should be applied. A hole must be prepared in the ground to receive the framework, the scraper being fixed at the height suggested in Fig. 2. The earth around the framework should be well stamped down.

**BOOT TREE.** There are various patterns of boot trees, and to use them to the best advantage they should conform as nearly as possible to the shape of the boot worn. It would not do, for instance, to put a round-toed tree into a pointed-toed boot, as it would be almost certain to stretch the toe out of shape. A boot that is treed-up immediately after wearing and left until again required will retain its original shape. *See Boot.*

**BORACIC ACID.** One of the most useful of the mild antiseptics is boracic or boric acid. For soothing irritated or painful eyes, one part of boracic acid to forty parts of water is a widely used lotion. Mixed with equal parts of powdered zinc oxide, it is a good dusting powder. For excessive perspiration of the feet, a powder containing one part of boric acid, two of starch, and two of zinc oxide, dusted into the socks, gives excellent results. In saturated solution boracic acid forms a non-irritating, antiseptic lotion excellent for cleansing sores.

**BORAGE.** The flowers and also the aromatic leaves of borage are used for flavouring such beverages as claret-cup or negus; the leaves and young tops may be employed in salads. The flowers are blue, the leaves oblong and clothed with white hairs, the stems about 2 ft. high, hollow and rough. The plant is best grown as annual, seed being sown out of doors in spring. A foot apart is a suitable distance for the plants, which like a rather dry and stony soil. *See* Claret Cup; Negus. Pron. Bŭrridge.

*Borage. Flowers and leaves of the aromatic garden herb.*

**BORAX.** The white powder known as borax occurs naturally in California, and has the chemical name of biborate of soda. It is much used as a mild antiseptic and as a water softener. Dissolved in glycerin (1 oz. of purified borax in 6 oz. of glycerin), it is known as glycerin of borax, and is used for thrush and in other forms of sore mouth. Good results have followed the administration of borax in epilepsy. As a gargle for sore throat the proportion to use is 1 oz. of borax dissolved in a pint of water. As an eyewash 8 grains of borax in 1 oz. of water is the proper strength to employ. Borax ointment, made by mixing 1 oz. of borax with 8 oz. of spermaceti ointment, is an excellent application for chilblains or cracked nipples. For softening water a teaspoonful of borax is added to a ewerful of water, the advantage of borax over soda being that borax does not affect even the most sensitive skin. Borax is no longer used as a food preservative.

**BORDEAUX.** The wines of Bordeaux contain the least amount of sugar, alcohol, and acid of any, and are not fortified with any spirit. They are generally divided into four classes, which differ in taste, colour, bouquet, durability, and price. In the first class are what are known as the Chateau wines, such as Chateau Lafite, Chateau Latour, Chateau Margaux, and Chateau Haut Brion.

The second class comprises wines such as Rauzan, Beaune, Mouton, Leoville, La Rose, Pichon, and

Longueville. In the third class are wines such as Chateau d'Issan Poujets, Cantenac and Giscours. In the fourth class are the clarets, St. Julien, Pauillac, and St. Estephe. *See* Claret; Grape; Sauterne, etc.

**BORDEAUX MIXTURE.** The most effective spray for apples and pears is Bordeaux mixture, and it can be relied on to prevent scab. The Ministry of Agriculture Leaflet No. 245 describes its preparation and use in orchards. The best formula is: copper sulphate, 4 lb.; best quicklime (in lump form), 4 lb.; and water, 50 gal. The copper sulphate should be dissolved in a small wooden vessel at the rate of 1 gal. of water per lb. of sulphate. On no account should iron or tin vessels be employed.

The lime should be slaked to a fine paste with a little water in another vessel, and water added gradually to make a milk, and finally diluted in a large barrel to the requisite amount (46 gal.). The 4 gal. of copper sulphate may now be poured slowly into the diluted milk of lime, and the mixture stirred thoroughly during the process. The two solutions may be kept separately for a long time, but after mixing the solution should be used at all events within 24 hours. *See* Apple; Pear.

#### **BORDERS: THEIR EFFECTIVE GARDEN USE** Choice and Arrangement of Flowers and Plants

In this work the reader will find entries on the various plants and flowers mentioned in the following article. *See* also Bedding; Gardening

A garden border is, strictly, an expanse of soil devoted to the culture of flowers, fruit or vegetables, which has the shelter or protection of a wall or fence along one side. Modern usage, however, gives the name to any extended flower bed, e.g. one by the side of a lawn or in front of a shrubbery.

Borders are described as herbaceous, mixed, spring or autumn flowering, according to the nature of their contents. The best are those which rely chiefly upon perennial subjects for their seasonal beauty. Beautiful herbaceous borders are practicable in almost every garden, provided the site is open and unshaded, and the soil good and of sufficient depth to permit of a bed of friable mould 18 in. to 2 ft. deep. A short, wide border is better than a long and narrow one, as the narrower the border, the more difficult it is to arrange the plants in bold groups. In very narrow borders plants have to be restricted to the small kinds.

In a 6 ft. border most of the large kinds would have to be left out or used in units, but with a support at the back for climbers or creepers, satisfactory groups of the smaller plants could be formed.

The great majority of hardy herbaceous plants flourish in ordinary well-cultivated soil. Heavy soil needs rough digging and full exposure to weather some weeks before the time comes for planting, which is best done in early autumn or February-March. Let no effort be spared to get a deep bed of friable soil.

Deep and thorough hoeing is essential during the growing season. If the border is being made beside a path, the front area should be levelled and rolled to a width of not less than 2 ft. and turf laid, a strip of well-kept sward forming an admirable foil for flowers.

In dealing with a single-faced border, one backing a wall, hedge, etc., the planter will work from back to front; but in dealing with a double-fronted border, he will work from centre to front on two aspects.

If there is no wall, fence, hedge, etc., shrubs or small trees should be included to provide a permanent background. This should not be attempted in a border less than 12 ft. wide, but, instead, some of the taller, coarser herbaceous perennials—golden rods, sunflowers, and mulleins, for example, might be used.

The following is a short selection of the principal border plants:

#### TALL PLANTS FOR BACK AREAS

Campanula ( <i>pyramidalis</i> )	Golden rod
Delphinium	Hollyhock
Helenium	Mullein
Foxglove	Coneflower
	Sunflower

#### MEDIUM PLANTS FOR MIDDLE AREAS

Coreopsis	Lupin
Erigeron	Michaelmas daisy
Day lily	(small kinds)
Gypsophila ( <i>paniculata</i> )	Monkshood
Helenium	Phlox
( <i>Crimson Beauty</i> )	Red-hot poker
Lily	Sea holly
	Spiraea

#### DWARF PLANTS FOR FRONT AREAS

Campanula	Pink
Carnation	Potentilla
Columbine	Poppy
Geum	St. Bruno's lily
Inula	Sea lavender
Iris	Snapdragon
Montbretia	Veronica
Pentstemon	Viola
Peruvian lily	

It has to be remembered that not only must there be liberal spacing between the various groups, but also between the components of each group.

Rose pillars may be introduced with good effect. As a rule the best line for them is just behind the centre, and they need not be nearer than 12 ft. apart.

In the double-fronted border, the centre will be occupied by hollyhocks, eremuruses, larger Michaelmas daisies, willow herbs, mulleins, delphiniums, golden rods, and other tall or bulky plants, not forgetting the rose pillars. In the half-centre spaces will go phloxes, monkshoods, heleniums, coneflowers, spiraeas, peonies, etc.; while in the front will come day lilies, erigerons, sweet Williams, antirrhinums, columbines, Canterbury bells, coreopsis,

geums, pentstemons, cinquefoils, achilleas, leopard's banes, evening primroses, heucheras, pyrethrums, and globe flowers.

The following is a selection of plants suitable for borders only 4 or 5 ft. wide. They may be set singly if the border is as short as well as a narrow one, or grouped in threes if it is of fair length:

Achillea	Jacob's ladder
Antirrhinum (intermediate)	Japanese anemone
Aubrietia	Jerusalem Cross
Borage	Leopard's bane
Campanula ( <i>persicifolia</i> )	( <i>Doronicum</i> )
Carnation	Lungwort
Christmas rose	Meadow rue
Cinquefoil	Montbretia
Columbine	Pentstemon
Coreopsis	Peony
Oranes-bill	Peruvian lily
Day lily	Phlox
Evening primrose	Plantain lily
Foam flower	Pyrethrum
Gaillardia	St. Bruno's lily
Geum (Mrs. Bradshaw)	Scabious
Goat's beard	( <i>Scabiosa Caucasica</i> )
Golden drop	Sea lavender
Heuchera ( <i>sanguinea</i> )	Sedum ( <i>spectabile</i> )
Incarvillea	Stokesia
Inula ( <i>glandulosa</i> )	Toadflax
Iris	Veronica ( <i>longifolia</i> )
	Wallflower

Border. Herbaceous border is a large garden at Hindhead, Surrey. The clipped holly bushes make an effective background for the sequence of flowers, those shown being the blossoming of June.

It should be an aim with the flower gardener so to dispose his plants that each area of the border has bloom throughout the season; and to aid him to accomplish this, the most important plants are given in three groups:

#### EARLY FLOWERING HARDY PLANTS

Columbine	Peony
Geum	Pink
Iris (some)	Pyrethrum
Leopard's bane	Thrift

## MID-SEASON HARDY PLANTS

Achillea	Hollyhock
Anchusa	Iris
Campanula	Lily
(most)	Loosestrife
Campion	Lupin
Canterbury bell	Monkshood
Cape hyacinth	Montbretia
Carnation	Moon and ox eye daisy
Cornflower	Mullein
Day lily	Phlox
Delphinium	Poppy
Evening primrose	St. Bruno's lily
Foxglove	Spiraea
Goat's rue	Veronica

## LATE BLOOMING HARDY PLANTS

Coneflower	Pentstemon
Golden rod	Red-hot poker
Japanese anemone	Sedum ( <i>spectabile</i> )
Michaelmas daisy	Sneezeweed
	Sunflower

To let plants alone year after year is to invite gradual degeneration, and it is an accepted idea that the most vigorous perennials should be divided every two or three years. Some take a full year to re-establish themselves after being transplanted. Among them are peonies, perennial poppies, Christmas roses, lupins and others with long, tap-like roots. When such plants are overcrowded it is quite possible carefully to lift portions of growth without disturbing the main roots.

Most hardy plants like sunshine, but a few will succeed in the shade, and some of these are given in the table below:

American cowslip	Leopard's bane
Anemone	Lily
Asphodel ( <i>Asphodelus</i>	Lily of the valley
<i>ramosus</i> )	Meadow rue
Auricula (Alpine)	Meadow saffron
Barrenwort	Monkey flower
Bergamot	Narcissus
Bleeding heart	Periwinkle
Campanula	Polyanthus
Campion	Primrose
Christmas rose	St. John's wort
Columbine	Saxifrage
Cyclamen	Sedum ( <i>spectabile</i> )
Dog's tooth violet	Snake's head
False hellebore	Snowdrop
Foam flower	Snowflake
Foxglove	Solomon's seal
Fumitory	Spiraea
Globe flower	Winter aconite
Grape hyacinth	Wood hyacinth
Honesty	Wood lily
Lady's smock	Woodruff

*Border Terrier. Prize-winning specimen of this popular breed of dog.*

**BORDER TERRIER.**

This is a very interesting breed of terrier which has achieved a not inconsiderable degree of popularity during recent years. According to the Earl of Lonsdale these terriers have been kept in the Kennels at Lowther Castle for over a century. The Border Terrier should weigh 13 to 15½ pounds and its colour is either red wheaten, blue and tan or grizzle but the first named colour is certainly the most popular and it is one that is generally accepted. The coat should be harsh in texture and close-fitting. A compact body and straight limbs, with catlike feet are essentials, whilst the head should be broad in skull, strong in muzzle and jaws level, with V-shaped ears. The tail should be carried gaily but never docked. *See Dog.*

**Borecole.** This is the name of the vegetable more usually called curly kale (q.v.).

**BORING:** And Boring Tools. Boring is any process for making a hole in wood, metal, or other material, and, strictly speaking, it is a machine process. Apart from the recognized drilling operations, the tools mostly used for boring include single hand tools, such as the bradawl and gimlet, double-hand tools such as the brace and bit, and the regulation wood-boring machine. This last consists of a wooden or metal base, with an angularly adjustable upright member carrying a spindle, rotatable by means of bevel gears and two crank handles. The tool is usually an auger bit and fed into the work by means of a rack and pinion, actuated automatically or by hand.

Bradawls are used to make holes for nails and screws. The brace and bit are employed to make holes from a small size up to 1½ in. or 2 in. diameter in wood.

Holes are bored in brickwork or stone by means of a steel chisel or bar shaped with four flutes, thus forming an X-shaped cutter. Sometimes a jumper or tubular cutter is used. Either is pressed against the brickwork, given a blow with a hammer, rotated a quarter turn, and given another blow, and so on until the tool is driven in to the required depth. China and glass are bored with a special drill stock.

When the lathe is used, if the object to be bored can be mounted on a faceplate or held in a chuck, it is customary to bore the hole with a hand tool, or preferably a tool held in the tool post of the slide rest. If the nature of the job prohibits this treatment, it is customary to bolt the work to the saddle of the lathe, adjusting it by means of packing blocks until it is axial with the lathe centre. A rough hole having

been previously cast or drilled through the work, a boring bar is inserted through the hole and mounted between centres in the lathe.

*Boring. Vertical boring machine for large timber.*

A cutter is adjusted to the correct diameter and secured with a wedge or otherwise to a transverse slot in the boring bar. The latter is set in motion, and the work fed up to the tool, which thus bores the hole. A rough cut is usually taken first, followed by a smooth or finishing cut. Other methods of boring include the use of the oxy-acetylene blow pipe. *See* Bit; Blow Pipe; Brace; Bradawl; Drill; Gimlet.

**BORZOI.** This dog is a Russian wolfhound of great size, graceful form and majestic appearance. He is a first-rate house dog, perfectly companionable, and of affectionate disposition. The colour is white, variously marked with yellow, fawn, brindle, blue, or black, or the coat may be without markings.

The long, slender head is triangular in shape, with dark eyes, and small thin ears set far back. The long coat may be either flat, curly, or wavy, but it must not be at all woolly; on the neck it should form a profuse curly frill. The long tail, carried low, should be well feathered. *See* Dog.

*Borzoï. Champion of the Russian breed of large white wolfhound. It is one of the tallest dogs.*

**BOSTON:** A Good Card Game. For this there are four players, the cards rank as at whist, are cut for deal and choice of seats. The cards are shuffled only once throughout the game, and the player to the right of the dealer cuts, leaving at least five cards in each packet. The player opposite the dealer cuts the pack, and the top card is turned up for trumps. This suit is called first preference, and the suit of the same colour second preference. The remaining two suits are plain suits.

The object of the game is to win a nominated number of tricks. Beginning with the eldest hand, each player in turn bids that he will win a certain number of tricks, naming his own trumps, or to lose a certain number of tricks without trumps. The player whose bid is accepted plays against the other three.

The bids rank as follows: Boston, to win 5 tricks; to win 6 tricks; to win 7 tricks; little misery, to lose 12 tricks after discarding a card which is not shown; to win 8 tricks; to win 9 tricks; grand misery, to lose every

trick; to win 10 tricks; to win 11 tricks; little misery with the cards exposed, also called little spread; to win 12 tricks; grand misery or big spread with all the cards exposed; grand slam, to win every trick.

Players are provided with white and red counters, the latter being worth five white. One red is placed by each player in a pool, and when there are more than 25 reds in a pool, the surplus is set aside, only 25 being allowed to be seen on each deal. No bid of less than 7 tricks wins a pool unless the adversaries insist on playing the hand out. If a player wins the nominated tricks he is paid by the others and takes the pool for 7 tricks or over. If the loss be double the pool he pays his opponents. One red counter must be placed in the pool for a misdeal and four for a revoke. Players are only paid the number of tricks they have originally bid, though they may win more.

A bid must be made with named trumps. The next player may say "I keep," meaning that he bids the same number of tricks in one of the preference suits. A player calling higher says "I keep over you." If all pass, the deal is void, each player sorts his cards in sequence and they are packed and cut for a fresh deal. Whichever player wins the bid, eldest hand always leads. When little miseries are played, each player discards a card which he does not show. Spreads must be laid down before any card is led.

The actual paying for winning a bid varies, but is generally as follows: 10 for 5 tricks; 15 for 6; 20 for 7; 25 for 8; 35 for 9; 45 for 10; 65 for 11; 105 for 12; 170 for 13; 20 from each player for little misery; 40 for big misery; 80 for little spread; 160 for big spread, with corresponding penalties for losing.

**BOTTLE.** The average household does not make as much use of carefully washed old bottles as it might do. The ordinary graduated medicine bottle, for example, makes an excellent liquid measurer. Most of them are divided off into teaspoonfuls or tablespoonfuls. Besides the advantage of quickness in measuring a number of tablespoonfuls of liquid the bottle is more accurate, as tablespoons vary in size considerably.

Bottles are in constant request in photographic work. Different shapes or different sized bottles should be used for developing, fixing, and other solutions, so that they can be handled and used in the dark room, where the light is not always sufficiently clear to read the labels.

A simple way to remove a cork that has fallen into a bottle is to make a loop of string, or preferably wire, and insert it into the neck of the bottle. Turn upside down and shake until the cork comes into such a position that the loop of string or wire catches it, when it can be forcibly withdrawn. For a cork that has broken off in the neck of a bottle insert the blades of two penknives on opposite sides of the cork, and pull the handles slightly towards one another and slowly twist and pull. This will generally remove the cork.

The stoppers of glass bottles are sometimes difficult to remove. One method is as follows: Place a little olive oil between the stopper and the mouth of the bottle, stand the latter in a pan of cold water, and heat the water slowly. Take the bottle out and allow to cool. In the cooling process some of the oil will be drawn in between the stopper and the bottle neck and loosen it. Often a tight stopper may be removed by wrapping the neck of the bottle in cloths dipped in hot water. This allows the neck to expand sufficiently to force the stopper out. It is advisable in the case of bottles which are constantly in use to tie the cork or stopper to the neck of the bottle.

*Bottle. Simple method of extracting a cork which has fallen into a bottle.*

Warm water and soap first, then a thorough rinsing with cold water, will clean most bottles; and if they are wanted to dry quickly a little methylated spirit should be sluiced round inside the bottles and the latter stood upside down to drain. Small bottles may be cleaned with a solution of egg-shells in lime juice. Discolorations can be removed by putting into the bottle a raw potato (cut into pieces) with a teaspoonful of salt and twice that amount of water. Shake well and when the bottle is clean rinse with cold water. Alternatively, rinse with strong caustic soda. Salt and vinegar is an old-fashioned way of cleaning bottles which is effective. A bottle which has contained petrol should be washed out with thin, warm milk of lime.

Bottles sent by post should be wrapped in corrugated cardboard, as a protection against breakage. It is advisable to label all bottle-containing liquids, for it is not always possible to tell what a bottle contains by the appearance or smell of the contents. *See* Baby; Cork; Feeding Bottle; Hot Water Bottle.

**BOTTLE WAX.** Ordinary sealing-wax has a basis of shellac, which readily melts at a flame, and quickly sets when the heat is withdrawn. For bottle wax resin is used instead of shellac, the properties of which it resembles. A preparation made with resin answers well as a sealing for bottles and parcels, and is cheaper. Bottle wax is used for wine bottles and to keep airtight jars or bottles of pickles and syrups. The following table, gives representative recipes:

RED.	Resin	2 lb.
	Tallow	½ lb.
	Vermilion or red lead	3 oz.
	Resin oil	1½ oz.
BLUE.	Hesin	4 lb.
	Cottonseed oil	5 oz.
	Zinc white	1 oz.
	Ultramarine	4 oz.
GREEN	Resin	2 lb.
	Tallow	3 oz.

YELLOW.	Brunswick green	1 oz.
	Prepared chalk	½ oz.
	Resin oil	½ oz.
	Resin	5 lb.
	Tallow	½ lb.
	Chrome yellow	5 oz.
	Prepared chalk	1 oz.
	Resin oil	2½ oz.

The general process of preparation is to melt the resin and tallow in an iron pan over a gas flame, taking care that the mixture does not catch fire. When this is done rub down separately the colouring matter and other powders ordered with the resin oil or cottonseed oil. This should then be stirred into the melted resin. When the mixing is completed the wax should be poured on to a warm plate which has been slightly greased, and rolled into thick sticks by means of a warm roller.

## THE BOTTLING OF FRUIT

### How to Secure Successful Results

The articles on the various fruits suitable for bottling, e.g. Apricot; Loganberry; Plum, etc., may be consulted for further information

Fruit may be preserved for an almost indefinite time if it is properly bottled. This object is attained by placing the fruit to be preserved in a suitable jar and then raising the temperature sufficiently to destroy or render inactive any germs present on the fruit. The jar is then sealed, so as to prevent germs from entering from the outside. This is termed pasteurisation.

Screw-top glass jars are the best, though those supplied with a metal spring are quite satisfactory. Before use the bottles should be carefully tested for possible flaws, as the seating for the rubber bands is apt to be imperfect. When small quantities of fruit are to be bottled, a large saucepan or fish kettle for heating water will suffice for a steriliser, provided it is deep enough. For fairly large quantities, a pan holding one or two dozen bottles is necessary. Care in the choice and renewal of rubber rings is essential.

Fruit for bottling should be of good quality and not over-ripe, or fermentation may take place. It should be graded, wiped and prepared, e.g. currants stalked, plums stoned, pears cored and halved, etc.

Pack it tightly in the bottles without bruising it, and fill them with cold water to overflowing. Place on the rubber ring, cap and screw-band or clip; screw up and then release slightly to allow air to escape during pasteurisation. Clips or springs allow the air to escape automatically. Place the bottles in the pan in which they are to be pasteurised; the cold water in the pan must just be within an inch of the tops of the bottles. Different fruits require different treatments, but for most the following method will be found satisfactory:

With Thermometer.—Bring to the required heat

slowly at the rate of approximately 2° Fahrenheit per minute. A temperature of 155° to 180° is necessary.

**Without Thermometer.**—Bring the water very slowly to simmering or until the hand cannot be held on the pan lid. When this point is reached lift up a bottle for examination. If the fruit is still firm in the bottle, put it back in the pan; but so soon as it begins to move about when the bottle is twisted it is ready to come out.

*Bottling. Showing how a perfectly sealed jar can be lifted by the cap.*

Should the water in the pan become too low through boiling, more should be added, but it must be of the same temperature as that in the pan. When ready the bottles should be removed, the covers at once securely fastened down, and the bottles allowed to cool slowly. Hot bottles must be placed on a cloth wrung out in hot water to prevent cracking. When quite cold, remove the screw or clip and test the efficiency of the seal by lifting the bottle by the cover.

#### The Dry Method of Bottling

The dry method of bottling, which is more particularly suited for plums and gooseberries, is very simple. Pack the fruit tightly in the bottles, and place in a slow oven on a piece of wood, cardboard or asbestos, or the bottles crack at once, until the fruit shrinks slightly; it is then ready to come out. Have boiling water ready, remove one bottle, fill up with the boiling water, and fasten securely before taking another bottle from the oven. See that the lids and fittings are warm before being placed on the bottles.

Though glass jars with a special device for sealing are to be preferred, if they cannot be obtained, ordinary wide-necked bottles or jars may be used, and sealed. The necks of the bottles should not be larger than is necessary for the insertion of the fruit. Sealed bottles should be examined from time to time, in case fermentation or mould growth occurs in any of them. If this happens the contents should be consumed without delay. Ordinary bottles or jars should not be packed so full of fruit as special bottles, on account of the sealing necessary to render them airtight; otherwise pasteurisation should follow the lines of bottling in special bottles.

Two layers of parchment paper may be pasted separately one over the other and tied with fine string, provided that the bottles are afterwards kept in a cool, dry place. Corks may be used instead, scalding them well first, and then sealing the tops with bottle-wax.

The use of syrup is not essential, pure water being equally suitable and rather more transparent. This bottling being done without sugar, when the fruit is needed for use pour juice into a pan and add sugar to make a syrup. Bring this to boil, then add fruit and cook over top of stove very slowly for a few minutes only. Fruit bottled under the National Mark, always

reliable, can be bought without hesitation.

**BOTULISM.** The form of food poisoning known as botulism is due to the presence of a microbe in fruit or vegetables which have been canned or bottled; nearly all the outbreaks have occurred where the preserving was done at home. The symptoms are vomiting and diarrhoea, with abdominal pains, cramp, and paralysis or weakness of the legs, and perhaps difficulty in speaking. Death may result.

The danger of poisoning is removed by cooking the food before use; warming is not sufficient. *See Food Poisoning.*

**BOTTOM HEAT.** The term is applied in gardening to the process of raising the temperature of the soil in which plants are being grown in a heated greenhouse. It is usually obtained by running a row of hot water pipes underneath the borders, but occasionally, as with mushroom beds, the desired effect is obtained by the ferment of manure.

Bottom heat is chiefly used to hasten the growth of seedlings and cuttings for planting out purposes and for forcing early vegetables.

Bottom heat should be used very sparingly when forcing half-hardy subjects for bedding out, otherwise the young plants will grow up very tall and weedy. Soil temperature can always be taken by means of thermometers manufactured for the purpose. *See Gardening; Greenhouse.*

**BOUGAINVILLEA.** This is a greenhouse climbing plant, a native of S. America. As it loses its leaves in winter, it is valuable because it does not interfere with the admission of sunlight into the house for the benefit of other subjects. Its rose-coloured flowers are borne in bracts from spring till summer. Rich loam (old turf) soil suits it admirably. It thrives in a temperature which may vary from 55° to 70°, according to the season. The shoots should be hard pruned in spring.

*Bougainvillea. The delicately tinted flowers which make this plant a popular greenhouse climber.*

**BOUILLON.** To make this clear broth, wash and dry 2 lb. lean beef and cut it into small pieces. Chop any bones, and soak bones and meat in 2 quarts cold water for half an hour, add a teaspoonful salt and bring the broth slowly to boiling point.

Then skim it and add to it a carrot, an onion, and a turnip, prepared and cut in quarters, a small bunch of herbs, paisley and a bay leaf, 2 cloves, 4 allspice, 6 peppercorns, and 2 chopped sticks of celery. Simmer

(do not actually boil, or it will be cloudy) for 3 hours, removing any scum. Strain through a fine clean cloth into a basin and leave until cold. Remove all grease, re-heat and carefully season before serving in small soup cups, a tiny dust of chopped parsley being added to each cup. Sufficient for about 12 persons.

**BOUQUET: Of Flowers.** The florist's elaborate bouquet is usually presented on ceremonious occasions, at public functions, and also at weddings, though at the latter the sheaf of long-stemmed flowers or the round, closely packed quaintness of the Victorian nosegay is often seen.

For the sheaf, long-stalked lilies of any kind, gladioli, tulips, carnations, or a mixture such as delphiniums and pale pink roses be used. The flowers are arranged in the same way as in a florist's bunch of fine daffodils, but a layer of moss or fern is placed between graduated row of stalks, and tied in with them, to form a packing which prevents the flowers from shifting, and the whole is completed by ribbons.

The Victorian bouquet is a round massing together of small blossoms, and the more compact and conventional it is the better. A delightful example is composed of pink moss roses in the centre with circles of forget-me-nots, white pinks, mauve and purple violas, magenta stocks and mignonette, widening out to the desired size. The whole should be encased in the lace paper holder the period and tied up with narrow ribbons to match the flowers.

The etiquette of bouquets is simple. For the débutante, on presentation, or other lady attending a court, the bouquet is not included in dress regulations, but may be carried if wished, and is usually a costly affair, chosen at a court florist's to match the dress. The wedding bouquets for bride and bridesmaids are the gift the bridegroom. At the beginning of the service the bride hands her bouquet to the chief bridesmaid to hold. It is permissible for a widow-bride to carry a bouquet of coloured flowers. *See* Bride; Flowers.

**BOUQUET GARNI.** This is more delicate in flavour than the packet of mixed dried herbs, and is used for sauces and stews. It is made of a few sprigs of parsley, a bay leaf and a sprig of thyme tied up together.

*Flowers of Bouvardia, a favourite greenhouse shrub.*

**BOUVARDIA.** There are pink, scarlet, double and double white varieties of Bouvardia, which is a greenhouse shrub bearing flowers in autumn and winter. It is a dwarf and bushy, and grows well in a compost of three parts loam, one part peat-mould, and some sand. Pots of 5 in. or 6 in. diameter will suit it. The plant should be stood in a shady place in the garden, or in a frame during the summer, and brought into a warm house in September.

After flowering, the young growths should be cut back to the old wood. New shoots ripen during the summer, and produce flowers the following winter. Propagation is effected by young shoots inserted in pots in spring.

**BOW.** The bow is the means whereby the strings of a member of the violin family are made to vibrate. It consists of a slender stick of snake-wood or Brazilian lance-wood, cut straight, following the grain, subjected to heat and then slightly bent. Strands of white horse-hair are carried from the top of the bow to the nut, the latter being fitted with a screw; it is tightened for playing, and relaxed after use in order to preserve the resilience of the wood.

*Violin Bow. A. Point. B. Stick. C. Hair. D. Wrapping. E. Heel or nut. F. Screw.*

It is a characteristic of horse-hair to possess certain tooth-like roughnesses, which, aided by resin rubbed on to it, catch the string of the instrument, and cause it to vibrate and thus sound. In course of time the hair wears away to smoothness, and the bow must then be re-haired. Holding the bow in his right hand, with the thumb upon the nut, the player draws it across the string at a right angle, but with the stick slightly inclined towards the left hand and about midway between the bridge and the finger-board. The wrist must be kept loose and supple, and the movement of the forearms should be free, but without any unnecessary motion of the elbow. By variation of pressure, and by differences of movement in the bow, the player, is able to secure all gradations of tone, as well as any desired species of phrasing.

**BOWDEN CONTROL.** The Bowden wire control for cycles and other machines of the same kind consists primarily of two members. The cable, or inner member, is composed of fine wire strands twisted together. The outer member, or sleeve, is formed of square-section non-rusting wire wound close up like a tension spring, and covered on the outside with a flexible waterproof material, as shown at A (Fig. 1). The working principle of this form of control is as follows: The inner member is fastened at one end to the part to be controlled, and its other end anchored to the control lever (B and F, Fig. 1), which shows the mechanism controlling a carburetter. There are numerous forms of control levers, all of which work on the same principle. Particulars of the brake control mechanism are given in the article on brakes (q.v.).

An advantage of the Bowden control lies in its adaptability for all classes of control where awkward turns have to be overcome. To ensure easy working never assemble the control without first coating the wire with a mixture of thin oil and fine graphite. The

best method to secure the wire to the control is, where possible, by the use of the nipple supplied by the makers. If this is not practicable, double the wire over and bind with thin copper wire, not forgetting first to solder the wire where you have to cut it, should it be too long. The control lever must be right home against the outer casing. It should not be forgotten that the lever to be operated is at rest, i.e. that the length of naked wire showing at the end attached to the lever to be operated must be equal to the distance travelled by the lever during its full movement (F, Fig. 1).

*Bowden Control. Fig. 1. Separate parts of the mechanism controlling a carburettor (see text).*

*Fig. 2*

*Fig. 3*

*Fig. 2. Diagrams illustrating methods of making temporary repairs. 1. Bind with cotton. 2. Then fold ends down and bind very tightly. 3. Wire folded and bound with a pin inserted through the loop. If these temporary repairs are called for where a drum shaped nipple is employed the nipple must be omitted the knob taking its place.*

*Fig. 3. Permanent repair: correct method of securing a Bowden wire into the nipple. 4. Solder here and finish off as shown at A with a file.*

So that the position of the lever may be set to a given position when at rest, a form of adjustable stop is provided as shown in C (Fig. 1). By such a stop the position of the outer member may be brought closer or

withdrawn further from the operated lever, the result of so doing being either to lengthen or shorten the radius of movement. This adjustable stop consists of a sleeve (a), cupped at the end to receive the outer casing and screwed the whole of its length, so that it may be positioned where required in the stop (b), and locked by means of the nut (c).

A tension spring is attached to the lever to be operated, so that it is pulled back to its original position when the control lever is released, or returned to rest, as the case may be, according to whether it is of the friction design, B (Fig. 1), that stops where placed, as used for throttle controls, etc., or of the free design, D (Fig. 1), as used for cycle brakes and exhaust controls. In one type of Bowden control the spring is placed over the cable at the controlled lever end, and the whole enclosed in two tubes, the outer one being stationary with the outer member, and the inner one travelling with the wire (E, Fig. 1). Fig. 2 shows various methods that may be employed as temporary only, by which it is possible to get home if a breakage should occur on the road. Fig. 3 shows the correct method of securing the Bowden wire into the nipple. *See Bicycle.*

**BOWL: How to Make.** In silver, copper, bronze, brass or Benares metal, bowls hold plants or flowers. In papier mache or pottery they are useful for bulbs, cut flowers or fruit, and are charming for this purpose in coloured stone-ware. Glass and lustre bowls also have a decorative value.

The making and ornamenting of a bowl of simple form in one of the ductile metals, such as copper, brass, or silver, can be accomplished at home with the aid of an anvil-block and a few tools. These comprise a ball pene hammer, a round-faced hardwood mallet (Fig. 1), a few ornamental punches, a pair of tinman's snips, pliers, and file.

The anvil-block can be made from an odd length of hardwood about 6 in. by 4 in. wide by 6 in. deep. Set it with the end grain upwards, and fasten it to a baseboard with a piece of felt on the underside, as in Fig. 2, if the work has to be done on a table. It is preferable to hold the anvil-block in a vice. The best material to begin on is sheet copper about No. 20 gauge.

Cut a disk of copper of about 6 in. diameter and file the edges clean and smooth. Then draw circles from the centre of the disk, spacing the lines  $\frac{1}{2}$  in. apart. Holding the disk in the left hand, press it flat on to the anvil-block, so that the centre of the disk may be over the hollow in the block, and strike a blow near the centre with the round-faced mallet. This will cause an indentation or stretching of the copper, and it is by a series of light, rapid blows, producing numerous indentations, that the bowl is ultimately shaped. If the hammering, commenced in the centre, is carried steadily round and round the bowl, using the lines as a guide, until the rim is reached, then working back to the centre, the metal will speedily assume a bowl-like form, as indicated in Fig. 3. The next step is to beat out

as many of the hammer-marks as possible, obliterating them by light blows, and using a curved faced block or the curved corner of the block shown in Fig. 2.

*Bowl. Implements used in beating out an ornamental metal bowl. See text.*

Repeated hammering hardens the copper, and when this is observed the metal must be annealed, which renders it quite soft. The edges of the disk may exhibit a tendency to cockle or pucker, but this will be of no great consequence when the design exhibits a scalloped edge, as shown in Fig. 4. This is formed by hammering the edge in a hollow-shaped part of the anvil, as in Fig. 5, working scallops on opposite sides of the bowl instead of progressing round the rim. The ornamentation, consisting of a conventional floral garland, is formed with the aid of a steel punch with a leaf-shaped end, held between the thumb and forefinger of the left hand, while the bowl is supported

between the third and fourth fingers, as in Fig. 6.

A circular block shaped as in Fig. 7, seen in section in 7A, will facilitate the flattening of the base. The use of the block is shown in Fig. 8, where the hammer is seen beating the base to a flat surface and forming the stiffening rim in the bottom. A final touch up with the hammer, giving a light blow or two here and there, will produce the finished bowl (Fig. 9), which then only requires scouring with silver sand and water and a good rubbing with metal polish. *See Dent Iron Work; Bulb; China; Finger Bowl; Salad Bowl.*

**BOW LEGS.** Rickets in children are usually the cause of bandy or bow legs. The legs should be loosely bandaged from the ankle to the crutch with a wide, soft flannel bandage. Then splints 4 in. wide, carefully padded with cotton-wool, should be bandaged along the outside of the thigh and leg. The splints should extend well up above the hip joint, and some 3 or 4 in. beyond the sole of the foot, and should be worn during the day for a month or so.

**BOWLS: How to Play.** The full-sized bowling green is 42 yd. square with six rinks and a ditch about 6 in. wide all round, but the game may be played on a smaller space and is in vogue on many private lawns as well as on club greens throughout Great Britain. In the north some of the greens are crowned to slope from the centre to the ditch, but in the south they are generally level.

All that is required for the game is a jack and a few sets of bowls, together with an india-rubber mat about 22 in. by 14 in. The jack is an earthenware ball which should not exceed 2 ½ in. in diameter nor more than 10 oz. in weight; it serves as the tee and must be at least 25 yd. away from the mat on which the player stands. The bowls are of lignum vitae or other hardwood, or in some cases of composition; they must not exceed 16 ½ in. in circumference and 3 ½ lb. in weight, and are made with a bias, one side being weighted in such a way that the course of the bowl tends to run in a curve. The extent of the bias varies, but, strictly speaking, the bowl should draw at least 6ft. in a distance of 30 yards.

Any number of players up to four may oppose each other in a separate game, and on a full-sized green almost any number in reason can get a game. If there are only two players, or two on each side, each player uses four bowls; in a three-a-side game each player has three bowls, and in a rink, or four-a-side, each has two bowls. In all cases the points (or ends) are 21 up.

*Bowls. Above. 1. Correct way of holding the bowl or wood. 2 and 3. Two wrong ways of holding.*

*Correct attitude immediately after delivery of the ball, one foot being still on the mat. (Courtesy of Jarrold & Sons, Ltd.,)*

In an ordinary game one of the leaders places the mat within a yard or two of the boundary. He then places on the mat one foot, which he ought not to lift. He rolls the jack in any direction which seems convenient. There are rules about the order in which each player bowls, but the last to bowl are the two skips, as the captains are called. If the players are expert nearly all the bowls will be lying close to the jack some time before the turn of the skips comes. Till then they remain behind the jack and direct the aims of the other bowlers.

When all the shots have been delivered the players examine the positions of the bowls nearest to the jack, and 8 times out of 10 there is no difficulty in finding the bowl which is nearest, and wins the end for its side. If there is any doubt, accurate measurements are made. When the point has been settled the leader of the side which has won the end takes the mat and rolls the jack to some other part of the green, and the game then proceeds as before.

**BOW SAW.** A bow or frame saw is used for cutting out various curved shapes in wood. It consists of a central bar with two end members, the horns of which are drawn inwards by a cord tensioned by twisting the lever or tourniquet.

*Bow Saw. How the saw should be held with both hands to ensure a steady cut.*

The opposite ends have handles movable in the holes drilled to receive them. The saw blade is long and narrow, pierced at each end to receive a pin. Slots are cut in the metal ends of the handles and the saw is retained in position by slipping it into the slots and inserting the pins. The blade should be tensioned by twisting the cord. The saw is generally used with a vertical up-and-down movement, the teeth cutting on

the down stroke.

Good quality bow saw frames are made in beech or similar hardwood. The length of the blade depends on the size of frame, 12 in. being suitable for amateur use. The width of the blade should be governed by the work to be done. For delicate work use the narrowest blade, and with fine teeth; for large work use a wider blade with coarse teeth. Three different widths of blade will be ample as a selection for amateur work. The work should be held in the vice and both hands used on the bow saw, the sawing being done in a horizontal position when possible. *See Saw.*

**BOW WARE.** A soft paste porcelain made at Bow and Chelsea in the 18th century. Old Bow is generally chalky white and coarse and heavy for its size, although some is of eggshell thinness. It has a glassy lead-glaze, which with age has become iridescent and discoloured, often with brown patches and stains.

*Bow Ware. Chimney piece ornament characteristic of this porcelain. (Courtesy of Law, Foulsham & Cole, Ltd.,)*

The figures, usually designed for chimney-pieces, were more highly coloured than Chelsea, and often have square holes at the back for the metal stems of candle-nozzles. Bow never imitated Sèvres vases or Dresden groups, but was successful with partridge, hawthorn, and dragon services in the Chinese taste, as well as with blue-painted ware, white with modelled reliefs, openwork baskets, sprigged tea-sets and landscape mugs. It was mostly unmarked.

The common use of the anchor-and-crescent device in some styles often causes true Bow to be labelled Chelsea or Worcester. The marks are easily forged, and inexperienced collectors should beware of the Bow imitations with copied marks cleverly turned out in Paris and elsewhere. *See China.*

**Bow Window.** So called on account of its shape, this type of window is commonly termed a bay window. *See Bay Window.*

**BOX: The Tree.** The common species is a compact evergreen shrub with a characteristic pungent smell, thriving in most soils. It is a pronounced surface rooter, and is perfectly hardy. It grows up to 10 or 12 ft. in height, but is of very slow growth.

Box is easily increased by cuttings in frames in late summer. The lower branches may be layered into the soil in autumn, when suckers may also be drawn off and planted. The plant used for edging is a form of common box which is propagated by means of small rooted pieces in May. Box is one of the chief

subjects used in the practice of topiary work, which is the art of clipping trees and shrubs into fantastic forms of birds, beasts, ships, etc. The timber of the full-grown tree is used for small turnery articles such as peg tops *See Wood*.

**BOX: How to Make.** In making the simple box shown in Fig. 1 the two end pieces should first be cut. These should preferably be thicker than the sides, and in any case stout enough to give a good hold to the nails. Then cut the two side pieces and, standing the ends upright with one side piece spanning them, nail the side to the ends, as in Fig. 1. Then add the remaining side and the bottom, nailing with thin wire or French nails.

*Box. Figs. 1 and 2. Diagrams showing how to make a plain wooden box. Fig. 3. Old box*

*strengthened with corner pieces inside.*

If a stronger box is wanted, or the ends are in several pieces, fit upright battens as in Fig. 2. It is customary when making this class of box to clench the nails, that is, drive them through the thinner wood into the battens and then knock over the projecting ends. A good method is to hold a spare hammer against the head of the nail while using another to clench the point.

A quick and effective way to strengthen an old box is shown in Fig. 3, where corner pieces of square wood are nailed to the inside corners. Incidentally, this enables the lid to be screwed on if desired, as the corner pieces are stout enough to hold a screw. *See Knife Box; Trunk; Window Box, etc.*

**BOX CALF.** Box calf is largely used in the manufacture of handbags and of boot and shoe uppers, the better grades being made from first selection calfskins. For the cheaper class of upper leathers, box-calf is imitated under the names of box kip, this being made from the East Indian small cow-hide and finished with a box pattern; or from split hides, in which case the leather is known as box sides. When chrome tanned calf is dyed brown instead of black it is called willow calf, and is frequently finished with the characteristic pattern of box calf.

All box calf is tanned by the chrome process, the skin being converted into leather by the action of chrome compounds, so that it is quite distinct from leather tanned with materials like oak bark. When first tanned the leather is of a blue colour; during later stages of manufacture it is dyed and finished, receiving the characteristic grain of box calf.

Genuine box calf is one of the best of all upper

leathers. It wears well, gives to the foot, and if properly lasted the shape of the boot does not spread or become unsightly after continued wear. Even under the influence of excessive perspiration a box calf upper is durable. It should not crack after long wear, and if it does it is a sign of faulty tanning.

As with other types, the life of a box calf upper largely depends upon its preservation. Cleaning and polishing with a good reliable polish is all that is required; but the polish must be of sound quality. *See Boot; Leather.*

**BOXING GLOVES.** In buying these gloves it is necessary to see that they fit the hands comfortably, for if they are too loose or too tight a great deal of discomfort is certain to follow. Many boxers pay little attention to their gloves, but they ought to be kept absolutely clean, free from grit and grease. When they are new they want no attention except to work the fingers frequently about in them, in order to make them pliable.

If, as may easily happen even in the mildest form of boxing, a sprinkling of blood should get upon the gloves, they should be very carefully cleaned with a little linseed oil, for if the blood is allowed to cake it will make a hard spot which may damage an opponent's face. On no account should the gloves be damped with water. If they have to be put away for any length of time they should be thoroughly but sparingly oiled, for leather always has a tendency to perish and harden when it is not in use. The gloves should not be placed in a damp room, nor in one which is too hot.

**BOX IRON.** The old-fashioned kind was fitted with a plug, made red-hot in the kitchen fire and then plunged into the metal case. This was superseded by electric or gas irons, with which a continuous heat can be obtained. These are convenient, but unless a special plug or burner has been provided, they cannot be used when the fittings are needed for lighting purposes. *See Flat Iron; Ironing.*

*Box Iron. Showing block of metal which is heated in the fire.*

**BOX MATTRESS.** A variety of the spring mattress, this is one in which the springs are enclosed in a horsehair or rugging stuffed mattress made on a strong wooden frame and fixed to the bedstead. It gives the bed a neat, upholstered effect, but an overlay has to be used as well. *See Bedding; Divan; Mattress.*

**BOX OTTOMAN.** This piece of furniture is a combination of the loner seat or couch, known as an ottoman, and a box, the latter being formed by enclosing the lower part of the article. The seat is made in the form of a lid so that it can be raised when required.

A box ottoman may be made from a large box with a hinged lid. The top is upholstered to make a comfortable seat, and the sides are covered in the same material.

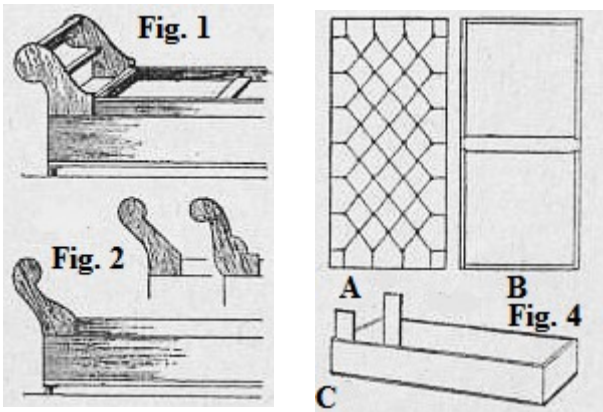

*Box Ottoman. A combined piece of furniture (Courtesy of Williamson & Cole)*

In addition to its value as a couch or bed, the box ottoman is serviceable for holding surplus things that crowd a room, bedclothes for an emergency bed, or even some of the household linen and underclothing. It is useful in the nursery for toys, appropriately loose-covered in coarse linen on to which toy designs are applied. Pine, if available, is suitable for use in constructing the box portion, the head scroll being of birch, beech, American whitewood or other hardwood.

If to be finished as a plain box without scroll head, the construction of the ottoman is of the simplest. A serviceable size will be 3 ft. 6 in. long by 1 ft. 6 in. wide, and 1 ft. 3 in. deep. Floor boards 1 in. thick and tongued are suitable, and are best dovetailed. A strong box, however, is made without the trouble of dovetailing by nailing or screwing a 3 in. by 1 in. clamp inside each of the longer sides, setting it back to the thickness of the short sides or ends, so that these can be nailed flush into the rebate thus formed, and a bottom nailed up to this. Castors should then be fitted, and this will complete the making of the base portion of the ottoman.

The lid may be of plain clamped boards of similar thickness and hinged to position, remembering to make the clamps sufficiently short to allow the lid to shut easily. The lid can be made as a tray, and is stayed from opening too far back by means of a couple of wide tapes nailed to the inside of the lid and the box side. The interior of the box can then be lined with sateen or any other material that is suitable for the purpose. In upholstering the sides and ends, these can be padded to curve nicely with cotton-wool and covered with cretonne or damask, carrying the material over the edges and into the inside of the box, where the edges are doubled and tacked down. The covering is edged along the line of the box bottom outside with variegated cord or gimp, tacked as before.

*Box Ottoman. Figs. 1-4.*

*Diagrams showing how to mark out and make a box ottoman with a scrolled head end.*

The lid of the box can be easily covered with an evenly distributed layer of brown wool between two layers of wadding, the edges of the canvas being tacked to the box edge, and the final covering stretched tautly over this and tacked with gimp, cord or ball fringe edging.

In constructing the box for an ottoman such as that pictured in Figs. 1 to 4, a length of 5 ft. to 5 ft. 6 in. should be allowed, including space for a head scroll. The height of the seat framing may finish 1 ft. 4 in. to 1 ft. 5 in. In this way the rails of lid or seat framing are 3 in. wide, the box sides 12 in. wide, and bottom 1 in., an additional 1 in. or so being allowed for castors. Material 1 in. thick should be used for sides and lid throughout, this latter being preferably of birch, and the parts dovetailed together, and the bottom screwed well home with 2 in. screws. In making the lid a 3½ in. by 1 in. stretcher is cut into and screwed to the bottom part in the centre, as indicated at Fig. 1. Stout brass butt hinges should be used.

There are various shapes for the scroll portion of the ottoman, such as drum, scroll, bolster, roll, pillow, etc. For this portion of the work deal is often unsatisfactory, on account of its tendency to split when a considerable number of upholstering tacks are driven in, and it is better to use birch or beech 1 in. thick. A plain scroll may rise 6 in. to 7 in. only, or with any taller type of shaping, 12 in. will be a serviceable allowance. A choice of shapes is offered at Fig. 2, and these will suggest a variation in the finishing.

The elevation view at Fig 3 (B) is of average size, and is set out in 2 in. squares. When cut to shape the two scrolls will be fixed in position to the box framing with four hardwood dowels each, the four stuffing rails upon which the upholstery is built having previously been fitted between. The number of these stuffing rails, which can be 2 in. by 1 in., may vary according to the

upholstery design to be carried out. A stretcher rail of the same height as the lifting lid is fitted, as Fig. 3 (A). The scroll can be stiffened by means of two pieces of 3 in. by 1 in. wood screwed to the inside of head portion of box, as at Fig. 4 (C), these being sufficiently long to project and form stays for screwing to the inside of front and back scrolls. A plan of the underside of box lid is seen at Fig. 4 (B). This shows the stretcher rail dovetailed in.

For comfort it is preferable to finish with a spring seat. For this about 3 dozen strong 4 in. springs will be required, and these should be tied down to about two-thirds of their height when put in and covered with hessian. Every attention must be paid to the even spread of the stuffing, arching it well in the centre and diminishing it towards the edges, so that they are regular and devoid of lumpiness. Unless this is done very carefully and methodically, the ottoman will never make a comfortable seat. A covering of calico over the second stuffing, especially where hair is used, is recommended previous to receiving the final covering. An improved effect is obtainable by buttoning the seat; a plan of this is shown at Fig. 4 (A). The head stuffing would then be buttoned to agree. *See* Divan; Upholstery.

**BOX PLEAT.** The material is folded alternately towards the left and right to give large flat pleats, which must be all of the same size. If the pleating is to be all round, the material required is twice or three times the length needed for a plain skirt, according to depth of pleat desired. They retain their shape better when deeply folded.

*Box Pleat. How the pleat in the material is tacked down ready for pressing; left, front; right, back.*

Fix the folds with pins as they are made, measuring accurately to get each box-pleat exactly the same size. When all the folds are pinned in position tack them firmly with a needle and cotton, noticing that the three edges, pleat and material, are even. Finish the pleating at the top by sewing it into a double band of material or binding. Box pleats only set well when firmly pressed.

For double box-pleating two folds are placed to the left and two to the right to separate each box-pleat. *See* Pleating.

**BOX THORN.** *Lycium chinense*, or the box thorn or tea tree, is a vigorous leaf-losing shrub bearing small purple flowers which are followed by red fruits in autumn. It grows quickly and densely and makes a useful screen, especially in seaside gardens. It flourishes

in ordinary soil in a sunny position and is increased by seeds sown in spring.

**BRACE: For Drilling Holes.** The carpenter's brace consists of a cranked metal bar, one end provided with means to hold the drilling implement or bit; the other end has a circular wooden knob or head. In the middle of the crank is a wooden handle free to rotate.

To use such a brace, a bit is inserted in the holder, which is known as a chuck. The left hand grasps the head, the right hand grasps the grip on the crank. The brace is held upright with the point of the bit exactly on the centre of the spot marked on the wood where the hole has to be drilled (Figs. 1-3).

The left hand is pressed firmly downwards, while the right hand is employed in rotating the brace and bit. The chuck is composed of a hexagonal exterior member that turns on a screw thread cut in the brace, this in turn contracting two or three jaws which grasp the bit or drill. Some chucks are only adapted for grasping brace shank bits, while others will do this and will also grasp ordinary circular shank drills. This kind is to be preferred for all-round use. Better quality braces are made with a ball-bearing head, which is a great advantage. The ratchet brace has a ratchet movement which can be thrown into or out of action by moving a sleeve on the crank. This device enables holes to be drilled in awkward corners or near to a wall, where it would be impossible to rotate a plain brace.

*Fig. 4.*

*Fig. 3.*

*Brace: methods of holding for different classed work. 1. Vertically, with forehead resting on hand. 2. Vertically, with chin as support. 3. Horizontally with weight of body against brace. 4. (Top) Engineer's hand ratchet brace.*

Amongst the uses of the brace, apart from drilling holes, is that of driving screws. This is accomplished very quickly by substituting a screwdriver bit. The enlarging of holes in metal or wood is done with a rimer bit. The cone-shaped recess to accommodate a screw-head is formed by the brace, using a countersink

bit. Rounding the ends of dowel pins is accomplished by using a dowel shaver bit and a dowel rounder bit. Shallow circular recesses or sinkings for a nameplate are formed with a brace and a Forstner auger bit.

The engineer's brace, Fig. 4, is a ratchet-driven tool for drilling holes. It is simple and effective, but is only employed where a hand drill would not be large or powerful enough, and when the work cannot be conveniently taken to a regular drilling machine.

A rim brace is largely used for removing and replacing the nuts on most types of detachable wheels on motor cars. They are made in two forms, the plain brace, and an improved form with ratchet. Separate sockets are obtainable to fit these braces, and thus various size nuts can be dealt with from 5/16 in. to 7/8 in. across flats. *See Bit; Boring; Drill.*

**BRACELET.** In the wide, old-fashioned varieties, which return to favour when bracelets are the vogue, one part likely to go wrong is the joint, through opening the bracelet too wide, straining the hinge and ultimately tearing it from its seating; this is prevented by attaching a safety chain just long enough to enable the bracelet to push over the hand.

*Bracelet. Figs. 1-3. Diagrams showing small repairs in a gold bracelet.*

Sometimes the small pin in the hinge will work loose and drop out. Another can be made by taking an ordinary stout brass pin and, with a pair of pliers, pushing it well into the joint until it is a tight fit, giving it a tap with the pliers to drive it home, Fig. 1. With a small file, nick the pin where it projects, break it off, and finish by filing it flat, Fig. 2. Should the clasp become weak, it can be improved by inserting the point of a

spring and raising, Fig. 3.

Where the front is set with jewels it should be examined periodically. Should one be loose, it is best to let the jeweller examine it, as a part of the setting may have worn away; but with a fairly new bracelet the edges of the setting may be rubbed down on the stone with the back edge of a pocketknife, or, if claw set, the

points pressed on to the stone with the blade.

Pins in the joints of a flexible bracelet sometimes fall out. A new one can be made with a brass pin, as described in stiff bracelets. Expanders depend on the strength of small coiled springs inserted in each link for their expansion. They ought not to be opened and shut more often than is necessary, or the springs will weaken. If this happens, it is best to return it to the jeweller for respringing. An occasional wash in hot water, with soap and a few drops of olive oil, will keep the springs easy and smooth running.

The gold slave bangle is hollow and is usually sold in 9 ct. and 15 ct. gold. The calibre is a circle closely set all round with small stones, which are held in position by rubbing over the outside edges of the hoop. The greatest care has to be taken of these, because if they are twisted it is almost certain that a stone will fly out, or at least be loosened. If one stone should be lost, the bracelet should be taken to the jeweller and a new stone inserted, otherwise they will all work out.

Ivory and tortoiseshell bracelets are inlaid with gold wire or elephant hair. The gold inlay is springy, and a jar may dislodge it. Should this occur, brush a little Canada balsam or seccotine into the groove, press the wire down, and bind tightly with thin string and leave for 24 hours. As heat renders tortoiseshell soft and pliable, it should never be put into hot water. Should the surface become dull with wear, it can be improved by polishing with jeweller's rouge and a soft rag, afterwards washing out with lukewarm water and soap.

**BRACING.** This term is applied generally to all such work as the strutting of a rafter to prevent its sagging, the fitting of a diagonal brace to a timber framework, or an angular strut or brace to support the back of a chair. The principle is that of stiffening a structure by means of a supporting brace generally placed diagonally between the parts to be strengthened, thus transmitting the weight from the overhanging, or weak part, to the wall, foundation, or strong parts.

*Bracing. Method of strengthening a door.*

The principle is shown in the ledged and braced door illustrated. The ledges, A, cannot entirely prevent the planks which form the door from sagging, but the two braces, B, act as brackets or supports, and also help to prevent warping. Other examples will be found in the

articles on Shed and Workshop.

**BRACKEN.** Although quite wild, this common fern (*Pteris aquilina*) has certain domestic or semi-domestic uses. The fronds are largely used for bedding cattle. They are also used to a slight extent for

thatching houses and stacks. The stem of the bracken contains starch and has been used as a food.

Except in the wild garden bracken is of no horticultural interest, and, unless the wild garden is a large one, should not be introduced, as it spreads with great rapidity when once it has taken root, and it is somewhat difficult to get rid of it successfully.

**BRACKET.** As ordinarily understood, a bracket is an L-shaped metal support for a shelf, although there are other types, such as the bracket of a lamp, or a gas bracket, or electric fitting.

The iron bracket (Fig. 1) is intended for the repair of chairs or other furniture; these are usually 2 in. or 3 in. long and  $\frac{1}{2}$  in. wide. The strong light shelf bracket shown in Fig. 2 is known as the London pattern; it is made from pressed steel, and is finished in black japan. Usual stock sizes are 3 by 4 in. to 12 by 14 in. Another type similarly made, but with the additional stiffness given by the curved brace or strut, is shown in Fig. 3. They are handy for the rapid erection of shelves, a convenient method being to screw the brackets to upright battens of wood securely attached to the wall and reaching to the floor.

*Bracket. Figs. 1-8. Forms of metal bracket in use for domestic or building purposes. See text.*

Shelf brackets intended to support plate glass or marble shelves are generally made in cast brass, either polished and lacquered or nickel plated (Fig. 4). The little upturned nib or lip at the outer end ensures the glass shelf from accidental movement. Such brackets are made in many sizes and shapes, also adapted for use on bars and posts for shop-window fittings.

Partition brackets (Fig. 5) are stout iron castings supporting a wooden or other partition, and can often be turned to good purpose by the amateur. Stock sizes range from 12 in. wide by 24 in. high to 14 in. wide by

48 in. long.

Bucket brackets (Fig. 6) are made in strong galvanised iron, and should be securely bolted to the wall to sustain the weight of a large fire bucket. Gutter brackets of two types are illustrated in Figs. 7 and 8, one to drive into a wall, and the other to screw on to woodwork. The householder should inspect the gutters and brackets occasionally, to be sure they have not sustained damage. If broken they should be replaced as soon as possible, as a damp wall is the result of neglected rain water gutters and their supporting brackets. There are numerous types of wooden bracket. Plain or ornamental wall brackets are everyday requirements in the home: they can be quickly made from odd material and coloured or decorated to suit any style of furnishing. This kind of bracket is effectively carried out in fretwork (q.v.).

Fig. 9

*Bracket. Figs. 9-12. Strong wooden bracket, for supporting heavy weights, with working drawings.*

Fig. 11

Fig. 12

The strong bracket shown in Fig. 9 is useful for supporting heavy weights, and the sizes given may be modified to suit requirements. The parts as shown in

Figs 10-12 consist of a plain top, cut from commercial 11 in. by 1 in. deal, planed up on the face and edges, and finished off with bevelled corners. The back is of heavier stuff, 1¼ in. thick, and has notches cut out at 3 in. centres from each end, 2 in deep at the front and 2½ in. deep at the back, and ⅞ in. wide.

The brackets are shaped as shown and can be sawn out with a handsaw, planed up on the top and front edges and cleaned up to shape at the back with a chisel. The half dovetail projection must be cut to fit tightly into the notches cut in the backboard, its purpose being to prevent the bracket drawing forwards and to relieve the screws of some of the work. To assemble the bracket put the back in the vice, then glue the edge of the bracket and the notch in the back, and screw the bracket firmly in place with 2½ in. No. 10 countersunk screws inserted through clearing holes drilled in the back. Then glue and screw on the top, using four screws at the back and three into each bracket. Drill holes through the bark and screw the whole to wooden plugs cemented into a brick wall, or to the studding on a plaster wall, or employ Rawlplugs. *See Bent Iron.*

**BRAD.** Generally this name refers to an oval section wire nail with a narrow oval head. They are preferable to the ordinary wire nail for much internal household work. Convenient sizes are ¾ in., 1 in., 1½ in., and 2 in.

Types of nails known as brads are illustrated in their actual size, and their purpose is apparent from their names.

*Brads of various sizes in common use. Top, floor brad; centre, carpenter's oval wire brad; bottom, left, shoemaker's brad; right, joiner's brad.*

**BRADAWL.** A small hand tool not unlike a screwdriver in appearance, the bradawl is used for making holes in wood preparatory to inserting a nail or screw. The secret of success in performing this operation lies in cutting across the fibres. Commence by pressing the bradawl firmly into the wood, cutting across the grain and as deeply as possible; then twist the bradawl a little, thus enlarging the hole, and again force it down, cutting across the grain, and repeat the operation until the hole is deep enough. If the bradawl is pushed in with the blade set the way of the grain it will act as a wedge and split the wood. Bradawls are made in 12 sizes, from 3/32 in. wide to 7/32 in. wide. Three sizes will meet most requirements; and it will be found convenient to buy them ready handled.

*Bradawl. How to hold this small boring tool.*

**BRAD - PUNCH.** A small steel punch, known as a brad-punch, is used for driving the head of a nail below the surface. These are made in four sizes, with cupped or hollow ends.

**BRAG.** In this card game, a variation of poker (q.v.), there are three special cards, the ace of diamonds, jack of clubs, and nine of diamonds, which may be called any card by the player holding them. Thus, a player may hold in his hand the ace of diamonds, king of clubs, queen of clubs, jack of clubs and ten of clubs. In that case he can call the ace of diamonds the ace of clubs to make a royal flush. The three cards are known as braggers. In brag, however, any natural hand beats any similar hand made with a bragger. Thus a pair of aces beats one ace and a bragger or three kings beat a king and two braggers. If two hands with braggers in each tie, the cards rank in the order ace of diamonds, jack of clubs, and nine of diamonds.

**BRAHMA.** Massive size and heaviness of leathering are the chief points in the appearance of the Brahma fowl, which formerly had a reputation for being a good layer and table bird, but is now kept almost exclusively for exhibition purposes. There are two varieties, light and dark. *See Poultry.*

**BRAID.** Composed of plaited threads, among the more familiar types are bootlaces, costume braids, Prussian bindings, cords and gimps used in upholstery, tinsel galons, and fancy artificial silk braids.

Costume braids, formerly made from worsted or mohair, are now composed of artificial silk. Russian braid, having a groove running down the centre, is easily stitched to other material.

*Braid. Method of applying Russian braid to a piece of material marked out with a pattern.*

To braid is to bind edges of revers, cuffs, etc., or to

stitch a fine make of braid over a design already marked on the dress or costume, outlining the design completely and forming an effective trimming. This is usually done by machine, but may also be stitched by hand. To do the actual braiding, place the braid on the garment—on the ink lines if a transfer has been ironed off—and sew it down with small running stitches along the groove that runs down the centre, as shown in the illustration. When the design is complete, the material should be pressed from the wrong side. The end of the braid can be made neat by sewing it to the eye-end of a large darning-needle, and pulling the latter through the material to the wrong side. Braids to be used for trimming purposes can be bought in widths varying from  $\frac{1}{4}$  in. to 9 in., and even 12 in. *See Binding.*

**BRaille.** The system of embossed reading and writing most widely used by the blind bears the name of its inventor. Braille has no resemblance to ordinary print. The letters are made up of a combination of dots, the largest number being six, arranged in three pairs. Space is saved by the use of contractions and abbreviations; but, even so, books in braille are very bulky. Much general literature is now in braille type in Great Britain, in addition to several monthly magazines and two weekly newspapers. There is also a free National Lending Library at 35, Gt. Smith St., Westminster, London, S.W., from which books are posted to all parts of the United Kingdom. Full details of the Braille system can be obtained by application to the National Institute for the Blind, 224, Great Portland Street, London, W. *See Blind.*

**BRAIN.** The brain is the predominant part of the nervous system, and, like all nerve centres, which originate nerve force as opposed to nerves, which merely conduct it, its activities depend upon nerve cells, of which it contains millions. These are spread out in layers on its surface, and to increase the area the surface is thrown into folds or convolutions. The cells vary in size and shape, and have different functions. The brain is the organ of consciousness and voluntary movements, and definite areas are mapped out for originating movements of the hand, the arm, the face, etc., and for vision, hearing, smell.

Movements on one side of the body originate on the other side of the brain, and in right-handed people the centre for speech is on the left side of the brain. There are other masses of cells at the base of the brain, and in the bulb, or medulla, where the brain becomes continuous with the spinal cord. In the latter are the centres for the functions which carry on the life of the body, heart control, breathing, swallowing, control of the blood vessels, and so on; hence injuries at the top of the spine are likely to be immediately fatal. The lesser brain, lying behind and below the main mass, is mainly concerned with the maintenance of balance.

**Injuries and Diseases.** Brain abscess is a serious complaint, requiring immediate surgical treatment. The cause may have been originally a blow on the head or an unclean scalp wound, from which the inflammation has extended inwards. A common cause is suppuration in the ear. The symptoms are disturbances of vision, recurring severe headaches, giddiness, and vomiting.

A person who has received a head injury of any severity will suffer from concussion or stunning, with more or less unconsciousness. If this deepens and the patient becomes comatose, breathing in a laboured, stertorous fashion, with flapping cheeks, and a slow, full pulse, which becomes feeble and irregular, it is probable that he is suffering from compression. In compression the body is paralysed, but if the damage affects one side of the brain, there may be, to begin with, loss of movement on the opposite side of the body. For treatment until the doctor's arrival, keep the patient lying in a quiet room with his head low. Apply cold cloths to the head. The condition may last for a long time.

Concussion is the name used to describe the conditions resulting from a blow on the skull, with a sudden shaking of the brain, which may or may not be accompanied by gross damage to the brain. The concussion may result in nothing more than a slight headache, dizziness, and mental "fogginess," lasting for but a moment or two; but in a well-marked, severe case there is loss of consciousness. For treatment pending the arrival of the doctor, the patient should be put to bed, and no effort made to arouse him. Hot water bottles should be put to the feet and legs, and cold cloths on the forehead. As a rule, recovery from concussion is complete.

**Cause of Softening of the Brain.** Should an embolus or clot block up a brain artery, and so cut off the blood supply, softening of the brain may take place, the part affected dies, and becomes liquefied. Brain tumours may be cancerous, tuberculous, syphilitic, or sarcomatous, etc. Disturbances of vision are common, and there is severe headache with vertigo and vomiting. There is likely to be mental disturbance also. The treatment depends on the diagnosis.

Lethargic encephalitis, also known as sleepy sickness, is an inflammation of the grey matter at the base of the brain mainly, and is due to a microbe. The

disease gets its name from the fact that most of the patients become drowsy. The eyes usually squint, and various nervous disorders, one of them resembling St. Vitus' dance, may be left when the drowsiness disappears. The symptoms are sometimes very slight, perhaps a tendency to fall asleep during the day, and some restlessness at night, with forgetfulness of the little things of everyday life; and the real nature of the condition might be overlooked, with detriment to the future health.

**BRAIN FAG.** Like all other working tissues, that of the brain may be tired by overwork. There is a difference in the amount of work which different individuals can do comfortably, but the natural capacity of any person may be reduced by a poor supply of blood to the brain or by the blood being of poor quality, as in anaemic states, or being loaded with toxins from the alimentary canal, when the contents of the last named are not moving along sufficiently fast.

A generous supply of blood is not only necessary for the provision of food and oxygen, but to carry off the waste products formed by the working cells. Organs which are acting receive more blood for the purpose, and after a full meal, when the stomach is getting its supply, the brain gets less, and this accounts for the somnolence and dullness of the mental faculties at such a time.

Brain fag comes quickly in the neurasthenic, and may be due to inherent weakness in the brain tissue; but a similar condition may be caused by overwork, especially when associated with worry, though worrying may also be a symptom of brain fag. Other symptoms are loss of power of attention, impaired memory, irritability, loss of pleasure in work and recreation, bodily weakness, perhaps digestive trouble, and a large variety of symptoms.

If the condition is well developed the patient must rest. For prevention we should aim at keeping ourselves physically fit by open-air exercise and other means. The idea that the best rest is a change of occupation is essentially a sound one, but should not be stressed. A sufficiency of sleep is all-important.

**BRAINS: Recipes for Cooking.** Calves' and sheep's brains are used in cookery, being sometimes bought separately, but usually sold with the head.

Having blanched the brains by washing in salted water until all discoloration is removed, soak them in cold water, then remove skin, wrap them in a piece of muslin, and put into a saucepan with a little onion, a teaspoonful of lemon juice or vinegar, a pinch of salt, a sprinkling of pepper and just enough cold water to cover them. Bring to the boil and then remove the brains and put into cold water until needed. One set of calf's or two of sheep's brains will serve 4-5 persons.

To fry, slice when blanched, and coat the slices with warm butter; then dip into well-beaten egg, cover with breadcrumbs, and fry. Alternatively, dip the slices into a rich frying Matter (q.v.) and fry till a golden brown. Fried either way, the brains may be served with a hot

piquant sauce, or garnished with slices of lemon.

Fried brain cakes or balls are useful for garnishing a calf's or sheep's head. To make them, chop the blanched brains up with the yolk of a hard-boiled egg, a tablespoonful of white sauce or cream, a little nutmeg, a little grated lemon peel, a pinch of herbs, and some seasoning. Add enough breadcrumbs to bring it to not too stiff a consistency, and when cool form into little flat cakes the size of a penny, or into balls. Dip them in flour, then in egg, cover with breadcrumbs and fry a golden brown.

For brains served on toast chop one set of calf's brains or two of sheep's rather coarsely, removing any stringy pieces. Whisk one egg until it is slightly frothy, add to it two table-spoonfuls of milk, and stir in the chopped brains, seasoning the mixture carefully. Heat 1 oz. butter in a pan, pour in the egg and brain mixture, and stir briskly with a wooden spoon over a very gentle heat until it becomes thick and creamy. Heap on pieces of hot buttered toast, and sprinkle with chopped parsley.

Scalloped brains make another appetising dish, prepared by cutting up a set of calf's or two of sheep's brains into small pieces, and placing them in a little less than 4 pint of white sauce to which a tablespoonful of cream and a few chopped mushrooms have been added. Season the whole, and put the mixture into 5 or 6 greased scallop shells, sprinkling each with breadcrumbs. Place a small lump of butter on top of each, and brown in a quick oven. *See* Calf's Head; Force-meat; Sheep's Head.

**Brain Sauce.** To serve with calf's head boil and chop a set of calf's brains, then add them to a thick melted butter or parsley sauce, well seasoned.

**BRAISING.** The process of braising can be carried out with success in casserole or saucepan, braising pans being costly utensils. Coals on the top are omitted, and the pan placed in the oven, in order that it may be surrounded by a gentle, even temperature. Braising, an economical method of cooking, develops a specially rich flavour, owing to the bed of mixed vegetables in the pan on which the food is placed. Mirepoix is the correct term for this vegetable mixture. Like stewing, this method of cooking is particularly adapted to meat or birds that, if cooked in other ways, would be tough, dry, and flavourless. No nutriment is lost from it, as the liquid reduces slightly and forms a rich gravy containing the nutritive and flavouring juices that may have been extracted from the food. In some cases it is advisable, if the food is very delicate, to place a piece of buttered paper between its surface and the lid to prevent scorching and drying. *See* Beef; Casserole.

#### **BRAKES: ON BICYCLES AND MOTOR VEHICLES**

##### **Their Mechanism, Fitting and Adjustment**

The articles Bicycle; Motor Car; and Motor Cycle should also be consulted. *See* further Coaster Hub.

The brakes generally used on bicycles comprise (a)

the cantilever front or rear brake (Figs. 1 and 2); (b) the caliper-action brake (Fig. 4); (c) back wheel brake fitted on the sprocket bracket (Fig. 5); (d) coaster hub brake. Rim brakes are operated through a system of rods and levers, or by means of Bowden cable control (q.v.).

*Brake: as used on bicycles.*

*Fig. 1. "Cantilever" front*

*brakes with Bowden control*

*Fig. 2. "Cantilever" rear*

*brakes: note independent*

*adjustment. Fig. 3. Older*

*type Bowden-controlled*

*front brake. Fig. 4. Caliper-*

*action front wheel brake.*

*Fig. 5. Brake attached to*

*sprocket bracket.*

Brakes of the caliper-action pattern are used where it is desirable to have the pads acting on the side of the rim instead of underneath, as in Fig. 4. Two arms, A

and B, are hinged at the top by the pin, C, and the brake pads attached to these arms engage the sides of the rim through the medium of the Bowden wire, drawing the extension arms of A and B together. A stationary U-piece, which is secured to the forks of the machine by means of the usual type of clips, retains the pin, C, in a true line with the wheel, and also carries the studs, D, that keep the arms A and B up to their work. With the back wheel pattern the studs, D, are dispensed with, because the arms, A and B, are kept up to their work by the direction of rotation.

Fig. 5 shows a back wheel brake made for attachment to the sprocket bracket with operating control rods. To fit this pattern proceed as follows: Unscrew the nut, A, and remove the rod, B, from the draw-bolt, C: Fit clip D on the down tube so as to bring tube, E, in line with the head. Fit fork clips, F, on the forks, but do not tighten. Then fit clip G on down tube, leaving the screws, H, and J, loose. Spring the stirrup, K, over the wheel, and place the pegs, Q, into the fork clips, F. The next operation is to adjust the screw, J, so as to leave the swing arm, M, a working fit, and tighten lock nut.

Tighten up screw, H, and carefully note that stirrup, K, lies parallel with the tubes, R, then tighten up lock nut. Now shorten the rod, B, if necessary, and pass it through draw-bolt, C, till there is sufficient tension on spring, L, to force back the swing arm, M; then tighten nut, A. Adjust the pad holders, N, up to within  $\frac{1}{8}$  in. of the rim by means of the milled nut, O, then lock hexagon nut, P, finally fitting the fork clips, F in position. The stirrup K when at rest must not butt up against the fork clips. A stop is provided on the hand lever by which the position of K should be set as shown. Figs. 3 to 5 illustrate brakes which are most commonly used on ordinary "roadster" bicycles; but the increasingly popular sports or racing models necessitate a severer type of brake altogether.

Fig. 3 shows an earlier type rim brake with Bowden control seen on older machines. Inner tube A is fixed to tension rod B, and outer tube C to clip D. U-piece G, fitted with pins H, passes through clips F.

Coaster hub brakes are sometimes employed in conjunction with a two and three-speed gear. Generally speaking, the coaster hub brake is designed on the internal expanding principle, employing either an expanding bronze ring or an expanding sleeve, the braking power-being applied by back-peddalling.

There has been a fashion recently for brakes of duralumin, not unlike the caliper-action in general principle. The noteworthy point about it is that it is fitted with springs which work from behind the arms of the caliper. But the outstanding development in recent years is the "Cantilever" Brake (Fig. 1), introduced in 1929. It is manufactured by Resilion Co., Ltd., from whom much of this information is obtained. It is suitable for all light-weight models and tandems, and agreement is general that it eliminates all the inherent faults of caliper brakes.

The brake members embrace the forks or seat stays

and are firmly anchored thereto by clamping shields which carry the cable stops and adjusters. Each side is independently adjustable to the rim with the greatest accuracy, and a useful saving of weight is effected by the absence of any bridge work which also enhances the neat, attractive appearance, giving the impression that the brakes are an integral part of the design of the cycle.

It is claimed that one cantilever brake with only 6 lb. pressure on the lever will stop an 11½ stone rider travelling at 16 m.p.h. on a steep slope in 20 yards, against 334 yards in similar tests of other brake-designs. A cantilever may be fitted with cranked levers for right or left hand, to suit the curves of either flat or upturned handle-bars. A cheaper model of the cantilever, with pressed steel quadrants, is nearly as efficient. Its leverages are worked out to give maximum advantage for small pressure on the handle-bar lever, and the brake is particularly suitable for ladies' bicycles because of its light and easy action, or for children's cycles where a small hand is to operate the lever.

Cantilever brakes (for forks ½ in. to 1¼ in.) cost between 10/6 and 14/6; the smaller model (weighing only 14 ounces) is only 7/6. Their sole drawback is the complicated adjustment which is necessary: the wheels must run absolutely true if the brake is to be effective.

**Motor Cycles and Motor Cars.** (See pages 249 and 250 for diagrams). The various types of brake used on motor vehicles may be classified under the following heads: Internal expanding as shown in the diagram, Fig. 6. External contracting, almost obsolete, but found in some hand-brake layouts. This type of brake, used for parking purposes is arranged behind the gear-box and operates on the propeller shaft. Both contracting shoes and contracting bands are embodied in the design.

In the motor cycle class there are various forms of internal expanding brakes, designed in nearly all cases to give maximum braking power in a forward direction, i.e. the expanding band is operated from one end only, its other end butting against a stop. This type (Fig. 12.) is usually controlled by the Bowden cable or adjustable rod systems. Other types of motor-cycle brakes follow car practice and employ the expanding two-shoe arrangement.

Figs 6 and 7 show the action of the Perrott-Bendix two-shoe internal expanding brake. This is adapted to give a complete servo action both forwards and backwards. Fig. 6 shows the two shoes with their operating mechanism, while Fig. 7 shows the operating mechanism in several positions. The shoes are connected to one another at their lower end by the short link *e*, and their upper ends are expanded so as to engage the inside of the drum by a floating lever, *f*, carrying two small rollers, *g*, one for each brake shoe. The lever, *f*, is adjusted angularly by connecting its lower end to a short arm, *h*, fixed to the brake operating spindle, the outer end of which carries the usual operating lever, *k*. Each of the brake shoes is free

to move within narrow limits determined by holes at their ends through which pass with a certain amount of freedom, pins *l'* *l''* fixed to the back or anchorage plate. A spring, *m*, contracts the brake shoes and keeps their ends in engagement with the rollers, *g*, in the usual manner.

The brake shoes are shown in their dis-engaged position at A in Fig. 7, the ends of the slots in the shoes then being forced against the fixed pins *l'* and *l''* by the spring, *m*. When the lever, *k*, is rotated to apply the brakes (B, Fig. 7), it imparts an angular movement to the floating lever, *f*, and the shoes are thereby forced apart until they engage the inside of the rotating drum. Both shoes are carried round in an anti-clockwise direction, their rotation being resisted solely by the pin, *l'*. The rotation of the brake drum thus drags round both shoes and increases the force with which they engage.

When the drum is rotating in a clockwise direction, as shown at C in Fig. 7, the operating lever, *k*, is moved as before and turns the floating lever *f*. The two shoes are, however, then dragged round by the drum in a clockwise direction, their rotation being prevented by the fixed pin *l''*, the pin *l'* being then out of action. A powerful servo action is thus obtained from both shoes as before. Friction washers, *n*, carried on fixed pins, prevent play of the brake shoes when they are disengaged.

**Principle of Front-Wheel Brakes.** Fig. 11 shows a front wheel brake. The control rods must be designed so that the brake may be applied irrespective of the position of the wheels; this is carried out by means of a universal joint, D, positioned on the control rod so as to be over the dead centre of the steering head.

With this class of brake it is generally necessary for the point of contact of the tire with the ground to coincide with the point touched by the imaginary lines, E, F, drawn down through the centre of the steering head and wheel. In the figure A is a ball joint allowing universal movement during spring deflection; B is a rod which is a sliding fit in C, the operating tube: E, F, lines meeting at the tire contact point with ground. Front-wheel brakes are without exception of internal expanding design. Often they are cable-operated, as in the Hillman Minx, a typical example of modern practice in front-wheel braking.

Front wheel brakes are more powerful than those operating on the rear wheels for the reason that the retarding force exerted by the road on the moving car causes the weight to be thrown forward, thereby increasing the pressure of the front wheels on the road surface and, at the same time, reducing that of the rear wheels. The more rapidly a car is pulled up the less will be the grip of the rear wheels and greater that of the front wheels; this explains why a modern car can be stopped in less than half the distance required by an old car having rear-wheel brakes only. In addition to the servo-shoe arrangement, other methods are employed to lessen the effort required of the driver

(Continued in page 251)

Fig. 12.A. Internal expanding brake on motor cycles: expanding band operated by a short lever *a*; B. arrangement of internal expanding brake on front wheel of motor cycle; C. lever and pull rod with fly-nut adjustment in motor-cycle brake actuating gear.

Fig. 13. Lockheed hydraulic brake: note pedal spindle *a* carrying lever *b* bearing on piston *m*.

in operating the brakes, various types of servo mechanism are employed. In the mechanical type a clutch or brake is dragged round by the transmission, and thus caused to apply the brakes. In another type the suction of the engine is utilised to create a vacuum in a brake cylinder. In some brake systems the braking effort is transmitted by hydraulic pressure (Fig. 13, Lockheed brake). This method has become increasingly popular in recent years. The system comprises an arrangement of pipes with a "master" cylinder and small cylinders. The master cylinder contains a piston which, when operated by a pedal, forces fluid through the pipes into the small cylinders. Opposing pistons in the latter are thus actuated and force the brake shoes into contact with the drums.

In what is known as a six-brake system, the pedal works four brakes, and the hand level controls independent sets of shoes in the rear brake drums. Systems in which the pedal controls the four-wheel brakes and the hand lever controls a transmission brake are known as five-brake systems.

Figs. 8-10 show the Girling system, a proprietary brake now incorporated into the design of a number of British cars. A special feature of this is the operating mechanism which gives accurate balance between the brakes on each axle and between front and rear brakes. The balance or "compensation" is obtained by the Girling linkage system: it is "built-in" and practically impossible to upset by maladjustment or neglect. It is used notably in Riley cars.

Brake linings are detachable. They should preferably be fibrous. "Brake-shriek" is due to the design of the brake rather than to the linings. It is uncommon in servo brakes. Remedy it by adjustment of either shoes, pivot or drum.

Unless brakes receive periodical attention, sooner or later they are bound to seize up, the cause of this in nearly every instance being the ingress of water which is liable to get in through lack of oil on the various moving parts. Always keep the brake parts well lubricated, by frequent use of oil or grease. In conclusion, it should be noted that the proper functioning of brakes depends more than is realized on the care of rods or cables.

**BRAMLEY'S SEEDLING.** This is a very fine cooking apple. The fruit is very large, flat, with a vivid green skin, changing to red on the sunny side, and the flesh is firm, crisp, acid and juicy. Some people eat this apple raw in order to cleanse the palate, but Bramley's seedling is essentially the fruit for tart, pie, or dumpling. It is best as a standard on a rather heavy clay soil. The fruit is ready to pick first of all in November, but with careful storage will keep till May or June. *See Apple.*

**BRAN.** The outer husk of the wheat grain, bran can be bought at little cost from any corn-chandler. It is used as a feeding stuff for horses and cattle, is one of the staple foods for rabbits, and is mixed with the meal in the fowl's warm mash.

It is often employed for packing, and is especially suitable for glass and china or other fragile material. A bag lightly packed with bran and warmed in the oven for a few minutes retains its heat, and is a substitute for a hot-water bottle.

Bright-coloured materials, cretonne, chintz, shantung, etc., will not fade if washed in a bran bath. To make one, about  $\frac{1}{2}$  pint of bran is required for every 2 quarts of water. Sew the bran into a bag of fine muslin, leaving plenty of room for it to swell, and put it, with the water, into an enamel-lined or aluminium saucepan. Bring to the boil, and stew for about  $\frac{3}{4}$  hour. Then pour off the water, fill again with cold, and stew once more for a shorter time.

As the bran softens the water, soap is unnecessary except for very dirty articles. The material is put into the first bran water. It should not be rubbed, but squeezed between the fingers, and put, when clean, into the basin containing the second brew. Rinse it finally in tepid water. No white or delicately coloured material should be washed in this way, as the water is tinted. The bran can afterwards be used instead of tea-leaves for keeping down the dust when the carpet is being swept. *See Packing; Poultry; Rabbit.*

**BRANDY.** This spirit is best drunk with plain water rather than with soda or any sparkling mineral. Hot brandy and water is an excellent "night cap". The finest liqueur brandies are drunk neat at the end of dinner after black coffee, being served in a large glass, convex towards the lip, and not filled to the top. Fifty years old is a sufficient age for a good liqueur brandy.

Medicinally brandy is used as a restorative in cases of temporary faintness, and a further use for it is found in the later stages of acute febrile diseases when the patient's powers are waning, e.g. in pneumonia, enteric fever, influenza, etc. Then a tablespoonful may be given every hour or two, in milk, and as much as  $\frac{1}{2}$  pint or more may be taken in the 24 hours. As a quick stimulant in an emergency, a teaspoonful of brandy in one or two tablespoonfuls of champagne is very effective. *See Alcohol; Cherry Brandy, etc.*

**BRANDY BUTTER.** This thick sauce may be served with plum pudding. Beat up 4 oz. butter to a cream, then add castor sugar until it is stiff and rocky, a few drops of vanilla, and a little liqueur brandy. Pile up in a glass dish. It is best made a few hours before it is wanted, and left in a very cool place until served.

**BRANDY SAUCE.** To make a sauce, which is often served with pudding, melt 3 oz. of loaf sugar in about  $\frac{1}{2}$  pint of water, and boil until syrupy. Add to this about a dessertspoonful of cornflour mixed into a creamy paste with water, and stir until it boils. Add about half a wineglassful of brandy before serving.

**BRANDY SNAP.** To make these biscuits take 6 oz. each of flour, butter, sugar and cane syrup, to which should be added  $\frac{1}{4}$  oz. ginger and a few drops lemon

lemon juice. Melt the butter, syrup and sugar together in a pan, and then stir in the sifted flour, the ginger, and the lemon. Pour the mixture into small rounds on a greased baking-tin and bake about 10 min. in a moderate oven. Roll them up when just cool enough to handle.

**BRAN TUB.** A tub full of bran, in which are concealed a selection of small toys, brightly-coloured bags of sweets, oranges, apples, or any other gifts is an old-fashioned but still popular amusement at children's parties and at garden fetes. If the tub is a deep one, a thick layer of bran is put at the bottom before any toys are introduced, so as to bring them within the reach of small arms. The tub is then filled with alternate layers of bran and toys, bran being on top when it is full. The children plunge a hand into the tub and pull out the gift they touch first. *See Children's Party.*

**BRASS.** One of the most useful of metals, brass is obtainable in rods, sheet, or tube. It is easily turned, filed, or soldered, takes a high polish, and can be coloured without difficulty.

Brass wire is sold in coils, from very fine to quite stout rods. Round stuff can be bought in drawn rods, with a clean and bright surface. Cast rods are rough and of little use to the amateur. Strip brass is the most convenient form in which to buy flat material up to 2 or 3 in. in width and 1 in. in thickness, down to 1/16 in. wide by 1/32 in. or less in thickness. Tubes are solid drawn and sold according to their outside diameter, and are stronger than the brazed tube commonly employed for gas-fittings. Brass-cased tube is made of iron covered on the outside with a thin layer of brass, and generally used in cheap bedsteads and for curtain rods and poles. Circular brass blanks from 1 in. to 4 in. diameter and 1/16 to 1/4 in. thick, as well as screwed brass rod, and brass gears of all kinds, are valuable aids to the home-worker.

Brass castings are extensively employed. Soft sheet brass, which can be readily hammered, is used for repoussé work, and can be cut with a fret-saw. Many stock patterns of pierced brass are obtainable. As brass does not rust, it should be employed for screws and hinges in damp places. For electrical work it is extensively used, being a good conductor.

**How to Lacquer Brass.** The cleaning of brass is an everyday task in most homes, much of which could be avoided by lacquering especially with such articles as door handles, fenders, and the like. The brass is first thoroughly cleaned and a mixture of paraffin and whiting is applied as a paste. Very dirty brass can be cleaned with a dilute mixture of nitric acid and water or sulphuric acid and water.

*When mixing the sulphuric acid it must always be poured slowly into the water; the water must never be poured on to the acid or an accident may result.*

Boiling in strong soda-water also cleans ordinary brass-

work. The work to be lacquered must be polished brightly, frosted or otherwise finished; it is then dipped into a hot bath of dilute soda water, rinsed in cold water and dried off in hot dry sawdust. This is to remove all grease. The work should not be touched with bare hands, but a piece of clean tissue paper should be used.

The next step is to heat the work evenly but slightly, and a film of moisture will form on the brass. Directly this disappears the lacquer is applied with a clean camel-hair brush in one even coat. The work must not be touched twice with the brush or it will be spoiled. The article is then turned about over the heat from a gas burner until it is dry, and set aside to harden off. Lacquer is obtainable in crystal or colourless; pale gold, which imparts a slight colour; or deep gold, as usually applied to domestic articles. If the crystal lacquer is used it will be absolutely invisible to the eye. Under normal conditions lacquer stands for a year or more without any other attention than that of an occasional dusting. *See Ash Tray; Brazing.*

**BRASS COLLECTING.** Examples of old brass work, which are within ordinary reach, belong to the last three centuries. They include caldrons and skillets, snuffers and candlesticks, mortars and door-stops, trivets and chestnut roasters, tinder-boxes and ember tongs, andirons and fire brasses, ladles and furniture handles, warming-pans and foot warmers, lantern clocks, trinket boxes, and table bells. Such objects enhance, when used with decorative discretion, the effect of lounges and halls furnished in oak or mahogany, with leather upholstery or deep-tinted tapestries, and self-coloured walls.

*Brass Collecting. 1. Horse amulets. 2 and 3. Figures made by brassworkers apprentices on completing their apprenticeships.*

Much continental hammered brassware, collectively called *dinanderie*, has for centuries been made round

about Dinant in Belgium. It includes coffers, platters, and Dutch tobacco-boxes with Biblical scenes based on old wood-cuts. The modern work is often poor in material and execution, but good examples are to be had.

4. *Alms-dish, with design of Adam, Eve and Serpent; early 16th cent.* 5. *Candle snuffers, 18th cent. (1, 2, 3 and 5 from the collection of Sir James Yoxall; 4. by courtesy of Fenton & Sons.)*

Oriental brass is best associated with eastern carpets and related colour schemes. The domestic brassware of the Hindu kitchen, whose unornamented surfaces are burnished daily, generally present delightful forms; such are water-bottles or lotas, both large and small, wide-mouthed milk bowls and shallow rice-dishes. Images of Buddha or of Indian deities, if not placed in trivial surroundings, may be displayed with one or two pieces of solid hammered Benares ware.

A good deal of modern English brass, including some which is spun or stamped by machinery, is in good decorative taste. The production of replicas is a thriving industry, and if they are of honest fabric and sold at their face value only they have ornamental uses. Spurious old brass is harder to detect than any other class of counterfeits.

Medieval brass is hardly possible to acquire except in the auction-room. It comprises pattens and alms-dishes, pilgrim signs and curlew hoods, astrolabes and sanctuary rings. Of a later age perforated horse-amulets, of which there are more than 1,000 designs, including rayed suns, horned bull's heads, and crescents, are charming in form and decoration. A full set of these harness-trappings consists of a face-brass, two ear-pieces, six shoulder ornaments, and six or ten metals for the martingale over the chest.

Stuart and Georgian pipe-stoppers, fob-seals, and other objects with engraved bases may still be met with in out of the way places. They frequently simulate or caricature the features of famous men of the day. There are also miniature reproductions in brass of period furniture, such as Chippendale tables, grandfather chairs, and the like. Some collectors specialise in old door-knockers, whose designs may be arranged to illustrate the development of taste. Gorgon-heads and other grotesque forms, derived from ancient sanctuary rings, are favourite designs for miniature knockers.

Delightful figures—they are hardly statuettes—were produced in the 18th century for the finials of door-stops and fire-dogs. They were often in pairs, such as peacock and pheasant, boy with dog, and girl with rabbit; besides groups and various national and allegorical figures.

Brass should be kept dry by regular leathering. Unpleasing stains may be removed with chalk moistened by spirits of turpentine; deep-seated tarnish will yield to weak oxalic acid applied by a rag, followed by washing and drying with whiting. Liquid polish serves for large surfaces, such as warming-pans, but if used for perforated or hammered surfaces deposits must not be left in the crevices. *See Benares Ware.*

**BRASS-BACK SAW.** Small brass-back hand saws are used for cutting thin, soft sheet metals and tubes, such as brass, copper, or pewter. They are inexpensive, and are useful in the home workshop, being preferable to a hacksaw for cutting brass tubings. *See Saw.*

**BRAWN:** *How to Prepare.* Take half a fresh or salted pig's head, 1 carrot, 1 small turnip, 12 peppercorns, 4 cloves, 1 blade of mace, 1 sprig each of thyme, parsley and marjoram, and some salt and pepper. The pig's head should be well washed in tepid water, rinsed, and put into a saucepan with sufficient cold water to cover it. Bring slowly to the boil and skin carefully; then add the vegetables, which should be cut into small pieces, the herbs and seasoning. Simmer the whole slowly until the flesh leaves the bones easily; then strain the liquid into a basin and put the head on a dish.

The meat has now to be cut from the head into small pieces and the tongue into thin slices, removing any skin or gristle. Return the liquid, skimmed of all fat, to the saucepan with the bones from the head. Boil quickly till reduced to half the quantity, then strain over the meat. Season again if necessary with pepper and salt. When slightly cooled pour into wetted moulds and set aside to get cold and firm. Turn out to serve and garnish with parsley. The time required for boiling the head depends upon its size, one weighing 6 lb. taking from two to three hours.

The inside of the moulds may first be decorated with some hard-boiled egg cut into thin dice or small fancy shapes.

To make spiced brawn, use 1½ lb. of lean beefsteak and a small pig's head which has been in pickle for a week. Place the meat and the head in a saucepan and cover with cold water. Bring to the boil quickly, skim well and simmer for 3½ or 4 hours. Then strain off the liquor, remove the bones, and chop the meat finely. Season the brawn with cayenne pepper, salt and a little allspice. Make the meat moist with a little of the liquor carefully freed from fat, and press it into a plain round mould with a heavy weight. It can be turned out next day.

For veal brawn take a knuckle or any bony piece of veal and wipe with a clean cloth, removing any fragments of bone. Put the meat into an enamelled saucepan, cover with cold water, and bring it to boiling point. Skim the liquid well, add an onion, stuck with cloves, and a teaspoonful each of salt and pepper.

Simmer very gently till the meat comes off the bones and the gristle is nearly melted. Having taken out and boned the meat, chop it into small pieces, add two or three hard-boiled eggs cut into slices, and season the dish lightly with salt, lemon juice, and chopped parsley. Arrange all in a mould. Pour a little strained stock over it and set it aside to cool.

Calf's head brawn is useful, and if a little care is taken in arranging the pieces of egg in the top of the mould, it can also be made ornamental.

Take about 1 lb. of boiled calf's head (q.v.) and ½ lb. of boiled ham or bacon, and cut both into neat dice. Shell and cut three hard-boiled eggs first into thick slices, and then cut the latter into quarters. Arrange pieces of the egg in any pretty design at the bottom of a plain mould or basin, and then fill up loosely with layers of the head, ham, and any egg that remains. Between each layer sprinkle in a little seasoning, made by mixing 1 teaspoonful of grated lemon rind with 2 teaspoonfuls of chopped parsley and salt and pepper.

Heat ½ pint of the liquor in which the head was boiled. This should be a stiff jelly, but if it is not, reduce by boiling without the lid to about two-thirds of the original amount. Dissolve in this stock 3 sheets of gelatine, but do not let the liquid boil. Then strain into the mould till the latter is full, and put a plate on the top of the mould with a weight on it. Leave until cold and set. Wipe off any fat that may be on the top, dip the mould into hot water to loosen the jelly from it and turn the shape out on to a dish, garnishing with tufts of washed cress or lettuce.

**Fish and Vegetable Brawns.** For fish brawn the ingredients are some white fish and the bones of a rabbit or chicken or some veal bones. It needs also a little onion, pepper and salt, some chopped parsley and hard boiled eggs. Cover the bones well with water and stew them well and slowly, adding the pepper, salt, and onion before straining. Decorate a mould with a little chopped parsley. Fill half full with alternate layers of flakes of cold fish and hard boiled eggs in slices. Then strain in the stock gently till the mould is full. When cold turn it out. It should be served decorated with parsley.

Egg and vegetable brawn can be made as follows: Boil 2 eggs hard and slice them. Make some clear stock with a few bones, strain it through muslin, and to each pint of stock add ¼ oz. gelatine. Arrange in a wetted mould the slices of egg, some slices of tomato and cold potatoes, and season with pepper and salt. After putting in one layer of these add a little of the stock in which the gelatine has been dissolved. When set add another layer of eggs, etc., and continue the process until the mould is full.

To make rabbit brawn, thoroughly clean a rabbit, cut it into joints, and let it simmer gently for 2 hours. Then take the meat from the bones, and cut it into small pieces. Arrange these in a plain, round mould with 2 hard-boiled eggs and ¼ lb. cooked ham, cut small. Add to 1 pint stock ½ oz. gelatine, and dissolve it very thoroughly. Pour this over the rabbit and turn it

out when cold.

**BRAZIL NUT.** Imported into Great Britain from South America, the Brazil nut is a favourite for dessert. The kernel yields an oil used by artists and watchmakers.

Brazil nut cutlets are made from 4 oz. breadcrumbs, the white of one egg, 3 oz. skinned Brazil nuts, ½ pint white sauce, 2 teaspoonfuls mixed herbs, and a pinch of powdered mace. Put the breadcrumbs and nuts through a mincer, add the herbs, and mix all with the white sauce. Beat up the white of the egg to a stiff froth and add it lightly to the mixture. Shape the whole into cutlets and fry in hot fat; then drain and dish on a doily, garnishing with parsley before serving.

**BRAZING.** Brazing is a method of uniting metal parts by means of a film of brass in the form of alloy, known as spelter. Metals that are usually brazed together are steel, wrought iron, brass, and copper. Cast iron is not usually brazed, as better results are obtained by autogenous welding.

The various stages in brazing are as follows: Thoroughly clean the parts to be brazed, apply a suitable flux to the joint, then assemble the parts, and secure them so that they cannot move relatively during the brazing operation. Next apply the spelter to the joint. Heat the work thoroughly until the spelter runs or melts and unites with the metal parts. Finally clean the job, and remove any scale or surplus spelter.

The tools and materials required are a powerful brazing blow-lamp, or preferably a gas blow pipe supplied with air from a foot bellows, a stout iron pan on legs, and filled with coke or lumps of asbestos, some spelter, borax in powder form, and a few rough pliers or tongs for holding the work while brazing. Some soft iron wire and a packet of brazing pins are needed to secure the parts, unless they are screwed or driven tightly together so that they cannot move while being operated upon.

A simple example is to braze a steel tube into a steel socket. Clean the joint thoroughly by polishing with emery cloth, or by filing or grinding, and paint it with a solution of powdered borax. Now force the tube into the socket; there is no fear of its being too tight, as the brass will run into the joint although there is apparently no room for it. The danger is in having a slack joint. A brazing peg has next to be inserted. For this purpose drill a hole through the socket and tube, insert the small end of the peg, and drive it in hard with a light hammer.

**Use of the Blow Pipe.** Now place the work on the brazing pan and pack asbestos cubes around the back and sides, leaving space for the burner flame. The idea is to retain as much heat around the joint as possible. Light up the blow lamp or gas blow pipe, adjust the flame to burn clean, that is, without yellow streaks or any trace of smoke. Move the lamp about so that the flame warms up the asbestos and the metal generally.

Watch the borax or flux around the joint, and directly this begins to bubble and turn white, apply the spelter to the joint. Spelter is obtainable in granular form, like brass filings, and can be mixed with an equal proportion of powdered borax. In this state it is applied to the joint with a metal rod. Heat the end of this rod, dip it in the spelter, and sufficient will adhere. Apply this to joint and as much more as is needed.

If spelter is bought in the form of brass wire it is roughly square in section and sold in rolls. Cut off a few feet and coil up one end, then heat the other and dip it in the powdered borax, a globule of which will adhere. Then heat the work steadily and thoroughly, at the same time melting off a piece of the spelter wire, or brazing wire, as it is usually called. Push this with the end of the rod into its place, or as near as possible; continue to heat the work, apply a little more flux from time to time to prevent the surfaces oxidising, and watch for the spelter to melt. When it begins to melt, watch where it runs. It should disappear into the joint. Spelter will follow the heat and the flux, and will not adhere to the metal except where the flux has been applied. Be careful not to inhale the fumes given off during the brazing process.

To be sure of the job being a sound one, it will have to be turned over. When one side is brazed, keep the flame on the work so as not to lose the heat, and turn the work over with the tongs. When satisfied with the job, turn off the blow lamp flame, and allow the work to cool off before touching it. When it is black hot, take it from the pan, holding it with tongs, and with a wire brush remove all surplus flux and scale: being in a plastic state it should brush off easily. When quite cool, the scale has to be cleaned off, by pickling in a weak solution of sulphuric acid and water. The pickle should be made in an earthenware or glass jar and preserved for future use. Leave the work in the pickle for an hour or so, then wash it in hot water, and file and polish until the metal is clean and bright. If feasible, run some oil or paint into the interior of the pipe to prevent it from rusting.

The secret of success in brazing is clean work at the start, sufficient heat applied in the right place, and to see the spelter run nicely and freely. On some work the spelter and borax mixture can be applied direct to the work and then heated, but generally on all steel or iron parts the brazing wire is the best.

Brass and copper are brazed in the manner already described, but call for more care and skill on the part of the operator. The brass has to be heated to a dull red heat before the spelter will run, and at that heat the brass itself is on the verge of melting. It is best to use a soft spelter strip or specially prepared white spelter, as this melts at a lower temperature than ordinary brazing wire. The same care is needed at all stages of the work. Much small brasswork is, however, joined by a process known as hard soldering or silver soldering. *See Brass; Soldering.*

**BREACH OF PROMISE.** An action for breach of promise of marriage can be brought by a man who has been jilted, but almost invariably the plaintiff is a

woman. The lady must prove that the defendant promised to marry her. The promise need not be in writing or words but may be presumed from conduct. The plaintiff's word and oath alone are not sufficient to establish a case. She must be corroborated; and this corroboration generally takes the form of love-letters; an engagement-ring; evidence that the lady was introduced by defendant to some other person as his fiancée.

It must be proved that defendant had broken his promise. This he may do by breaking it off formally; or by getting engaged to or marrying someone else; or by neglecting to marry the lady within a reasonable time. For a promise to marry means to marry within a reasonable time.

The damages recoverable are practically whatever the jury like to award. They generally give the plaintiff anything she is out of pocket for trousseau and the like; something for injured feelings; and something for what may be called the value of the match. A promise by a minor (under 21) to marry is void; but if he makes a fresh promise after he is 21 he may be sued if he breaks it. *See Engagement; Marriage.*

## BREAD AND BREAD MAKING

### Essential Facts for Every Housewife

This entry is followed by several dealing with various uses of bread, and by other relevant headings, including Bread Basket; Bread Cutter, etc. *See also Baking; Diet.*

The necessary ingredients for household bread are flour, yeast, sugar, salt, and warm water. For small loaves, rolls, etc., baking powder may take the place of yeast, and butter, milk and eggs may be added. As a rule,  $\frac{1}{2}$  oz. yeast, a teaspoonful each of sugar and salt, and rather more than a pint of water are used to 1 lb. flour. The same proportions are employed for brown bread, but wholemeal flour is substituted for ordinary white flour.

The method of preparing household bread is as follows. Mix yeast and sugar well together, add a tablespoonful of tepid water (tepid being  $\frac{1}{3}$  boiling water and  $\frac{2}{3}$  cold), cover basin with a clean cloth and stand in a warm place until yeast is well risen and frothy. Meanwhile, measure flour into a basin and warm it, either in front of the fire or on the rack above the range. When yeast has frothed, pour it into a well, made in centre of flour with a warm wooden spoon, and sprinkle a little of the flour over it and a teaspoonful of salt round edges of flour. Cover basin with a cloth, put in a warm place and leave until yeast has cracked well through flour. Stir in gradually the tepid water, preferably with a warm palette-knife, and the mixture is ready for kneading.

Kneading presses the yeast cells between the grains of flour, and by it the dough is rendered smooth and elastic. A warmed board, lightly sprinkled with flour, must be used. Turn dough on to this and knead (i.e. rub firmly together and pound) with both hands. The

success of the loaf depends largely upon the kneading, and a light, firm touch with dry, warm hands is essential. When the dough has become smooth and elastic turn it again into a warm basin, cover, and set to rise in a warm place until it has at least doubled its size. This takes about 2 hours. Then turn once more on to board and knead quickly and lightly before forming into loaves. These may either be stood upon a large, floured baking tin or small floured bread tins may be used. This done, let the dough stand (or prove) in a warm place for 20 min. It should always be remembered that uniform warmth is the secret of yeast bread. If raised in too cool a place a very close consistency will result; if too hot, a solid cake of flour will follow, or loaves with large holes in them.

During the time of final proving the oven must be made very hot. All yeast bread must be baked in a very hot oven at first, to kill the yeast. After the bread has risen still further, and browned, the heat may be gradually reduced. Allow about 1 hour for baking a half-quartern loaf and  $\frac{1}{4}$  to  $\frac{1}{2}$  hour longer for a quartern loaf. When the loaves sound hollow on being tapped briskly underneath, they are done. They should be cooled on wire trays and turned upside down.

**How to Make French Bread.** French bread is made with Vienna flour. Milk is added to the yeast and sugar instead of water; tepid milk and sometimes a little beaten egg is employed to mix the dough. Kneading, rising, proving, etc., must take place as previously explained, and after forming into plaits, rolls, etc., the dough must be brushed with beaten egg and allowed to rise again for ten minutes. A very hot oven is again needed. Small fancy twists and rolls usually take about 15 min. to bake.

*Bread and Roll Making. 1. Kneading the dough. 2. Pricking dough in baking tin. 3. Glazing rolls.*

Any good pastry flour can be used for fancy bread.

Currants, sultanas, or a pinch of mixed spice or cinnamon may be added if desired.

*4. Placing top on cottage loaf. 5. Milk rolls in fancy shapes. (1, 2, 3, and 5, courtesy of Country Life, Ltd.)*

Three rolls of a richer variety are illustrated in Fig. 5, two of which are dealt with in the text. To prepare, sieve together in a warmed basin  $\frac{1}{2}$  lb. flour and  $\frac{1}{2}$  teaspoonful salt, rubbing into them 1 oz. butter. In another warmed basin mix a little less than  $\frac{1}{2}$  oz. yeast, with  $\frac{3}{4}$  teaspoonful castor sugar; then warm up  $\frac{1}{4}$  pint or less of milk, adding to it a small, well-beaten egg. Pour the latter mixture into the yeast and sugar, mix all well, and then add the whole to the flour and salt. Beat up all these ingredients, and put the covered dough in a warm place to rise for about one hour. When it has risen, divide it into four portions, and from one of these make a plait roll. Divide the piece into three equal parts, rolling each until it is about 5 or 6 in. long.

Pinch these strips together at one end before plaiting them, and finish the bottom in a similar manner.

The horseshoe roll is made by forming a portion of dough into a triangle and, taking the longest side, rolling it over to the point. Twist the roll to form a horseshoe, and cut it across the top in several places with a knife. The roll with a plaited effect on top is made by dividing a piece of dough into two unequal portions, and placing the smaller part, plaited in the way already described, on top of the larger piece, shaped to form an oblong. Let the rolls rise in a warm place for 20-25 min.; then brush them over with milk, and bake them for about quarter of an hour.

**Method of Making Aerated Bread.** Aerated bread is so called because the bread is raised by means of the carbonic acid gas given off from baking-powder when moistened. It is made as follows: Take 1 oz. baking-powder and  $\frac{3}{4}$  oz. salt to every 2 lb. flour, incorporating the salt and baking-powder well into the flour before moistening. Pour about a pint of water into the centre of the flour and make it quickly into a dough.

Divide it into loaves and brush over with milk. Put the loaves into the oven immediately. No time must be lost between the moistening of the flour and getting the loaves into the oven, otherwise part of the aeration will be lost. Bake in a quick oven for about half an hour.

Bread raised with baking-powder is made by simply rubbing fat into the flour and adding salt, baking-powder and sugar. The dough is mixed with water or milk (the latter preferably sour) and when formed into rolls or small loaves should be brushed with beaten

egg. Ten minutes in a hot oven is sufficient for small baking-powder dinner rolls or loaves. To make these rolls, sift with  $\frac{1}{2}$  lb. fine flour  $\frac{3}{4}$  teaspoonful baking-powder, and  $\frac{1}{4}$  teaspoonful salt into a basin. Rub in 1 oz. butter and mix all into a stiff dough with 1 gill sour milk or water. Divide it into 6 equal portions and make these up into round rolls. Bake them about 10 min. and serve them hot. These rolls can be made suitable for tea if the butter is increased to 2 oz. and a like quantity of castor sugar added: also, if an egg is beaten up and added to the liquid when mixing up the flour.

**Value of Wholemeal Bread.** Wholemeal bread, which includes all the bran, may prove indigestible for some people, or may even produce irritation of the digestive tract. But those who can digest it receive additional nourishment, including a much larger portion of organic phosphates, which are indispensable to the chemistry of the body. Also, in wholemeal bread we retain the vitamins which are so necessary to growth.

Without a doubt, wholemeal bread is the bread which should be supplied to children. Among the well-to-do the deficiency in vitamins and organic phosphates may be made good by other articles in the diet, such as butter, eggs, and fresh vegetables; but children who are brought up on skim milk, margarine, and white bread are starved of things necessary to their proper growth, and rickets and ill-defined forms of disablement may result.

With regard to the irritating effects of wholemeal bread on the intestinal tract, this may be in many cases the stimulus required to produce a proper movement of the bowels and prevent or cure constipation. New bread is apt to be indigestible; it is better to use it a day old. The proper toasting of bread makes its digestion easier; but this does not apply to hot buttered toast, on which the butter has been made less digestible by heat. If butter is used, it should be put on when the toast has cooled.

In diabetes it is necessary to limit the amount of starch in the patient's diet, and starchless bread is sold for this purpose. It is made from gluten, the sticky substance in dough, bran, casein, the proteid in milk, curd, nuts, and almonds. Some samples are quite free of starch, but others contain more or less of it. Such bread should be bought of a reliable maker to ensure its being what it is represented to be.

**BREAD AND BUTTER PUDDING.** To prepare this, butter a pie-dish and sprinkle currants or sultanas or spread a little jam or marmalade on sufficient slices of bread and butter to half-fill the pie-dish. Beat 2 eggs to a froth and mix them with a pint of milk and a tablespoonful of white sugar. Pour in this custard and let the bread soak in it for half an hour, or until it is soft. Stand the pie-dish in a deep baking-tin with water round the dish, and bake the pudding slowly till set and browned lightly. The water round the dish together with the slow baking prevent the custard from curdling.

**BREAD BASKET.** The craftworker can make the raffia bread basket shown in Fig. 1 with one bundle assorted colours and  $\frac{1}{2}$  lb. natural raffia. It measures 8 in. across when finished and is bordered with blue, orange, white, brown and black raffia.

*Bread Basket. Fig. 1. Basket woven in raffia in several bright colours.*

Thread a raffia needle with a strand of natural raffia and take six more threads level at one end. Bind these together with the first, taking eight or nine wraps over from front to back. Now coil into a small ring,  $\frac{1}{4}$  in. in diameter, to begin spiral for base, going in a left-hand direction. Take a few wraps with needle-strand round the ring and coil and then make a knot-stitch, by bringing the needle through from the back between the coil and the ring on the left of the last stitch. Then take it across front of this stitch and pass needle through on the right of this stitch, bring it round to left again, between ring and coil. This part of the process is finished by taking needle round coil.

*Bread Basket. Fig. 2 (left). Design of the raffia weaving.*

Make a long stitch, by taking needle through centre of ring from the back, then over coil, as before, and make another knot-stitch. Continue the operation in this way until the one row is completed, then thicken foundation coil by adding a few more strands to make it  $\frac{1}{4}$  in. thick.

When the base is 6 in. across, gradually raise the coil to form the first row of the side of the basket, and make each succeeding row a trifle wider, until the sixth row gives a diameter of 8 in. to the bread basket. Carefully watch the shaping and see that the sides are well balanced.

*Fig. 3. Chart showing colour schemes.*

The border is now begun with "original weave" instead of knot-stitch. For this take the raffia round the coil and insert the needle under one of the stitches in the previous row, thus securing the loose coil to the basket. Point needle in slanting direction to left when inserting, and then proceed to make every stitch in patterned border in this manner.

The design is shown in Fig. 2. It is built up by use of the colours, row by row as shown in the chart, Fig. 3. Taper off the finishing end to a point and bind the last inch of coil to previous coil.

If the diameter has worked out at more than 8 in. or less, the design must be adapted to fit before introducing colours. A cardboard circle 8 in. across fitted now and again to the inside, as the basket is worked, helps to keep the sides to shape.

Fig. 4

Fig. 7

Fig. 5

Fig. 6

Fig. 8

Fig. 9

*Figs. 4-9. Basket or tray made in wood, in the form of a boat, with explanatory diagrams.*

The amateur can also make the wooden bread basket or boat in Fig. 4, which exhibits Norwegian influence. It is made by cutting the bottom, Fig. 5, from  $\frac{1}{2}$  in. wood, such as mahogany or oak, and the edges are bevelled as indicated. The two sides, Fig. 6, are cut from similar material not more than  $\frac{3}{32}$  in. thick, bent to shape, glued and pinned to the base, the ends being held together temporarily by strings wound round them.

The two handles are sawn to shape from a piece of material 6 in. long,  $1\frac{1}{2}$  in. wide, and 1 in. thick, as in Fig. 8. The V-groove, Fig. 7, is cut out with a chisel to fit closely on the ends of the side pieces, A, B. The horns are carved, and when completed the handles are glued and pinned in place. A cover piece, C, Fig. 7, is cut to shape and glued in position in the apex of the triangular joint at the ends. The construction is clearly indicated in the section, Fig. 9. The work is completed by sand-papering and polishing, or by stencilling in liquid washable colours.

### BREADCRUMBS: In Cookery.

Finer if rubbed through a wire sieve with the hand than if grated, fresh white crumbs are used for puddings, bread sauce, and often for crumbing fried foods, although dried crumbs will be found best for this purpose.

To prepare the latter put any fresh white crumbs that cannot be used in a baking-tin in a slow oven to dry, but not colour. Turn them over now and then, and when quite dry and crisp re-sieve them, and when cold store in a dry tin with a well-fitting lid. These will keep for years, as long as they are dry, and are used chiefly for coating foods brushed with beaten egg previous to frying.

Dried browned crumbs are often called raspings, as some bakers sell them when they have rasped over the surface of the loaves. Put any crusts left from making white crumbs, or any small stale pieces of bread, on a tin in a moderately hot oven and bake until they are a golden brown. They must not be darker. Then crush between paper with a flat iron or rolling pin or pass them through a breadcrumb crusher. The crumbs are passed through a wire sieve and stored in dry tins. Browned crumbs are needed for dusting over hams and bacon and for dishes served au gratin.

Fried breadcrumbs are served hot with roast game. Put about 3 tablespoonfuls of fresh white crumbs into a frying-pan with 1 oz. butter, and stir about until the crumbs are a golden brown. Add more butter if they seem too dry. Then drain on paper, add a light dust of salt and pepper, and serve separately on a hot plate.

**BREAD CUTTER.** For cutting bread or bread-and-butter three types of bread cutter are made. One has a rotating knife like a bacon cutter, another is fitted with guillotine or falling knife, and another with a cutter in a frame that is pushed backwards and forwards.

The first pattern is in extensive use, a typical model being illustrated. The cutter is adjustable to cut thick

or thin as required, and rotates in bearings in the frame. The bread is placed on the back of the plate or is pushed past the cutter. These machines seldom give trouble, and only require keeping perfectly clean and occasional sharpening.

*Bread Cutter with loaf from which a thin slice is being cut.*

**BREAD FRITTERS.** Use either ordinary household bread or French dinner rolls, cut into rounds. Cut 6 or 8 neatly shaped pieces of bread or rolls  $\frac{1}{4}$  in. thick. Heat  $\frac{1}{2}$  pint of milk with the thinly pared rind of half a lemon till it is well flavoured. Dissolve in this a tea-spoonful of white sugar; take out the lemon rind, and pour into the milk a well-beaten egg. Pour this mixture on to the bread, and have ready a frying-pan containing 2 oz. of butter.

Directly the bread is soft, fry the pieces a golden brown on each side in the hot butter. Lift out of the pan, drain well, sprinkle with castor sugar and serve quickly with jam sauce (q.v.)

**BREAD PAN.** An old-fashioned but reliable bread pan is made of earthenware, with an earthenware cover. Such pans have the advantage of maintaining a more equable temperature than enamelled iron bread pans. Scrupulous cleanliness is essential together with periodical removal of breadcrumbs, and the placing of the vessel in a cool, dry place.

**BREAD POULTICE.** Cut up bread, stale if possible, into small pieces and put into a bowl which has been scalded. Pour boiling water over, cover bowl with a plate and put by the fire for a minute or two. It is then beaten up with a fork, excess of water being removed by wringing the mass rapidly in a towel, and the poultice is applied between layers of muslin. If a piece of jaconet or oiled silk is applied so as to overlap the poultice all round by about  $\frac{1}{2}$  in., the heat will be retained longer. *See* Poultice.

**BREAD PUDDING.** To prepare this, soak  $\frac{1}{2}$  lb. stale bread in cold water until soft. Drain and press out water, put in a basin and mix with 3 oz. butter, marg., or chopped suet. Add 3 oz. flour, 3 oz. sugar,  $\frac{1}{4}$  lb. currants or sultanas and a little chopped peel. Beat an egg, mix with a gill of milk, and stir these in with about  $\frac{1}{3}$  teaspoonful mixed ground spice or nutmeg. This pudding can be either steamed for  $1\frac{1}{2}$  hours in a greased basin covered with buttered paper, and served hot, or baked in a greased pie-dish for about 1 hour in a moderate oven, and served either hot or cold.

**BREAD SAUCE.** To make bread sauce, which is served with chicken, etc., boil about  $\frac{1}{2}$  pint of milk with a small onion in which a few cloves have been stuck for flavouring. Add 2 oz. of soft breadcrumbs and cook gently for 15 min. It should be seasoned, a very little powdered nutmeg added if liked, then a piece of butter, and, if desired, a little cream.

**BREAKAGE.** It is illegal for a mistress to deduct anything from a servant's wages to pay for any crockery that the girl breaks when washing or dusting, unless she has expressly agreed with the girl that she will do so. If a maid breaks anything on purpose, or by gross negligence, the mistress could, no doubt, sue her in the county court for the damage done or dismiss her summarily; but beyond that she cannot go. The law regards accidental breakages as one of those incidents of domestic service that may happen without anyone being specially to blame. *See* Servant.

**BREAKFAST: How to Serve.** The British habit of eating a good breakfast encourages the housewife to make the meal as attractive and varied as possible. Many people, men especially, are most conventional in the matter of bacon and eggs; though fried tomatoes, potatoes, parsnips, bananas and mushrooms can all be served in turn with the bacon for a change.

*Breakfast. A wholesome breakfast of fruit, brown bread and butter and coffee, the attractiveness of which is enhanced by the linen cloth and gaily patterned china.*

It is convenient to provide a hot dish and a cold one, where there are several in a family. For instance, with hot fish, cold bacon or a galantine may be on the sideboard; with eggs, soused herrings, brawn or sardines. As a hot dish, uncurled whittings cooked in a fireproof dish with butter and parsley are often liked for a change, or dabs fried whole with a grilled tomato placed on top. Dried haddock is apt to be woolly unless a thick one is chosen, and well basted with milk and a lump of butter before serving; kippers are good cooked in a tin in boiling dripping and then toasted for a minute or two to crisp them. These dishes, when

served, may be on a heater on the sideboard, or sent to table in attractive oven-ware.

Eggs can be cooked in many ways, but a simple plan is to put some butter into a flat fireproof dish and, when melted, break the eggs into the dish and replace in the oven for a few minutes till set, sprinkling with a little chopped parsley to serve.

**Value of Cereal Foods.** Porridge is a valuable adjunct to the family breakfast. Many children take a dislike to this, and the reasons are usually because it is not stirred enough, and is therefore lumpy; because it is not cooked enough, or because the salt, which flavours the oatmeal, is forgotten. A change from porridge is a saucerful of one of the ready-cooked cereal foods which, served with hot or cold milk with stewed fruit or a little cream, is most nourishing. Fruit should always find a place on the breakfast table. Some people eat only toast and butter with grape-fruit or an orange, while the habit of finishing up breakfast with an apple is an excellent one for children.

Stands must be placed under hot tea or coffee pots if there is no tray or if this is of wood. For coffee a good mixture is equal quantities of Mocha and Plantation, with a very small amount of French chicory. If impossible to roast and grind the beans at home, only a small quantity of coffee should be bought at one time. A change for children is a big jug of cocoa made with milk. Should there be any sour milk left over from the day before, it does not take long to make a few soda scones, or ordinary rolls may be popped into the oven for a few moments.

A well-laid table is a great appetiser. A cheerful scheme is fruit in some quaint pottery bowl, or one of polished wood, on a coloured damask tablecloth, with jam, etc., in attractive dishes. While preserving harmony with the decorations of the room, breakfast china and table linen may introduce more colour and be more informal than those in use at other meals. Thus cottage china may be seen with check cloths, or orange pottery with unbleached linen appliqué with fruit and flowers. As a general rule the patterned service looks best with plain coloured linen edged perhaps with a border to tone.

What is known as a breakfast, service in a shop is a somewhat incomplete affair, unless several silver or other ware articles are to supplement it. It is sold for 6 or 12 persons, and usually only consists of that number of cups, saucers, and plates, a milk jug, a sugar basin, and a teapot. Breakfast dishes, toast rack, egg cups, larger plates, coffee pot, hot milk jug, cream jug, slop basin, jam and butter dishes are not included.

For those who prefer everything to match, or who do not wish to have silver articles used daily on account of the cleaning that they involve, there are a good many stock patterns, in which it is possible to buy each piece as required, including the extra articles named, together with porridge or stewed fruit plates, and grape-fruit holders. A stock pattern has the further advantage that any breakage can be replaced.

In earthenware—or as it is often called, semi-porcelain—these stock patterns are reproduced in some

of the old designs such as Chelsea, Worcester, Lowestoft, etc.; they are not expensive, and the jugs and dishes in plain old-fashioned shapes are attractive, especially if breakfast cloths and napkins are cross-stitched in colours and designs to correspond with patterns selected.

In pottery there is not so much variety, except in bright colouring, particularly suitable for country house use. In china there is a wide range of flower and conventional patterns. For the nursery amusing rhyme illustrations and animal designs in stock patterns can be obtained. These suggest delightful tablecloths to correspond. *See Appliqué; Tablecloth.*

**BREAM.** Wrap the cleaned fish in buttered paper, and bake in the oven for about ½ hour. A more elaborate way is to stuff the fish with forcemeat made of breadcrumbs, chopped suet, and anchovy paste or chopped oysters, with mace, salt and pepper as seasoning. Bind the forcemeat together with milk or beaten-up egg, and cook the stuffed fish in the oven for about 40 min., keeping it basted all the time with dripping. Bream may also be broiled. In cleaning do not remove the scales.

**BREAST:** In Cookery. This name is given to the joint of mutton, veal, or venison below the shoulder, and including the thin end of the ribs. A similar piece of beef is called the brisket (q.v.). A breast of mutton can be stuffed and boiled or roasted, and is better boned, or it is difficult to carve.

Skin and bone the breast, taking away some of the fat, then spread it about ½ in. thick with forcemeat, sage and onion, or some other stuffing, taking care that the stuffing does not come too near the edge of the meat. Roll up and tie with tape, then drop into just enough warm water to cover and simmer slowly. Skim off any scum, but keep the lid on the saucepan as much as possible. It should require 15-20 min. boiling to every lb. and 15 min. over. It is equally good served with hot carrots and turnips, or cold with salad.

To roast, bone, stuff, and roll in the same way, and put in a good oven. Baste well, and allow ½ hr. to the lb. Serve it with apple sauce. This dish is known as mock duck.

Breast of lamb can be cooked without boning. Trim and put in a stewpan with enough stock to cover. Add a bunch of herbs and an onion stuck with a few cloves, and let the whole simmer gently until the bones can easily be removed. Season the meat, brush over with egg and breadcrumbs, and hang in a broiler before a clear fire, turning it so as to brown both sides. The dish should be served hot with mint sauce.

To boil a breast of veal, cover with warm water, adding parsley and a few peppercorns. Allow 20 min. to the lb. and 20 min. over. Serve with onion or parsley sauce and boiled bacon. It can also be broiled similarly to breast of lamb, but just before serving squeeze the

juice of a lemon over it.

A breast of venison can be stewed, roasted, or broiled in a similar manner.

## BREATHING AND BREATHING EXERCISES

### How to Improve Health and Strength

This article is one of an important group that deal with the care of the body. See also *Gymnastics; Physical Training, etc.*

The process of breathing, or respiration, is one by which carbonic acid is removed from the blood, and oxygen is supplied. The carbonic acid, produced by combustion in the tissues, comes from all parts of the body, chiefly in the plasma, or blood-fluid. The oxygen combines with the haemoglobin in the red corpuscles, and is distributed to every part. Hence the necessity for maintaining the blood in a healthy condition, with abundance of red corpuscles. Breathing is controlled by the respiratory centre in the medulla oblongata, or bulb.

Inspiration is accomplished by increasing the size of the chest cavity, the diaphragm being drawn downward into the abdomen, the ribs being elevated, and the breastbone, especially at its lower end, being moved forward. For free and full inspiration it is necessary that neither the chest nor the abdomen shall be constricted by tight clothing. In ordinary expiration no muscular effort is made, the chest and lungs contracting by their own elasticity; but in forced expiration, as in coughing, sneezing, singing, etc., many muscles come into action.

The number of respirations of a healthy adult is about 14 to 18 per min., one respiration occurring to each 4 or 5 beats of the heart. During exercise and in feverish diseases, the rate of both breathing and the heart-beat is increased, and as a rule both go up and down together. In some morbid states the respirations are diminished.

The air changed in the lungs of a healthy adult at each respiration, which is called tidal air, is about 20 cu. in. By a forced inspiration 100 cu. in. more can be breathed into the lungs. This is called complementary air. After an ordinary expiration, a further 100 cu. in. of supplemental air can be expelled by means of the abdominal and chest muscles. But the lungs are never entirely emptied, and after this forced expiration, about 100 cu. in., which is called residual air, remain in the lungs.

During every 24 hours the immense quantity of 400,000 to 600,000 cu. in. of air passes into and out of the lungs in an adult person at rest. In hard work this quantity is greatly increased. Vital capacity is the quantity of air which a person breathes out by a forcible expiration after he has taken the deepest possible inspiration. This in an adult man averages 225 to 250 cu. in. Women average about three-fourths of the vital capacity of men. The vital capacity is usually measured by an instrument known as a spirometer.

**Breathing Exercises.** In such exercises the normal breathing movements are exaggerated, with the result

that more oxygen is taken into the blood, more carbon dioxide expelled in the lungs and the circulation improved. These exercises are particularly beneficial to people who lead a sedentary life. In order that the air inspired may contain plenty of oxygen, practise breathing exercises in the open air, or by an open window. No restrictive clothing should be worn to hinder the expansion of the chest or abdomen. Stand in a natural, unconstrained attitude, with the shoulders erect. Practise the exercises between others; always breathe in through the nose and keep the mouth closed until the breath is exhaled. Do not repeat each exercise more than four times in succession.

*Breathing Exercises. Fig. 1. The hands are placed on the diaphragm, pushed forwards on inspiration and drawn inwards on expiration. Fig. 2. Arms are held horizontally in front of body at the beginning of a deep inspiration. Fig. 3. They are then carried outwards and backwards, the abdominal wall is pushed out and the ribs raised.*

that more oxygen is taken into the blood, more carbon dioxide expelled in the lungs and the circulation improved. These exercises are particularly beneficial to people who lead a sedentary life. In order that the air inspired may contain plenty of oxygen, practise breathing exercises in the open air, or by an open window. No restrictive clothing should be worn to hinder the expansion of the chest or abdomen. Stand in a natural, unconstrained attitude, with the shoulders erect. Practise the exercises between others; always breathe in through the nose and keep the mouth closed until the breath is exhaled. Do not repeat each exercise more than four times in succession.

(1) Stand with hands placed one over the other on the upper part of the abdominal wall. These should be pushed forward on inspiration and drawn inwards on expiration without moving trunk (Fig. 1).

(2) Same position, but with arms by side of body. Raise arms sideways above head, the abdominal wall is pushed outwards and the ribs are raised on inspiration. On expiration, the arms are lowered to starting position, the abdominal wall is drawn inwards and the ribs descend.

(3) Standing, the arms are held horizontally in front of body and parallel to each other. On inspiration they are carried horizontally outwards and backwards, and the head is extended, the abdominal wall pushed outwards and the ribs raised. On expiration the arms and head are brought back to the starting position, the ribs descend and the abdominal wall is drawn inwards (Figs. 2 and 3).

(4) The arms are held at a slight angle from the sides of the body, on inspiration the arms are turned outwards, head extended, ribs raised and abdominal wall pushed forward. On expiration, the arms, head and ribs return to starting position and the abdominal wall is contracted. *See Chest.*

**BREATHLESSNESS.** Shortness of breath on exertion may be due to a large number of causes, e.g.

obesity, anaemia, adenoids, emphysema, organic disease of the heart, disordered action of the heart, neurasthenia, Bright's disease, the abuse of tobacco, and tight lacing. See Anaemia; Heart; Lung, etc.

**BREECHES.** Whether designed for walking or riding, sports underwear for women, or period costume, the general style of breeches is a loose thigh, a close knee, and a tight fit below the knee. The looseness above the knee should be at the sides, and never at the inside of the legs, where the garment should be clean fitting.

Walking breeches are fastened below the knees by either buttons or laces, the latter being arranged to come on the front of the leg, while the former should be just off the shin-bone, on the outer side.

Riding breeches should be very loose on the outsides of the thighs, the knees should be tight, and below the knees skin tight. Extra inside leg length is needed, to provide the necessary "arch" for sitting the horse. The materials are of heavy weight and firm texture, such as woollen or Bedford cords. Velvet cords are sometimes employed. Knee strappings may be of the same material as the breeches, but are more often of buckskin. Either leggings or top boots are worn.

**BREEZE BLOCK.** Fine cinders, crushed coke, furnace clinker, and burnt brick are used under the name of breeze in the construction of blocks for house building. When made up in the form of concrete, breeze blocks are fire-resisting, light and porous, suited for partitions and other internal walling. The surface is rough and takes plaster readily, while wooden sheetings or battens can be nailed directly to the blocks.

As a floor covering breeze blocks are laid on a damp-proof course set direct on the concrete foundation. The blocks are set in mortar, and if laid to a fair level the floorboards can be nailed directly to them. The damp-proof course may be any bituminous sheeting, or good roofing felt if set in hot pitch.

Coke breeze blocks, which are often used for exterior wallings of bungalows and other dwellings, should be built in the form of a hollow wall, with a cavity between the inner and outer skins, cross-bonding being effected with galvanised iron wall ties, or by using some of the ready-made hollow bricks.

When a limited number of blocks are wanted they can be made up on the site, by casting in wooden moulds, which need not be anything more elaborate than shallow boxes of suitable size, generally about 24 in. long, 12 in. wide and 3 in. deep. The concrete is mixed in the proportions of 1 part of Portland cement to 5 parts of coke breeze, these being measured by bulk, as in a pail, and not by weight. Only sufficient water is added to make the mass hold together; complete mixing is essential. The blocks are set to break joint. See Cement; Concrete.

**BRIBE.** It is not an unknown thing for tradesmen to pay what they call commission to domestic servants. If the mistress knows about it, and permits it, well and

good. But if she does not, the law regards every such payment as a bribe paid to the servant.

The servant may be summarily dismissed and is legally liable to disgorge everything received. An action will lie against the tradesman for damages.

Further, a criminal prosecution will lie against the tradesman and the servant. It makes no difference at all that the tradesman has only charged ordinary market prices.

## BRICKS AND BRICKLAYING

Materials and Processes Described and Illustrated

Related articles include Architecture; Building; Garage; Greenhouse; Mortar, etc. See also Drawing

Bricks are the staple material used in Great Britain for walls and general house building purposes. Good bricks are durable, but require careful selection for outside surfaces, both in regard to weather-resisting properties and artistic effect. They have a longer life and lower cost of maintenance than most other building materials; their fire-resisting qualities are good, and insurance rates for brick buildings are generally less than those for other forms of construction, timber especially. Brick buildings are easier to raise money upon, and they sell more readily.

Brickwork generally is measured by the rod of 272 ft. super, reduced to 1½ bricks in thickness. Sixteen bricks will make a wall one brick thick and 3 ft. long of 4 courses, or 1 ft. in height. A 9 in. wall would take just twice that number. When laid flat, 32 bricks will be needed to cover 1 sq. yd.; that is, an area of 9 sq. ft.; but, if laid on edge, 48 bricks would be required.

*Brick.: principal kinds.  
Top, Left, Fletton brick.  
Top middle, sand-faced red.  
Top, right, London stock.*

*Left white glazed.*

For ordinary purposes, bricks can be reckoned as measuring 9 in. long, 4½ in. wide, and 3 in. thick; they weigh on the average about 7 lb. each when dry. A brick will frequently absorb 7 to 8 oz. of water. For outside facings a good rule is to reject any brick that absorbs more water than 15 per cent, of its dry weight.

The kind of brick in most general use is known as the Fletton. It is hard and square but not of good colour, and is reputed not to last long in damp and exposed places. It is so lacking in porosity that plaster will not adhere to it, but has to hang on to the mortar joints in the brickwork. Flettons are a raw red in

colour, and are extensively employed in building walls which are faced with bricks of other kinds.

The London stock brick has quite a different character. It is soft, sandy, and porous, and able to hold plaster. From a hygienic point of view it is better suited to house building than the Fletton, because it will breathe, or allow air to pass through the walls.

The red, sand-faced, hand made facing-brick is the most highly esteemed wherever it is obtainable. It is made chiefly in the southern and eastern counties. In the north, west, and Midland the pressed red brick of even shape and smooth surface is used for facing. Staffordshire blue bricks are in demand for foundation work, or any purpose where the maximum resistance to damp is of importance.

Glazed bricks with a white or coloured surface are made of fireclay and glazed in the same way as pottery. They are used for halls and bathrooms and in courtyards for external facing where light is lacking.

On the top edges of garden walls and parapets or gables of houses coping bricks are used, specially shaped to throw off water and protect the brickwork under them. Splay bricks and others with mouldings on one edge or one end are used to form plinths, strings, cornices, or window-sills on the external faces of buildings.

**Amateur Bricklaying.** (For illustrations see page 266). Although brick-laying is a skilled trade, simple work is quite within the capacity of the amateur. For most work, a 9 in. wall suffices; in fact, for small erections, such as the lower part of a greenhouse, a 4½ in. wall will be quite serviceable. Nothing should be attempted above 8 ft. in height, because the matter of scaffolding for higher buildings involves operations in which experience is essential.

A brick wall must have a solid and level foundation to rest upon. After marking out the ground, a trench, must be dug, in which to pour the concrete for the foundation. Upon this foundation are laid the brick footings, consisting of two courses or rows of bricks. The foundation concrete should be wider than the lowest course of footings, and for a single storey building may be 2 ft. wide and not less than 6 in. thick. This allows for two courses of footings built with bricks, and as these should be buried below ground-level, the bed of the concrete must be not less than 1 ft. 3 in. deep. Before digging out the ground, stakes should be driven in to define the corners and angles of the trenches, both inside and outside, and, in addition, lines or cords should be stretched tightly between the stakes so as to act as guides.

The ground should be dug out correctly to these lines, and pegs should be driven in along the middle of the trenches so that the tops of the pegs are all at the correct level for the finished concrete bed, acting as a guide when filling. If the earth shows signs of falling in at the sides, keep it in place with rough boards set vertically on edge and secured with short stakes or pegs. Make the bottom of the trench hard and firm. Prepare a convenient part of the ground on which to mix the concrete, and then shovel it into the trench,

ramming it down with a rammer, and taking care to test the surface to ensure that it is level both across the trench and lengthways. A spirit-level on a straight batten of wood, at least 6 ft. in length, is required in order to get the foundation concrete level. The pegs previously inserted should be accurately levelled by commencing from one corner and adjusting the other pegs accordingly until all are level. While the concrete is setting, the mortar—if lime is used—should be prepared.

### First Stage in Building a Wall.

Next set lines along the sides of the work to lay the bottom course of footings by, 9 in. from the centre line of the wall to be built. Put the lines on the outside and work from the inside. Spread a bed of mortar 18 in. wide in such quantity that when pressed down it will make a joint about ½ in. thick. Then bed down the bricks in two rows of headers (Fig. 1). As the bedding proceeds the excess mortar that squeezes out at the sides should be picked up with the trowel and thrown on the bricks already bedded. Lay the first course thus all round the foundation and flush it up with mortar as the work proceeds, to fill the joints. This and the next course may be laid without putting any mortar on the bricks to form vertical joints.

Proceed similarly with the next course of footings, joining as shown in Fig. 2. The course will be 13½ in. wide, 6¾ in. each side of the centre of the wall. Flush up with mortar as before; that is, fill all joints with mortar.

On these two footing courses, which require only ordinary care in laying, begins the brickwork proper. Stretch two lines at right angles as before, 4½ in. outside the centre lines of the walls, and work now on the outside. The first operation is to build up 4 courses of bricks at the intersection of the two lines, to form the angle, and a similar quantity at the other end of the piece of wall to be now built. Fig. 3 shows the first course in plan, and Figs. 4 and 5 show the angle in elevation. These corner or end pieces must be plumbed up on both faces with the plumb rule in order to ensure the wall being upright.

This done, the line is stretched from corner to corner at the level of the top edge of the first course, forming a true line to work to when laying this course. The course being finished, the line is removed to a similar position on the second course, and so on till four courses are built (Fig. 6). The operations are then repeated for another four courses. First the corners are taken up, filled and plumbed, then the work filled in course by course between.

**Brickwork in the Garden.** (For illustrations see page 264). Apart from wall use, bricks are effective in place of paving for small gardens and courts, cottage approach paths, and steps; also for edging lily ponds, for floors in summer-houses, piers for pergolas and path-designing in sunk rose gardens.

In formal town gardens the rich warmth of red

bricks economises labour, as it intensifies the colour value of flowers arranged in small, neat bedding sections, or in stone vases, and does away with gravel or grass. The contrast of stone or metal ornaments adds to beauty all the year round, and evergreen shrubs seem brighter against brick-work.

For pergola piers, antique facing-bricks or thin rustics may be used either in yellowish or reddish purple colours. A grey or fawn mortar joint should be chosen, as white spoils the effect. As the piers are small they should be built in cement and sand and with cross joints. For paths and practical steps, harder paving bricks can be obtained; while for small surfaces, 6 in. fireplace bricks may look more suitable instead of those of the standard 9 in. length. When making dry walls, or wide steps for a rock garden to be partially covered with outcropping plants, ordinary bricks can be used. Overburnt (burr wall) bricks may be chosen to add to the pleasing irregularity of the colour scheme and diminish cost of material by more than half for retaining walls where mortar joints are used. The surface for paths should be even and laid on an ash foundation, which admits of quick drainage after rain. The bricks may be laid flat and lengthwise as in stretcher courses of masonry.

Round a sundial, or other central ornament, bricks may be laid without mortar, so that moss or little rock plants can grow through the crevices. A wide terrace or kitchen garden path may have the middle of paving bricks or stones and the sides of bricks laid without mortar. This treatment is suitable for the latter path when flowers are grown on either side and it continues a decorative effect from the house or flower garden to an alcove or ornamental corner where brick-work is again employed.

*Brickwork: its use in the garden. Brick steps arranged in expanding semicircles lead to a brick-built seat.*

*How bricks may be used for paths and other purposes.*

*Small brick courtyard laid at three different levels.*

*Close-up of simple low dry wall, with its outcroppings of rock plants*

*How to build pergola piers of thin rustic bricks; careful plumbing course by course is important to ensure a truly vertical pier.*

*General effect in a garden: both the dry wall and the piers of the pergolas are made of brick. Notice how the brickwork is combined with paving stones on steps and path.*

Before beginning to lay out any scheme, a plan should be carefully drawn to scale of the proposed brick-work. See Garden.

The bond illustrated is English bond, the easiest to build and the strongest when built. (Diagrams showing the chief types of bond are given below.) Observe carefully the arrangement of bricks in the illustrations, noting the positions of headers and closers. The vertical joints, called in the trade perpend, must be correctly, that is vertically, over one another the whole height of the wall.

Brick. Fig. 8. Kinds of bond in general use. A and B. English bond. C and D. Flemish bond. E. garden wall bond. F. stretching bond.

The damp course in amateur work is best composed

of a double course of slates or ordinary tarred roofing felt in long strips 9 in. wide, bedded in mortar and with mortar on it to receive and bed the course above it. The damp course should be at least 6 in. above the level of surrounding ground and below the lowest woodwork, the purpose being to prevent dampness rising from the ground, as slates are impervious to moisture.

The amateur can supplement the information given here and confirm it by watching a bricklayer at work. The mortar can be thrown on and the bricks set in place very quickly, striking them on the top with the handle of the trowel to level them. Special care must be taken before bedding each brick to apply a pat of mortar to the end or side to form the vertical joint, and also to flush up each course with mortar to fill up the whole of the internal joint.

The simplest way of finishing the external mortar joints between the bricks is by striking them as the work proceeds. This is done simply by cutting off the excess of mortar that squeezes out when the bricks are bedded, using the trowel as a knife placed flat on the face of the work, thus pressing the mortar with the trowel along the upper edge of the joint, until it is very slightly below the surface of the upper brick and flush with the face of the lower brick. For the inside surface of the wall a flush joint is better and is made by pressing the exuding wet mortar with the trowel, and making it flat or flush with the wall. The edges should be neatly trimmed off with a trowel, guided by a straight edge. A pointing trowel is best for amateur use on this work, being smaller and lighter than the ordinary bricklayer's trowel. When the mortar has set for an hour or so the wall can if necessary be washed down with clean water and a hard brush, to remove any surplus mortar from the face of the bricks and leave them clean and bright.

Vertical work next to a door-frame or a window must be jointed and bonded in the same way as shown for the corner of the wall. Figs. 6 and 7 show the bonding for left and right hand verticals respectively. Openings should be placed so that brick dimensions can be adhered to in the brickwork, i.e. a stretch of wall should be multiples either of  $4\frac{1}{2}$  in. or 9 in. in length. This avoids cutting of bricks. Joints should not be less than  $\frac{3}{8}$  in. in thickness.

Bricks have to be cut to act as closers and for other purposes. This is done as follows (Fig. 9): Mark a line on the brick where it has to be cut, then press a bricklayer's bolster or chisel on the line and strike it a light blow. Repeat the operation on other sides, then lay the brick on a smooth, firm surface and strike the bolster a firm, hard blow, thus cutting the brick. See Cement; Concrete.

**BRIDE.** It is usual for a bride to wear a white wedding dress, though a coloured one is occasionally chosen, and many brides are married in the clothes in which they are going away. A widow who re-marries does not wear white. It is said that the bridal dress should include:

Something old, and something new;  
Something borrowed and something blue.

The veil may fulfil two of the requirements, for brides often borrow an old and beautiful lace veil. This can be arranged under a wreath of orange blossom, or of orange blossom and myrtle. Jewelry is not usually worn by the bride except the bridegroom's gift. No rings are worn on the occasion before the ceremony. If she carries a bouquet that also is his gift.

The bride walks up the church on the arm of her father, or whoever is to give her away, and at the chancel steps the bridegroom awaits her. She takes her place on his left, the veil over her face, and when the ceremony is ended she goes out to the vestry on his left arm. In the vestry she signs her maiden name, and comes down the church on her husband's right arm with her veil thrown back. *See* Marriage; Wedding.

**BRIDEGROOM.** With the assistance of his best man the bridegroom makes the arrangements for the wedding, as far as the church or place where it is held is concerned, and pays the expenses incurred there. He must be ready to receive the bride on arrival, and is responsible for the arrangements for leaving the church and departure for the honeymoon. *See* Best Man.

**BRIDESMAID.** For a very quiet wedding bridesmaids may be limited to two or dispensed with altogether; but if it is to be a Society function the number may vary from four to twelve. In this case the bride will see that the bridegroom's relatives are duly represented.

No tactful bride will allow her bridesmaids to wear colours that do not suit them or to be involved in expense beyond their means, and in planning the dresses she will bear this in mind. It is customary for the bridegroom to make a present to each bridesmaid, and if bouquets are carried he provides these too.

On the wedding day the bridesmaids arrive first at the church and await the coming of the bride. Upon her arrival they follow her up the church and stand behind her throughout the ceremony. The principal bridesmaid takes the bride's gloves, bouquet or prayer-book, and holds them until the service is over. The head bridesmaid follows bride and bridegroom into the vestry, and generally signs the register. Finally, the bridesmaids leave the church behind the newly wedded pair.

## BRIDGE: CONTRACT AND AUCTION

### The Modern Contract Game: Auction and Some Variants

The ancestor of both these games is whist. The first form of bridge differed from whist in its play by having

a hand exposed on the table and by the introduction of no trumps. Other main differences are in:

1. Scoring—including penalties for breach of contract.
2. The manner in which the trump suit is decided.

In the early days of auction the dealer had the right of naming the trump suit or to leave the decision to his partner. Auction bridge, as its name implies, extended this decision to all four players, and the value of the tricks in the different suits also underwent a change. The present game of auction bridge, formerly known as royal auction bridge, dates officially from 1914, in which year the English laws were revised.

Though contract bridge owns the same ancestor it is more correct to say that it is a direct offspring of Plafond, rather than of auction bridge. It came to this country in 1928 by way of France (where Plafond was played) from America, though an Englishman claims to have introduced it as early as 1920. Though the old game of bridge is dead, auction bridge still survives in spite of the popularity of contract.

The following principles apply to both games:

The requisites are two packs of cards of different colours, and a score sheet for each player. The four players cut for partners, choice of seats, and for the deal. The drawers of the two highest cards are partners against the drawers of the two lowest cards, while the drawer of the highest card has the choice of seats and cards. In cutting, the ace ranks as the highest card in any suit, and cards of equal rank take precedence in the order spades, hearts, diamonds, clubs; e.g., the three of spades is a higher card than the three of any other suit.

Partners sit on opposite sides of the table. This is shown in the diagram below, A and B being partners against Y and Z:

These positions are sometimes designated as East and West, North and South.

Assuming that Y or North is the dealer, B shuffles the cards chosen and Y passes them to A to cut. This he does by taking off a portion from the top and placing it towards the dealer beside the bottom portion, which must contain at least four cards. Each player may shuffle once, and the dealer shuffles last. Z shuffles the other pack and places it on his right.

After the cards are dealt in the usual way each player looks at his cards and, starting with the dealer, calls in clockwise rotation. If any player wishes to pass he says "No bid." If, in the first round of the auction, the four players say "No bid," the hand is thrown in and the next player, B, deals with the other pack.

Otherwise the auction continues until the bid, double or redouble made by one player, has been passed by the other three.

**Scoring.** The object is to score sufficient points by tricks to make a game. The side which wins two games out of three wins the rubber, for which extra points are scored. Points are also scored for honours and penalties. (Ace, king, queen, jack and 10 in each suit are honours.)

The score sheet or scoring block is marked with a horizontal line and all points for honours, penalties and bonuses are scored above this line. Points for tricks are scored below the line and only these count towards the game. The final bid in the auction becomes the contract, and, if a suit is named, that suit becomes the trump suit, and the hand is played by the player on the contracting side who first made a bid in that suit; he is named the "declarer."

If the declarer fails to make his contract his side scores nothing for the tricks won by him and the opponents score, in respect of each under trick, so many points above the line. The opponents can never score below the line.

A trick consists of four cards, one from each player, and the highest card of the suit led takes the trick unless it is trumped. There are 13 tricks in a hand. Making seven tricks is equivalent to making one odd trick. A player who bids one, two or three diamonds (say) contracts to make 7, 8 or 9 tricks in all. If a player makes 6 odd tricks—i.e. 12 tricks in all—it is called a "little slam" and a "grand slam" if he makes all 13 tricks.

The first lead is made by the player sitting on the left of the declarer, and the partner of the declarer puts his cards face upwards on the table immediately the card is led and is known during the play of the hand as "dummy." The player who takes the trick leads to the next trick.

As regards the auction, each successive call, other than "no bid," must be higher than the last preceding one, but the values are different in auction and contract. A double does not alter the value of the call in the auction but affects the scoring of tricks and penalties. A player may not double his partner's bid. It is usual to designate spades and hearts as "major" suits, and diamonds and clubs as "minor" suits.

**Features of Auction.** The similar features of the two games having been dealt with, the differences must be examined. For the sake of clarity these are not contrasted side by side, but auction bridge is taken first.

Suits rank as follows: Clubs, Diamonds, Hearts, Spades, with respective trick values 6, 7, 8, 9 and, if there are no trumps, 10 points.

These points are doubled in the case of a doubled contract, or quadrupled in the case of a redoubled contract.

If the declarer fulfils a doubled contract his side scores a bonus of 50 points, and 50 points for each over trick. These points are doubled in the case of a

redoubled contract.

If the declarer fails to fulfil his contract his side scores nothing for the tricks won by him, and the opponents score, in respect of each under-trick, 50 points, doubled in the case of a doubled contract and quadrupled in the case of a redoubled contract.

The bonus for a little slam is 50 points, and for a big or grand slam, 100 points.

A game consists of 30 points which, of course, can be made in one hand or by degrees in two or more hands. When one side scores a game a horizontal line is ruled underneath, so that any points scored by the opponents cannot count towards the next game.

The side which first scores two games wins the rubber and obtains a bonus of 250 points. The totals of both sides are then added, and settlement is made on the difference.

For scoring of honours see rule 33.

The value given above to each trump suit decides to a certain extent the course of the auction or the succession of legal bids.

The value of a bid is determined by the trick values obtaining to a bid of its denomination, e.g., Y declares 1 heart, B 1 spade, Z 2 clubs and Y can then bid 2 no trumps, value 20 points. Then Z, if he wishes to make an overcall in clubs, will have to call 4 clubs (24 points) not 3 (18 points). (Majority calling, whereby 3 clubs overcalled 2 no trumps, was played for a short time only.) Three clubs, however, will overcall 2 spades though both have an 18-point value.

### Principles of Bidding and Play

The aim of a bid is to discover the best combination in which the hands can be played to the advantage of any one side. The old principles of auction bidding have entirely changed (except, perhaps, in the case of a few die-hard camps) by the introduction of contract for, even if some auction players refuse to play contract, they have watched it and taken to themselves some of the principles of contract bidding.

It is impossible in a short space to deal thoroughly with the question of bidding and play in both auction and contract, but the main principles are given below under contract which auction players should read.

Many books, perhaps too many, have been written on the principles of play and bidding at both games but it is strongly urged that the best way for beginners to learn and players to improve is by watching four good players.

The latest laws of auction bridge were published in 1932, and they are styled International in that they were brought out by the Portland Club, the Whist Club of New York and the Commission Française du Bridge. Every player should read these laws.

### Contract Bridge, the Modern Indoor Game

So popular has this game become that it is true to say that as Lawn Tennis has become *the* outdoor game of the nation, so Contract has become the indoor game. Leagues and other bodies have been formed and even

County associations. Matches are played internationally and many tournaments and congresses are held in this country. This is mainly due to the inherent qualities of the game which provides infinite possibilities in the exercise of skill both in bidding and in play, and which gives the opponents of the declarer so much more interest in defence against a contract, but it is also due in some measure to Mr. Ely Culbertson, who made it possible for thousands of people to become reasonably good players by introducing a system which gave them a logical and scientific method of hand valuation. Even Mr. Culbertson's fiercest critics will admit this. Whether he was the inventor or merely collated the opinions of others does not affect the question.

Where contract branches off from auction (the scoring is based on the same principles but the details differ) is that the contracting side cannot score more points towards game, i.e. below the line, than they have contracted to make. For instance, if Y Z contract to get 3 odd tricks in spades, and get 4 or 5 or a little or grand slam, they merely score the points attaching to 3 odd tricks below the line, the over tricks being scored above the line. Further, no slam bonus is given unless a slam is called. It will be seen how much more interest this gives to both the contractors and the defending side, for, since the former have usually called up to the limit of their strength, any mistake in the play of the declarer is punished and a good defence is at a premium.

A further difference is the vulnerability of a side. Either side which wins a game of a rubber is what is known as vulnerable, and the penalties for the non-fulfilment of a contract are tremendously increased. This adds piquancy to the game, for the non-vulnerable side can by overcalling, which entails only comparatively light penalties, push the vulnerable side into a contract which entails heavy penalties in the event of failure.

It often pays the non-vulnerable side to go down 4 or 5 tricks to prevent the other side from scoring a certain slam, and this will be apparent from the table of penalties.

**Scoring in Contract.** The trick values at contract are as follows:

When Clubs or Diamonds are trumps

20 points per odd trick

When Hearts or Spades are trumps

30 points per odd trick

When there are no trumps 40 points for first trick, and 30 for each subsequent trick.

In doubled contracts, odd trick points are doubled, and quadrupled in redoubled contracts. Vulnerability does not affect points for odd tricks. 100 points constitute a game.

Premium points for under tricks and over tricks and bonuses for honours and slams will be found in law 39.

**Quick Tricks and Defensive Honour Tricks.**

**Playing or Probable Tricks.** The former have long been recognised, the others, with the introduction of contract. Quick tricks are any ace, any K Q of a suit. The standard table of defensive honour tricks (H.T.) is as follows:

2 Honour Tricks	A K of any suit.
1½ Honour Tricks	A Q K Q J of any suit.
1 Honour Trick	Ace, K Q, K J 10 of any suit, Kx & Qx of different suits.
½ Honour Trick	Kx, Q Jx of any suit in Qx & Qx of different suits,
and certain plus values like King alone or Qx.	

N.B.—A king in your partner's suit counts 1 H.T. and a Queen ½ H.T.

It will be found that in all four hands of a deal there are from 8 to 8½ honour tricks. The number of honour tricks in a hand measures the defensive strength of a hand e.g., a hand with 2½ H.T. will make 2 or 3 tricks in defence, whereas the attacking strength of a hand is measured in probable or playing tricks as follows:

Count H.Ts. first—each worth one playing trick.  
Trump suit: for every card more than three: 1 trick  
Side suit: for every card more than three: ½ trick  
To take an example of a hand:

S. A Q xxx. — H. K J xx — D. Q xx — C.A	
Honour Tricks	3½ playing tricks
Long Trumps	2 playing tricks
Long Side Suits	½ playing trick
Total	6 playing tricks

Don't count any possible ruffing tricks—full value has been given for the long trumps. This valuation is based on normal or average distribution. The course of the bidding generally shows the distribution.

The valuation of a hand in a partner's suit is slightly different, for now ruffing tricks are counted.

Honour tricks: so many playing tricks

Long trumps ½ each

Long side suit ½ each

Ruffing tricks So many according to the following table

	With 4 or more trumps	With only 3 trumps
For doubleton	1 trick	½ trick
singleton	2 tricks	1 trick
void	3 tricks	2 tricks

**Systems.** The approach-forcing system (sometimes misnamed the Forcing-two) is perhaps the most played, and the honour trick table above and the bidding principles below belong to that system.

**Bidding Principles.** Remember that at contract each successive bid must name either a greater number of odd tricks than the last preceding bid or an equal number of a higher denomination.

The requirements for an opening bid of one of a suit are:

- (1) at least 2½ honour tricks
- (2) at least 4 playing tricks
- (3) a biddable suit.

As regards (3), biddable suits are:

- (a) a four-card suit headed by a Q J, or better
- (b) a five-card suit headed by a K or R 10
- (c) a six-card suit headed by a Knave, or better
- (d) any seven-card suit.

The requirement for an opening bid of one no trump is now 3½—5 honour tricks with all suits nearly guarded.

It is impossible to go into details of bidding, but with the above valuations it will not be difficult to follow some general reflections.

Original bids of three of a major suit or four of a minor are strong bids showing strong and long trumps with at least 3½ honour tricks. Four of a major or five of a minor suit are pre-emptive bids on weak hands in defence but with 8 or 9 in the suit.

**Responses to Partner's Opening Call of One of a Suit.** If possible, keep the bidding open; call one no trump with even 1 H.T. Don't put him up in his suit unless you have at least Q and two others or four little ones. Even if you can put him up, call a biddable suit of your own before doing so provided you have 1½ to a honour tricks. He will continue the bidding because a positive, i.e. change of suit, is forcing for one round, and on the next round you can raise him in his suit. If, however, your hand is useless except in his suit, raise him even without any honour tricks, e.g., your partner goes one heart, raise him to four on: S.- H. Q xxxxx, D. Q Jxx, C. x x x. If you have a very strong hand make what is known as a forcing bid, i.e. go one more trick either in his suit or in your own suit than necessary to overcall, or go two no trumps if you have a level distribution with three suits guarded. If on the other hand you have a hand which is quite useless in his suit but very useful in your own suit make a double jump bid, i.e. one diamond; three hearts.

A forcing bid is so called because it compels you and your partner to continue calling until a game bid is reached.

To force in a suit you want from 3 to 3½ honour tricks. The opener can also force by opening with two of a suit. This means that he has practically a game in his own hand.

Response to bids of more than one of a suit follow naturally from meaning of original bids.

**Doubling.** A double can be either (1) informative whereby you ask your partner to call his longest suit; (2) for penalties when you wish to penalise your opponents in their call. To differentiate between these

two:

- (a) A double of one or two of a suit or of one no trump is informative provided your partner has not called. If he has called the double is for penalties.
- (b) The doubles of all higher bids are for penalties.

**Hints on Play.** (1) *Play of the Declarer.* The Declarer can see 26 cards and after the first lead he should map out his plan of campaign. When there are trumps he must decide, according to the distribution in the two hands, whether to get out his opponent's trumps, or first utilise dummy's trumps by ruffing or whether it will pay to cross-ruff.

He should count up all certain tricks and see where others may be made, or, put in another way, how he can "eat his losers."

He must never try for overtricks, if, by so doing, he is endangering his contract.

In no trumps he must try to establish a long suit before his opponents do.

*Play of Defending Side.* Everyone should master the orthodox table of original leads which can be found in any books on Bridge. They are based on sound principles and common sense.

Generally against a no-trumps call:

1. Lead the highest of a sequence whether major or minor.
2. Lead the highest of touching honours when holding three honours.
3. Lead the fourth highest card when holding fewer than three honours.

With seven cards in a suit, headed by A K or K Q, lead A or K respectively.

Against a suit call (1) and (2) still hold, but the first part of three does not since one's object is to make tricks quickly. Therefore from K Q x x, lead King and from A x x x lead Ace.

If some other lead is possible do not lead from a tenace or from a king or a queen unless, in a no-trump declaration, you wish to establish a long suit.

(A tenace may be described as a sequence of three cards with the middle one missing, e.g., A Q or K J or Q 10. A Q 10 is a double tenace.)

The lead of the fourth highest is based on the eleven rule, which is as follows:

Subtract the number of pips on the card led from eleven and this gives you the number of cards higher than the one led in the other three hands. Since you see two hands you know how many the declarer has.

After dummy is exposed, his cards and the information your partner may be able to give you by suitable leads and discards will determine your subsequent play.

Endeavour to prevent a long suit in dummy becoming established, sometimes by holding up a high card and sometimes by taking out a card of entry.

If you want your partner to continue a suit, play a high card—a six or higher—and if you have the opportunity a lower one later. Further, if you have to

discard on any suit to which you cannot follow, throw a high one of the suit you want your partner to lead.

The international laws were revised in 1935.

### Duplicate Bridge

Rubbers are not usually played in Duplicate Bridge. Each hand is a separate unit at a stated score but with no partial score. The first four hands are played at the following scores (1) love all, (2) Z Y game, (3) A B game, (4) game all. In each subsequent group of four the order is varied so as to give each player an original bid at each of the scores. This can be done in 16 hands or in 4 groups of 4 hands.

Duplicate boards can be obtained in sets of 16, on which the varying scores are marked, but these are not necessary. They contain pockets for the 4 hands of 13 cards each. A match is played generally between teams of 4. Two members of one team occupy the positions of A and B at one table and the other two those of Z and Y at the second table, which should preferably be in another room. The opposing team takes the other places.

Each hand is played at both tables. This is done by each player playing his cards in front of him (not into the centre of the table) and turning them over when a trick is completed. At the end of the hand all players collect their own cards and put them back in the boards or in envelopes provided for the purpose marked A, B, Y and Z, and the complete hand goes into the other room.

The play and scoring are exactly like Contract except that for a non-vulnerable game 300 points are added and for a vulnerable game 500 points. Auction scoring can be used, in which case the game points are respectively 125 points and 250 points.

### Bridge for Three

Three-handed auction, otherwise known as cut-throat or skip, is played by three players, all against all. The simplest method is for the three players to sit on three sides of the table, leaving the fourth seat vacant, and to keep their seats throughout the rubber. The cards of dummy are then dealt to the vacant seat.

The final declarer of the highest bid plays dummy's and his own hand, and shifts dummy's cards to a convenient position facing him.

**Variation in Scoring.** Since there are no complete laws for this game, it is advisable to play it under auction laws with the following variation in scoring *if desired*.

Each player scores the trick value of the suit of each honour he holds up to three honours. (Four or five or four aces in one hand score the same as at auction.)

One hundred points are scored by each player for every game he wins, and the winner of the rubber adds a further 250 points to his score. At the conclusion of the rubber (if four games or two if both won by the same player) the total scores obtained by each player are added up separately, and each player wins from, or loses to, each other player the difference between his score and that of the said other player.

A variation of this game is also played. The dealer takes out the first or last 4 cards of the pack when cut and places them face downwards in the centre of the table. He then deals the remaining 48 cards in the usual way. The hand opposite the dealer is then turned up and becomes the dummy of the final declarer. The final declarer takes the 4 cards into his own hand and gives, from these 16 cards, one to dummy and one to each of his opponents, the last 2 face downwards.

This variation does away with the gambling for dummy while the distribution of the three cards calls for great skill.

### Bridge for Two

There are four variations for two players: Double dummy, draw auction, draw bridge and blind auction.

Draw auction and blind auction have little in common with auction bridge, while draw bridge is an improved form of double dummy. Blind auction, however, is very useful for training card memory, and for this reason deserves a description.

**Draw Bridge.** This is played by the use of two card racks. These ingenious devices, obtained from most stores, enable each player to conceal his dummy's cards from his adversary. The players sit at adjoining sides of the table with the racks in front of them at a convenient angle. The cards are dealt into four hands. Before the bidding begins each player picks up the hand opposite to him and places the cards in his rack. Bidding, playing and scoring are as at auction.

The game is more interesting than ordinary double dummy, because, although each player knows his opponent's 26 cards, he does not know how they are distributed.

**Blind Auction.** Thirteen cards are dealt to each of the two players, the remaining half of the pack being placed face downwards. The dealer makes the first call, which his opponent can overcall or double, just as at auction. Neither player knows what the other has got, as there are 26 cards unaccounted for, and anything may happen. The strangest bids may succeed. But after this first hand has been played, the remaining 26 cards are dealt, 13 to each player. The dealer bids first, as before, and the bidding and scoring are as in auction.

A good player with a card memory will know every card that is in his opponent's hand from the cards that were played on the first round.

Contract scoring can be used in all these variations.

A variation of contract introduced from Vienna in 1938 is 5-suit contract. The pack is increased to 65 with a new suit called Royals. The odd card has the special power of a joker. Hazards and freak hands are greatly multiplied.

**BRIDGE PARTY: How to Give.** Many hostesses find that a bridge party given every two or three weeks is a means of discharging social obligations. The invitations may be by telephone or by informal letter.

For an afternoon party the hours are from 3 to 6.30. For the evening, from 8.30 to 11.30. If guests are asked a quarter of an hour before play begins, coffee—and liqueurs if liked—may be served, and there is less danger of play being held up by late arrivals.

The hostess should make up her tables so that the various players are suitably arranged; really good players together, and those whose play is of an inferior calibre placed at tables together also. If there are only two or three tables and all the players are equally matched, the hostess may ask her guests to arrange tables and partners by cutting before the game begins.

Folding card-tables can be bought so reasonably that the household may be equipped with one or two. The most useful tables, 30 in. by 30 in., accommodate ash trays, and some have racks for ash trays and glasses.

*Bridge Party. Card table covered with black moiré and equipped with glass and ash tray racks. The scoring pads and ornamental pencils are pleasant.*

Removable covers for green baize tops are easily made in furnishing velvet or moire, trimmed at the edge with tinsel galon, or the tables can be permanently covered with black moire, as shown in the one illustrated. Two clean packs of cards must be allowed for each table, and also four scoring pads and pencils.

There is usually an adjournment for tea or light refreshments during the afternoon or evening. At a small party such refreshments may be prepared on a side table. Otherwise they are served in the dining-room, and the guests at each table go at the conclusion of the rubber, after the hostess has in general invited them to do so. Any variety of sandwich, made with brown bread and butter, or white, or with bridge rolls, small cakes and fruit salad in glasses, may be served with suitable drinks either for the afternoon or evening party. *See At Home; Sandwich.*

**BRIGHT'S DISEASE.** Nephritis or Bright's Disease is the name given to inflammation of the kidneys, which may be acute or chronic. The principal causes are exposure to cold and wet, especially after alcoholic excess, poisons of fevers, e.g. scarlatina or tonsillitis, or irritant poisons like carbolic acid, can-

tharides or turpentine. Acute nephritis may follow a large burn.

The acute form of the disease is always serious, because it causes accumulation of poisonous material in the system through the kidney being thrown out of action more or less. The chief signs may be headache and vomiting, or there may be drowsiness and convulsions, followed by unconsciousness. This condition is known as uraemia. Sudden dropsy of the lungs with great difficulty in breathing and a copious expectoration may occur at any time, and the doctor should be sent for at once.

During the attack milk should be the only food taken. A hot moist pack should be tried. He may remain in the pack from 15 to 20 min. Convulsions in children would be treated with a warm bath.

In chronic Bright's Disease two main varieties occur, the large white kidney and the small red kidney. Take regular easy outdoor exercise, avoiding over-fatigue. Keep to a simple, nourishing, largely vegetarian diet, be moderate with tea and coffee, and give up alcohol in every shape and form. The bowels and the skin must be kept active. Two or four grains of cascara at night, or a teaspoonful of Epsom salts before breakfast, may be taken. To keep the skin active, a daily bath at the temperature of 80° to 90° should be taken, followed by a brisk rub down with a rough towel. Plenty of plain water, mineral water, or weak lemonade should be drunk between meals to keep the kidneys well flushed out. *See Kidney.*

**BRILL: Ways of Cooking.** Steamed brill contains more flavour and nutriment than boiled. Wash, dry, and trim 1 lb. or more of cut brill. Rub over with a little lemon juice, and lay it in a steamer, covering it with a piece of greased paper. Heat the water under the steamer, and boil steadily for about 30 min., or until a knife can be easily slipped along between the bone and the flesh. Lift out carefully and place on a warmed fish-napkin, or fish-drainer, on a hot dish. Garnish with slices of lemon and serve with a tureen of fish sauce. One pound of brill is sufficient for 4 persons.

*Brill, a table fish resembling the turbot.*

Grilled brill is easily prepared. Fillet it, saving bones, etc., for fish-stock. Warm 1 oz. butter, and brush over the fillets and season them. Heat and grease the gridiron, lay on the fish, and grill for 10-12 min., or until slightly browned. Place on a hot dish, with a little

butter robbed over each piece, and a dust of pepper. Serve with parsley, anchovy, or lobster sauce. *See Fish; Sauce.*

**BRINE BATH.** By using the Droitwich or other salts in the proportion of 10 lb. to 30 gallons of water, brine baths can be prepared at home. They are useful in sciatica, lumbago, and chronic rheumatism. The bath should be maintained at blood temperature (98°). The patient should stay in it for 15 to 30 min., then be quickly dried and put to bed. *See Bathing.*

**BRIOCHE:** A Fancy Bread. For this yeast cake, put  $\frac{1}{4}$  lb. flour on a board, making a well in the centre. In the well dissolve  $\frac{1}{2}$  oz. yeast in a little tepid water, and then enough water to mix the whole into a soft paste. Knead well, form into a ball and slash the sides with a knife. Leave in a warm place to set the sponge.

Now take  $\frac{3}{4}$  lb. flour, and into a well in the centre put a level teaspoonful of salt and sugar and a teaspoonful of water. When dissolved add 4 oz. butter (melted) and 3 beaten eggs. Mix and knead well. The sponge should now have risen to three times its size. Spread it out on the paste and knead them together until full of air bubbles. Form into a cottage loaf, or into small twists and rings, brush with egg, and bake in a moderate oven on a baking sheet. Currants, candied fruits, etc., may be added if desired. *See Bread.*

**BRIQUETTE.** Coal dust, with a binding material such as clay, tar, resin or sawdust, made into briquettes or blocks of fuel. Coal-tar, pitch and ordinary coal tar are most generally used, but satisfactory briquettes have been made with clay. Resin is expensive as a binding agent and, like sawdust, is too inflammable. The blocks are made either by heating the pitch and coal dust together or by mixing the coal dust with tar without heat.

**BRISKET:** A Cut of Beef. For an appetising method of stewing brisket or breast of beef use this recipe: Rub vinegar and salt over 4 or 5 lb. fresh brisket and leave for 2 hours before dressing. Cover with stock in a small stewpan and skim well after bringing to the boil. Simmer slowly for  $\frac{3}{4}$  hour, and then add a carrot, half a turnip, 2 strips celery, 1 $\frac{1}{2}$  onions, 8 peppercorns, a few sprigs parsley and thyme, and seasoning to taste. Continue cooking slowly for 2 hours.

When just done, heat 1 oz. butter in a saucepan, with 1 tablespoonful flour, and cook until the mixture becomes golden-brown in colour, stirring frequently. Take out meat and remove bones, then strain stock, and add sufficient water to make up  $\frac{3}{4}$  pint. Pour this into pan containing the butter and flour, stir it until the mixture reaches boiling point, boil for 2 or 3 min., and season with salt and pepper. Serve as a sauce separately, but garnish the meat with the vegetables. *See Beef.*

**BRITANNIA METAL.** In the manufacture of

tea and coffee pots, dish-covers, spoons, etc., Britannia metal is largely employed, being silvery white with a bluish tinge. It may be electro-plated with silver, but being, when of good quality, a hard alloy and capable of taking a high polish, it is often used in its own natural condition.

Britannia metal articles must not be left—to dry, for example—on the hob of a fireplace or anywhere exposed to flame or a very high temperature. If damaged they may be repaired by soldering.

As cleaning agents, liquid metal cleaners may be used, but there is nothing better than warm water with a little soda, or plain soap and water followed by a very soft brush or a wash-leather with the least touch of putty powder. *See Electro-Plating.*

**BROACH.** Long and slightly tapered, these tools are invaluable for rapidly enlarging holes in metal, hardwood, or fibre. Broaches, which are sometimes known as taper reamers, are made in numerous sizes, from a very fine one to  $\frac{3}{8}$  in. It frequently happens that on a job such as fitting a pair of hinges, the screws are just a shade too large for the hole. In such a case a few turns with a broach will enlarge the hole, and the job can be at once completed. These broaches are frequently fixed into wooden handles: but a better plan is to use an adjustable handled tool-holder.

**BROAD BEAN.** Of this bean plant the two chief types are the Longpod and the Windsor, and several varieties of each. The Longpod beans are now chiefly grown. Information on the cultivation of the broad bean is given in article bean (q.v.).

**How to Cook.** Broad beans are nutritious, but should be eaten with some fatty food, such as bacon or a butter sauce, to increase their food value. Salt should be added after cooking, as it tends to harden the beans if put into the water when boiling commences. Young broad beans, when taken out of their thick, woolly pods, can be cooked in boiling water to which a little sugar is added, until tender, probably 20 to 25 min. They are then drained and served in a hot dish with parsley sauce and boiled bacon, served separately.

For broad beans à la crème boil 1 pint of young broad beans until soft. Then remove the whitish skins, and put the green beans in a stewpan with 1 oz. butter, and dredge in 2 teaspoonfuls flour and 1 oz. grated cheese. Toss beans in this, and pour in  $\frac{1}{4}$  pint cream and milk mixed, or only milk. Add a dust of sugar, some seasoning, and 2 teaspoonfuls chopped parsley. Stir gently until boiling, then heap them in a hot dish and garnish with sippets of toast.

To make broad bean soup put a quart of shelled beans and a sliced medium-sized onion into a saucepan of boiling water, and boil until soft. Drain off and save water for stock, unless it is blackish. Remove tough, outer skins, and rub green part of beans through a hair or wire sieve. The former will make the smoother soup,

but the latter requires less time and labour.

Melt 1 oz. butter in a saucepan; into this stir 1 oz. flour and  $\frac{3}{4}$  pint milk and stock mixed. Boil and stir this mixture until it forms a sauce. Blend this with the beans, adding more milk or cream if necessary. It should be of the consistency of rich cream when finished. Season it with care, then strain it into a tureen, and serve it with croûtons.

## BROADCAST RECEIVING SETS

### Main Factors to Consider in Their Choice

Other information is given in such articles as Aerial; Condenser; Eliminator; Selectivity; Short Wave; Television; etc.

The modern radio receiver is a highly-developed piece of apparatus, and its design is the result of many years of steady improvement in circuit technique and manufacturing methods. The sprawled assembly of individual parts that characterised earlier sets has given way to a scientific system of unit chassis construction. It is largely for this reason that there are now no special problems attached to mass production of receivers. In fact, most of the processes concerned are entirely mechanical, and a model can be duplicated in any quantity with the certainty that there will be negligible variations in performance. The elements of chance that used to be present have been eliminated and any set should be as good as any other one of a specific design. At one time it was regarded as inevitable that a design should lose efficiency when subjected to repetition on a large scale, but the development of metal screening has been so successful and the progress in valve design and manufacture has been such that very high orders efficiency are achieved in compact, easily duplicated constructions. Other advantages of modern systems of quantity production are that purchasers receive good value for their money and that servicing is facilitated.

*Broadcast Receiver. Example of a modern alternating current 4-valve mains set of the "all-wave" type which will give good results on practically all wavelengths*

*from 18 metres to 2,000 metres (W.B.)*

There have also been considerable improvements in the appearances of sets, for highly-paid artists are engaged by all the manufacturers to design attractive cabinets in distinctive, modern styles. In the more expensive models the cabinets may be of solid mahogany or walnut, but in most cases veneers are employed. The use of plastic materials such as bakelite has also become widespread and with them many

beautiful effects and finishes are obtained; moreover, they are not easily affected by atmospheric or temperature variations.

**Mains Sets.** If the house is served by the electricity supply mains, a mains set which will derive the current for its operation from them can be used. The current consumed will be low and not likely to exceed that taken by one electric lamp of medium brilliance. It is necessary to know the nature of the supply before the set is ordered, for there are three types of mains sets. These are:

1. A.C. Sets for working on Alternating Current mains only. They are generally designed for 200-250 volts, but special models for other voltages are readily obtainable. Similarly, it is only in unusual cases that the mains supply will have a periodicity different from those falling within the normal range of 40-60 cycles.

2. D.C. Sets for working on Direct Current Mains only. These are not so adaptable for the reason that it is not possible to vary the voltage of a D.C. supply by the expedient of interposing a simple transformer as is the case with A.C. The voltage can be stepped down by means of resistances, but it cannot be stepped up. Modern valves require voltages of the order of 120 upwards, so that if the D.C. supply has a pressure lower than that, then special steps must be taken if reasonably efficient results are to be obtained, such as, for example, the use of a "rotary transformer." This comprises a rotating device which is, in effect an electric motor and dynamo combined.

3. Universal Sets operate on either A.C. or D.C. mains, but when connected to D.C. mains they are subject to the same limitations as are D.C. sets in regard to the supply voltage.

"Transportable" is the term usually applied to a mains set which, by virtue of its possessing a frame aerial needs no external aerial or earth connection. It can be carried from one room to another and connected to any convenient light or power point. As in the case of portable battery sets, it will probably be highly "directional". That is to say, it has to be turned round so that its frame aerial lies in line with the direction of the broadcasting station which it is desired to receive. Many transportables and portables are fitted with turntables in their bases so that they can easily be swung round.

**Battery Sets.** These are for use where there are no mains supplies. The batteries required are a small accumulator, which must be recharged every few weeks at a cost of from 3d. to 6d., and an H.T. dry battery which needs periodically to be replaced. In addition, many battery sets also use a grid-bias battery. This will be "dry" and demand replacing, but at longer intervals. With the aid of special valves such as "Class B's" and "low-consumption pentodes" it is possible to obtain splendid volume from a battery set with a

comparatively economical H.T. current; nevertheless, H.T. battery replacements remain a considerable item in the running expenses. Therefore, it is advisable to note the "H.T. consumption" of a particular set, and to ascertain what this will mean in terms of H.T. battery replacements. H.T. batteries are sold in "triple" or "super" capacities, and while these naturally cost more than the standard types, it may well be that their use would prove more economical.

*Broadcast Receiver. The modern portable battery-operated set is so designed that, by the use of special low consumption multiple valves, it is both economical and highly effective. This is a 3-valve W.B. Stentorian portable weighing 23 lb.*

*Broadcast Receiver. Scientific unit construction methods have resulted in economy combined with a high standard of efficiency and reliability. This H.M.V. receiver shows clean chassis design*

*and the full use of a metal screening for all components, which gives unvarying performance.*

A portable set is a receiver of a completely self-contained nature having accommodation for batteries and a built-in frame aerial. For this type of instrument an unspillable accumulator must be used. This can be of either the "jelly acid" or the "free acid" variety. The latter, which is designed on the principle of the unspillable ink-well, is in most cases to be preferred.

The most important factors to consider in choosing a set are as follows:

(a) The conditions of guarantee and the facilities for servicing the receiver in the event of a fault occurring in it.

(b) The cabinet work and standard of mechanical craftsmanship. The controls and switches should operate smoothly and without slip or undue "backlash."

(c) Quality of reproduction. Speech is a good test. The sibilants ought to come out clearly but without emphasis, and final "explosives" (t, d, p, etc.) be plainly audible. The piano should be heard naturally and without losing its distinctive timbre. Bass notes should sound full but clean and without "boom." Note the "background" for hum or crackling noises.

(d) Selectivity. The ability to separate one station from another is a prime essential in any radio set, and a high degree of selectivity is needed in order to combat modern ether conditions, especially if it is desired to

listen to distant stations.

(e) Simplicity of operation. The actual number of controls is unimportant if they are accessibly placed and their purposes are understood and their handling simple. The dial should have the station names plainly marked and accurately placed.

(f) Wave-range. An "ordinary" broadcast receiver will receive medium and long-wave stations only, but an "all-wave" set embraces the short-waves as well. Short-wave reception is possible over great distances with even small "all-wave" sets, but it is liable to great variations. With no set, however powerful, can there be a guarantee of consistently reliable reception from, for example, any one particular American short-wave station. An 'all-wave' set does not necessarily enable the sound programme of the television station to be received, though there are special models which will embrace the television wavelengths.

(NOTE.—A specially geared tuning control is essential if the short-wave stations are to be quickly and easily located.)

(g) Refinements. A tone control is not so important as a volume control, but is very useful to use in conjunction with it, should the volume control not be of the type which automatically corrects the tone at different volume levels. Automatic volume control is to be found in many sets in addition to a manual volume control. Its function is to offset the fading which tends to occur when receiving distant stations after dark. Visual tuning indicators enable stations accurately to be tuned-in by the eyes, which are much keener organs than the ears. (Accurate tuning is particularly necessary with a super-heterodyne type of receiver if distortion is to be avoided.)

**BROCADE.** Brocades are always figured and usually in floral patterns, and generally the pattern is woven. According to one classification brocades have their groundwork formed by the warp or lengthwise threads, and their ornamentation by the weft or crosswise threads. The name implies a rich decorative fabric, usually carried out in silk, artificial silk, or mixtures of silk and cotton, with or without metallic threads.

**BROCCOLI:** To Grow. For practical purposes broccoli may be called the winter type of cauliflower. Sowing is done as with curly kale, and the gardener who requires broccoli from October to May should make three sowings at regular intervals during April and May. Broccoli should not be planted between potatoes. To guard against injury from quick thawing after frost, the plants should be bent over until the stems are almost parallel with the ground, inclining the heads to the north if the rows run east and west, and west if they run north and south.

Some varieties are suited for autumn, some for spring, as follows:

Autumn: Michaelmas White, Self-protecting,

Autumn Protecting, Walcheren.

Early Winter: Christmas White, Snow's Winter White, Early Purple Sprouting.

Late Winter and Early Spring: Knight's Protecting, Penzance, White Sprouting, Leamington, Late Purple Sprouting.

Late Spring and Early Summer: Model, Late Queen, Methven's June, Latest of All.

The following standard sorts would give a good succession if sown together early in April: Walcheren, Snow's Winter White, Leamington and Latest of All, always provided the winter was fairly open.

*Broccoli: two varieties of this winter vegetable. Right, Purple Sprouting sown in winter or early spring. Below. Late Queen, sown in spring or early summer.*

**How to Cook.** Strip off the outer and all withered leaves, cutting the remainder level with the flower. Soak well in cold salted water with heads downwards to draw

out any insects. Then cook for 10-15 min. in boiling salted water, the flower part downwards and the pan uncovered to preserve the colour. Test by piercing with a skewer, and when tender drain well, put on a hot dish and serve with a tureen of melted butter. Broccoli breaks if boiled too fast. The colour and crispness of this vegetable will be speedily lost unless it is at once taken out of the water when cooked.

With cheese sauce boiled broccoli makes an excellent dressed vegetable. Lay the cooked heads neatly on a buttered au gratin dish and coat with cheese sauce. Dust the surface over with two tablespoonfuls of grated cheese, mixed with a small tablespoonful of browned crumbs. Put dish in the oven and bake quickly until the cheese is browned and serve at once. *See* Cabbage; Cauliflower; Curly Kale.

**BROGUE.** This heavy-soled shoe has a tongue which folds over the instep to prevent water entering the eyelet holes. Brogues are used when heavier sporting boots are unnecessary. Imitations of the real article are sold, with punched toe-caps and vamp, and sometimes with the fringed tongue.

**Broiling.** *See* Grilling.

**BROMIDE PAPER.** Bromide papers of different

surfaces, glossy, matt, and of different tints, white, cream, etc., are almost exclusively used for making the so-called gaslight prints and enlargements from photographic negatives. Newer forms include the chloro-bromide papers with a wide range of tones from brown to warm black.

The paper is so sensitive to light that an exposure of a second or two behind a negative placed a few feet from an electric lamp or gas mantle is sufficient to print a picture on it. It is too rapid to be printed by daylight. After exposure, a picture quickly appears in a developer, which, in two or three minutes, produces a print of black colour. All operations up to and including fixing must be done by orange or yellow light.

One or two small pieces of the paper are exposed for different times, and developed in order to find the correct time for which to expose the paper. If the picture comes up slowly and remains pale, the paper has been exposed for too short a time; if it comes up quickly and soon becomes dark and foggy, the exposure has been too long. The paper should be exposed so that a bright and vigorous print is obtained with about 2 min. development. Practically every bromide paper yields first-rate results with amidol, metol, or metolhydroquinone developer.

The exposed sheet of paper is placed, coated side up and without previous wetting, in a dish and flooded with enough developer to cover it; or a number of pieces may be quickly slipped at intervals into a larger quantity of developer. When fully developed, as shown by its vigour and depth, each is rinsed in clean water for a few seconds and fixed in a bath made by dissolving 4 oz. of hypo and ½ oz. potass, metabisulphite in 20 oz. of water.

Chemicals for this fixing bath may be bought as acid fixing salts. Each print is best fully immersed under the surface of the bath for a second or two; and as prints accumulate in the bath they must be moved about so as to separate them from one another and ensure their being fully fixed. This is best done with a rounded stick, so as to avoid contaminating the fingers with hypo, which must on no account be allowed to get into the developer. Prints will be fixed in 10 or 15 min. They are then washed for an hour in running water, or in successive lots of clean water which is renewed every 5 min. Dry by hanging up on a line with clips or by laying out on blotting paper. Bromide prints may be changed from black (q.v.) to brown or sepia, or to red, blue or green. Of these toning processes (q.v.) that most largely used is sepia toning. Chloro-bromide papers give warm blacks and browns by development control.

**BROMIDES.** There are several drugs of great use in medicine which owe their virtues to the possession of the chemical element called bromine. They are potassium bromide, sodium bromide, ammonium bromide, and hydrobromic acid. All these preparations have practically the same action and are used for

sleeplessness, nervous excitability, palpitation, etc., but when the drug has to be taken over a long period sodium bromide is preferred to potassium bromide.

The bromides are given in whooping-cough, ammonium bromide being considered the best for the purpose. Diluted hydrobromic acid is often taken with quinine. It helps to dissolve it and also to prevent the disagreeable effects sometimes produced by quinine. Giddiness may be alleviated by one of the bromides, and if full doses are taken every 3 hours for several days before going on board ship, seasickness may be prevented or diminished. Sleeplessness due to worry and nervous excitement may be relieved by 30 grains of potassium bromide in half a glass of soda water. Another use is in irritable conditions of the pharynx and larynx. In epilepsy bromides are given over long periods.

Bromism is the condition produced by over dosage with bromides over a period and characterised by mental dullness, heaviness of the legs, unsteady gait, drowsiness, anaemia, an acne eruption and other symptoms. The addition of a little arsenic to the mixture usually prevents any eruption when bromides are being taken.

**BROMPTON STOCK.** This is the popular name of a variety of the genus *Mathiola*, a half-hardy, biennial flowering plant. The seed is sown in May. In cold districts it is wise to winter the plants in a frame and put them out in spring. The plants average about 18 in. in height, and the flowers are sweetly perfumed.

*Brompton Stock. Flowers and foliage of the double red variety, useful for beds and borders.*

**BRONCHITIS: Care and Cure.** While rarely dangerous to healthy adults, bronchitis is serious for infants or old people, in consequence of its tendency to spread to the lungs. It may be defined as catarrhal inflammation of the mucous membrane which lines the bronchial tubes or air passages of the lungs.

Acute bronchitis is most common in spring and autumn; it may develop from an ordinary cold in the head or be part of some ailment, such as measles, influenza, or whooping-cough, and is due to the invasion of the air passages by germs. The attack begins with symptoms of a cold in the head, including perhaps sore throat. There may be little or no fever. The extension of the catarrh downwards produces hoarseness and a raw feeling in the chest, behind the breastbone. The tubes feel irritable, and there is a hard barking cough which may become paroxysmal. The chest feels tight and oppressed. At first there is only a slight sticky sputum, but in about a week's time this becomes freer, and increases the patient's comfort.

In treating bronchitis the patient should be confined

to his room, and it may be necessary to put him to bed. A hot bath or a hot mustard and water foot-bath and a mustard plaster applied to the chest are useful. The inhalation of steam from a jug of steaming water, to which a teaspoonful of Friar's balsam has been added, helps, to soothe the racking cough, the patient covering his head and the jug with a towel. If there is difficulty in getting up the sputum, ipecacuanha wine in 10 minim doses may be given three or four times a day in a little water.

When bronchitis descends into the lungs, affecting the tiny end branches of the bronchial tubes, the patient's restlessness and distress increase, the temperature becomes higher, he has much greater difficulty in breathing, and the cough is more marked. The lips and the finger-tips are often livid. The immediate attention of the physician is essential.

### Emergency Treatment

In a child the condition may be ushered in by convulsions, and the child should be put in a warm bath. During the course of the illness the child may suddenly become very blue and breathless; there also the warm bath would be used and cold water thrown on the child's chest to induce deep breaths. These measures are, of course, only pending the arrival of the doctor.

After several attacks of acute bronchitis the lungs, particularly in middle-aged persons, may lapse into a chronic condition; but more often chronic bronchitis is associated with some other condition, such as heart disease, emphysema (barrel-shaped chest), diseased states of the lung induced by dusty occupations, gout or chronic kidney disease. Frequently the disease takes the form of a cough, which develops regularly at the start of each winter and lasts until the following summer.

Sufferers from chronic bronchitis should pay particular attention to keeping the bowels regular. Two to three grains of cascara taken at night are usually all that is required. For the morning cough a hot alkaline drink, such as the following, sometimes gives relief:

Sodium bicarbonate	2 drams
Potassium bicarbonate	1 dram
Chloroform water	4 ounces

Take one tablespoonful, mixed with two tablespoonfuls of very hot water, immediately on waking.

A thorough rubbing of the chest with ordinary soap liniment or hartshorn and oil, and then covering the chest with a warm jacket of flannel, is also advisable in chronic bronchitis. *See Cough: Lungs.*

**BRONCHITIS KETTLE.** Special kettles made to emit a great volume of steam, which moisture is useful in assisting the breathing in bronchitis and similar complaints, are made and sold for this purpose. In case one of these is not at hand, an ordinary kettle can be used. Filled with water, this should be placed on the fire and allowed to boil freely. With thin cardboard or brown paper, or, if these are absent,

with ordinary newspaper, a large trumpet-shaped roll should be made. Place the narrow end of this over the spout of the kettle and the wide end near the patient's bed, which, for this purpose, must be fairly near the fire. The roll can be supported by putting a piece of tape round it and fastening the other end of this to an overhanging projection of some kind. This improvised kettle will be found very useful in attacks of croup (q.v.).

*Bronchitis Kettle with extended spout.*

**BRONZE.** Genuine bronze is generally found in the home in the form of statuary and ornaments. It is an alloy, chiefly composed of copper and tin, and is harder and more durable than copper or brass. Bronze has a pleasing dark brown colour, and is capable of taking a high polish.

The so-called bronze powders are metallic colouring materials used in the same way as gilding preparations. The article to be treated is coated with gold size, after which the bronze powder is sprinkled evenly over the surface. Various tints are to be obtained, in addition to powders simulating gold, silver, aluminium, etc.

**Bronze Collecting.** When selected with taste, bronze figures or vessels are restful to the eye. A classical centrepiece, such as a good bronze replica of a full-length Mercury may be appropriately flanked by a pair of unglazed Parian figures; it would lose in effect if placed between pieces of highly decorated china.

Egyptian bronzes are often forgeries rather than replicas, except such things as sphinx paperweights, and have little decorative merit of their own. It is otherwise with the statuary bronzes of the Renaissance, or some admirable modern works. These are in some instances available in replica, and artistic reproductions have to be distinguished from inferior castings which are turned out abroad in great numbers for cheap decoration.

Replicas, of ancient Chinese and Japanese temple bowls, koros or incense-burners, lanterns, bells, and Buddhist images are desirable acquisitions. The modern school of Japanese bronzists has produced excellent work, including animal groups and figures, worthy to be set out with choice porcelain jars. Some Saracenic and Persian work, especially when damascened in silver, and certain bronze lamps and figures from Ceylon are also good.

The natural patina or crust of genuine old bronze is often imitated in replicas, and such finishes are not to be rejected if carried out sincerely. The intentional production of tints and sheens, either by oxidation or by liquid varnishes, reaches its highest level in eastern bronzes. Their effects are sometimes due to the admixture with the copper-tin base of silver and other metals, sometimes to the use of metallic pastes, which are burned in and polished. Imitation patina is produced by green varnishes, which are liable to flake, or by sal ammoniac.

Art-bronze is a term applied to much metal work of a trivial kind, and is especially affected by producers of tasteless ornaments, and thin stampings used as furniture panels. The collector of bronze ware for its antiquarian interest usually preserves his treasures in cabinets. They may include a great variety, from weapons of the Bronze Age to Anglo-Saxon buckles and brooches, and medieval bells cast before brass had displaced bronze.

Natural patina ought not to be scoured away. Inartistic stains may be removed, without destroying the patination, by means of a half-lemon dipped in salt. Sometimes antique bronze when unearthed is found to be oxidized throughout, and in that condition cannot be cleaned at all.

**BRONZING.** By the process of bronzing any article made of metal, wood, plaster, or other material is given a bronze-coloured surface. Iron and steel are bronzed by exposing them to the vapours of heated aqua regis, and dipping them into melted vaseline. Plaster and wood are coated with size, then a metallic bronze powder is applied.

Dilute sulphuric acid and dilute nitric acid produce a bronze colour on many metals. The most artistic effects are obtained by the use of bronzing acids on brass or copper ware. The acids are obtainable from any dealer in such substances.

The brass object is first cleaned and polished, either by mechanical means, as with emery powder, or by dipping in dilute nitric acid and washing off in hot water. The work is dried in hot sawdust, and must not be touched with the hands. Make a rubber of fine wood-wool shavings or linen, wearing rubber finger-stalls on the finger-tips to prevent the hands getting stained. Slightly warm the work, then wipe it over once only with the bronzing acid. Keep the work free from draughts, and move it about over, but not too near, a gas flame. A deeper colour can be obtained by using a stronger solution or by repeated and continued applications of the rubber, always taking care to work evenly.

**BROOCH.** The simplest form is the safety pin; all other brooches are elaborations of the same idea. For a valuable brooch a good safety catch is the best form of insurance against loss.

In the case of the brooch fitted with a hook or a point-protecting catch, a safety chain should be attached. There is little difficulty in attaching it to the brooch, provided there is a small aperture through which the jump ring can be passed and afterwards closed with a pair of pliers. Instead of a safety chain, an efficient catch known as a fish tail can be fitted by a jeweller without much trouble. It consists of a small plate, shaped like a fish tail, as in Fig. 1, and operated by a small hinge set close to the existing catch. Fig. 2 illustrates a good form of safety catch, known to jewellers as the Tiffany catch.

*Brooch. Fig. 1. Fish tail safety catch fitted to a brooch.*

*Figs. 2, 3. Tiffany catch, open and closed.*

Should brooch pins break or come out, it is quite a simple operation to replace them. Retailers of jewellers' sundries stock brooch pins of all sizes in metal and gold. Perhaps the best investment is to buy a packet of assorted metal pins. If the old pin has broken

off and the joint portion is still in the brooch, it can be removed by tapping out the piece of wire on which it is hinged with a stout needle and a light hammer, or the side of a pair of pliers. Take from the packet a pin long enough for the brooch, and, holding the head in the pliers, carefully file from each side of the joint sufficient to allow the pin to fit the gap from which the broken piece has been removed. Then take a piece of brass wire and file it slightly taper, so that it will go into the hinge, and force it home, as indicated in Fig. 3. Afterwards, with a file, nick the wire on each side of the hinge, as shown in Fig. 4, break it off, and finish by filing it flush.

*Brooch. Figs. 3 and 4. Fitting a new pin and nicking it with a file previous to filing flush.*

### Care of Gem Brooches

Long bar brooches, if set with stones, should not be used to fasten thick material, as the weight of the material may strain the setting, so that the stones become loose and drop out. If the pin has got strained and lost its spring in this way, it can be temporarily restored. Hold the brooch in the left hand, and, with the thumb and first finger of the right hand, gently bend back the pin close to the joint. All brooches set with stones should be examined periodically, to make sure the gems are tight and the settings in good order.

A brooch set with jewels may be cleaned with warm water, a few drops of cloudy ammonia and an old toothbrush. Do it in a hand-basin and not over a lavatory basin or sink. Should a stone be lost in this way, open the trap fitted in most waste-pipes, as the gem has probably been stopped in this. Mothers with young children should not wear brooches unless fitted with a point-protecting device.

Sometimes a brooch pin will turn up at the point, and on withdrawing will bring with it a thread of the material. The point can easily be straightened out. Hold the pin flat on a hard surface and, with a steel knitting needle, as though sharpening a pencil, press straight the distorted point. A pin that is blunt at the point may be sharpened with a few rubs on a piece of emery cloth.

**BROODER.** This is the name given to a heated chamber connected to one or more outer chambers or chicken runs. It is an adjunct to the chicken incubator, and is used in order to raise chickens artificially when it is not possible to make use of a sitting hen. *See* Chicken; Poultry.

**BROODINESS:** How to Cure. This condition in a hen is characterised by a peculiar clucking noise accompanied by feverishness, indicating the desire to sit. Apart from clucking, the desire to sit is further evidenced by the hen sticking tight to the nest. She should either be allowed to obey her instincts by being entrusted with a sitting of eggs, or broken of the habit.

To break up a broody hen, as it is termed, is quite a simple matter if taken in hand in the early stages. At the first indication of broodiness, remove the hen to a coop with a slatted floor, that is, a floor composed of laths nailed crossways two inches apart. The coop is

raised from the ground by bricks placed at each corner so as to allow of a free current of air beneath.

In such a coop it is impossible for a hen to sit with any degree of comfort, and, being obliged to roost willy nilly, she quickly loses the desire. A few days' confinement will suffice to cure her, and in the course of a week or so she will resume laying. *See Poultry.*

**BROOM:** The Plant. This name is given both to cytisus and genista, hardy spring and summer flowering shrubs of great garden value. They thrive particularly well on poor or light land. When planting brooms it is important to choose small plants which have been grown in dower pots, not in the ground.

*Broom. A favourite hardy broom (Cytisus adreanus), bearing red and yellow flowers in early summer.*

Some of the brooms are tall shrubs suitable for grouping in the flower garden and shrubbery; others are of low growth and may be grown in the rock garden. Of the tall kinds, which bloom in spring or early summer, some of the most beautiful are *Cytisus albus*, white, *praecox*, cream, *scoparius*, the common yellow broom and its variety *andreanus*, bronze red and yellow. Beautiful low growing brooms are *Cytisus Ardoinci*, yellow, *kewensis*, cream, and *Beanii*, yellow. New varieties have flowers of brilliant colours. The genistas are in full beauty in summer—all have yellow flowers. The brooms come readily from seeds, which may be sown outside as soon as they are ripe, or in spring in a cold frame. Cuttings strike in sandy soil if inserted under a hand-light in summer or early autumn. Layers may be put down in autumn.

A greenhouse species, *genista fragrans*, grown by market gardeners, is a neat shrub with small, sweet-smelling golden flowers, continuing in bloom for a long time. It is grown in soil composed of two parts loam, one part peat and sand. Propagation is by cuttings in spring, preferably in a propagator. Small pieces of the new wood root readily in sandy peat, the more so if a heel of older wood is taken with the cutting. The plants which result should have the points taken off when they are 6 in. high, in order to cause them to break, and the side shoots thus obtained should also be stopped when about 4 in. long; this ensures neat bushes with several branches.

From May to midsummer the plants may be kept in a cold frame, and watered and syringed regularly. From that time to October they will be better on a bed of ashes in the open. They should be housed in autumn. A winter temperature of 45° to 55° will suit them. After they have flowered they may be cut hard back, repotted, and syringed. They will then break afresh, and, after the necessary cuttings have been taken may be hardened in the frame.

**BROOM:** For Sweeping. Brooms are made of bass, white fibre, horsehair, bristle, and coconut fibre. The stocks or handles are of alder, birch and beech, and with the exception of certain bass brooms, the knots are invariably set with pitch. The so-called hair broom, for household use, in best qualities is of pure bristle at least 4 in. in length. Other qualities are less economical in the long run.

Points to look for in a good broom are the long, springy flag-ended bristles and the even pitch-set knots, with the outer row of knots well spread. It may be found that the outer knots are small and close made of bristle, with the inner knots large and composed of inferior mixtures. These can be detected by placing the hand across the surface of the broom and noting the greater readiness with which bristle will spring back when released, as compared with the less springy substitute. The knots in a good hair broom are set outwards to obtain the maximum spread for the sweeping surface.

If the tufts of hair are stuck in with pitch, known as pan work, the holes should be well filled and a neat ring of pitch be visible at the edge of each hole, and there should be no waste of space inside the outer row of knots. When not in use a broom should be stood up in a reverse position or hung up. The best carpet brooms are made of Venetian whisk, straight, stiff, and durable. In most homes the carpet sweeper has ousted the carpet broom for floor sweeping, but it is still employed for upholstered furniture. Superior makes are fitted with plush protectors at each end of the stock, thus minimising risk of scratching fragile furniture, polish, etc.

In the yard or outdoor broom pure bass serves best. For very hard wear these are faced with knots of cane or whalebone. Water will not deteriorate bass, but stiffens and keeps it in condition, so it is suitable for washing-down purposes.

The common coconut fibre broom is a cheap substitute and valueless. For hard wear, as in stable use, whalebone is mixed to give an added stiffness and durability, and in the case of heavy scavenger brooms the front row of holes is filled with split cane.

To obviate slipshod attachment of the handle an attachment can be procured which will enable the broom to be used both ways, trebling the life of the bristles, and the two-way metal attachment fits and secures any ordinary broom-handle.

For sweeping up the litter made by falling leaves, cut grass, and so on, the garden broom or besom is highly satisfactory.

Garden brooms are made from birch twigs, cut from the trees after the periodical clearing of woods which is constantly going on. The twigs selected are up to about four feet long, and these are bunched with the strong ends level, and then tightly bound together with strip or split cane, one strong binding at the end and two or more at intervals of a few inches. A stout staff with pointed end is then driven up through the tied ends to

make a handle, which is fixed by a plug passing between the bindings and through a slot or hole previously cut in the handle. *See Brush.*

**BROOM RACK.** This is a useful article for the home, and will also commend itself for the ease with which it may be made, and the small amount of material required. Fig. 1 shows the rack complete, consisting of a wood back, with pegs to hold brushes and brooms. Details of the rack appear at Figs. 2 to 5. A hardwood, such as birch elm, could be used, or ordinary deal would be very suitable. The best finish will be with stain or varnish, or varnish alone.

*Broom Rack. Fig. 1. The completed rack.*

The back, as at Fig. 2, is 1 ft. 6 in. long by 6 in. wide, and should not be less than  $\frac{3}{4}$  in. thick. The long pegs for the brooms, two of which will be required, are shown at Fig. 3. and must be cut from wood  $\frac{3}{4}$  in. thick. A tenon 1 in. deep by  $\frac{3}{4}$  in. long is formed at the back end of these pegs for fixing to the back of the rack. The shorter pegs for hand brushes are seen in Fig. 4, and at the back end of each peg a tenon  $\frac{1}{2}$  in. deep by  $\frac{3}{4}$  in. long is formed. Figs. 3 and 4 show  $\frac{1}{2}$ -inch squares.

Mortises are cut through the back of the rack to receive the tenons on the ends of the pegs, and a chamfer about  $\frac{3}{4}$  in. square is cut around the edges of the back, as at Figs. 2 and 5. The pegs are glued to the back. For hanging the broom rack, two holes should be bored through the back, so that it may be fixed to the wall with a couple of brass-headed nails.

*Fig. 2*

*Fig. 3*

*Fig. 5*

*Fig. 4*

*Broom Rack. Figs. 2-5. Diagrams showing working details of the parts*

**BROSE.** This dish of

Scottish origin may be prepared with pease meal. Put two tablespoonfuls of this into a basin and stir into it  $1\frac{1}{2}$  gills boiling water. Put the mixture into a saucepan and boil carefully for 5 min. Season with salt and pepper, add a piece of butter the size of a walnut and serve very hot with milk.

For another variety of brose, break sufficient stale brown bread into  $\frac{1}{2}$  inch pieces to fill a  $\frac{1}{2}$  pint measure, and stale white bread to fill a  $\frac{1}{4}$  pint measure. Put these brown and white pieces into a double-pan, add 2 oz. of butter and  $\frac{1}{2}$  pint of milk, then cook it until the bread is quite soft and the milk absorbed. Add salt or sugar to taste, and serve in hot porridge bowls. If the bread is very stale more milk will be necessary. It is best not stirred during cooking.

**BROTH.** The unclarified stock made from beef, mutton, veal, chicken, etc., is garnished for broth with neat cubes of the best parts of the meat, and vegetables used in its preparation, with the addition of a little rice or pearl barley boiled in it.

**BROWN: In Clothing.** For autumn and winter wear, brown in varying shades is always in fashion, as the colour is warm and looks well in heavy fabrics. For women there is also the advantage that it tones with most furs. For country, sports and travel wear, brown is a good choice, as it does not show dust, and smart accessories for both sexes, shoes, boots, knitted wear, scarves, etc., can be obtained in this range more easily than in any other colour. Lighter colours can be successfully dyed brown.

**BROWN BOOTS: Their Care.** In making brown leathers for boot uppers, it is essential that the boot maker should use skins which are free from defects. After tanning the raw skins it is customary to sort them over carefully, and to employ those which are at all defective for lower grade blacks. This influences the price of the finished boot or shoe, so that good brown boots are dearer than black.

After a few days' wear cheap brown boots lose their smart appearance. This may not be so noticeable in the case of cheap black footwear, as manufacturers can more readily fake the uppers of the black boot after the latter has been made. But with brown boots touching up can only be done on a small scale with a pigment finish. Such finishes consist of a pigment colour similar to those used in paint manufacture, and some binding substance like shellac. When this is applied to the defective grain surface of the leather, the tiny particles of pigment fill up scratch marks, etc., forming a smooth surface. After a little wear this finish becomes ineffective, and the boot begins to look shoddy.

**Cleaning and Reviving.** No polish should be applied to the surface of brown or coloured boots until all the dust has been removed, otherwise the bright brown tone of the leather will gradually dull. If it is desired to revive the original colour, the following

method has been found satisfactory. The boots are placed on trees and brushed with a warm solution of soft soap. Ordinary soap is useless for this purpose. This is then washed off with clean water, soft soap rubbed into the leather and allowed to remain until nearly dry, when the excess of dry soap should be wiped off with a damp rag and the boots allowed to dry thoroughly. If a good polish of the required shade is applied the brown boots should look like new.

Trouble is often occasioned by grease spots on brown boots. Apply a paste of fuller's earth, which should be left to dry before wiping off. It absorbs most of the grease without taking out the colour, and a second application should complete the absorption. If water or rain spots are allowed to dry, the leather is likely to be spotted with light patches. For these blemishes make a strong decoction of shag tobacco, and lightly touch them with the liquid until they resume the requisite deeper shade. Then apply a good polish to the whole surface.

#### Black Boots from Brown

To convert brown boots into black needs care if the job is to be undertaken at home. First, all dirt should be removed with a clean brush. Then polish is removed by going over the upper with a cloth or sponge soaked in petrol, followed by a similar application of methylated spirit. This, of course, must be done in the open, away from naked lights. The boots are allowed to stand for some time in the open air, in order that all the petrol left in the leather may volatilise. The surface is next lightly rubbed with a cloth dipped in either a weak soda solution or some weak ammonia, after which the uppers are wiped over with warm water.

By this time all foreign matter should have been removed, and the cleaned surface is ready for the dye, which can be bought at any leather goods or oil and colour stores. Two applications or more will be needed, then the boots are allowed to dry, slowly and thoroughly. They must not be put in front of a fire to dry. Finally, the uppers are blacked over with a good black boot polish.

**Brown Boot Polish.** The pastes employed for shining brown leather boots have a basis of beeswax and turpentine, the yellow colour being given by an aniline dye such as bismarck brown or phosphine. It is sometimes necessary to remove stains and discoloration before applying polish to brown boots. The best cleanser is a thick cream of gum tragacanth to which 2 per cent, of oxalic acid has been added. *See* Boot.

**BROWN BREAD.** Unfermented brown bread can be made in this manner. Mix well  $\frac{3}{4}$  lb. wholemeal with  $\frac{1}{4}$  lb. white flour, 1 teaspoonful each salt and sieved carbonate of soda, and two teaspoonfuls sieved cream of tartar. Rub finely into these 2 oz. margarine, butter, or dripping, and mix to a soft dough with about  $\frac{1}{2}$  pint milk. Knead quickly and lightly, and shape into round loaves. Gash rather deeply across the top,

place on a floured baking-tin, and bake in a quick oven for about 30 min., or till well risen, lightly browned, and firm in the centre. If there is butter milk or sour milk, use that for mixing, and only one teaspoonful of cream of tartar. *See* Bread.

**BROWN BREAD PUDDING.** Make 4 oz. brown breadcrumbs by rubbing stale bread through a wire sieve. Put  $1\frac{1}{2}$  oz. butter into a basin, warm slightly, and add 2 oz. castor sugar. Beat these with a wooden spoon and stir the yolks of 2 eggs into the creamed mixture, then add crumbs, grated rind of a lemon or an orange, a few grains each of grated nutmeg and powdered cinnamon, and a gill of milk. Mix all together and stir in lightly the whipped whites of the eggs. Pour the mixture into a well-greased basin, twist a piece of greased paper over the top, and steam the pudding gently for 1 hour. Turn out to dish, and pour round the pudding hot jam or other sweet sauce.

**BROWN HOLLAND.** This plain, unbleached linen fabric for children's dresses and the like is imitated also in cotton. The window holland, usually brown and employed for blinds, is almost always of cotton, finished in a special manner to throw off dust.

**BROWNING.** For colouring soups, gravies, and puddings, this is sold in bottles, but may be made at home. Put 4 oz. white sugar into a saucepan and stir over a low fire till the sugar is melted. Boil gently, and when it turns a rich brown, pour into the pan  $\frac{1}{2}$  a pint water. Boil gently until the consistency of warmed treacle; stir occasionally, and skim if necessary. Cool, pour into a clean bottle, and cork for use. Well-made browning should be neither bitter, from overcooking, nor sweet, from insufficient colouring of the sugar.

**BROWN JOHNNIE PUDDING.** An excellent steamed pudding made by mixing 6 oz. each flour, finely chopped suet, and golden syrup with 1 tea spoonful ground ginger. Beat an egg frothy, mix with  $\frac{1}{2}$  a gill milk, and beat these into the flour, etc. Have ready a thickly-greased basin, and the water boiling in the steamer.

Put one teaspoonful of bicarbonate of soda in a small basin, mix smoothly with two teaspoonfuls of milk, and stir thoroughly into pudding mixture. Turn it at once into the basin, twist a piece of greased paper over the top, and steam for two hours. Turn out on to a hot dish, and pour round it some hot sweet sauce.

**BROWN PAPER.** Brown paper is sold in sheets, the most ordinary size being 29 in. by 40 in., with 24 sheets to the quire. Three qualities are obtainable, according to the thickness required.

**BROWN ROT: To Prevent.** During the summer and early autumn fruit trees are frequently attacked by a disease which produces on the fruit soft brown areas. These increase in size until the whole fruit is affected.

*Brown Rot. Left, apples affected by rot. Right, fruiting spur, showing putules of the same fungus.*

*(By permission of H.M. Stationery Office and the Ministry of Agriculture)*

Diseased fruits which become attached to the tree gradually dry up and shrivel, and these produce a new crop of spores and spread the disease.

The best preventive measure, as is pointed out in Leaflet No. 88 issued by the Ministry of Agriculture, is the removal and destruction of all mummified fruits during winter. They should be collected, and either burned or deeply buried. All infected spurs, together with cankers on the stem, should be cut out.

When fruit is to be stored, the greatest care should be exercised in discarding all fruit showing signs of brown rot, for the disease will not only continue to develop in the affected individuals, but will spread to others. It is advisable to spray with a tar-oil wash in winter and with Bordeaux mixture before the blossoms open and again as soon as they have fallen. *See Apple.*

**BROWN SCALE:** How to Spray. Gooseberry, currant, peach and nectarine are all liable to the attacks of the insect known as brown scale. The insect leaves a pale scar when removed from a twig, and it has a preference for the older branches. The remedy is winter and spring washing, of which particulars are supplied in leaflet No. 88 issued by the Ministry of Agriculture.

*Brown Scale. Right, undersides of larva. Below young female, highly magnified; m=mouth; c=channels to respiratory tubes.*

Complete pruning before spraying operations are commenced; and in old and badly infected trees remove as much of the old wood as possible. The spraying apparatus should have the nozzle fitted

at an angle of about 45 degrees so that the spray may

be conveniently directed to the undersides of the branches where the insects are usually more abundant.

The best winter wash is lime-sulphur. The concentrated lime-sulphur solution can be bought ready made, and should be diluted to winter strength—3 quarts of lime-sulphur (1.3 specific gravity) to 10 gal. water. A good paraffin emulsion is:

Paraffin	2 pints
Soft soap	2 lb.
Water	10 gallons

Dissolve the soft soap in about a gallon of boiling water. Remove the soap solution from near the fire, and while still hot add the paraffin. Churn the mixture very thoroughly, add soft water to make 10 gal., and make sure that there is no paraffin floating on the surface.

*Brown Scale. Right, peach twig affected by brown scale.*

**BRUISE:** Its Treatment. The colour of a bruise is due to the blood which has escaped from the vessels into the surrounding tissues. It is usually at first a bluish-black.

To prevent the further escape of blood into the tissues, an ice bag or a series of towels wrung out in cold water should be placed over the part. The ordinary lead water and opium lotion poured on a handkerchief and then bandaged loosely over the bruise is a good home remedy.

If the skin is broken, and oozing is taking place on the surface, wash the part well with running water for a few minutes and dust it thickly with boracic acid powder or paint with tincture of iodine. Then apply a piece of boracic lint, and bandage as firmly as is comfortable. Place the lower part at rest; if a lower limb, elevate on a pillow; or the upper, place in a sling. A hot bath taken soon after the injury will help to relieve pain and stiffness. After a few days massage the part gently. *See First Aid; Sprain.*

## BRUSHES FOR HOUSEHOLD AND GARDEN USE How to Choose and Keep Them in Good Condition

Further details will be found under such headings as Boot Brush; Clothes Brush; Paint Brush; Tooth Brush. See also Broom; Carpet Sweeper; Vacuum Cleaner.

Brushes are divided into two kinds, simple and compound, according to the way they are made. The former consist of one tuft only, an example being the brushes used by the artist; and the latter of more than one tuft, among them being most of the brushes used in the home. Brushes in which the tufts are placed side by side are known as stock brushes.

The principal raw material used in the manufacture of brushes is bristle, almost wholly pig or hog bristle. This is collected, partly sorted, and sold in lengths from 1½ to 7 in. It is dressed, combed, and mixed before being made up according to the particular class of work for which it is intended. Bristle is exceedingly springy, and will maintain this property under ordinary conditions until worn away by use. Hence the chief value of bristle for making brushes.

### Materials Other Than Bristle

Among other materials used are fibre (Mexican grass), Mexican whisk, Bahia bass, and horsehair. Fibre and drafts (horsehair) are the chief materials used for mixing with bristles as well as for substitutes. Skunk fur is used for a light dusting brush with an adjustable head convenient for edges of panelling and for lighting fixtures, as shown in the illustration. A finely cut rubber brush, arranged in a spiral round wire is excellent for cleaning bottles and vases.

*Brush: two labour-saving patterns. Right, light brush of skunk fur, with adjustable head, for dusting lighting fixtures.*

*Left, scrubbing brush with long handle working on a swivel, which saves kneeling.*

For fancy brush handles and backs, rosewood, satinwood, and ebony lend themselves to an excellent finish. Owing chiefly to the increasing cost of bristles, imitations and substitutes are plentiful and lead to unsatisfactory wear in some cases.

Scrubbing-brushes made of a mixture of fibre and bass, and known as union, are cheap and serviceable. The one illustrated with a long handle working on a swivel saves kneeling and stooping. Shoe, stove, and similar brushes are made with the root end of bristles obtain the required stiffness. Best makes are wire-drawn, with screwed-on backs. Small hand brushes bristled both sides are convenient for removing dust from cushions and rugs. Racks for holding brooms and brushes are illustrated under the heading Broom.

**Fibre and Bristle.** High prices call for an examination of brushes used for decorating. A common fibre brush is intended for rough work where lime is used. Whether tied on the handle in two knots with wire or string, or nailed on with tin or leather, a good finish is usually an indication of a well-made brush. The sash brush or tool of more than a dozen sizes is best made in a forked handle, and bound with a string or copper wire. The bristles are held together with a cement of resin and oil, and pulled into the handle while they are hot.

The distemper or whitewash brush with two knots is

an expensive article. Five to 6 in. bristle is used, and the wire, which should not be stinted, may be secured by solder at the corners. All first quality distemper brushes are stamped pure bristle, or covered with a similar guarantee. Black China bristle, while good in appearance, does not compare in usefulness with other bristles, mainly because it does not carry or hold paint or distemper.

A moderate adulteration of bristle with fibre and horsehair is quite acceptable for ordinary purposes. A popular brush, and one that has replaced many more expensive varieties, is the flat tin varnish. These are made of China bristle, and in sizes of an inch and upwards, and are intended for general use, including varnish work. They are usually bevelled at the top of the bristle, which gives them the appearance of a part-worn brush.

A common fault with all paint brushes is the presence of free or loose hairs, which have not been caught by the cement or held by pressure, and one by one come out to spoil work and weaken the brush. Passing the hand over the top of the bristles, as if to test the spring, will cause these undesirable hairs to rise, and any considerable quantity denotes an unsound article. These loose hairs are particularly objectionable in pastry brushes.

In the process of making, paint brushes have probably been subjected to extreme heat and other unhealthy conditions, and manufacturers frequently issue instructions to purchasers which should be strictly observed, or the maximum of wear will not be obtained. During intervals of work paint brushes should be suspended in the paint or distemper and not allowed to rest on the working end, otherwise they will become clogged and for a time unworkable. Before putting aside after use, they should be thoroughly cleaned and ready for use on the next occasion. Much can be done by wiping out on old boards, and water will remove any remaining whitewash or distemper.

Paint, varnish and enamel brushes must be softened and squeezed out in a little turps or paraffin, and finished with a warm solution of soap and hot water, working on a stone sink or board and removing all traces of turpentine or paraffin, as this destroys any cement in the brush.

**BRUSSELS CARPET.** The floral designs in worsted Brussels are seldom in use, but the hair carpets, made from cowhair, and sold in natural, undyed grey or brownish mixture colouring, and also in many good shades, are tasteful, durable and cheap. Black or coloured borders to these squares look well in small living rooms and for bedrooms. For a stair and passage carpet it is more dependable in the undyed than in the dyed shades. *See Carpet.*

**BRUSSELS SPROUTS.** The leaves at the top of the Brussels sprouts stem are excellent as a vegetable, but should be left until all the sprouts have been

gathered.

The seed is sown outdoors early in April, and the seedlings are planted finally in June or July. For an early autumn crop seeds are sown in a frame in February.

*Brussels Sprouts. Plant with many sprouting shoots.*

Loose sprouts are generally the result of over-crowding and too light a soil, which, perhaps, has been badly dug. Directly the lower leaves turn yellow, and part company with the stem under slight pressure, the sprouts may be removed, but there must be no wholesale clearance of the leaves. The stem is cleared of sprouts from the bottom upwards.

The best varieties include Exhibition, London Market, Aigburth, and Standard. Medium-sized plants, with medium-sized sprouts of superior flavour, are given by such varieties as Matchless, Wroxton, Scrymger's Giant and Imported. Smallest of all is Dwarf Gem. It is an excellent little variety that reaches maturity much more quickly than large varieties. Moreover, while the larger varieties require at least 2½ ft. each way to give of their best, 18 in. suffices for Dwarf Gem.

The enemies of Brussels sprouts are the same as the pests of other greens, with the addition of the cabbage snowy fly (q.v.).

**How to Cook.** The usual method of cooking this vegetable is by boiling. Trim, rinse under cold water and leave to soak for an hour in cold salted water. Drain them and put into a saucepan of boiling salted water. If using hard water put in a small saltspoonful bicarbonate of soda, for hard water spoils the colour of green vegetables.

Boil quickly until they are soft through, but not broken, probably for about 15-20 min., and then pour into colander, drain and return to pan. Add for 2 lb. sprouts ½ oz. butter, a little dust of pepper and a few grains of grated nutmeg.

Brussels sprouts au gratin form an excellent supper or luncheon dish, prepared with 1 lb. cooked sprouts and cheese sauce. *See Au Gratin; Cheese Sauce.*

**BRUSSELS SPROUT SOUP.** This delicate green purée can be made entirely with milk. Cream increases nutriment and richness, but is not essential.

Trim and wash 1 lb. Brussels sprouts and put in a saucepan of fast-boiling salted water, with a small onion and a very small saltspoonful of bicarbonate of soda. Boil quickly until they are soft. Drain off water and with a wooden spoon rub them through a sieve. Put back these sieved ingredients, or purée, stir in one quart of boiling milk and reheat without letting it actually boil, or the colour will not be so good. Add one gill cream and season carefully. The soup should be as thick as good cream, so add more liquid, or a little thinly mixed cornflour, and reboil it, even should the colour suffer, if the consistency is wrong.

**BUBBLE AND SQUEAK.** Use up ¼ lb. cold potatoes, 2 oz. fat cooked bacon, ¼ lb. of cold cabbage or other cooked vegetables, some pepper and salt, and some fat for frying. Mash potatoes, chop cabbage, cut bacon into small squares and mix all together with seasoning. Heat the fat in a frying pan, and fry the mixture until brown on both sides; then shape into a flat cake. It should be served very hot.

**BUCKET:** For Household Use. The strength and durability of galvanised buckets can best be judged by the weight. A common bucket with seamed sides weighs about 3 lb., a good quality riveted about 5 lb., while a very strong contractor's bucket with a welded iron hoop around the rim or a similar hoop at the bottom weighs about 10 lb. These weights are for the 12 in. size.

Fire buckets, enamelled red or blue, weigh about 4 lb., and when used for fire protection purposes should be hung on a bracket, and always kept full of water.

For home dairy purposes, enamelled buckets are used, but once chipped they should be discarded as there is a risk that a small particle of the enamel may get into the milk.

Wood pails for stable use made of oak have narrow galvanised iron hoops. They need to be well looked after, otherwise the wood shrinks or they develop leaks.

The enamelled bucket, with or without lid, quickly becomes rusty if no attention is paid to keeping it in good condition and free from dirt. A convenient form of housemaid's pail has an exterior receptacle for a scrubbing brush, and a small one for holding the soap. Another pattern has an interior receptacle and a cinder sifter that facilitates the process of cleaning the grate.

Ordinary galvanised buckets are quietened by binding the handle or bail with cord, or fitting a rubber ring. An enamelled bucket that has been chipped can be treated with bath enamel applied to the damaged places, and put on in the same way as for a bath.

**BUCKRAM.** A stiff material made of very coarse linen or cotton, and usually stiffened with glue, buckram is used to stiffen the edges of articles in dressmaking and fancy work, etc., or as an interlining.

**BUCKSKIN.** Deerhide or sometimes sheepskin, tanned in a particular way and dressed with oil to render it flexible, is used under the name of buckskin to make riding breeches and gloves.

Buckskin may be washed with soap and warm water, rinsed and dried, but this dries and stiffens by removing the oil dressing. An ounce of yellow ochre rubbed into a paste with a teaspoonful of salad oil, and then mixed with water into the consistency of cream, may be applied to the leather. The garment should be hung to dry and the paste be removed afterwards with

a soft brush. The pliability can in large part be restored by rubbing the leather between the hands.

**BUDGERIGAR.** There is no parakeet more popular than the little green bird with the primrose forehead commonly called the budgerigar. It thrives best in an aviary, but may be kept in a cage, and as it practically lives on millet seed, feeding is a simple matter. It greatly enjoys greenstuff in the shape of the grass of canary seed, which may be easily propagated in a pan. Fresh water and gritty sand must always be within reach. A pair can be used for breeding, the season being from April to July. As a parakeet, the budgerigar is subject to importation regulations given under parrot (q.v.). *See* Aviary.

**BUFFET.** Antique buffets belong to the oak period and were frequently designed and made in the 16th and 17th centuries. These are still copied and somewhat similar pieces are to be found in Jacobean style oak for use as sideboards or as hall furniture. The word buffet also denotes a long table at which refreshments are served at an entertainment; or a side table and the cold meats, etc., placed thereon at meal times. *See* Sideboard.

**BUFF KNIFE.** The buff knife or scraper is used in the repairing of boots and shoes, more particularly in the finishing stages. A buff knife should be sharpened by thinning the edges and then turning them over by rubbing flat on the edge with a smooth steel rod. This turns up a burr or slightly raised portion, which forms the actual cutting edge. *See* Boot Repairing.

**BUFF-TIP MOTH.** This common moth is generally distributed over Great Britain, but is most abundant in the south of England, where in late summer its caterpillars defoliate branches of elm, hazel, lime, oak and willow. With the wings extended to full width of nearly 2½ in. the moth is very striking and conspicuous; but the living insect at rest with the wings closed round the body may be mistaken easily for a decayed twig broken roughly. The forewings are brown-grey, paling to silver-grey on their hinder margin, and the tip of each bears a large oval blotch of pale buff. The hindwings are pale yellow.

Appearing in June or July, the female moth deposits her eggs in batches on the leaves of the trees named above, to the number of 60-80 in a batch. These are whitish above, with a dark dot in the centre and dark beneath. They hatch in about a fortnight, and the softly-hairy yellow caterpillars, with longitudinal broken lines of black, feed in company until nearly full grown. In September or October they change to purple-brown chrysalids on the surface of the earth. The caterpillars being warningly coloured are immune from the attack of birds, but by smartly jarring the attacked branches with a stick numbers may be brought down into an upturned umbrella or sheet, from which they may be collected and destroyed.

*Buff-tip Moth. 1. Eggs. 2. Caterpillar. 3. Chrysalis. 4. Perfect Moth.*

**BUG.** Although the word is frequently used in the American sense to indicate any kind of insect, it is applied correctly to insects of the sub-order Hemiptera, which live by imbibing the juices of plants or animals. The bed bug is a well known example of the animal feeders, but the great majority—there are about 450 British species—confine their attentions to plants.

The plant-feeders in Great Britain seldom occur in sufficient force to cause appreciable damage; but in other lands they include the mosquito-blight of the Indian tea-gardens, the chinch-bug that attacks corn and the cotton-stainer that depreciates the cotton crop.

The bug, or bed bug, is a flat, oval insect, a fifth to a quarter of an inch in length, with six legs and a pair of antennae before the prominent eyes. Its colour is chestnut-brown or a mahogany tint. It has a characteristic odour which helps to make it a pest. Introduced from abroad about three centuries ago, the bed bug spread rapidly and settled in wainscoting and heavy furniture. To-day, with our cleaner habits, it is less abundant; but the most scrupulously clean houses may be invaded by its walking in, or by its introduction with furniture, either from factory or sale-room.

To allay the irritation set up by its attack, the affected part should be touched with liquid ammonia, sweet oil or tincture of iodine. Any article of furniture known to harbour the bug should have its suspected corners and crevices painted with either of the petroleum oils applied with a painter's sash tool. Where the infestation has assumed more serious proportions, the room should be fumigated with sulphur, all crevices of windows and doors, as well as the chimney, being made tight, and the door kept closed for 24 hours after the sulphur has been ignited.

The bed bug has been convicted of acting at times as carrier of the germs of relapsing fever, and it has been suspected of transmitting other diseases. Cockroaches

eat bugs, and the same good office has been attributed to the minute reddish ant, which is itself a pest in some houses. *See* Ant; Apple; Cockroach.

**BUGLE:** How to Sound. The bugle is akin to the trumpet, but has a shorter and more conical bore; it is used chiefly for calls in the army. The sounds that can be produced are the natural harmonic series:

These sound a tone lower, as the instrument stands in the key of B flat. It is always written for, however, in C. Of the above sounds, the lowest C (fundamental) is of weak tone, and is not used. The B flat also is rather too flat to be available, while the highest C is not employed for the army calls.

The instrument should be held firmly, but not too tightly, in the middle of its thickest portion, not too near the mouthpiece. The lips being placed to the mouthpiece in such a way that none of the breath is wasted by escape at the side, the player utters the syllable "too," the tongue being between the lips and quickly drawn back. The first endeavour should be to produce the middle C as a holding note. When this can be done with certainty, it may be varied rhythmically by the device of tonguing ("too-too"), and subsequently the other notes can be produced by means of increased pressure.

**BUHL.** The chief characteristic of buhl, or boule, work is the application of thin coats of tortoiseshell veneering on prepared wood. The surface is inlaid with delicate tracery in metal, especially brass, and these inlays are adorned with tortoiseshell tracery. Brass feet, bracket, edgings and other ornaments are also used, either to protect the corners and edges of the piece or for decorative purposes.

*Buhl Work. End of a commode made of pine with brass, ebony and tortoiseshell marquetry work; early 18th century. (By permission of the Director, Victoria and Albert Museum)*

Trouble with the brass inlay in buhl work is probably due to the perishing of the adhesive used in the laying. In the endeavour to press the brass back into position a kink often develops, and this must be removed as far as possible by taking out sufficient brass to enable the inlay to be hammered on something hard slipped under.

Shellac cement, either heated or reduced to a thick consistency in methylated spirit, may answer the pur-

pose. The cabinet maker's method is to use the best Scotch glue of good consistency, and full hot. Have at hand some means of pressure that will apply to the position of the inlay—i.e. a weight, a handscrew, or even a strong 4 in. paperclip may answer; also some flat pieces of wood and brown paper. Apply the glue, using no more than is necessary, to the back of the brass, and press back into position with a hammer-head. Then lay the brown paper over, and the flat wood over this, before applying the weight or handscrew for compression. The brass must be held in position till the glue has set.

## BUILDING: THE LEGAL ASPECT

### Important Points for the Prospective House Builder

The following article affords a valuable introduction to such entries as Architecture; Bungalow; Cottage; Garage; House. *See also* Drains; Garden; Sanitation

The man who proposes to build his own house should first of all familiarise himself with the exact legal character of the intended property, and the obligations that may be laid upon him, particularly by local authorities.

In Great Britain certain acts of 1925 made various changes in the land laws, in the direction of greater simplicity. Land may be either freehold or leasehold. Freehold means that land and the house upon it are held in fee simple, and is the nearest thing in law to absolute personal ownership of land.

Leasehold means that while a man purchases the bricks and mortar of the house from the builder, he does not purchase the land on which it stands, but hires it on lease for a stated number of years, 99 in most cases, but occasionally 999, at a fixed yearly rental. The ground landlord, besides retaining his proprietary interest in the land, acquires the same interest in the house built upon it, and at the end of the lease can, through his descendants, gain absolute possession of the house. Moreover, the tenant at the time may be obliged, if the house needs repairing, to execute those repairs at his own expense, and in the case of an ordinary dwelling house has no claim on the ground landlord for any part of the outlay.

The holder of a lease of agricultural land has the right to claim compensation from the ground landlord in respect of buildings that have improved the value of the land. But the only protection available to the non-agricultural leaseholder is by way of modifying clauses in his covenant with the ground landlord, entitling his heirs to get back from the latter a little of what they give him.

More often than not the ground landlord, owing to his tenant's indifference as to what may happen 100 years hence, succeeds in imposing a restrictive covenant that leaves the leaseholder with little choice as to the kind of house he may build or the use he makes of it when built. Restrictive covenants are also attached to the sale of many freehold building estates, but these generally relate to stipulations as to the number of houses to the acre, the prohibition of offensive trades,

building in front of a certain line and so on.

There are three methods open to the purchaser of a freehold house. He may pay the whole purchase price in cash; or he may obtain a fixed or permanent mortgage on part of the value, subject to the mortgagee's right of foreclosing; or he may obtain an advance from a building society, repayable by instalments, plus interest on the capital, each month, quarter or year, according to arrangement. The last is the method usually chosen by those who cannot put down the whole price.

### Terms of Contract

When the purchaser has made his arrangements with the builder the next step is the signing of a contract. With this goes the payment of a deposit, in most cases 10 per cent of the total purchase money. The contract binds the builder to finish the house by an agreed date, and the customer the purchase on entering into possession on that date. In the interval a formal deed for the conveyance of the property is drawn up usually by the purchaser's solicitor, who submits it to the other party for approval. In small and straight forward transactions it often happens that the builder's solicitor acts for both parties, in order to keep down the costs; but when investigation of title is necessary, or any other point is involved on which dispute might afterwards arise, the purchaser will do well to have his solicitor.

The charges of solicitors for advising vendors and purchasers of real property are regulated according to the amount of the purchase money. These charges, which are payable by each of the two parties, may, however, be varied by written agreement or reduced by one solicitor acting for both. Both a contract and a legal conveyance must be stamped. The Stamp Act imposes a scale of charges which work out at about 5s. for every £50 of the value, if the latter exceeds £500. When a building society's financial help is required, the borrower is called upon to pay the surveyor's fee and expenses, and a small fee, amounting to 10s. per cent. as a rule, on the value of the loan.

### Authority of Local By-Laws

There remains to be considered the purchaser's relationship to the local authority. When the house is to be erected on a developed residential estate, he will find that such matters as the submission of plans for the local authority's approval have been arranged for, and the builder will see to it that the plans involve no breach of the local by-laws. But if the site is on undeveloped land, and the builder does not accept any responsibility for a breach of the local by-laws which the plans may involve, then the purchaser should study these by-laws very closely indeed. By-laws are stringent enough to add considerably to the cost of the house. Recent legislation affecting house building include London Building Act (1930), the Town Planning (1932), Ribbon Development (1935) and Public Health (1936) Acts.

In any case the matter of future road charges should be carefully investigated. Very often a building

firm developing an estate will undertake the construction of everything connected with it, including drainage and roads. The latter are made with the authority's approval; but even then the authority does not renounce its right to call upon the occupiers of houses on a particular road to remake the road at their own expense in accordance with the authority's ideas. The builder may give a personal assurance that no such demand will be made for a number of years, but he will rarely give it in writing, and it is always as well to allow for this contingency in estimating the ultimate cost of the house. The only site that is immune from the danger of road charges is that fronting on a road that the local authority has already taken over and made up.

**BUILDING SOCIETY.** A building society exists primarily for the purpose of receiving money from its members and lending it to them or to others to enable them to buy or build houses. In the United Kingdom building societies must be registered, and the registrar of friendly societies examines their accounts. The funds of a society must be invested upon mortgages of real or personal property, or in trustee securities. Two-thirds of the money advanced on mortgage can be borrowed by the society.

To become a member of a building society it is usually necessary to buy one or more shares. For these payment can be made by instalments and the member's liability is limited to the shares he holds. In addition, the societies receive money on deposit, paying interest on this according to the state of the money market, but usually giving a higher rate than the banks. Money on deposit can be withdrawn often without notice, although in the case of large sums notice is required.

Money may be borrowed either on building society mortgage or on ordinary mortgage, the security given being a mortgage on the property. In the former case it is for any time not exceeding 15 years, monthly repayments of principal and payments of interest being made. In the latter case, the principal is repaid by quarterly instalments, but these repayments do not begin until three years have elapsed. Interest is paid monthly, as in the case of the other class. The rate of interest varies and commences on the day the mortgage is executed. After the first year it is charged on the balance of the principal which remains unpaid at the beginning of the year. An additional 1 per cent is charged during the first three or four years of the mortgage.

An applicant for an advance should fill up a form of registration and pay a registration fee of 1s. The property to be mortgaged is then surveyed. For this fees average a guinea for each £500 of the mortgage below £1,000, and a guinea per £1,000 above. Extra travelling expenses are liable to be charged for property more than five miles distant.

The officials of the society will, on receipt of the

surveyor's report, decide whether or not the advance shall be made. If the decision is favourable, the entrance fees on the shares necessary to make up the amount of the advance should then be paid. The title deeds or the abstract of the title should be handed to the society's solicitors, who, if the title is approved, will prepare the mortgage deed, and on its execution and the receipt of the law charges will pay the amount.

The scale of law charges is £2 12s. 6d. for an advance not exceeding £500; £3 3s. for one between £500 and £1,000; and £1 1s. extra for each £500 or fraction of £500. Persons who wish to erect a house cannot, of course, obtain money upon it until something is in existence. In such cases it is usually possible to arrange for the builder to wait for his money, or the bulk of it, until it can be obtained from the building society. *See Mortgage.*

**BULB:** How to Grow. In the popular sense bulbs include daffodil, hyacinth, narcissus, iris, tulip, crocus, lily, snowdrop, and many others, some of which are not really bulbs, but rhizomes or corms. Bulbs should be heavy in proportion to their size. Soundness may be tested by pressing the thumb on the hollow at the base; this will be firm if the bulb is sound and soft if the bulb is unsound. Reject all soft, spongy bulbs. Flower growth must be preceded by strong, healthy root action, and the cultivator should give it every encouragement.

*Bulb. Diagram showing the correct methods of growing bulbs, and some of the common mistakes which are made.*

Both size and weight have to be considered in selecting bulbs. Hyacinths are graded and sold at different prices according to grade. A bulb about 2½ in. through in its thickest part is a

first size bulb, and will command the best price for the particular variety. Nevertheless, a bulb is often less than 2 in. through and still a first size bulb, as the

varieties differ in respect of the size of their bulbs. The bulbs of daffodils, tulips, and lilies vary a good deal in size. If lily bulbs are shrivelled they should be laid in coconut fibre refuse about a fortnight before planting.

*Bulb. Two examples of indoor culture; left, single narcissus; right, white Dutch Roman hyacinth.*

There is no better compost than three parts of sound loam, one part of thoroughly decomposed leaf-mould, half part of decayed cow manure, and sufficient coarse sand to ensure the free passage of water. The compost should be thoroughly mixed some time before it is required for potting. It should be moist but not sodden.

If new pots are used, they should be well soaked for several hours, and allowed to dry. Figs. 5 and 6 in the diagram show correct potting, with ample drainage, and the bulbs resting on a base of silver sand. Bulbs should not be planted deeply, as in Fig. 7, or too much above the badly drained soil, pictured in Fig. 8. To drain, place a large piece of broken pot over the drainage hole, smaller pieces over and around it, and

still smaller pieces above these, then some of the rougher parts of the compost.

*Bulb. Fritillaries grown out of doors.*

**Bulbs Grown in Water.** Bulbs are also grown in glasses of water, rainwater when possible. To keep it pure, a few pieces of charcoal are put into the glass, as shown in the diagram. It is not necessary for the bulb to touch the water; it should rest just above the surface, as in Fig. 1, not in the water as in Fig. 2. Loss of water must be made good from time to time. Bulbs in glasses are best kept in a dark cupboard until they have made considerable root growth, as shown in Figs. 3 and 4 of the diagram. Staking is sometimes essential, and wire supports should be employed.

Some bulbs, more especially the bunch-flowered narcissi, do well in bowls when placed among pebbles and water, but the more customary method for indoor culture is to plant in a mixture of shell and fibre.

The mixture at the start should be fairly damp. A

#### **BULBS: FOUR POPULAR VARIETIES FOR GROWING IN THE HOME**

**For the culture of bulbs in general see under the heading Bulb. Fuller and more detailed information is given under the individual names: e.g. Tulip , Freesia ,Hyacinth , and Fritillary.**

Lord Kitchener Daffodils

Michael Angelo Daffodils

Yellow and striped Crocuses

White and Rose Scillas

**BULBS: FOUR OTHER VARIETIES OF DECORATIVE SPRING FLOWERS**  
 Two popular kinds of daffodil are shown above. Directions for their culture may be taken from the general article on Daffodil.

good deal of wetting and turning will be needed to get it to this stage. Such bulbs as hyacinths, tulips, and narcissi should be planted in the bowls so that the crown of the bulb just shows above the mixture. They should be kept in a dark, cool cupboard or cellar for six or eight weeks.

**Bulbs for Table Decoration.** For table decoration, at a time of year when cut flowers are scarce and dear, relays of bowls should be planted with bulbs from August till December; the earlier plantings ensure a floral display at the close of the year. Bowls filled with flowering bulbs of the dwarf scarlet tulip look attractive on the Christmas dinner-table, while hyacinths brighten the sitting-rooms.

As the flowers themselves form the pattern of the decoration, the plainer the bowls are in design the better, and they should be chosen to harmonise in colour both with the room and the bulbs when in flower. Black Wedgwood bowls enhance the blighter hues, while green lottery, matching the leaves and layer of moss which should hide the crowns of the bulbs, also looks well. Daffodils in shiny brown and pink tulips or hyacinths in greyish-blue stoneware howls are effective in most rooms. *See* Crocus; Daffodil; Hyacinth; Tulip, etc.

**BULLACE.** Wild plum which grows in English woods and hedges. The small fruit is less bitter than the sloe, and it attains its full flavour only after being frosted. It may be used for fruit tarts, jelly, etc., much in the same way as the purple damson.

*Bullace. Prolific branch of this variety of small wild plum.*

The yellow-green or black fruit is ripe in October, and is produced in great abundance. The bullace may have the general treatment given to plums. It likes a rather heavy, cool soil. Very little pruning is required. The Langley bullace is the best for gardens. *See* Damson; Plum.

**BULLDOG.** The big head and wrinkled face of the bulldog are read by some persons as the outward and visible signs of a savage disposition. Yet there is no dog that is safer and that will with a sweeter temper endure all the indignities that may be put upon him by a young child. As a house guard, his methods are his own; instead of warning off an intruder by barking, he

prefers to administer punishment silently, and he is not persuaded easily to relax his hold.

*Bulldog. Champion of this breed, showing the massive shoulders and widely separated front legs.*

In selecting a bulldog, choose one whose body is broad and thick-set, and his head large even in proportion to his body and square-looking—as deep as broad; the thin, small ears set high on the head, the upper part falling to the side. The rough, broad nose should be black, the nostrils large and wide, separated by a sunk line. The thick, muscular neck should be short and arched; the chest broad and deep, keeping the short, straight boned forelegs far apart. The hind legs should be long and less massive; and the round, smooth tail should taper sharply in its short length from a thick base. His gait should be heavy and slouching. The maximum weight for a bulldog is 60 lb.

There is a toy race, known at shows as the miniature bulldog, which is in every respect save size a replica of the ordinary breed, but its weight is limited to 22 lb. The French bulldog is apparently a variety of the smaller breed, but distinguished from it at a glance by its erect ears; those of other bulldogs are always drooping. *See* Dog.

**BULLET WOUND.** The first-aid treatment of gunshot wounds may involve the treatment of haemorrhage, fracture, and shock. It calls for the greatest care to avoid further contamination of the wounds by dirt, thereby increasing the dangers of septic inflammation and tetanus.

Bleeding from the wound may be arrested by pressure as described under bleeding, or in the case of a limb by an improvised tourniquet.

Firm pressure should not be applied on the skull or over broken ribs. Simply apply cloths wrung out of clean, cold water. Such cloths should also be put on a wound of the abdomen, and then a towel pinned round or two broad-fold bandages. Fractures of the limbs should be fixed by padded splints, and of the ribs by broad-fold bandages, before an attempt is made to remove the patient.

Wounds should be washed by pouring over them cold boracic lotion, if possible, or cold water, and then covered with boracic lint or clean rags. Shock is treated by keeping the patient covered up, chafing the limbs, applying hot bottles, and giving hot drinks of tea or coffee, or, if all bleeding from a limb be stopped, a little spirits and water.

In wounds of the trunk care will have to be taken in giving anything to drink at all till the doctor's arrival. A bullet may remain in the body without any bad result whatever, though if it is easily removable it is desirable to take it out. *See* Bandage; Bleeding; First-Aid; Fracture; Tourniquet.

**BULL MASTIFF.** Although a crossbreed pure and simple the Bull Mastiff has been accepted by the Kennel Club in its classification, and this has enabled the breed to achieve prominence. At one time known as keeper's night dogs, their duty is the protection of person and property. A bull mastiff with its massive frame and stout build is necessarily a formidable foe. The prevail-ing colour is brindle, either light or dark,

but fawn specimens are not uncommon. A dog of this breed should be massive in all proportions —the head heavy, the jaws level, and teeth sound and strong; the neck thick and well rounded, the chest deep, the ribs well sprung, the loins short and strong and the limbs big boned, straight, well carried and well placed in relation to the body. Common faults are cowhocks, splay feet and weak quarters. Careful training is necessary.

#### **BULL TERRIER.**

The modern examples of the breed have less of the bulldog strain and more of the terrier of their original ancestry.

*Bull Terrier, a powerfully built breed of dog.*

Except for his black nose and small black eyes, the bull terrier should be wholly white, with a close, short coat of stiff glossy hair. The head is long and flat, wide between the semi-erect ears and tapering to the nose. The jaws are long and powerful, and the nostrils open. The shoulders are muscular and slanting, the chest wide and deep, and the legs straight. The rather short tail tapers from a thick base to a fine point, and is carried without curl horizontally. The bull terrier varies in height at shoulders from 12 in. to 18 in., and in weight from 15 lb. up to 50 lb. *See Dog.*

**BUMBLE BEE.** The bumble bee performs a useful service in the garden by fertilising flowers, but sometimes it causes injury, particularly to broad beans and antirrhinums. The honey being secreted deep in the blossom, the bee has a difficult task to force its body down to the nectaries. It finds an easier way by puncturing the calyx and petals from outside, and then drawing up the sweetness from within. The result is that pods in embryo are often spoiled by the puncturing and fail to develop properly, with a consequent reduction of crops. *See Bee.*

**BUMBLE FOOT.** The heavier breeds of poultry are more particularly subject to the disease known as bumble foot. It consists of a swelling in the ball of the foot which, soft at first, gradually hardens and, becoming full of pus, is very painful. The cause is commonly attributed to the fowl jumping to the ground from a high perch, but it is also liable to arise from injury caused by contact with hard substances, such as glass or rough stones.

The symptoms are lameness and a disposition to squat down. To cure it, apply bread or linseed poultices, and then cut and expel the pus, afterwards applying a simple ointment. The foot should be bandaged for a few days, and the bird placed in a pen by itself where it cannot perch but has to rest on straw. *See Poultry.*

**BUMBLE PUPPY.** This children's game can be played by two or more persons. A pole should be planted firmly in an open piece of ground. The height of the pole varies with the space available, as the taller the pole, the greater the space required, but it should not be much shorter than 10 ft.

From the top of the pole an old tennis-ball in a string or crocheted bag is suspended by a stout cord to about 3 ft. from the ground. The first player must hold the ball out and strike it with a racket, his aim being to wind the cord round the pole before his opponent is able to hit the ball back. When one or the other player be taken. The great rapidity of movement necessary and the quick accord between hand and eye make it an excellent practice for lawn-tennis. The game is also called stick-tennis or spiro-pole.

A game of whist played regardless of rules is given the name of bumble puppy, which is also an alternative name for the old game of nine-holes.

**BUN: Plain and Spiced.** Of much the same consistency as bread made with yeast, sweetened, and currants or raisins added, for buns the dough is formed into rounds and browned well on top.

Spiced buns are also made with yeast. The following is a good recipe to be used for these or hot-cross buns: Sieve 1 lb. flour,  $\frac{1}{2}$  teaspoonful mixed powdered spice, and a good pinch of salt into a warm basin, rubbing into them  $\frac{1}{4}$  lb. of butter. Then make a well in the centre of the paste. Put  $\frac{3}{4}$  oz. compressed yeast into another warm basin with a teaspoonful sugar and beat to a cream. Stir in  $\frac{1}{2}$  pint lukewarm milk and 2 well-beaten eggs, and then pour all into the centre of the flour, etc. Mix the whole lightly and beat until smooth; then cover the basin and put it into a warm place so that the dough may rise to twice its original size. This should take about 1  $\frac{1}{2}$  hours.

Clean 3 oz. currants by rubbing them on a sieve with a little flour, and add to the risen dough, together with a little less than  $\frac{1}{4}$  lb. castor sugar. Shape the dough into small buns and place on a greased, floured tin a little distance apart. For hot-cross buns mark a cross on each with the back of a knife. Leave them in a warm place for 10-15 min., when they should be almost double their original size. Then brush over with milk and bake in a hot oven for 10-15 min. *See Bath Bun; Rock Bun.*

**BUNG: Of a Barrel.** In everyday use, a bung presents three problems: how to get it out, how to replace it, and what to do when it is not tight and allows the contents to leak.

The withdrawal of a tightly fitted bung is almost impossible without damaging it, but a sharp steel spike, curved at one end and handled at the other, will sometimes prove effective. Careful prizing with a screwdriver is occasionally successful, or three corkscrews inserted into the bung, tied together with string and then pulled. When all else fails the bung can be driven through into the interior of the cask.

This necessitates the construction of a substitute. Provided a sufficiently large piece of cork is available, fashion it into a bung by cutting the cork with a penknife. Otherwise a circular piece of wood, such as that from the end of an old cornice pole, is easily shaped with a chisel and rasp. To obtain a good fit, try the bung in the hole and give it a twist; this will show up the high spots on the bung, and by cutting these off a good fit ultimately results. A disk of washleather or cloth will be found helpful in securing a tight joint. Bung holes can be enlarged or made with a tool known as a bung borer, but a drill and a cabinet rasp will answer. Steel drums containing oil and wood preservative are much more convenient if patent combined bung and pourer be substituted for the customary cork. A home-made substitute is simply made and consists of a bent tube, about  $\frac{1}{2}$  in. diameter and an air inlet pipe about  $\frac{1}{8}$  in. bore, and curved. Both are inserted into holes drilled in the cork bung. The drum can be sealed by inserting a cork into the mouth of the tube. *See Barrel; Cork.*

#### BUNGALOW: PLANS AND BUILDING DETAILS Ten Typical Examples of Attractive Dwellings Described and Illustrated

The reader may usefully turn to *Architecture; Bricklaying; Cottage; House;* and other articles dealing with constructional matters; as well as to *Building; Drawing, etc.*

For the purpose of this article the word bungalow is assumed to mean a house with all its rooms on one floor, to be lived in all the year round, and one that in construction and quality of finish will bear comparison with its higher-built neighbours. The bungalow can offer real advantages in reducing running and service expense.

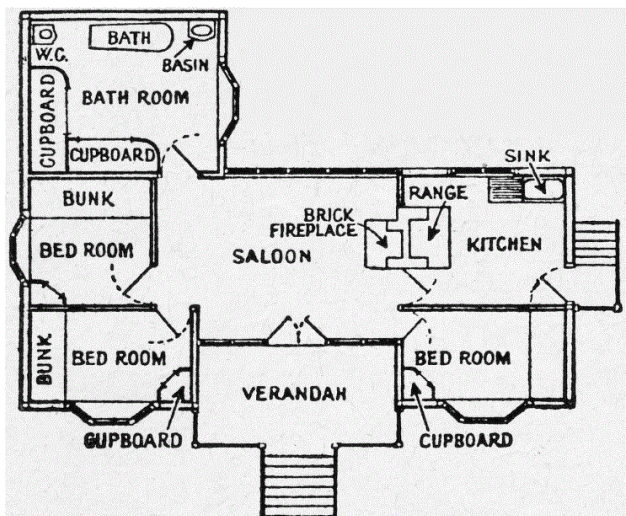

Most bungalows fall into two divisions: those with a central living-room or lounge, with the various rooms, including bedrooms, opening directly from it; and those with a hall or passage from which all the rooms are entered. The drawbacks of the first type are obvious; whether it is worth considering on account of the large gain in cubic contents—that is, cost—is for the occupier to decide. Fig. 1 illustrates the central-room type. This is a compact little riverside bungalow; in winter the many doors incidental to this type become a serious drawback. In Fig. 2, a cosy-looking bungalow of permanent construction, the same type of plan is rather more developed. There is a small vestibule to screen from outside draughts, and a comfortable sitting-room independent of the common living-room.

When we consider the second type of plan, in which the rooms are separated by communicating passages, or hall, we at once come on the great difficulty of the bungalow designer. He must compromise between a long, narrow building, which is economical of roof span but wasteful in passages, and the broader type of plan, compact as regards communication, but lavish in the height and spread of its roof. It is for these reasons that most examples save the smallest assume the L, the U, or the E shape, the additional cost of hips and valleys

being compensated for by the lesser roof span and decreased passage space.

The bungalow shown in Fig. 3 tends to the U shape, and has the charm of that most sympathetic of all roofing, reed thatch. The ingenious disposition of the rooms will be noticed in this example since, although it contains four bedrooms, the winding passage is relatively both short and well lighted.

The L-shaped type bungalow is shown in Fig. 4, a well-arranged and well-lighted plan, which is also compact and easy to roof. This example also possesses the excellent arrangement of placing the living rooms en suite, so that two moderate rooms can, on occasion, be thrown into one large one if required.

*Bungalow. Fig. 1. Bungalow at Staines, with verandah facing the Thames; below, plan showing arrangement of rooms round a central saloon. (Designed by T. Davison, A.R.I.B.A.)*

All these examples, with the possible exception of Fig. 1, illustrate bungalows which are meant for more or less constant residence, and built of permanent materials. They can thus be fairly compared with the average two-storey house, and offer distinct advantages. On the other hand, the week-end bungalow, for merely staying in, is so varied in size, purpose, and construction, that it is impossible to generalise. Being built for a different standard of life, the materials often are poor, and the general level of

finish such as would not be tolerated in an ordinary house. Owing to the absence of a staircase, it is usually easier to give any desired aspect to rooms than in the two-storey house. This concession, however, is modified by the difficulty of grouping bedrooms and, without excessive passage way, keeping their doors away from the entrance hall, a desirable point. Site and aspect usually have greater influence upon the plan in the bungalow than in the house. The most accommodating site is one with access from the north or north-east, which gives service quarters, etc., on the colder entrance side, with the living quarters to the south or southwest, overlooking the gardens and catching the maximum of sunshine.

Whether bedrooms should face east or not is a matter of personal choice. A small point that is often overlooked is the value of some suggestion of plinth or base, lest our bungalow tend to look like the top portion of a house half sunk in the ground. For the same reason the utmost should be made of any little difference in level, terrace, or steps.

Fig. 2. Bungalow at Renshurst, Kent, built of brick, roughcast, with tiled roof and genuine half-timber work in the gable. Above, plan. (Designed by T. Millwood Wilson)

The roof will usually be spreading and low in pitch, if only for the sake of economy, and this, if well proportioned, combined with broad eaves, will do much to give a restful effect as well as a useful shadow. Chimneys, in the nature of things more numerous in the bungalow, should be grouped and arranged when

possible to sit squarely on a ridge, or at least should bear some definite relation to the roofing scheme rather than protrude apparently at random, as is so often seen. Scale should be carefully considered, and accessories such as railings, porches, trellis work, etc., are most useful in preserving this. The usual fault is to make them too clumsy and lacking in elegance. If the roof is of thatch it is better to form the gutters and downpipes of wood in the old manner.

### Brick the Best Material

The most general and, other things being equal, most usually satisfactory material for the walls is brick.

Whether this is finished with facing bricks good enough as regards texture and surface to be left, or whether cheaper bricks are to be used, and the outside to be finished with plaster or lime washed, depends upon the materials obtainable and restrictions of cost. In any case, unless roughcast or plaster is to be applied outside, the walling of the building in order to ensure weather-proofness, should be hollow.

An economy that is perfectly satisfactory in one storey buildings is two walls of brick on edge with the through headers acting as bonders, or ties. This requires an external covering of plaster, etc., but effects a saving in bricks, and is amply strong enough to support the small weights of a bungalow.

Many efforts have been made to popularise wood construction in England. It is worth noting, however, that in America, one of the great homes of building in wood, there has been a growing tendency to revert to brick construction. Wood construction usually implies a solid braced framework of wood, covered externally with overlapping boarding, the inside walls being plastered or covered with a substitute, such as asbestos sheeting, match, or pressed fibre boarding. The main advantage of the wood house is the speed with which it can be erected compared to other forms of construction. In general, too, its initial cost is less, though a well-constructed wood house is by no means much cheaper than a brick one, especially if solid floors and substantial foundations are employed. Its disadvantages are obvious—shorter life and greater upkeep; in fact, before building a wood house its yearly cost of upkeep and repairs should be ascertained and capitalised and added to the initial cost.

Pisé-de-terre, that is, walls of earth rammed between shuttering until homogeneous, is a very old method of building. On account of its inherent weakness it is unsuited for lofty walls, and therefore more particularly applicable to the bungalow type. It also needs to be made of considerable thickness, this latter failing being its greatest charm. Like the wood building, however, it requires ordinary brick foundations and chimneys, and some form of surface protection. Fig. 3 shows a bungalow of this material, in which the pleasing effect of the softened corners will be noticed. As, however, many soils are unsuitable for this method, the prospective builder will do well to

(Continued in page 299)

### BUNGALOW: ARCHITECT'S WORKING PLANS, ELEVATIONS AND PERSPECTIVE SKETCHES FOR TWO EXAMPLES OF THIS LABOUR-SAVING ONE-STOREY TYPE OF PERMANENT HOME

These two dwellings are excellent examples of Bungalows which are genuine homes meant for constant residence and built of permanent materials. They demonstrate methods of planning and construction by which the disadvantages of the week-end type of bungalow are successfully overcome, while maintaining all the advantages of construction of the one-storey home. The design above is of a bungalow at Halstead and is of U-shape, with the service rooms on the north side round a diminutive courtyard, a service hatch and sliding door giving communication between the kitchen and dining room. The bedrooms are well separated from the living portion of the house without being cut off by space-wasting passages. This represents a developed form of the U-shape illustrated in Fig. 3, page 299, which provides about the same accommodation.

*(From Plans and drawings specially prepared by P.D. Hepworth, A.R.I.B.A.)*

obtain expert advice before deciding on his site.

*Bungalow. Fig. 3. Bungalow at Beaulieu, Hants. The walls are made of pisé-de-terre.*

*Fig. 4. Bungalow in Nottingham, without chimneys, as heating is by gas. It is of stucco-faced brick blocks. Above, plan. (Designed by D. Howitt, A.R.I.B.A.)*

#### Use of Concrete for Walls

Concrete forms a fourth method of wall construction. This may be either cast in shuttering on the job, or the wall built of previously cast blocks. Systems are innumerable. Probably one of those using cast blocks with two or more cavities in their thickness will make the best wall. In general, concrete for domestic building is not now widely used. For inside walling, however, the thin wall of "breeze" concrete blocks has almost entirely superseded the division of plastered studding.

Assuming a raft of concrete over the site, the floors may be either hollow or solid. In the first case the board is laid on wood joists, on dwarf brick walls, a short distance above the surface concrete, having—what should be, but often is not—a well-ventilated space below. The alternative is to lay the floor boards solid on the concrete in mastic, on the principle of a wood block floor. This method has been rapidly gaining in favour of late years, owing to its convenience and greater safety from dry rot.

Setting aside such materials for the roof as asbestos compounds and corrugated iron, there remain slates, thatch, or tiles, which may be either flat, as in Fig. 2, or the pantiles. If slates are used, an endeavour should be made to obtain one of the thicker varieties and to vary the colour. They usually look best over a whitewashed wall. If a sawn stone ridge is not used, the ordinary half-round ridge tiles, alternately tarred and whitewashed, make a good substitute.

Windows may be of casement form, either wood or steel, or the familiar boxed sash window. There is little difference in the cost between them, what there is being rather in favour of the casement. If casement windows

are used with shutters, these should open inwards, a fact which must be remembered when designing inside curtains.

Internal arrangements on different principles are indicated in the plans accompanying Figs. 1-4 and A to F. Detailed arrangements common to house and bungalow are discussed under the heading Architecture.

Bungalows are naturally harder to heat than houses, and if a central heating system is used, special attention should be paid to securing sufficient fall to the pipes. Moreover, bungalow chimneys, on account of their lesser height, are rather more susceptible to down draughts, and trees or buildings adjacent must be considered. There will usually be found ample room for storage purposes in the roof. Rough boarded and provided with a generous-sized trapdoor, it becomes a useful box-room, etc.

#### Comparison with a Small House

It is interesting to consider the relative merits and cost of a bungalow and a two-storey house. The average idea is that it is much cheaper to obtain the same accommodation in bungalow form, that passages are eliminated along with staircase, and that by having one storey half the brickwork is saved. Such conclusions cannot be said to be justified. As to actual saving, the omission of stairs, upper flooring, joists, etc., is obviously in its favour, but the area of ground flooring is practically doubled. As regards walling, the gain is small, since the lower height is usually more than offset by the greater perimeter. Chimney stacks, too, though less in height, tend to be more numerous and less easy to group. Damp course foundations tell heavily against the bungalow, as also does increased roof area, with its consequent greater length of gutter and ridge. On the other hand, there is greater speed in erection, and certain advantages, such as decreased scaffolding and easier supervision. Many of these points do not apply to the very small and simple bungalow, which may, even in initial cost, prove the cheaper. Above a certain size, however, the one-storey type tends to overtake and pass the house, though many will think the relatively small increase in first cost more than justified by its inherent advantages.

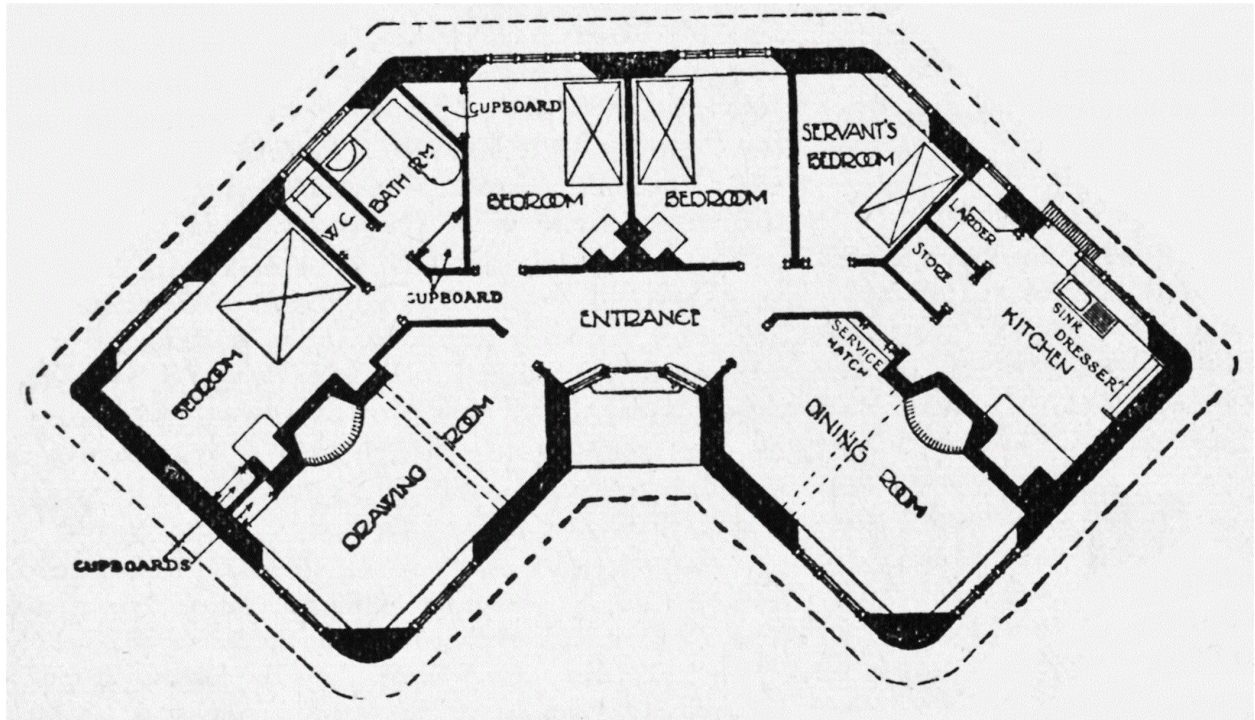

A careful analysis made by Mr. Edwin Gunn, F.R.I.B.A., concerning the approximate cost of a bungalow and a two-storey cottage of almost identical accommodation gave a working result of 9 per cent, extra to the former in initial cost. This granted, however, the advantage of having all the rooms on one floor is undoubtedly great and is increasing with the steady development of mechanical devices.

#### BUNION: How to Treat.

A bunion is a swelling over the joints of the foot; it is usually found on the first joint of the great toe. It occurs with displacement of this toe towards the other

(Continued in page 303)

These examples are supplementary to those given in pages 295 and 299 where the general principles of bungalow construction are discussed.

Above, garden front elevation. (P.D. Hepworth, A.R.I.B.A.) Left, (A), plan of U-shaped 4-bedroom bungalow with service rooms on North.

(B) Plan and Elevation of 5-roomed bungalow costing about £725 in London.

(C) Photo and plan showing large living room, garage and two bedrooms; brick rendered "Snowcrete"; cost, detached, about £900. (Taylor Woodrow Ltd., and Barr & Mead, Ltd. Agents for Bungalows B and C.)

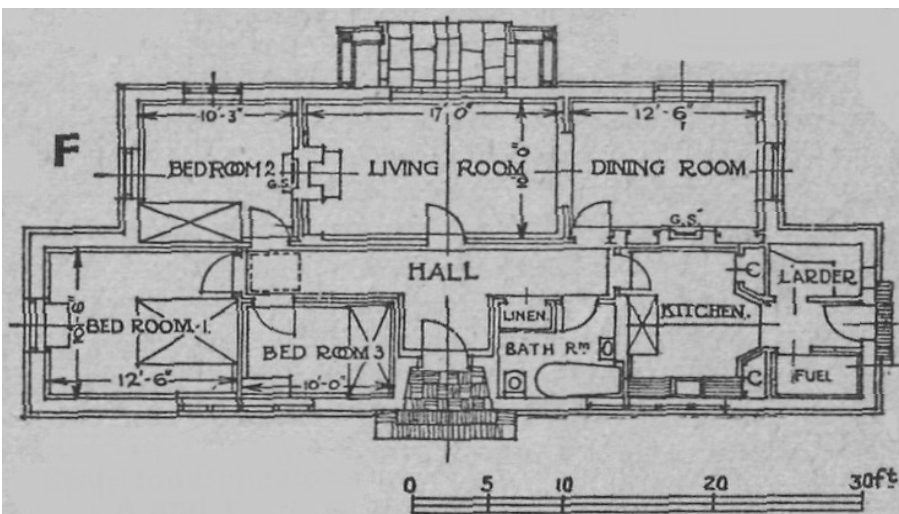

These examples are supplementary to those given in pages 295 and 299 where the general principles of bungalow construction are discussed.

(D) Well designed bungalow in brick. Note high porch in angle and absence of corridors. Cost about £605.

(E) Left and above. Bungalow with 3 good bedrooms, large lounge, 18 ft. by 14 ft., and glass roofed loggia; cost about £850.

(F) Left and above. Attractive design on long shaped plan with 3 bedrooms, living and dining rooms and service rooms well separated without wasteful passages. Thatched roof can be tiled. Perspective sketch from garden, above.

(E): New Ideal Homesteads Ltd.;  
(F): P.D. Hepworth, A.R.I.B.A.

Scale for Bungalows A and F.

toes by pressure of tight, badly shaped boots, or in cases of osteoarthritis. The resulting irritation causes thickening of the skin.

The first step towards a cure is the provision of a properly shaped boot, that is to say, straight on the inside. It may be necessary to have a boot specially made so that there is no pressure on the inflamed part. If the deformity is at all pronounced, a metal splint may have to be worn.

If inflammation occurs, tincture of iodine may be painted on, one or two coats nightly for three or four nights; but if there is suppuration, a doctor will have to let the matter out. *See* Corn; Foot.

**BUNSEN BURNER.** Universally used in laboratories and workshops, the Bunsen burner may be called the foundation design of all gas cookers and domestic gas fires. The principle of the burner is to utilise the velocity of a jet of inflammable gas or vapour issuing from a tube under some pressure to draw into the gas currents of air and to mix the air with the gas before it is ignited. There results a flame which may have very little illuminating power but is intensely hot.

A common modern form is shown in the diagram. The gas inlet is the inclined passage *a*; air is admitted at the bottom, the amount being regulated by the adjustable disk, *b*. *See* Gas.

*Bunsen Burner. Diagram of a common type.*

**BUNTING.** This material, a somewhat coarse, open-textured worsted, is generally woven in rather narrow widths and dyed in brilliant colours, being cut and sewn to make flags. It is rarely used for any other purpose except stand or stall decoration for a garden sale of work or flower show.

**Buphthalmum.** Name of the hardy perennial popularly known as ox-eye (q.v.).

## BUREAUX: ANTIQUE AND MODERN

Practical Hints for Collectors and Handicraftsmen

Other articles of similar nature are Cabinet; Chair; Chest; Sideboard. *See* also Chippendale; Inlaying; Joint; Sheraton; Walnut, etc.

There are only a few bureaux of earlier date than the reign of Queen Anne in existence, these being chiefly specimens from Cromwellian times. Walnut bureaux are a familiar feature of Queen Anne furniture. They usually had a glazed case or a cabinet of drawers above, were fitted with a sloping lid, and surmounted by pediments of various kinds, which never entirely went out of fashion right through the 18th century.

Bureaux were made by Chippendale and

Hepplewhite. The former made many that had above a bookcase enclosed by two doors, or a china cabinet. Above the cornice the broken pediment is found, and sometimes in the centre a crown and feathers. The inside fittings followed the Queen Anne models as regards their arrangement, but with carved decoration or lacquer work. An oak bureau should cost less than one of walnut or mahogany, because the two last-named woods were used for finer pieces. Mahogany bureaux over 150 years old are rare.

Secret drawers were often concealed in the complicated interiors of bureaux. A place where one may be looked for is on either side of the central pigeon-hole, where a little decorative column is sometimes placed. That column hides the drawer, discovered by putting the hand through the central pigeon-hole to the back and feeling there for a secret spring which releases the column, which then comes away with a narrow drawer behind it. Another drawer—a very simple device—may be placed at the back of two little brackets which are sometimes found to right and left of a central recess underneath the row of pigeon holes. These small brackets simply come out as drawers.

**Antique Patterns.** The illustrations on this page show fine examples of bureaux. No. 1 is a somewhat unusual example. Made of walnut towards 1700, it stands on cabriole legs with hoofed feet. The top is fitted with eight small drawers, four pigeon-holes and in the centre a cupboard. The pillars on either side of the cupboard should be noticed, as they form the backs of two secret slots, intended for hiding papers.

No. 2 is typical of the Chippendale period to which it belongs. The fine lacquer work ornamentation showing Chinese inspiration and influence and also the broken line of the pediment should be noted.

No. 3, of walnut, has interior fittings not unlike those of No. 1; but the four long drawers in the body of the piece suggest a more practical design, which has been very considerably imitated since.

*Bureau: antique examples. Left 1. Walnut bureau on cabriole legs and hoof feet, late 17th century.*

*Right 2. Piece of the Chippendale period ornamented with lacquer work.*

*Right fig. 3. Walnut bureau with shaped interior fittings. (1 and 3, courtesy of Gill & Reigate, Ltd.; 2. Victoria and Albert Museum, S. Kensington)*

Apart from its decorative effect, a bureau takes up less room than a writing-table, has deeper drawer space, and affords an opportunity of quickly enclosing a considerable amount of correspondence.

**Making a Bureau.** For the bureau shown on the next page, Fig. 5, mahogany stained to a rich plum colour, and either bright or dull polished, is successful, while waxed walnut has always a refined appearance. Oak, stained and polished to a Jacobean or nut-brown colour, will leave little to be desired for Fig. 3, and birch, beech, and basswood are efficient substitutes for a cheaper article, all these three taking stain well.

For a medium-sized article the apportioned width may be 2 ft. 6 in., whilst a small size may be put at 2 ft. wide. The height to table top is 2 ft. 6 in. and the enclosed slope rises from 10 in. to 12 in. above this. The depth back to front is 1 ft. 5 in. over the side. Two different styles of bureau are pictured, and taking the oak or Jacobean (Fig. 3) it will be seen that the main construction consists of two parts. The case encloses drawers and pigeon-holes, being separate from the base support, which is in the form of a stool, with recessed top into which the case drops. A front elevation of this bureau is given at Fig. 1, showing fairly deep drawer accommodation in the general dimensions marked, the width being 2 ft. 6 in. The depth of 1 ft. 5 in. marked on the side elevation allows for ample service. If shallower drawers are desired, the stool could be increased in height by a couple of inches or so with good proportions. A sketch of parts which will be handy for reference is seen in Fig. 4, which shows clearly the chief joints and fittings.

The sides (A) are of  $\frac{3}{4}$  in. thick hardwood, or  $\frac{7}{8}$  in. thick if faced. The front edge is vertical for 1 ft. 4 in., and then is cut back to a point  $9\frac{1}{2}$  in. from the back edge, to which it finishes at right angles and at a height of 2 ft. 3 in. This  $9\frac{1}{2}$  in. takes the top shelf, which should be of equal thickness with the sides.

The inner shelf or table top (C), in line with which the fall will open out, is best dovetail-grooved into position, but could be tenoned or dowelled to sides. It is shown as of equal width with the sides, but could be of 11 in. width only, so that, when fitted, it projects 1 in. under the stationery box (inserted later), and gives a bearing. The joint into sides is stopped  $\frac{1}{2}$  in. from the front edge of the sides, and the part pushed home.

The bearer rail (D, Fig. 4) is  $2\frac{1}{2}$  in. to 3 in. wide, by  $\frac{3}{4}$  in. thick, and enters into the sides with a couple of tenons. A couple of similar rails can be dove-tailed in at E, one at front and one at back, instead of the full width bottom of the case.

The runners (F) are tongued to the rails in addition

to being grooved to the sides, and are a clean-up from stuff 3 in. wide. They should also be grooved as well as the inner edge of rails to receive dust-boards (G), which are desirable to limit the drift of dust in course of service.

A check or short inner upright (K) is fitted  $\frac{3}{4}$  in. away from case sides on each side of the upper drawer, entering with a couple of tenons top and bottom; the resulting  $\frac{3}{4}$  in. space between serves for the slide (J) to travel in.

The slide supports the fall when down. It is made 3 in. wide, and mounted on a block (H) to make up the balance of height with the top drawer. The slide can be eased from  $\frac{3}{4}$  in. thickness, and should travel smoothly without play.

The drawer fronts (L, M) are shown in Fig. 3 as broken in design, but can be mitred up in the plainer manner indicated at Figs. 4 and 5 with neat effect. The section is  $\frac{1}{4}$  in. thick by  $\frac{3}{4}$  in. wide, and is obtainable in 10-ft. lengths ready for gluing and pinning as required. The drawer sides are  $\frac{3}{8}$  in. thick, backs  $\frac{3}{8}$  in., and bottoms  $\frac{1}{4}$  in., all dovetailed together in the usual manner. Handles of the pear-drop variety, with bolt and nut fastening, are preferable for the Jacobean design (Fig. 1).

*Bureau. Figs. 1-3. Jacobean bureau and details for making it.*

Figs. 4-5. Design for Georgian bureau with three drawers.

The back can be of  $\frac{3}{8}$  in. or  $\frac{1}{4}$  in. thickness, matched or plain, and may be rebated in or screwed on. The grain should run horizontally.

The fall or flap (as Fig. 3) can be framed up of  $\frac{1}{2}$  in. thickness, with a panel  $\frac{1}{4}$  in. net clamped each end and screwed behind. A  $\frac{3}{4}$  in. by  $\frac{1}{4}$  in. section mould is mitred up to drop in on face. Alternatively the fall can be framed up of  $\frac{3}{4}$  in. thickness with  $\frac{1}{2}$  in. panel grooved in, and the recess moulded on the solid. It will be rebated to lap partly over the edges of the sides and top shelf.

The stationery case is practically a separate box for insertion, and optional in its arrangement of pigeon-holes and drawers, etc. The surround can be of  $\frac{3}{8}$  in. thickness, dovetailed or nailed together, and the divisions of  $\frac{1}{4}$  in. or  $\frac{1}{8}$  in. in thickness, V-grooved into position.

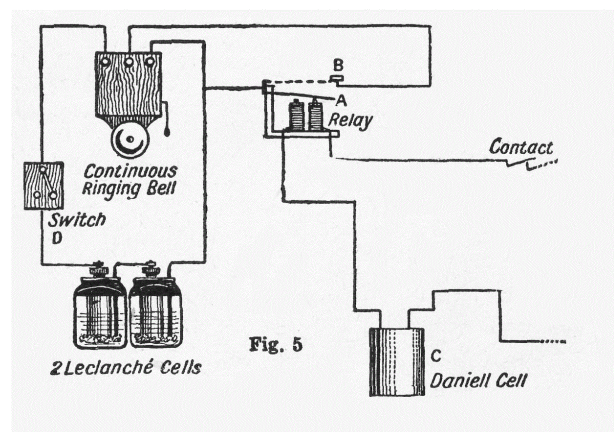

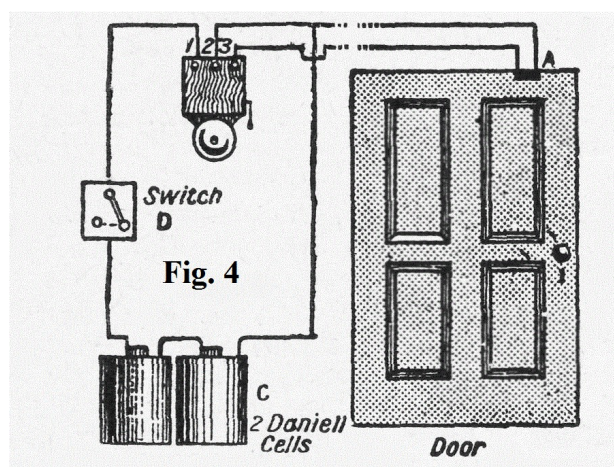

The stool base (Fig. 1) has  $1\frac{3}{4}$  by  $1\frac{3}{4}$  in. net legs, with the top rails dovetailed in as Fig. 2, and braced in the angles. The recess into which the upper casing (Fig. 4) drops is formed by a mitred mould on three sides, as in Fig. 2. Ball or mock twist turning is indicated, and blocks are provided for the underframing rails at sides and back to be tenoned in.

The foregoing details apply to the alternative design, Fig. 5, in a general way. A ledge on three sides is provided in place of the shaped rail of Fig. 3, and the fall can be of  $\frac{1}{2}$  in. thickness, mitre clamped each end, and with a  $\frac{1}{4}$  in. applied panel on face as an alternative to the grooved-in panel, which should finish flush on the inner side when lined with leather or cloth for writing. Being more in the Georgian style, circular handles of the rosette pattern are most suitable.

**BURGLARY:** Alarms for the Home. An alarm should be worked automatically by the entrance of the intruder, and so wake the inmates. The best system is electrical. It depends on the operation of a contact by opening or shutting a door or window.

Fig. 1 shows the door or window contact consisting of an arm carrying two contact plates normally separated from each other; these are forced together by means of

a pawl whenever a door opens beneath it. The device is fixed to the architrave over the door. Window contacts are made on the same principle (Figs. 2 and 3).

Burglar Alarm. Appliances and circuits that betray opened windows or doors (see text).

In the closed circuit alarm system the essential feature is that when in action the circuit is closed, a current of electricity flowing constantly along the wires and through the alarm contacts. The moment this circuit is opened, as by the opening of a window or door, or by cutting the wires, the alarm bell rings.

The wiring diagram, Fig. 5, illustrates a typical alarm circuit; but as many contacts as needed will be wired on the same principle.

Fig. 4 shows a single door contact at A, with a bell of the ordinary vibrating type, with the addition of a third terminal, this being in connexion with the contact post. A battery of Daniell cells is shown at C, and a switch at D, as a cut-out for use when the alarm is not needed. When this switch, D, is closed, current flows from the battery through the switch to terminal 1 on the bell, thence through the magnet coils to terminal 3, through the contact A, and back to the battery. This energises the bell's magnets, and attracts the armature, pulling it out of contact with the contact post, and maintaining it in this position until the circuit is broken, as by the opening of the door. When this happens the bell will continue to ring until the door is again closed.

This system suffers from the defect that if the door is again closed, or the severed wires reunited, the bell will cease to ring. For this reason a relay can be introduced with advantage, as it can be used, as shown in Fig. 5, to close a local circuit to a continuous ringing bell. The bell can only be stopped ringing by opening the switch D and resetting the catch on the bell.

The ideal protection is obtained by combining both systems, fixing open and closed contacts at every point to be protected.

The battery for any closed circuit system has to be of a suitable type, as the current is flowing constantly. The battery that is in most extensive use for this work is the Daniell (q.v.). Others are the Edison-Lalande, the Fuller and the Bunsen.

**Burglary Insurance.** Burglary is robbery from a dwelling-house by night. Night means between 9 p.m. and 6 a.m. of the next day. Housebreaking is a robbery from a dwelling-house between 6 a.m. and 9 p.m. Both offences connote a breaking-in or a breaking-out. If a thief finds a door or window open, and gets in that way, he is not a burglar or housebreaker, but if he steals anything, he has committed larceny from a dwelling-house. A householder ought to get a policy covering him against these risks. *See Insurance.*

**Burglary Prevention.** Adequate protection is often provided by building in strong iron bars for bathroom, larder and frequently kitchen windows.

*Burglary Prevention.*  
*Fig. 1 Key secured by spring wire clip round handle.*

*Fig. 2.*  
*Window bar fixed with coach-bolts.*

Fix them to woodwork with coach-bolts (not screws) the nuts being covered with plugs (Fig. 2). Casement

windows can

have the protecting bars crooked or bent outwards to allow the window to open. *See Bolt, Lock, Alarm, etc.*

**BURGUNDY.** Burgundy is a wine from the Haute- Bourgogne, Basse-Bourgogne, Maconnais and Beaujolais, in France. Fuller in body and of greater alcoholic strength than claret, it possesses a fine, clear, dark-red colour and charming bouquet.

Many fine wines come from Pommard, Volnay, Savigny and from Beaune in the Côte-d'Or. The last-named is perhaps the best known amongst the cheaper Burgundies. A true Burgundy can always be known by its clear dark red colour and bouquet.

Burgundy matures quickly, and a wine of 10 to 12 years old is in its prime. It should be slightly warmed before drinking.

**BURGUNDY MIXTURE.** A useful spray for potatoes to prevent summer blight, is named Burgundy mixture. To make a 1 p.c. solution put 1 lb. copper sulphate in a wooden tub containing 8 gal. of water and allow it to stand a few hours. When dissolved, put 1½ lb. soda in ½ gal. hot water and when dissolved cool down with 1½ gal. cold water. Pour the 2 gal. of soda solution slowly into the large tub. Its method of application is identical with that of Bordeaux mixture. *See Bordeaux Mixture; Potato.*

**BURN:** How to Treat. Injury caused by dry heat or flame is called a burn; a scald is the result of moist heat. There are various degrees of burning. It may cause simple redness or greater redness and blistering, but leaves no scar on healing (first degree).

Destruction of all the layers of the skin may be caused along with the nerve endings, so that there is less pain, but a deep and permanent scar remains (second degree). If the tissues underlying the skin are destroyed the result is deep scarring with deformity (third degree). Charring of the bone may also occur. The immediate effects are the pain and some degree of shock.

*The doctor should be summoned at once if the burn is at all severe, or if shock is present.*

Pending his arrival shock should be treated by putting the patient to bed, with hot-water bottles at his

legs and by his sides, and giving him hot drinks—tea or coffee, or a little diluted spirits, or a teaspoonful of sal volatile in a wineglass of water. The patient should be kept perfectly quiet and free from worry.

Children may very carefully be put in a warm bath; this will lessen the shock and facilitate the removal of the clothing from the burnt part. If any burnt clothing adheres, it should be soaked thoroughly, and if it does not come away easily it should be cut round.

With regard to first-aid dressing, there are various suitable remedies; the one chosen will depend upon what is handy. Greasy applications should not be used except for slight burns as they are usually difficult to remove. If blisters are small they should be left, but if large they should be pricked with a clean needle or scissor point. A good method of dealing with them is to thread a needle with white cotton and to boil these for a quarter of an hour in a clean pan. The needle is passed through the blister from end to end, and the cotton cut, leaving about half an inch on either side. The fluid contained in the blister gradually drains away.

In most hospitals the treatment for severe burns is now tannic acid. First-aid methods must anticipate this. Grease, which might spoil subsequent tannic acid treatment, should be avoided. Tannic acid preparations can readily be obtained for home use. Smaller ulcerations may heal quite well if treated with ambrine, boro-vaseline or lint, one of the many tannic acid jellies, or picric acid (1 p.c. in watery solution).

Paraffin preparations may be used for burns of the first and second degree. If not available, the burn should be covered up with cloths soaked in boracic acid solution, or in the case of a limb it might be immersed in warm water in which 4 heaped tablespoonfuls of baking soda have been dissolved till the doctor sees it. The cloths should be kept moist with the solution, as if allowed to dry they adhere to any raw surface.

When much scarring takes place after a burn, there is a tendency for the scar to contract, and if a joint is involved its movement may be impaired; or where opposed surfaces are involved, they may adhere together. The greatest care should be taken in carrying instructions given by the doctor regarding the position in which the parts are to be kept. *See* Bandage; Carron Oil; First-aid; Scald.

**BURNER:** How to Keep Clean. In oil lamps for table or wall use the burner is generally made of several pieces of brass, variously arranged. One part adapted to screw into the reservoir or oil container is called the body; another part, to guide and support the wick, is the wick tube, and a part to support the glass or shade is the gallery.

The wick tube generally has an extra part to accommodate a shaft and cog wheels to raise and lower the wick. Oil burners for heating stoves are made on similar lines, but some burners have perforated metal cones in place of a chimney, and these vaporise the oil, which then burns with a hot, blue flame.

The modern gas burner is made on the lines of the Bunsen. Gas stoves of all kinds have one or more atmospheric burners. These automatically mix the air

and gas in correct proportions to ensure a hot flame, although the best makes are fitted with independent means of adjustment.

*Burner: sectional diagram of two types of paraffin oil lamp burners. Fig. 1 Duplex flat wick.*

Fig. 2, with spreader.

Fig. 2

To obtain the best results from any form of burner, cleanliness is essential. A dirty oil lamp always gives off a strong odour. See that all screw-threads on lamp bodies and fillers are sound, and that the requisite washers are present and in good order. Wipe off carefully any spilt oil. Paraffin oil burners are easily cleaned by removing the wick and boiling

the burner for half an hour in strong soda water, drying off over the fire.

Incandescent gas burners should be cleaned from time to time by removing them from the bracket or fitting, taking the burner apart, and blowing or brushing away all dust and accumulated dirt. If this cleaning is not done occasionally the air passages become clogged with dirt, and a greater proportion of gas has to be burned. The same remarks apply to warming and cooking stoves. The burner is in this case generally made of cast iron. When dirt or dust accumulates within the passages cast into the burner, it is removed by boiling in soda water, or by brushing. *See* Acetylene; Bunsen Burner; Gas; Lamp.

## BURNING BUSH.

*Burning Bush. Flower spikes and leaves of a garden plant with a particularly pleasant scent.*

*Dictamnus fraxinella*, as the burning bush is known to botanists, is a herbaceous hardy perennial, 2 to 3 ft. high. It bears alternate pinnate leaves and purplish red-veined flowers in summer, and has a pronounced and agreeable odour. During hot weather the plants exude a volatile, inflammable oil which may ignite if a lighted match is put to it. If stock is wanted, it is best to break up one plant only and use small portions of the fleshy roots.

**BUSH FRUIT.** This term is usually applied to small fruits such as raspberries, currants and gooseberries, but larger fruits also may be grown in bush form, e.g. the apple. Bush fruits are commended to those with only limited space, and, given suitable soil and position, provide good crops with very little trouble. November is the best time for planting. After-care is important, light hoeing and freedom from weeds being of great benefit. Under-cropping with low growing vegetables, if necessary, may be carried out almost to the stems of the trees.

**BUTCHER'S BROOM.** A native evergreen, found on the heaths, butcher's broom has angled, erect stems, and rigid, twisted spiny leaves, on the centre of which the greenish white flowers appear in early spring. They are followed by red berries in early winter. The height is 2 to 4 ft. This shrub is dioecious, i.e. male and female flowers are on separate plants. Both must be planted to ensure fruits. A good shrub for shady places.

*Butcher's Broom. Spray of foliage and berries of the evergreen heath plant.*

**BUTLER: His Duties.** The butler is the head manservant. He has charge of the wine cellar and the plate, supervises arrangement of meals, and directs the servants who wait at table. It is the butler's duty to announce visitors whom the footman has admitted and ushered in. If there is no valet, the butler looks after his master's wardrobe and sees that his clothes have been brushed and laid in readiness. At night he sees that the house has been properly closed up. The butler generally takes his meals in the housekeeper's room, and is responsible for the indoor men servants.

**BUTLER'S TRAY: To Make.** The principal object of the butler's tray is to provide a corner where dishes can be placed while meals are served. It consists of an oblong tray on a stand, and has flaps on either side; when raised and fixed, these form an edging to prevent plates slipping off the tray. Holes cut in the flaps allow the fingers to pass through so as to carry the tray (Fig. 1). The stand is X-shaped and collapsible.

Another type, without flaps, and carried by means of fixed handles, is simply made either in mahogany, oak,

or white deal. The top should be 2 ft. to 2 ft. 6 in., and 18 in. wide, using  $\frac{3}{4}$  in. material. If deal is used, a piece should be obtained which is 9 in. wide and double the length required. This is cut in two and the pieces glued together, so as to get the 18 in. of width required for the top.

Two battens about 2 in. wide are screwed to the underside (Fig. 2), the edges and corners being bevelled. These not only strengthen the tray but prevent the wood from warping through hot dishes being placed on the tray. A narrow edging should be fixed round the sides with round-headed brass screws.

*Butler's Tray. Figs. 1-4. Diagrams showing details of an easily made butler's tray.*

A convenient height for the stand is 2 ft. 9 in. It is made in two separate frames, one fitting inside the other, so that one will be 2 in. wider than the other. If the top is 2 ft. in length, the legs should be cut off 3 ft. 1 in. long, from 1 in. deal, the width being  $1\frac{1}{4}$  in.

Place all the legs together and mark across them the centre, where a hole is bored to take the bolt, which should be as thin as possible so as not to weaken the legs; also mark the length. The legs have to be cut at an angle to conform to the top and floor.

Next, screw at the top of each pair of legs, a cross-piece 3 in. wide, and another piece 6 in. from the bottom 2 in. wide, as in Fig. 3, allowing 2 in. difference between each frame; the top pieces are bevelled at the same angle as the top of the leg. The frames are fastened together by two bolts (Fig. 4), the hole being bored large enough to take the collar, which is slightly longer than the thickness of the two legs.

To prevent the frames from opening too far, three pieces of webbing are tacked to the top cross-pieces. When fastening these, it should be noted that the stand fits just inside the two battens under the top, so the webbing should be cut accordingly. A suitable finish can be given by staining the wood a dark shade and then polishing. The brass handles should be fixed after polishing.

**BUTTER AND BUTTER MAKING**  
Simple Methods for Use in the Home Dairy  
Consult further Diet; Vitamin; and the entries in this work on Cheese; Cream; Milk, etc.  
See also Churn; Separator

Butter is essentially the fat of milk. If fresh milk is allowed to stand for several hours, the fat in the form

of cream rises to the surface, the larger globules first, and the small ones only after a long period. The cream, skimmed from milk that has been allowed to stand, contains besides the fat also some of the curd (casein) of the milk and some of the watery part, of which the skim milk principally consists. This method of obtaining cream for butter-making leaves still some of the milk fat among the skim milk. The milk is placed overnight in large shallow basins and in the morning the cream is skimmed off.

A more effective separation is obtained by the use of a machine called a separator. This revolves at a high speed, some 1,000 revolutions per minute, and, as the fat and the water are of different weight, the fat is driven in a layer to the top, and is drawn off by a tube fixed at the plane where the watery part ends and the fat layer begins. These machines are made in small sizes, suitable for home use. In one of these small separators an iron enamelled stand and crank are screwed to a table, and on them rests the separator proper, consisting of an upper bowl-like part into which the milk is poured. In the bottom of this bowl is a small hole plugged by a metal rod. This must not be removed until the separator is revolving at full speed.

Beneath this bowl, and fitting into it, is another small bowl containing a number of inverted, cone-shaped disks fitting closely one over the other. These revolve when the crank handle of the separator is turned, and by their rotation the fat or cream is separated from the watery part of the milk. The cream runs out through one spout and the separated milk through another, and both are collected in separate basins. After the separator has been used, it is taken apart and its component portions washed in boiling water to which a lump of washing soda has been added. It is then rinsed in clear boiling water, dried and put together again. The crank-handle should be oiled two or three times a week.

Each day the cream separated can be run into the same basin and then set aside to ripen or become fit for churning. When the cream is two or three days old the butter is of a richer colour and flavour. The best temperature at which to churn the cream is about 60° F.; if it falls below this the churning has to continue longer before butter materialises. In hot weather it may be desirable to stand the churn in a basin of cold water to which chips of ice should be added.

**Churning and Washing.** For use in small households, the best kind of churn is a glass jar with a screw top, through which passes a rod holding wooden paddles inside the jar and a handle for turning them, like that of a mincing machine or egg whisk. The churn and paddles must be scalded before use, and everything must be thoroughly clean. The top of the churn is taken off and the ripened cream poured into the jar. The top is then screwed on and the handle turned, slowly and steadily at first, and gradually quicker, until the revolutions of the paddle are almost sixty a minute. The cream becomes thicker until it is like a thick custard. After a few more turns of the paddle it becomes grainy and little flecks of butter appear.

The churn is then opened and a cupful of cold water thrown in. It is then screwed down again and the paddle gently turned.

After about six turns the grains of butter become bigger, sticking together in clots, and most of the buttermilk sinks to the bottom of the churn. The churn is then opened and its contents poured into a basin.

*Butter. Simple butter maker for household use. (Courtesy of the Staines Kitchen Equipment Co., Ltd.)*

*Butter. Making butter pats: 1. Place butter on mould. 2. Cut away surplus, first top, then bottom half. 3. When moulds are separated, the pat will come out. 4. Pair of moulds. 5. Butter cooler in pottery. (4, courtesy of Staines Kitchen Equipment Co., Ltd., 5, courtesy of Selfridge & Co. Ltd)*

Clear water is put in a second basin, and by spoonfuls the butter is lifted out of the butter milk and placed in the water. The butter is squeezed and kneaded with wooden spoons to get rid of the buttermilk. The washing water is changed repeatedly until it remains clear. If buttermilk is left in the butter it will not keep, and also has a sour flavour. When the last washing water has been drained off, the butter is sprinkled with fine salt and the latter well worked in; this helps to preserve the butter.

The quantity of butter produced by a given quantity of milk varies. The average should not fall much below ½ lb. from a gallon of milk. If too much water is left butter soon turns rancid. When the quantity made is for domestic use, the butter may be first prepared as described, and then remixed with a small quantity of fresh milk. If prepared for commercial purposes it must not contain more than 24 per cent of water. The commendable points about milk-blended butter are that

it has a pleasant flavour and a creamy consistence. It does not keep well, but in small quantities this is not so important.

Butter, being easily contaminated, should be kept in the coolest part of the larder, away from meat, fish, onions, or other strong-smelling foods. When choosing salt butter, test it by plunging a knife into it. If, when withdrawn, the knife has an unpleasant odour, the butter may be regarded as rancid.

Butter contains the food principle or vitamin also found in beef-fat, the yolk of eggs, and in fish-oil. As a food butter is a heat-producer. In an average diet about two ounces per day, including cooking, is enough. Much information on butter-making and means for overcoming faults and difficulties is given in Leaflet No. 184 issued by the Ministry of Agriculture.

**Butter Cooler.** The various types include those made of porous pottery the butter being placed on a tray which rests upon another containing water. The cover is placed over the butter and rests in the water, with the result that the porous pottery absorbs a considerable amount of the water and so becomes cool. Butter coolers are also made in zinc.

**BUTTER BEANS.** Prepared and used similarly to haricot beans, these beans are larger and possess a more delicate flavour. The skins are somewhat indigestible and if desired may be removed by putting soaked beans in boiling water for a few minutes, and then into cold, when the skins will easily come off. To serve as a hot vegetable, soak 1 lb. beans overnight, then put into a saucepan of cold water, with a piece of dripping or a lump of fat. Boil until tender (2-3 hours), replenishing with hot water, if necessary, and about ¼ hour before serving add salt and other seasoning to taste. They are excellent eaten with boiled bacon, or they can be served with tomato or cheese sauce on hot buttered toast.

To make rissoles, prepare ½ pint beans as above, adding 1 teaspoonful mixed herbs with seasoning about ¼ hour before done. Pass through sieve and mix with yolk of one egg and ¼ pint stale breadcrumbs. Shape mixture into balls or flat cakes, coat with white of egg and more breadcrumbs, and fry golden brown.

A good thick soup is made by soaking and skinning 1 pint beans and putting them into 3 pints cold water or unsalted stock, with celery, onion, tomatoes, chopped parsley and pepper.

(Salt must not be added until beans are tender.) After boiling pass the whole through a sieve, boil up and add 1 oz. butter and more water or stock, if necessary. A ham-bone or bacon trimmings, added while soup is cooking, improves the flavour. *See Beans; Haricot Beans.*

**BUTTERCUP.** The yellow buttercup of the meadows and pastures is a wild species of the *Ranunculus*, and is also known as the crowfoot. This is a very troublesome weed in gardens. It must either be spudded out or killed by dropping carbolic acid on the crown of each plant. Another method is to dip an iron

skewer into sulphuric acid and force it down the centre of the plant. The best remedy, however, is thorough digging of the ground, picking out and destroying all the roots as digging proceeds.

## BUTTERFLY AND MOTH COLLECTING

### Securing and Preserving Favourite Specimens

Following the entry *Birds' Eggs*, another article that deals with a collecting hobby, the reader will find instructions about making a suitable cabinet for his exhibits

In making a collection of butterflies or moths two methods are adopted: to catch the mature insects with a net, and to rear the caterpillars. By the latter method more perfect specimens will, as a rule, be obtained.

The butterfly net is made of mosquito netting or leno, with a hem of stouter material around the mouth through which passes the cane frame. If made at home it is advisable to purchase a brass Y-tube. The lower arm of this fits on the end of a stick and the upper arms take the ends of a curved cane which, before bending, measures about 3 ft. The depth of the net-bag should be twice the width of its mouth, and should have a rounded bottom, the stick being the length of a walking-stick.

*Butterfly Collecting.*  
*Glass-bottomed box, 1½ in. diameter, used for catching moths.*

Armed with this net, the collector visits such places as he has observed to be the haunts of butterflies: flowery fields, green lanes, heaths, the borders of woods and the open rides through them. For butterflies this must be in sunshine, preferably in the morning. Moths, being mostly night-fliers, must be sought after sunset. While many moths are attracted to light, others may be trapped by dipping rags in a boiled mixture of coarse foot-sugar dissolved in beer. The rags are pinned to trees, or a stripe of the sugar painted on the tree trunk. These baits are visited with a lantern; the moths will be captured easily, each in a separate glass-bottomed box, about 1½ in. in diameter.

Many kill their butterflies whilst still in the net by nipping the fore-body between finger and thumb; and if neatly performed this is effectual by compression of the chief nerve centres. Others put their captures into a cyanide killing bottle, or bring them home alive, each in its box.

Specially made entomological pins of various sizes are used for pinning, and these are obtained from the dealers by the ounce, ½ or ¼ oz. A pin of a size proportioned to the stoutness or slenderness of the insect's body is passed straight through the fore-body (thorax) and the protruding point inserted in the central groove of a corked setting board. The wings are then carefully arranged in the conventional manner,

and secured in position by strips of thin card pinned to the cork surface, but not through the wing. The antennae and forelegs are secured in a similar manner. The specimens should be allowed to remain undisturbed until the hind body has become stiff, which takes from 10 days to a fortnight. A little disk of paper with the locality where taken and the date should be transfixed by the pin under the insect.

**1** *Butterfly Collecting. Some requisites: 1. Breeding cage for caterpillars. 2. Setting board with specimen in position beneath thin paper for drying. 3. Specimens in position in cabinet drawer.*

Caterpillars for rearing may be obtained by noting plants whose leaves have been partly eaten; the spoiler may be hiding on the underside of the leaf or lower down the stem. The beating of trees or bushes over an open umbrella will yield many caterpillars. At home these should be placed on a sprig of the proper food in a breeding cage, which may be a box with a glass front and with perforated zinc or wire gauze at the back or top. The food can be kept fresh by having a small bottle of water with a hole bored through the cork large enough to take the stem of the plant.

In the cabinet drawer the insects should be arranged in vertical rows, each species with a neat label bearing the name below the specimens, which should include one of each sex, an example set with the lower side uppermost, and any others that show marked departure from the typical form, colour or markings. The latter are known as aberrations and varieties.

The drawers of an insect cabinet are un-divided, the bottom is lined with sheet cork to receive the points of the fine pins, and the framed glass lid fits airtight. There are cells to contain camphor or powdered naphthalene, as without one of these deterrents the specimens will be reduced to dust by mites, book-lice or other enemies. The cabinet should stand clear of the wall—especially an outside wall—to ensure safety from damp.

Should a cabinet be considered too expensive an item on beginning the collection, the insects may be housed safely in store-boxes which can be obtained from any dealer for a few shillings. A very suitable cabinet for butterflies or moths can be made on the lines of the birds' egg cabinet described under that heading.

**BUTTERFLY FLOWER.** The schizanthus, or

butterfly flower, is a greenhouse plant that blooms abundantly in summer. The best results are obtained by sowing the seeds under glass in September and repotting the seedlings as is necessary, finally placing them in 7-in. pots. They develop into fine plants and bloom in May and June. Seeds may also be sown in the greenhouse in spring. There are many varieties. The colours include rose, orange, and lilac, as well as white.

**BUTTERMILK.** This is useful in making biscuits, cakes, scones, etc. When combined with bicarbonate of soda, less cream of tartar is required than where fresh milk is used.

**Butterscotch.** *See* Toffee.

**BUTT JOINT.** The simplest of all joints is the butt, which might be described as the abutting of one piece of material on to another. It can be made in wood, metal, or other material. It is in woodwork that the butt joint is mostly used, and it is generally secured by glue, nails, or screws.

*Butt joint in wood secured by screws.*

There are certain essentials to success in making a simple butt joint. The work must be measured correctly, cut off square and true, and assembled and nailed together in proper order.

In metal work, a butt joint is usually riveted, brazed, or welded, examples being the riveted butt joint of a girder or bridge and the welded butt joint of ordinary gas pipe. *See* Box; Joint.

**BUTTON.** Small machines and supplies of button moulds are obtainable for making cloth-covered plain buttons, thus enabling the home dressmaker to turn them out neatly covered in any kind of self material.

Craft workers in metals can make enamelled and filigree buttons, and also original designs in beaten metal. Neat fingers and a hook are needed to plait strips of leather into buttons suitable for tweed coats.

The larger sized moulds, if for embroidered buttons, may be covered by hand. Cut out a circle of material half again as large as the mould, whip round the edge, place over mould, and draw up tightly, finishing off underneath. In most cases it is better to embroider the material, either in silks, wools, or beads, before it is cut up into circles for covering the moulds; but care must be taken to keep the design within the area of stuff that will show on the right side when the button is finished.

To sew buttons on firmly, stitch many times to and fro through the garment and the holes in the button or its shank or the material covering it. Finish before fastening off by winding the cotton tightly several times round stitches, between the button and stuff. A thin

material may be strengthened if a small square of stuff is put on the wrong side of the garment and sewn in with it and the button. For heavy coat buttons strain is avoided by a small button placed on other side of the material and stitches taken through both buttons.

**BUTTONHOLE: How to Make.** Before cutting buttonholes important points to decide are whether they are to run across or down; whether they will look better rounded at one end or square at both ends. If the button is to rest at one side of the buttonhole when the garment is fastened, then a round end at that side allows the button to fit in snugly.

To make certain that buttonholes are even, take a piece of light cardboard and make a notch in this, within one end, corresponding to the distance required between each buttonhole, and thus mark their positions. Buttonholes are usually sewn with a thick twist cut a little longer than the length required for one buttonhole. The starting of a new thread before the buttonhole is complete spoils the even effect. Take  $\frac{3}{4}$  of a yard of twist for a  $\frac{3}{4}$  in. buttonhole and proportionate lengths for a larger or smaller one. Use buttonhole scissors for cutting and make a clean slit of the required length. Where the rounded end is to be, hollow a little out with the scissors. If the material is woolly or liable to fray, it is necessary first to overcast all round with cotton. Where the buttonhole is to be worked through a double thickness, it is important to tack round the position for the buttonhole, to keep the layers from slipping when working.

*Buttonhole.*

1. Making a round end.
2. Buttonhole with round end.
3. Buttonhole-stitch.
4. Making a square end.
5. Buttonhole with square end.
6. With rounded and square ends.

Commence stitching at the end farthest from edge of material, and work from left to right. Insert needle through buttonhole from back to front about  $\frac{1}{8}$  in. from lower cut edge, and taking the doubled silk that comes from the eye of the needle, put it under the

protruding point of the needle from left to right; then draw the needle through, pulling it upwards so that the knot of the stitch comes exactly on the cut edge of the buttonhole. Repeat for the other stitches, making them exactly equal in length. When the rounded extremity is reached the stitches must diverge like the points of a star. For a square end make a row of buttonhole stitches at right angles to the line of the buttonhole and have knotted ends inwards, but first make two or three straight stitches across the end. *See* diagrams below, also Appliqué.

**BY-PASS: How to Test.** The name is given to a mechanical device whereby a gas burner (for example) can be lighted up or turned down without matches. One type of construction is seen in the diagram and consists of a separate small passage-way, controlled directly by the gas tap.

In the best makes of gas-burner the by-pass has a regulating screw and locking nut. The lock nut is to hold the screw in place when the correct adjustment has been found. If the by-pass flame is too small it will be blown out by the rush of gas from the burner, thus causing an escape which, in a closed room, may have serious consequences; if too big, it will waste the gas and cause the mantle to be blackened and soot up.

With some makes of incandescent burners the gas tap turns off the gas to the by-pass when the burner is fully lit, but re-admits gas to the by-pass when the light is lowered. Such burners need careful adjustment, or are liable to fail if turned on or off too quickly.

*By-pass. Sectional diagram of incandescent gas burner, showing arrangement of by-pass.*

The nozzle of the by-pass tube will become choked up with deposit after lengthy and continued use; it can be cleaned by wiping with a dry rag and pricking out the hole with a very fine wire, or a burner pricker. On most gas geysers the by-pass jet is controlled by a small tap, but the same principles of adjustment and cleaning apply.

**CABBAGE.** Growing freely in all soils, the cabbage is a very hardy plant. It can be sown to yield produce at most seasons, but chiefly in spring, early summer, and autumn. If the hearts are not cut too low,

### 'B' RECIPES: A SELECTION SHOWN IN ACTUAL COLOURS

*Birds'-Nest Pudding*, made of apples cored and filled with sugar, put in greased pie-dish, with lemon-flavoured sago boiled and poured over, and the whole baked in a moderate oven. *Black Currant Tartlets*, made of short pastry filled with syruped fruit. *Bread and Fruit Pudding*, more usually called *Summer Pudding*. *Beef Tournedos*, thin fillets of beef, fried and garnished with mushrooms, sliced tomato or mashed potato.

but near the base of the lower leaves, the stump will throw up secondary sprouts.

It enjoys a deep, rich soil, but while the ground may with advantage be fertile, it should also be firm, especially for the spring crop. Yard manure of any kind is suitable. Sulphate of ammonia or nitrate of soda, 1 oz. per sq. yard, should be applied occasionally in spring and summer.

Cabbages for late summer and autumn are sown in March and April, for spring in July and early in August. One ounce of seed should produce 1,000 plants. Like borecole, cabbage is transplanted. Large sorts are planted out 2½ ft. all ways, medium sorts 2 ft., small or very compact varieties, 18 in.

Some varieties of cabbage are suitable for sowing in spring, others for sowing in July and August. Excellent sorts to sow in summer are Harbinger, April, Flower of Spring, Mein's No 1, Ellam's Early and Emperor, they will supply produce in spring and early summer. The following, if sown in March, will furnish cabbages in late summer and autumn: Little Pixie, Tender and True, Imperial, Enfield Market, Emperor, and Winningstadt.

*Cabbage. Diagrams illustrating points to be observed in planting.*

1. Cut off tap root at 'a' before planting.
2. Place in hole and lever over soil with dibber (a).
3. Correctly planted cabbage.
4. Badly planted cabbage, with space beneath root.
5. How to plant in dry soils.
6. Method of planting in wet soils.

Colewort is a first-rate small cabbage to sow in April and May for autumn produce: the seedlings should be thinned out to 10 in. apart, not transplanted. Red or pickling cabbage is sown in August. Savoy cabbage, a valuable hardy winter vegetable, is sown in April and May. The Drumhead cabbage, from an April sowing, yields firm hearts in late autumn.

The Portugal cabbage, or couve tronchuda, is valued for the sake of its thick midribs, which are almost as good as seakale, as well as for the head of cabbage. It is grown from seeds sown under glass in March or out of doors in April.

Chou de Burghley, which produces a broccoli-like head, is sown under glass in March for an autumn supply, or out of doors in May for spring use.

Bolting or premature running to seed is most troublesome in the spring crop sown after midsummer; it is most likely to occur when a dry autumn is followed by a wet winter. Sowing the right varieties at the right time, planting on a firm bed in October, and hoeing and feeding in spring are measures which are likely to prevent bolting. *See Black Rot.*

*Cabbage. Above. Conical cabbage. Right. Hard-headed cabbage of Drumhead variety.*

#### **Cooking the Cabbage.**

To boil cabbage, first remove all discoloured leaves and the stump of the stalk. Halve the cabbage, or, if it is large, quarter it, and then remove a wedge-shaped piece from the stalky centre. Wash the cabbage and let it soak in cold salted water; then put it in a saucepan containing plenty of fast-boiling water, allowing to each quart of it a tablespoonful of salt and a piece of soda the size of a large pea.

Boil the cabbage quickly, the lid being off the pan, for 15 to 40 min., or until the leaves and smaller pieces of stalk are tender. The time needed will depend on the age and size of the cabbage. Strain off the water through a colander, pressing the cabbage firmly. Heat again in the saucepan with 1 oz. butter; add seasoning and serve in a hot vegetable-dish, cutting the cabbage across in portions.

The water in which greens have been boiled must never be poured down the sink without afterwards flushing it with water. It is better to pour it away outside if possible, since it often has a strong and somewhat objectionable odour.

Stuffed cabbage provides an excellent way of using up scraps of meat. Should there be no scraps in the

(Continued in page 315)

larder use  $\frac{1}{2}$  lb. of sausages, preferably pork. Wash and trim a savoy cabbage, put it in a pan of boiling, salted water, and boil it until it is half done, then drain it well. Cut it nearly in half, and remove a piece out of the centre.

If using sausages, remove the skins and mix with the meat a good dust of salt and pepper, 2 dessertspoonfuls chopped parsley, 1 dessertspoonful chopped onion, and 1 oz. rice, which has first been boiled until tender in salted water. If scraps are being used, cut off all skin and gristle, chop the meat finely, and use it instead of the sausage-meat. Next press the mixture into the cavity in the cabbage, put the two halves together, bind them round with a piece of tape, then wrap the whole in a piece of muslin, put it in a pan with plenty of boiling salted water, and boil until the cabbage is tender. Take off the muslin, and tape, arrange the cabbage in a hot dish, and pour round it some brown sauce. This is sufficient for four persons.

**CABBAGE APHIS.** This is a pest frequently found in colonies on the outer leaves of the cabbage. It does not affect the hearts, except by weakening the constitution of the plant. If the plants have good soil to grow in and are stimulated by vigorous hoeing, no further steps are needed. Should the pest threaten to give them a serious check, it may be as well to use an insecticide; but this is only likely while the plants are young; at a later stage the outer leaves can be broken off.

**CABBAGE CATERPILLAR.** The caterpillars which are so destructive to cabbages and cauliflowers are usually those of white butterflies or those of the cabbage moth.

*Cabbage Caterpillar. Left, pupa and caterpillar. Right, white cabbage butterflies. (By permission of H. M.*

*Stationery Office at the Ministry of*

*Agriculture)*

White butterfly caterpillars perhaps feed more on the outer leaves of cabbages, while those of the cabbage moth burrow more into the hearts of the plant. In a normal year the pests can be kept under control in a small garden by hand picking. During the periods when white butterflies are seen on the wing in some number, crops liable to attack should be examined about once every 7 to 10 days, and all clusters of eggs should be crushed.

It is unwise to use poisonous sprays on green vegetables, but syringing the plants, especially

underneath the leaves, with paraffin emulsion or with a solution of salt, 2 oz. in 1 gallon of water, does good. Paraffin emulsion is made by dissolving a handful of soft soap in a little hot water, adding an eggcupful of paraffin and 2 gallons of water. This treatment is necessary in July and August. If the above simple solutions do not prove sufficiently effective, the following suggestions are offered in Leaflet No. 69, issued by the Ministry of Agriculture.

Slaked lime in powder or lime and soot are sometimes dusted on the plants when damp. Fences, etc., surrounding allotments should be searched for the chrysalides of white butterflies. When the ground is dug, a look-out should be kept for the brown chrysalides of the cabbage moth, which should also be destroyed.

**CABBAGE FLY.** The larvae of a grey fly infest cabbages in summer and cause them to turn yellow and droop in the hot sun. Its name is *Anthomyia brassica*, or the cabbage fly, and it must not be confused with the aphid or green fly. The male cabbage fly is quite a slate colour; the female is lighter. Spraying or the wholesale use of insecticides is not of much use. The only safe plan to prevent the pests from spreading is to pull up infested plants and burn them, at the same time giving the ground a good dressing of lime.

*Cabbage Fly larvae, highly magnified.*

**CABBAGE MOTH.** The cabbage moth is a dark brownish grey in colour; the caterpillar varies in colour between green and brown.

It feeds upon lettuce, mangold and various wild plants, but is especially fond of cabbage. Unless care is taken in dissecting and washing close hearts before cooking, the full-grown caterpillar may make its appearance at the table. The moths should be watched for in the evenings of June and July, when they are egg-laying. The caterpillars feed from July to October, when they go under ground to pupate and pass the winter.

*Cabbage Moth, the caterpillar of which is a destructive pest.*

The most effective method of dealing with this pest is to hunt for the caterpillars, which feed during the day-time as well as at night. The plants may be watered with soapsuds, a little paraffin oil being added; but this should not be done if the cabbages are likely to be cut within a period of four or five weeks.

**CABBAGE ROOT FLY.** One of the most destructive of insect pests, the cabbage root fly attacks cabbages and cauliflowers chiefly, but also sprouts, broccoli, and turnips, young vegetables suffering more severely than older plants. If an affected plant be pulled up it will be noticed that most of the small lateral roots have been eaten away, and the maggots are to be found around the main root or in the soil close by. It is in the maggot stage that the insect is injurious, the flies causing no direct harm.

A most satisfactory method of control is to protect the plants by means of tarred felt disks, particulars of which are contained in the Ministry of Agriculture's Leaflet No. 18. The disks act as a mechanical device preventing the flies from laying their eggs near the roots of the plants. The disks should be placed quite flat on the ground round the stems of the plants directly the latter are planted out.

It is also advantageous to earth the soil up slightly around the plants, so as to form a flattened ridge. It is important to keep the surface of the disks free from soil. Once the plants have made good growth they have been tided over the most vulnerable period, and the soil can be earthed up over the disks, as the latter are then no longer necessary.

*Cabbage Root Fly.*  
A. fully developed fly.  
B. larva. C. tail-end of larva. D. pupa.  
(By permission of Ministry of Agriculture)

**CABBAGE SNOWY FLY.** Resembling in appearance a minute moth, the cabbage snowy fly is a four-winged insect allied to the scale-insects. With wings fully spread it measures only  $\frac{1}{8}$  in. across. Both body and wings are coated with wax in a meal-like form, and this is shaken off where their yellow elliptical eggs are laid, so that the presence of the latter is revealed by these dusty patches. In spring they may be seen fluttering about the cabbages and laying their eggs on the undersides of the leaves. The flat little larvae that emerge suck the juices of the plant, and the evidence of their presence is a yellowing patch on the other side of the leaf.

Washes and sprays have been recommended for dealing with this pest, but seeing that it is always on the underside of a broad, greasy leaf all liquids run off the upper surface without affecting them. The only practical remedy is to locate the larvae by means of the yellow patches, and then either to destroy them by pressure or by cutting off the leaves and burning them.

#### **CABINETS: ORNAMENTAL AND USEFUL**

For the Connoisseur and the Amateur Woodworker  
Related articles are those on Bookcase; Bureau;  
Chair. See further Birds' Egg Cabinet; Coins; Corner

#### **Cupboard; Cutlery; also Antique Furniture; Cabinet Making**

At first little more than an oblong box, the cabinet, owing to the skill of the Flemish workmen in the 16th and 17th centuries, became a magnificent piece of furniture. The wood was carved, inlaid or polished, and the piece adorned with ivory, tortoiseshell, or precious stones. The doors were beautifully painted, sometimes on the inner sides as well as the outer. The interiors were often remarkable for their elaborate decorations, these taking the form of floors made of alternate squares of ebony and ivory, and adorned with columns and mirrors, the whole resembling a palace hall in miniature.

Cabinets were made in England in the 17th century, when walnut came into vogue. Flemish influence was strong, but something was copied from Chinese cabinets, which were then being imported: hence the use of lacquer, in which excellent work was done towards the end of the century. The stands were beautifully carved and sometimes silvered. In the 18th century some cabinets were made of mahogany, but lighter woods were still much favoured, satin and tulip among them. Another development was the introduction of glass into the doors, these cabinets being chiefly used for the display of china, glass, etc.

**Making a Mahogany Cabinet.** (See also page 317)  
The cabinet shown in elevation in Fig. 1 could be carried out in mahogany, when it would go well, with any furniture of the Chippendale type. It has an enclosed centre cupboard and two glazed cupboards at sides. A glazed door might be fitted to the centre compartment also if desired.

The base should be taken in hand first. The long rails at back and front are tenoned into the outside legs, and the end rails are similarly tenoned to the legs. The two inside legs are bridle jointed to the front rails. A shallow groove the width of the leg is cut on the front of the rail. Fig. 3 (E), and the rest of the thickness of the rail is taken out of the leg. The rails may be shaped with the bow saw. The shoe for the legs is shown Fig. 3 (A). A centre cross rail might be added to stiffen up the base. Mouldings are mitred round as shown in Fig. 2, and supported by blocks glued to rails and mouldings at short intervals.

The construction of the carcass is shown in Fig. 2. The partitions may be dovetailed or tenoned to the top and bottom. If the latter plan is adopted the tenons should be wedged after glueing up. The top and bottom are lap dovetailed to the sides of the carcass. The back is match boarded, each board being fixed with two screws at top and bottom. The frieze box is of solid mahogany, the front corners being mitre dovetailed together and the back lap dovetailed. To allow for the width of the mouldings on front and sides the back rail of the frieze box is made a little wider. The top is fastened to the frieze by pocket screwing. The top moulding is shown in Fig. 3 (B). The pediment has base

and capping moulding as indicated in Fig. 3 (C) and (D).

*Cabinet: two antique examples. Left, William and Mary china cabinet on stand, veneered with oystershell laburnum. Right, walnut and marquetry cabinet on stand, late 17th century. (Courtesy of Gill & Reigate, Ltd.)*

The doors are mortised and tenoned together and then rebated. Slats are fitted for the bar mouldings, the ends being stub tenoned, and the slats halved where they cross. An astragal moulding, or a plain rectangular one, may be used for the bars, which are glued on to the slats. The panel of the centre door is caul veneered, the pieces being first fitted and glued to a sheet of stiff paper.

The shelves, which rest on fillets, are fitted so that the front edges come opposite the second and third bars from the bottom.

### CABINET MAKING IN THE HOME WORKSHOP The Tools Required and the Principles of Construction

Further practical guidance for the amateur on this subject will be found in the articles *Amateur Carpentry; Workshop, etc.* See too *Bench; Joint; Tenon; also Chisel; Plane and other tools*

Cabinet making includes the making of all the finer articles of furniture, such as bureaux. It is thus distinguished from carpentry, which refers to the constructional forms of woodworking, such as roofing, flooring, staircasing, etc.

Most articles of ordinary household furniture can be made by the man who understands tools and is fairly proficient in their use, and if to some knowledge of timber is added skill in the making of joints, the cabinet making that can be undertaken is only limited by considerations of time and cost.

Cabinet making differs from carpentry not only in regard to the character of the work, but also in the timber used. Speaking generally, the cabinet maker uses hardwoods, such as oak, mahogany and walnut, whilst the carpenter works in the softer woods of the pine, fir, and spruce families. Hardwoods are chosen for furniture because of durability, the extra strain they can withstand, and their rich colour and pleasing grain. It is obvious that the working of oak is more laborious than the working of yellow pine, and also that surfaces which are to be polished must be brought to a higher degree of finish than boards which are to be

painted or varnished. Cabinet-work is finer, and calls for more careful workmanship than that necessary with carpentry; the material is more costly, and the aim is to produce something which is pleasing to the eye as well as of practical use.

**Tools Required.** A hand saw with blade of 24 in. or 26 in. is required for cutting boards lengthways. A smaller tool of the same type is the panel saw with an 18 in. blade. A tenon saw of 12 in. is an essential tool, and later, for fine work, may be added a 6 in. or 8 in. dovetail saw. The bow saw is required for shaped work, and a compass saw, with its long tapering blade, is useful for interior shapes which the bow saw cannot conveniently cut. With delicate shapes in thinner wood the ordinary fretsaw is used.

Rough boards are first dealt with by the jack plane, and if a worker buys his timber in the rough he will also require a trying plane, which is requisitioned after the first operation with the jack plane. The smoothing plane—a smaller tool—is used to bring the board to a further degree of accuracy, and leaves it ready for scraping and glasspapering. Of other planes there is a great variety, many being of iron. The toothing plane, with the cutting-iron milled to resemble saw teeth, is used to roughen the surface of a board preparatory to veneering. The router is for grooving timber across the grain. In addition there are planes for rebating, for ploughing, for shooting shoulders and mitres, and the range of moulding planes.

Other tools required include a range of chisels from  $\frac{1}{4}$  in. to  $\frac{3}{4}$  in., one or two gouges, a ratchet brace and boring bits, a try square, marking gauge and cutting gauge, a couple of spokeshaves, oilstone, glue kettle, rasp, file, two screwdrivers (large and small), several bradawls, pincers, pliers, mallet and hammers. A substantial bench is necessary, and a pair of hand cramps.

**Principal Joints Used.** Apart from a knowledge of joints, some of the general principles of cabinet construction should be clearly understood. A plain table of the simplest type, for example, is put together as Fig. 1. The legs (A) are mortised on their two inner faces to receive the tenons of the rails (B). If lower rails are to be introduced to strengthen the legs they will also be tenoned in, as at C. In the illustration a stub tenon (D) is shown on the top of the leg. This will enter a shallow mortise cut top of the leg. This will enter a shallow mortise cut in the underside of the top. The top itself will be glued down and additionally held either by pocket-screwing through the rails or by fitting glued blocks in the angles formed by rails and top.

In the case of a table which is to be fitted with a drawer, the method of construction usually followed is shown at Fig. 2. The ends (E) are tenoned to the legs, but at front, in stead of the upright rail, as in Fig. 1, there is a top rail (F) and a drawer rail (G). The upper rail is dovetailed to both leg and end as indicated; lower rail is tenoned to the leg. Drawer runners, etc., will afterwards be added. When a shelf with a rail is wanted below, the usual method for a light table is to tenon the rails (H) to the legs. The shelf (J) is cut at the

corners to fit the legs, and screwed to the rails from underneath. A section of this is shown at K.

*Cabinet Making. Figs. 1-3. Diagrams illustrating some of the principal joints used in making a table and light bookcase.*

*Cabinet Making. Fig. 4. Details of carcass construction. Fig. 5. Diagrams showing details of door construction. See text.*

When articles such as small bookcases, light sideboards, etc., are built with solid ends (Fig. 3), dovetail housing is adopted as the method of securing rigidity. A section of the dovetail housed joint is shown at A. In the case of the illustration sketched, the top of each end would be cut to enter a dovetail groove trenched in the top. The bottom shelf would be similarly dovetail housed to the ends, the joint in each case being stopped back about  $\frac{3}{4}$  in. to mask it in front. The middle shelves might be plain housed, as adequate rigidity is secured by adopting the method of dovetailing at top and bottom. The shaped rail shown under the top and also below the bottom shelf is tenoned to the ends and glue-blocked behind.

**Carcass Construction.** The term carcass is usually applied to the framed box which forms the skeleton of articles such as wardrobes, cabinets, chests of drawers, and bookcases. Fig. 4 indicates the carcass of a small wardrobe. The carcass would stand on a framed base, as shown, and have a loose frieze and cornice above. The top and bottom of carcass are dovetailed to the ends, the latter being rebated for a framed back.

Large articles of furniture are often made up of two or more carcasses. A tall bookcase or bureau will have

separate carcasses for the lower cupboard and the upper case, whilst a three-door wardrobe will probably be made up in three carcasses. The back of an enclosed article is sometimes matchboarded, but more usually framed up. Lighter items are now frequently fitted with three-ply boards. In the case of heavy furniture of the sideboard type, corner posts are added. To these framed ends are housed, and in front the carcass is connected by means of rails, dovetailed or tenoned in as in the case of a table.

Doors for cabinets, wardrobes, bookcases and sideboards are framed up of stiles and rails, mortised and tenoned together and rebated for their panels. Except in the case of very small doors the thickness for stiles and rails is generally  $\frac{7}{8}$  in. net. Wardrobe and bookcase doors which have to carry glass will need to be heavier. The width of the framing varies from  $1\frac{1}{2}$  in. to 3 in., according to the size of door. At Fig. 5 (A and B) are shown the mortised stile and tenoned rail of a door. The tenon is indicated with a shoulder, as C, and the stile is, of course, mortised right through. For light doors the shoulder may be omitted; in heavier doors the tenon is usually wedged, as indicated by dotted lines at C.

In the case of a cabinet with double doors, the meeting stiles may have an applied astragal on the right-hand door, as D, or the stiles may be rebated to engage as E, a bead being run up the edge of the right-hand stile to soften the joint. On the best work an astragal is rebated in as F. Fig. 5 also shows some typical examples of door panelling. The plainest treatment is indicated at G, a flat frame, with the panel sunk not more than  $\frac{3}{16}$  in. At H the frame has a simple mould run in the solid. J, again, shows the frame rebated to take an applied moulding, whilst at K the treatment adopted for heavier doors is indicated.

Working drawings for a dining-room cabinet are given on page 318, and other articles to which reference should be made are Bookcase, Bureaux, and Birds' Egg Cabinet. In the latter some leading features of cabinet construction are shown in detail, with large scale drawings.

**CABINET PUDDING.** For a hot pudding, well butter a plain mould and decorate the bottom with halves of glacé cherries. Break up about four stale sponge-cakes, and pack them loosely in the mould in layers, with a few chopped cherries or mixed candied fruits. Bring  $\frac{1}{2}$  to  $\frac{3}{4}$  pint of milk to boiling point, and beat up 2 eggs; let the milk cool slightly, and then pour it gradually on to the eggs, stirring all the time. Add about 2 tablespoonfuls sugar and a few drops of vanilla or other essence to the custard, then strain it over the cake in the mould, not quite filling the latter. Let it stand for at least  $\frac{1}{2}$  hour. Cover the top of the mould with a piece of buttered paper, and steam it very gently for one hour. Turn it on to a hot dish and serve with it any good sweet sauce. If preferred this mixture can be baked.

For a cold cabinet pudding ornament the bottom of a plain mould with cherries and angelica, cover these

with a thin layer of clear jelly, and leave it to set. Line the side of the mould with 3 oz. of Savoy biscuits, splitting the biscuits in half and arranging them alternately with back and front to the mould. Put 2 oz. of broken ratafias in the middle.

Next make a custard by beating up the yolks of 4 eggs—or, if preferred, 2 whole eggs—and adding  $\frac{1}{2}$  pint milk. Pour this mixture into a jug, stand it in a saucepan of boiling water over the fire, and stir until the custard thickens. Melt  $\frac{1}{2}$  oz. leaf gelatine in a little hot water and strain it into the custard. When cooled, add  $\frac{1}{2}$  gill of cream, with sugar and vanilla to taste. Mix all well together and pour it into the mould. When quite set turn it carefully out on to a glass dish.

**CABRIOLE LEG.** This carved leg found in certain styles of furniture has a projecting rounded knee at the top and a gradually tapering lower part, which is often carved with representations of a hoof, a shell, or an animal's paw grasping a ball. It is a feature of the Queen Anne style and was much used by Thomas Chippendale. In quite a different sense the word is used for a chair with upholstered back, arms, and seat, belonging to the Hepplewhite period. *See* Chair; Chippendale; Hepplewhite; Queen Anne.

*Cabriole Leg. Late 17th century pattern.*

**CACHOU.** By this name is known a small sweetmeat with aromatic flavouring which is slowly dissolved in the mouth to disguise the odour of intoxicating liquors, tobacco, etc. For this purpose cachous are generally carried in a small box.

**CACTUS: How to Grow.** If the cacti are to be grown in a room, a very light and sunny position in front of a window should be selected. In a greenhouse plenty of air and the avoidance of a damp atmosphere will be most likely to result in success. The great thing is to get the plants to flower, as in almost all cases the blossoms are exceedingly beautiful. The chief points to be noted are: In the first place, never give a cactus plant a large pot—that is to say, always let it be rather small for the size of specimen. Secondly, begin to water the plants freely in April, but keep the soil rather dry in winter. Thirdly, in the hot summer weather let the cacti simply bake in the sun, in order that all the shoots may become well ripened.

Perfect pot-drainage is essential. Fibrous loam should form part of the soil, but nearly an equal amount of sand and brick rubbish should be added; moreover, each pot should be one-third full of drainage material. About April is the best time to carry out the potting of cacti. Raising from seed is a very slow process, and by far the quickest method of propagation is by cuttings. Practically any part of the stem will grow if the piece has been dried in the sun for

several days before being inserted in a mixture of loam, leaf-mould, and small crocks. The cuttings are potted up as soon as they are rooted. The following are the principal kinds of cacti:

Cereus	Mamillaria	Phyllocactus
Echinocactus	Melocactus	Pilocereus
Echinopsis	Opuntia	Rhipsalis
Epiphyllum	Pereskia	

*Cactus. Right, variety called Old Man's Cactus, Cereus senilis.*

*Left, typical phyllocactus in bloom.*

Most of the phyllocacti are very free flowering, and a splendid white-bloomed variety is *albus superbus*. The well-known red, so often seen in cottage windows, is also another useful kind of phyllocactus. The epiphyllums, many of which bloom in the autumn and winter, are very graceful subjects, being crimson, pink or white in colour. The genus *cereus* has amongst it some free-blossoming kinds.

**CADDIS WORM.** This insect is a very attractive inmate of the aquarium, owing to its habit of building a cylindrical case of sand grains, gravel, grass-stalks, small leaves, or snail shells, each species selecting particular materials. They are the larvae of the caddis fly. There are about 150 British species, the larvae being found in ponds and streams. Their long, pale bodies are soft, except the head, fore-body, and six legs, which have a horny skin. To protect the soft hind-body they construct cases by uniting their building materials by silk filaments, with which also the tube is lined. These they drag over the bottom or haul up the stems of the water weeds, upon which they feed principally. Some species are carnivorous, and in the aquarium will destroy other aquatic insects.

*Caddis Worm. Protective tubes made by these worms and attached to twigs.*

When the larva is full grown it moors its case to weeds or stones, spins a silken web over each end of its tube, and changes to a nymph with free legs. Ultimately it leaves its case and climbs out of the water, throws off the nymph skin, and spreads the four hairy brown wings of the caddis fly. See Aquarium.

**CAERPHILLY CHEESE.** This cheese is considered to be specially suited to the needs of the underground workers. The most popular kind of

*Caerphilly* is a cheese of the quick-ripening variety, available for consumption a fortnight to three weeks after manufacture. It is, therefore, of a perishable nature and deteriorates in quality after four to six weeks, becoming dry. This cheese is made from morning's and evening's milk.

**CAFFEIN.** Alkaloid found in the dried leaves of tea, in the dried seeds of coffee, and in other vegetable preparations. The dose in medicine is 1 to 5 grains. Preparations in common use are *cafein citrate*, dose 2 to 10 grains, and *effervescing cafein citrate*, dose 60 to 120 grains.

The chief action of *cafein*, whether taken as a drug or in tea or coffee, is to stimulate mental activity. All the faculties become on the alert, the imagination is keener, and thoughts work faster. It also wards off fatigue. If the dosing is continued, as in prolonged, excessive tea or coffee drinking, an overwrought state of the whole nervous system results. *Caffein* has also a marked diuretic effect on the kidney tissues, increasing the flow of urine. The drug is therefore much used in heart dropsy, and other conditions in which it is desired to deplete the body of fluids through the kidneys. The *effervescing cafein citrate* is frequently prescribed.

*Caffein* is frequently used in heart disease, either alone or combined with other heart stimulants, such as *strychnia*; or it may be used in the form of coffee. When *phenacetin* is prescribed for headache, *cafein citrate*, 2 grains, may be combined with 8 or 10 grains of the former, with *cafein* counteracting any depressing effect of the *phenacetin* on the heart, and also enhancing the effect on the headache. *Caffein* is recommended for asthma, 2 to 5 grains of the *citrate* being given at bedtime and again during the night.

**CAIRNGORM.** Semi-precious stone of the quartz family. It is largely used in the mounting of Highland dress accoutrements; also for jewelry, chiefly brooches and buckles, seals and beads. In colour it varies from a pale-sherry tint through all degrees of smoky brown to almost black.

**CAIRN TERRIER.** This is an extremely popular variety, being a keen, sporty little dog, and one that is particularly suitable for living within the family circle. Apart from this it is used for ousting foxes from rocky cairns where a bigger dog could not go. Consequently he requires a strong muzzle for his size. A fair average weight is about 14 lb., but the tendency is towards a smaller breed.

*Cairn Terrier, a small sporting dog.*

The cairn is a short-legged, compactly built little dog with a rather foxy head, alert eyes, and small, pointed ears. The tail is carried gaily.

The outer coat is wiry and hard, and there should be a good under coat. The colour may be sandy, grey, brindled, or nearly black. Dark ears and muzzle on the lighter colours are appreciated. Eyes are dark hazel. *See Dog.*

## CAKES AND HOW THEY ARE MADE

### General Directions about Materials and Methods

Further details will be found under the heading of various cakes, e.g. Dundee; Genoa. *See also Baking; Decoration; Icing.*

Cake mixtures may be conveniently divided into four main groups: (a) Plain cakes, in which butter is rubbed into a relatively large quantity of flour; (b) Richer cakes, in which the sugar and butter are creamed (i.e. beaten to a cream) and flour and other dry ingredients added subsequently; (c) Sponge mixtures, which contain no butter, and (d) Gingerbreads, in which the butter, sugar, and syrup (or treacle) are melted together and poured into the dry ingredients.

Recipes covering each group are given below. Variations of these proportions and methods may be preferred by some cooks, but the examples given have been found satisfactory in practice. It is to be understood that wherever butter is mentioned, margarine may be substituted if desired, or for fruit cakes, a mixture of lard and butter.

**Plain Cake Mixtures.** A very plain mixture, suitable for an ordinary round cake or for small cakes (12 to  $\frac{1}{2}$  lb. flour) may be prepared as follows: Rub 3 oz. butter into  $\frac{1}{2}$  lb. flour. Add  $\frac{1}{4}$  lb. sugar and either  $\frac{1}{4}$  lb. currants or a teaspoonful of caraway seeds. (Alternatively,  $\frac{1}{2}$  teaspoonful of vanilla essence may be added after the egg and milk). Beat one egg, add to it rather less than a gill of milk, mix dry ingredients, put into a greased cake tin and bake one hour in a moderate oven. The 12 small cakes require 20 to 25 min. in a quick oven. By using  $\frac{1}{2}$  gill only of milk, a good rock cake mixture is obtained.

Another good cake of this type is called Bachelor Cake. To make it, add a teaspoonful of baking soda to  $\frac{3}{4}$  lb. of flour. Then rub in 3 oz. butter. To the mixture add  $\frac{1}{2}$  lb. sugar,  $\frac{1}{2}$  oz. each of cinnamon, allspice, and ginger,  $\frac{1}{2}$  teaspoonful of salt, 2 oz. chopped mixed peel,

2 oz. blanched and shredded almonds, 1 oz. caraway seeds,  $\frac{1}{2}$  lb. washed and dried currants,  $\frac{1}{4}$  lb. stoned raisins, and enough buttermilk to make the mixture into a moist dough. After beating for 20 min. place the dough in a greased tin, and bake for about 1 hour in a moderate oven.

**Richer Cakes.** A good sultana cake (Fig. 1) can be prepared as follows: Cream  $\frac{1}{2}$  lb. butter with 6 oz. castor sugar. Add gradually and alternately 1 lb. flour and a teaspoonful baking powder and four well-beaten eggs. (If self-raising flour is used no baking powder is

required.) Stir in a gill of milk, a pinch of salt and either  $\frac{3}{4}$  lb. sultanas or  $\frac{1}{2}$  lb. sultanas and  $\frac{1}{4}$  lb. finely chopped candied peel and beat thoroughly. Put mixture into a tin lined with greased paper and bake from  $1\frac{1}{2}$  to 2 hours in a rather slow oven. If a metal skewer inserted into the cake comes out dry, the cake is done.

A rather more elaborate cake of this type is known as Angel Cake. To make it, cream 4 oz. butter with 4 oz. castor sugar, add 2 well-beaten eggs and sift in  $\frac{1}{2}$  lb. flour mixed with 1 teaspoonful baking powder. Add  $\frac{1}{4}$  lb. sultanas, 2 oz. each of preserved cherries (quartered) and chopped preserved pineapple. Mix well, and if the mass seems too dry, soften with a little milk, but be careful not to make it too moist. Stir in a few drops of essence of lemon, place in a cake-tin lined with well-buttered paper and bake in a moderate oven about for about  $1\frac{1}{2}$  hours. The success of this cake depends on the thorough beating of the eggs and the gentle mixing of the flour.

*Cake. Fig. 1. Good sultana cake, a recipe for making which is given in the adjoining column.*

A very rich cake, suitable for Birthday or Christmas Cake, can be made, iced and decorated, as follows: Line a large cake-tin with greased paper (see Fig. 2), and then put  $\frac{1}{2}$  lb. butter in a warm basin, beating it with a wooden spoon to a soft cream. Add  $\frac{1}{2}$  lb. sugar, creaming the two ingredients together until they resemble whipped cream. Beat four eggs to a froth, stir them gradually into the mixture, and beat well. Sieve  $\frac{3}{4}$  lb. of flour, half a level teaspoonful of salt and two teaspoonfuls of ground allspice, adding these lightly to the whole.

Mix together 6 oz. currants, 6 oz. sultanas, 1 oz. glacé cherries (quartered), 6 oz. mixed chopped peel, 2 oz. shredded blanched almonds, and the grated rind of a lemon, afterwards stirring them into the other ingredients. Pour in 1 gill milk and 4 tablespoonfuls brandy, turn mixture into cake-tin, and smooth the surface quite level, using a knife dipped in hot water. To prevent the cake from burning underneath, a layer of salt or sand about an inch thick may be put in the bottom of the baking tin, and covered with greased paper. Then bake the cake in a moderate oven for about  $2\frac{1}{2}$  hours, and turn out on to a sieve (see Fig. 3).

When it commences to brown, lay a piece of thick paper over the top, letting it rest on the edge of the band that stands up above the tin. When cold, cover top of cake first with almond paste (q.v.) and then with royal icing (Figs. 4-5), and decorate it with caramelised fruits. The latter are prepared by boiling  $\frac{3}{4}$  lb. of loaf sugar in a saucepan containing sufficient water to moisten it, and stirring it over the fire until it becomes golden-brown in colour, and adding a few drops of lemon-juice. Take some greengages and apricots, cut into halves, and some whole grapes; dry these

thoroughly and drop them into the caramel mixture immediately after it has ceased to boil. When well coated, put the fruits carefully aside to dry, and then arrange them on top of the cake. Instead of the fruit decoration, sugar flowers may be used, made with an icing tube, and coloured (Fig. 6).

For a child's birthday cake, candles in tiny holders, the number denoting the age of the child, may form part of the decoration.

*Cake: stages in making a rich cake. Fig. 2. Cake-tin greased and lined with paper. Fig. 3. Turning the baked cake on to a sieve to cool. Fig. 4. Almond paste spread on top. Fig. 5. Cake covered with hard white icing.*

The necessary ingredients for royal icing are 2 lb. of icing sugar, 4 whites of eggs, and the juice of 2 lemons. Rub the icing sugar through a hair sieve into a basin, make a well in the centre, and put in the slightly beaten white of egg. Mix in a little of the sugar from the sides, then add half the strained lemon juice, and mix the whole to a rather moist paste, adding more lemon juice as required. If the lemons are large, all the juice may not be needed. Use the icing at once, smoothing it over with a large knife, dipping the latter in cold water occasionally.

Rich cakes should always be made a month or more before they are required for use; they should be packed (when cold) in several layers of greaseproof paper and kept in a dry and airtight place.

A Madeira mixture may be prepared as follows. Take 3 eggs and their weight in sugar and self-raising flour and the weight of 2 eggs in butter, and flavouring to taste. Cream butter and sugar, add eggs and flour gradually and alternately, stir in flavouring essence and beat very thoroughly. Put mixture in a cake-tin lined with greased paper and bake at once in a moderate oven from 1½ to 1¾ hours.

*Cake. Fig. 6. Final stage in making a rich cake: the finished cake decorated with ornamental flowers in icing.*

*Cake. Fig. 7. Layer cake with jam filling, the top iced and decorated with walnuts and glacé cherries.*

To make layer or sandwich cakes use 2 eggs and their weight in butter, sugar and self-raising flour and mix as for Madeira cake. Bake layer cake (Fig. 7) for about 1 hour in a rather slow oven. For Sandwich Cake, or Victoria Sandwich, divide mixture into two equal parts and bake in sandwich tins (greased and floured) for about 15 min. in a brisk oven. Layer cake should be cut through twice and spread with jam (preferably raspberry or apricot) or with whipped cream, sweetened and flavoured as desired. One excellent filling is made with minced Brazil nuts and sweetened whipped cream. A simple icing can be made by heating (not boiling) 1 lb. icing sugar with rather less than a gill of water and a teaspoonful of the desired flavouring. Pour over cake while warm and ornament with glacé cherries and walnuts or angelica.

**Sponge Cake Mixture.** One way of preparing this is to take 2 or 3 eggs and their weight in sugar and flour. Whisk eggs and sugar for about 15 min. and fold flour in lightly and thoroughly. Have ready a tin lined with buttered paper and sprinkled with sugar, put mixture in at once and bake in a brisk oven for about ¾ hour. For jam sandwich, divide mixture into two parts and bake in sandwich tins. This should take about 15 min. in a brisk oven. It is very important that this mixture should be made quickly and put into oven at once, and that oven door should not be opened until it is nearly done.

**Gingerbread.** A good plain gingerbread is prepared as follows: Melt ¼ lb. sugar, ½ lb. margarine, and ¾ teacupful of golden syrup in a saucepan over the fire. Beat up 2 eggs. and when the melted syrup is cool, add them to it and beat all together. Sieve together 1 lb. flour and 2 teaspoonfuls of ground ginger, make a well in the centre, and into it pour the syrup etc., mixing and beating the whole thoroughly.

Dissolve ½ flat teaspoonful bicarbonate of soda in ½ gill of milk, mix it with the other ingredients, and turn the mixture into a greased cake-tin. Bake the cake in a moderately hot oven for 1 to 1½ hours, then turn it on to a sieve and leave until cold.

The temperature of the oven should always be fairly high before cakes are put in. In a gas oven the burners should be left full on for about 10 min. previously and turned down about half way when cake is put in, i.e. rather less than half way for a 'brisk' oven and rather more than half way for a 'slow' oven. The oven door should not be opened for at least 20 min. after a cake has been put in, and when baking sponge cake, not until cake is likely to be done. The oven, it is to be noted, should be hotter for small and light cakes than

for fruit cakes.

To make a cake level for icing, a slice is sometimes cut off the top and cake turned upside down; but if mixture be kept higher at sides of tin than in the middle before putting in oven, the necessity for this is obviated to a great extent. Another method is to place a sheet of paper lightly across the side lining paper (which should always be higher than tin) as soon as cake has risen and browned slightly.

**CAKE STAND: How to Make.** Silver or plated silver stands having two or three tiers, and fitted with china or glass plates, are useful for the table.

Floor cake stands vary from 2½ to 3 ft. in height, and are made in metal and wood. Some of these fold up into small compass and have two or three tiers. To match the furniture of the room, stands are made of walnut, plain and inlaid mahogany, fumed oak, and other less expensive woods. One of the handsomest is made of black mahogany inlaid with English gilt, and having a pagoda design. Other Chinese designs are introduced on lacquered stands in colours to suit the scheme of the room.

*Cake Stand. Figs. 1-4. Three-tier floor-stand, and diagrams giving full details for making the various parts and fitting them together.*

A three-tier cake stand is shown in Fig. 1. There are

three shelves carried by side framework, which is provided with suitable feet at the bottom. The framework is connected by a crossbar at the bottom and a handle at the top. The wood selected should, if possible, match the surroundings in which the stand will be placed, oak (fumed and wax polished) or any of the polished cabinet woods being suitable.

The dimensions given in the diagrams are suitable for china plates about 9½ in. in diameter, so that, if larger or much smaller plates are to be used, the dimensions given should be altered accordingly. The framework at each side consists of two uprights (A) which are 2 ft. 9 in. long by ¾ in. square; a foot (B) and a top rail (C), which are cut from wood ¾ in. thick to the shape and dimensions shown in Figs. 2 and 3. The uprights are tenoned into the feet and top rails, as shown at Fig. 2, the length of the uprights between the shoulders of the tenons being 2 ft. 7½ in. The bottom crossbar (D) is 11½ in. long by ¾ in. thick. This bar is tenoned into the feet (B), the length between the shoulders of the tenons being 10½ in. The handle (E) is shaped as shown at Fig. 3 from wood ¾ in. thick. It is notched ½ in. over the top rail (C) and is fixed with screws driven through the rails. This completes the construction for the framework.

The shelves (F), are cut from wood ½ in. thick, and tenons similar to those shown at Fig. 4 are formed at each end for framing into the uprights (A). A rim

(G) is fitted above each shelf to keep the china plates in position. These rims should be cut from wood ¼ in. thick. They stand ¼ in. in from the outer edges of the shelves, as shown at Fig. 4. The inner diameter of the rims must be large enough to fit the rims at the bottom of the plates, which will probably be about 6 in. The edges of the rims could be bevelled as shown. The rims are glued to the shelves. It is usual to cover the shelves inside the rims with baize. In fixing the stand together all joints should be glued.

**CALAMINE.** This is another name for native zinc carbonate, and prepared calamine, which is used in medicine, is got from it by crushing and pulverising. The common calamine ointment, which is much used in inflamed conditions of the skin for its slight astringent effect, is prepared by mixing one part of calamine with five parts of benzoated lard. Calamine may also be used as a lotion.

**CALANDRINIA.** The annual kinds may be sown under glass in March or out of doors in April; they need well-drained soil and a sunny spot. *Grandiflora* (18 in.), *rose*, and *speciosa* (9 in.), crimson-purple, should be grown. *Umbellata* has magenta flowers.

**CALCEOLARIA.** The herbaceous calceolaria is

grown in pots for greenhouse decoration in May and June; the flowers are brilliantly coloured and make a striking display. Seeds are sown in May and June in pots of finely sifted sandy soil, and the plants are grown in a cold, shady frame during the summer. In autumn they are placed in the greenhouse, a temperature of 45 to 60 degrees being suitable.

*Calceolaria.* Left, clusters of the Golden Gem variety; right, profusely flowering herbaceous calceolaria.

The dwarf shrubby calceolaria, in yellow, bronze and other shades of colour, is a favourite summer bedding plant; it is not quite hardy except in warm, sheltered places, and is propagated by cuttings set in boxes of soil in a frame in September. Planting is done in May. Golden Gem is a favourite variety. There are several charming small-flowered calceolarias which are invaluable for the greenhouse in summer; chief among them are *integrifolia*, *amplexicaulis*, *Burbidgei*, and *Clibrani*. The John Innes strain of calceolaria provides plants 18-24 in. high, which bear small flowers in many colours. The shrubby kinds are increased by cuttings taken in late summer, the others from seeds sown in May.

*Calceolaria.* Diagrams illustrating the method of raising these plants from seed and cuttings. See text.

The seed is very small and, in the case of choice

varieties, is expensive. The compost is of loam, peat and silver sand placed in a box on a layer of broken crock, as shown in c and d, Fig. 1 and moistened by sinking the box in water. The seed is spread over the surface and covered with a little of the finest silver sand, as in b, Fig. 1. The box is kept in semi-shade in the greenhouse covered with a sheet of glass, as in a, Fig. 1, and when the plants are up they are removed to a frame, as in Fig. 2, kept there until well rooted. They are potted when the leaves are about an inch long, as in Fig. 3, and later transferred to a flowering pot, as in Fig. 4. A good mixture is one part each of loam and decayed hotbed manure to half a part of silver sand. Propagation of the shrubby varieties is by cuttings taken late in autumn with long heels sliced almost perpendicularly from the parent plant, as in Fig. 5, and inserted in a cold frame, Fig. 6.

The frame is kept closed for a few weeks to help the cuttings to form roots. During the late autumn and winter months it is necessary to ventilate the frame freely in mild weather and water must be given sparingly.

**CALCULUS.** A stone-like concretion known as calculus is found in the human body, especially in cavities which act as reservoirs. Thus, in the gall bladder, biliary calculus or gall stone occurs; in the pelvis of the kidney, renal calculus; in the bladder, vesical or urinary calculus.

The material of which a calculus is composed is frequently found to have gathered round a nucleus, e.g. blood clot, dried mucus, or a small foreign body. Such a concretion may give rise to few or no symptoms until it begins to make its way down the duct which empties the reservoir, when it may cause excruciating pain, as in biliary and renal colic. It may become stuck or impacted in the duct. See Gallstone; Kidney, etc.

## CALENDARS FOR HOUSEHOLD USE

Examples that are Easy to Make and Useful Bent Iron Work; Passe Partout; Stencilling are among the entries that those interested in making a calendar may consult with advantage

A calendar is quite simple to make. The necessary material, in the shape of cardboard or suitable paper, having been obtained, all that is necessary is to take a copy of the calendar for the previous year, and to move back all the dates by one, except for a leap year, when they must be altered by two. Thus the Sundays in January, instead of reading 4, 11, 18, 25, will read 3, 10, 17, 24. This done, with any elaborations that taste suggests, it may be mounted on to a piece of cardboard, wood, or leather,

Gift calendars are easily made by children on tinted mounting boards, which can be obtained in various sizes. One, 10 in. by 8 in., can be decorated with stencilling. A very pretty design is arranged so that room is left to fix a small tab calendar after the stencilling is completed. Appropriate stencils—a blue bird, a

squirrel, a ship, etc.—can be bought to be used with watercolour, and a small Jap brush. An alternative is to paste a photograph or a coloured print—outlining either with a black or coloured border, put in with pen or brush—on the mount. A smaller mounting board may be used and a booklet calendar fixed by two short lengths of narrow ribbon to hang below the board. A strip of firm paper should be pasted at the back of board and booklet in order to hold the ends of the connecting ribbons in place.

Stencils may be used on coloured suède. Take a piece about 7 in. by 3 in., place it on a flat board and stencil, on the suède side of the leather, the small design chosen. Mandarin inks or liquid stencil colours may be used. A border is painted or inked round the piece of suède, and appropriate words written, with the same colouring material, above the tab calendar. A hole is punched in the top of the suède through which a narrow ribbon is threaded to form a loop at the back and tied in a small bow in front. The lower end of the calendar may be fringed or the corners trimmed.

Lucky black cats, squirrels or birds, may be cut out of velvet and pasted on cardboard mounts cut to the shapes of the animals. A paper pattern should first be made by the help of a transfer. Glass beads may be used for eyes, fastened by wires at the back, the visible ends of the wires being covered with a dab of black paint to form the pupils of the eyes. The calendars can be gummed on the animals. Original designs can be drawn on the cardboard from which to cut the velvet.

A popular form is the slip-in mount which takes enlarged photographs.

*Calendar. Fig. 1. Diagram showing how a bird calendar can be made from velvet and cardboard.*

A calendar on which the figure of a bird is the main feature is shown in Fig. 1. A piece of cardboard is cut into a circle except for an extension at the bottom, as shown in the illustration, and is painted black. The figure of a parrot is then outlined, the upper part being on the circle, while the tail part, which is below it, is fitted with a backing of cardboard. A piece of blue velvet is pasted on to the figure, except that in one place, as shown in the diagram, a piece of green is substituted. The bird is apparently supported on a bough, round which claws, also of cardboard, must be cut, and these should be covered with yellow cloth. Finally the calendar proper can be hung on to the tail, and the whole suspended by a ribbon. Following the same design, other colours and figures can be used.

**Perpetual Calendars.** A perpetual calendar is illustrated in Fig. 2, details of construction being given in Figs. 3, 4, and 5. The work is simple; the side pieces are grooved to receive the front and back, the former being cut out and glazed. The top and base can be cut from the solid or built up from several layers.

The rollers are shaped as shown, and carry the linen band on which are marked the numerals 1 to 31. The upper and lower rollers have the names of the months and the days of the week respectively marked upon them. The work is completed by staining or polishing.

Another perpetual calendar is introduced into a linen sampler embroidered in cross-stitch, as seen in the illustration, Fig. 6, with a diagram, Fig. 7, showing back of calendar.

First take the strips of ribbon to match the colour of linen used and trace with a pencil on each, very neatly,

the days, dates and months. Outline these in black silk. Next draw the design on the linen and embroider the sampler in cross-stitch (q.v.), using delicate, old-world pinks, blues and greens. The little lady has yellow hair, pink and blue dress, yellow and green flowers. Blue French knots form her eyes and her face and arms are outlined in pale pink. The zig-zag design is in black, pinks, blues and yellows. The slots for the day, date and month are first buttonholed and then cut so that the strips may be inserted. The sampler is backed with cardboard, slots being cut exactly to correspond with those in front to allow the strips to be moved round. Join each strip to make a ring at the back (see diagram) and frame in a passe-partout frame.

*Fig. 2.*

*Calendar. Figs. 2-5. Perpetual calendar in box form, with explanatory working diagrams.*

Fig. 6. Perpetual calendar on an embroidered sampler in cross-stitch.

Fig. 7. Back of calendar.

**CALF.** The flesh of the calf is known as veal, and is a very delicately-flavoured white meat. The brains, head, heart, tongue, liver, sweetbread and kidneys of the calf are also used for the table, while jelly is made of the feet. The tongue, liver, and kidneys are smaller, more tender and delicately flavoured than those of the bullock, but the method of cooking them is practically identical. *See Brains; Liver; Sweetbread; Veal.*

**CALF: The Leather.** If the pelt is to be turned into old-fashioned calf leather it is tanned by steeping in an infusion of bark or other vegetable produce containing tannin. The leather, according to methods of finishing, will be either calf for boot uppers, gloves, etc.

There is another process of dealing with the pelt, and that is by immersing in a bath of chromium salts, which produces chrome leather. This may be finished black, when it becomes box-calf, or a shade of brown or yellow, known as willow calf.

Another finish is velvet calf. In this process the

natural grain is carefully removed in the buffing machine, leaving the surface with a fine velvety nap. In wax calf the finish is on the flesh side, and the grain or outer surface of the skin becomes the inner surface. This is employed for heavy boots, for shooting, fishing, and for agricultural boots. It is said to withstand the effect of stable and field wear better than chrome leather.

Calf uppers of heavy boots should be freed from all dirt and thoroughly dried after use. They should be treed to preserve the shape, and before wear given an application of dubbin if the weather is wet, or of good blacking if it is dry.

Patent calf is perhaps the most reliable patent leather that can be purchased. This is perfectly waterproof, and here again to assist the patent surface to be maintained it should be fed occasionally with a little castor oil lightly rubbed over and then wiped dry with a soft rag.

Russia leather owes its characteristic odour to the birch bark with which it is tanned. Like most other fine leathers, the original has been imitated, and much of the so-called Russia leather is tanned with other materials, and then scented with birch tar oil.

In dressing calf a certain amount of acid is absorbed which has to be removed by washing. When the leather is required for bookbinding this elimination has to be very thorough, otherwise the acid will in course of time cause the leather to deteriorate and rot away. *See Boot; Leather.*

**CALF'S FOOT JELLY.** Wash 2 calf's feet thoroughly in boiling water, chopping each into 4 pieces. Put these into a saucepan with cold water to cover them, and allow them to boil for 5 min. Lift out the 2 feet, throw away the water, and replace the feet in the saucepan with 5 pints of hot water, boiling it gently for 5 to 6 hours and keeping the stock well skimmed. By this time the liquid will be reduced to about 1 quart. Strain off, let it get cold, when it will be a jelly, and then remove grease from the surface, finally wiping it with a clean cloth dipped in boiling water.

Turn the jelly into a clean pan, add ½ pint of sherry, 6 oz. loaf sugar, the thinly-pared rind and strained juice of 3 lemons, 3 cloves, 1 in. of cinnamon, and the washed, crushed shells of 2 eggs and their lightly-whisked whites. Whisk all these ingredients over a moderate heat until the jelly boils up to the top of the pan. Let it sink again and reboil it. Do this twice; then allow it to settle for 10 min. by the side of the fire, keeping it covered. Strain it into a basin through a clean, coarse tea-cloth kept solely for this purpose, first scalded by pouring boiling water through it. Pour the jelly back again through the cloth two or three times if at all cloudy. Next pour the clear jelly into a wet mould, or moulds, and leave till set.

It is wise to test the stiffness of this jelly by cooling a little of it quickly. If too stiff add a little more sherry, water, or lemon-juice. If wished, omit the wine and use more water and lemon-juice, or add brandy or port

wine in place of sherry. If a clear jelly is not required leave out the shells and whites of the eggs, and after boiling the jelly for a few minutes, strain it through a hair sieve or a fine strainer. This is sufficient for about a quart of jelly.

**CALF'S HEAD.** Wash the head thoroughly and trim, making sure that the eye, the inner part of the ear, and all the soft, bony parts from the nose have been removed. Leave it to soak in cold, salted water for 2 hours; then lay it in a saucepan, with enough cold water to cover it, and boil it for 10 min. Throw away this water, put back the head with fresh water, and add 1 onion, 1 carrot, 1 turnip, and a few sticks of celery, all cut into small pieces, a small bunch of herbs, 6 peppercorns, 2 cloves, and 3 allspice, the last named being tied up in a small piece of muslin.

Let all these simmer for 3 to 4 hours, or until the meat is perfectly tender and comes away from the bones. Skim the stock well, lift out the head on to a hot dish, and serve whole with hot maître d'hôtel sauce poured over. Alternatively, cut the meat off the bones into large, neat pieces, arrange on a hot dish and pour over the sauce, garnishing the head with sippets of toast and cut lemon.

Another way of treating calf's head which has been boiled is to cut it into slices  $\frac{1}{2}$  in. thick, sprinkling the pieces on both sides with grated nutmeg, flour, and salt. Fry these a light brown, then put each piece into a stewpan. Mix a teaspoonful of flour with a little water till smooth and add it to the butter in which the head was fried, afterwards pouring in gradually  $\frac{1}{2}$  pint stock together with a wineglassful sherry and a tablespoonful Worcestershire sauce. Season the whole with a little cayenne and a tablespoonful lemon-juice, pour the sauce over the meat, and let all simmer for a quarter of an hour.

Calf's head is often served with tomato sauce. This dish is made from a boned, cooked head, about  $\frac{1}{2}$  pint tomato sauce, and  $\frac{1}{2}$  lb. macaroni. Divide the macaroni into pieces about  $\frac{3}{4}$  in. long, and boil rapidly in salted water until tender. Cut the meat into small slices, pour the tomato sauce into a stewpan, and add to it the strained macaroni and the meat. Season it to taste, and heat thoroughly. A calf's head makes a good brawn, and mock turtle soup can also be made with it. *See Brawn; Mock Turtle Soup.*

**CALICO.** The name is derived from the Indian port of Calicut, from which a large part of the calicoes worn in the western world used to be shipped.

What makes one calico better than another is the quality of the raw cotton used to begin with, the fineness of the threads from which it is woven and the number or closeness of those threads. Cotton cambrics, jaconettes, long-cloths and madapolams are included under this heading. Calicoes may be bleached, unbleached, or partly bleached, or printed, by machine or hand, in most colours. *See Cotton.*

Californian Bluebell. *See Nemophila.*

**CALIFORNIAN POPPY.** The *eschscholtzia*, or Californian poppy, is commonly seen bearing deep orange flowers with a yellow margin; but there are also white, pink and red varieties. Notable varieties are the white or alba; semi-double orange or flore pleno; Mandarin, which is orange shaded red; Rose Queen; Ruby King; Rose Cardinal, a creamy rose; Mikado, crimson; Geisha, which is orange scarlet; and Monarch art shades.

This showy annual is raised from seeds sown in the open in spring and autumn, and the seedlings thinned to about 9 in. apart. A light, friable soil and a sunny site are most suitable. In many gardens self-sown seedlings are numerous.

*Californian Poppy. Flower of the Californian Tree Poppy, Romneya.*

**CALIPERS: For Measuring.** These instruments are generally made of metal with firm joints; that is, the joint is so constructed that the calipers, when set to any given measurement, will not readily be displaced. They are made in various forms, those shown here being from 3 in. to 24 in. in length. The outside calipers are pear-shaped and adapted for measuring the diameter or thickness of a rod or bar. The inside calipers, used for measuring the bore of a tube or the diameter inside a ring, have outwardly turned ends or jaws.

*Calipers. Diagram showing how they should be used for making inside and outside measurements.*

The method of using is illustrated. It is essential for accurate measurement that the calipers should be held erect and the jaws kept at right angles to the axial line of the work. Inside calipers are held in a similar manner, with the centre of the joint on the axial line of the bore of the work. The distance outside the jaws is then compared with a ruler to obtain the dimension. In the case of outside calipers the dimension inside the jaws is taken. Improved calipers for very fine measurements have a screw adjustment. Spring calipers can be easily and quickly adjusted with considerable accuracy, by means of the screw nut. Thread calipers for measuring the diameter of screw threads have extra wide jaws, while odd leg or jenny calipers are for scribing the centres on a bar or for other marking out and measuring purposes.

**CALL: How to Pay.** In the country and smaller towns it is customary for the older residents to call first upon newcomers. They may call because asked to do so by a mutual friend, or, quite correctly, as an act of courtesy, without introduction. If invited to meet the newcomer at the house of a friend, they would be

almost bound to call at an early opportunity, unless they wish to slight both friend and newcomer.

This rule is obviously impossible in the larger towns, and therefore a newly arrived person has to take the initiative in such matters. She will usually have some kind of social introduction to one or two people, and will duly leave cards on them, or should her social circle be very large, she may send her secretary to leave cards. In India and most of the British dominions and dependencies this also applies. The newcomer will leave his or her card on the residents (as a rule the card is merely put into the letter-box or into a special box for the purpose fixed to the gate of the drive) and will write his name in the book at Government House, and such as desire the acquaintance will then take steps to improve it.

**Leaving Cards.** Usually the time for calling is from 3 to 6 p.m., from 3 to 4 being the most formal hour for mere acquaintances. When the lady called on is not at home, the caller should leave one of her own cards, and if married one or two of her husband's, one of his being for the lady of the house and the other if she is married for her husband. After a first call it is usual to leave only one of the husband's cards.

"Not at home" is often a polite formula, and may mean that the lady of the house is in but is not receiving. This must not be taken as a slight, and the caller, unless on very intimate terms with the mistress, should not ask any questions of the servant, but leave her cards. A man should not call on a lady unless she invites him to do so. It is usual for men to leave their hats and sticks in the hall, and not take them into the drawing-room.

The caller should not present cards to a servant when the mistress is at home, but should follow to the drawing-room door, where the name should be given, if unknown, to the servant. After shaking hands, the visitor should sit down near the hostess without waiting to be asked.

A formal call should only last about a quarter of an hour. It is usual to offer tea, but the offer is not usually accepted unless tea is already being served in the room. Women do not rise when other visitors are introduced unless they wish to show particularly courteous attention. A man would get up at the same time as his hostess, who always rises to greet a visitor of either sex. The same rule applies when a guest is leaving.

**Etiquette of Introduction.** When introducing, a man must always be introduced to a woman, whatever their respective rank or position, and, in the case of people of the same sex, the less important is introduced to the more important. An unmarried lady is always introduced to a married one, unless the former is of superior rank. The rule is to bow only on being formally introduced, but this is not usually adhered to if the people are introduced by the hostess as personal friends of her own, when it would seem frigid not to shake hands. If people have only bowed they do not usually shake hands, but bow again, at parting. Cards should be left or a call returned within a week or ten

days. *See At Home; Etiquette.*

**CALLIOPSIS.** The daisy-like flowers of the calliopsis (or coreopsis) are orange, yellow, crimson, and brown, growing on stems 1½-2 ft. high. The annual varieties are sown out of doors in March-April, where they are to bloom in summer. Several kinds are perennial, but as they are liable to perish after having flowered it is wise to sow seeds annually in June; the best are *auriculata superba*, *grandiflora* and *lanceolata*, all three bearing yellow flowers.

**CALL SIGN.** In wireless telegraphy this is an identification signal by which a transmitting station may be readily recognized, thus facilitating the transmission and reception of messages in Morse code. Call signs are also used by broadcasting stations.

**CALOMEL.** Calomel or mercurous chloride is a white, practically tasteless powder frequently used in medicines for its purgative action. It also acts as an intestinal antiseptic. Calomel is usually given at night, dose from one-half a grain to 5 grains, when the constipation is accompanied by headache, heavily coated tongue, and feeling of fullness in the pit of the stomach.

A saline such as Epsom or Carlsbad salts or black draught (compound mixture of senna) is usually given in the morning following. It clears away bile from the gall bladder. In various forms it is used in syphilis; combined with glycerin and solution of lime it forms black wash, which may be used as a lotion for sores of this complaint. It may be applied as a dry powder to relieve itching.

Calomel, the mercurous chloride, should not be confused with corrosive sublimate, or mercuric chloride, which is much more poisonous. *See Black Draught.*

**CALUMBA.** The dried root of the calumba plant, which is obtained in E. Africa, is used for medicinal purposes, being a bitter stomachic, increasing appetite and aiding digestion. As it contains no tannin it does not form a black, inky mixture with iron, in this way resembling quassia. Useful preparations are the infusion, which is made with cold water, dose ½ to 1 oz., and the tincture dose ½ to 1 dram. In anaemia the following may be given, a tablespoonful being taken in water thrice daily after food:

Citrate of iron and ammonium	1½ drams
Tincture of calumba	6 drams
Syrup of ginger	4 "
Water up to	6 oz.

As another illustration of the use of calumba in medicine, the following may be given to increase or stimulate the appetite, the dose being one tablespoonful in a wineglass of water, taken thrice daily just before food:

Nitrohydrochloric acid (dilute)	3 drams
Syrup of oranges	4 "

Infusion of calumba up to

6 oz.

**CAM:** In Mechanics. The cam is a projection on the side of a revolving mechanism, such as a shaft, which causes any fitment that is brought into constant contact with its profile to perform a reciprocating motion.

With internal combustion engine design the cam is used for other purposes than the operating of the valve gear, such as the operating of the oil pump, and also of the water pump that is sometimes fitted to assist the cooling system. In these cases the shape of its profile differs considerably from the cam employed for valve gear work, inasmuch as its action is more gradual, a steady reciprocating movement being all that is required, as illustrated at A.

*Cam. Diagrams illustrating actions of various cams; degrees indicate working period of cam's rotation.*

*Left. Cam on camshaft applied to raising valve tappet.*

*Cam on camshaft applied to raising valve tappet.*

B shows a cam with equal sides and a rest period at the top, i.e. a period of the cam's rotation during which the part being operated remains stationary. This design gives a quick opening, a long rest period at full open, and a quick closing. At C is given a cam having a moderately quick opening, a shorter rest period and a slower closing. D shows a cam with equal-sided faces and no rest period at the top. Generally speaking, it may be noted that the more rapidly a cam performs its lifting function, the more severe will be the blow given to the part to be lifted at the beginning of the operation. *See Motor Cycle; Valve.*

**CAMBRIAN WARE.** The term loosely comprises all the ceramic products of the Swansea works down to 1870, but collectors prize the opaque

china, not true porcelain, produced after 1802, and decorated with painted shells, butterflies, birds and flowers, or with local landscapes. Swansea china, a soft-paste porcelain made after 1814, often bears decorations in the same style. There are also salt-glaze stonewares and cream-wares, represented by jugs, tea-sets and other patterns, as well as mantelpiece figures, unglazed buff reliefs, some Egyptian black, and imitations of Etruscan ware. Milk-maid-and-cow figures are charming and characteristic examples. *See China; Pottery.*

**CAMBRIC.** Cambrics are made both in cotton and in linen. They are of light-weight, fine and closely woven, and much used for making handkerchiefs. Linen cambrics are cooler to the touch than cotton and stand more washing. *See Handkerchief.*

**CAMEL HAIR.** Very soft and warm to the touch, camel hair can sometimes be distinguished by the presence of certain stronger hairs of a darker brown. Camels grow two kinds of hair, one relatively short and downy, grown on the body; the other longer and coarser, on the haunches, hump, and mane. The long hair is combed out as far as possible, but a little remains.

The hair of camels is collected in Central and Northern Asia, and manufactured in the same way as wool in Great Britain and other countries. The natural colour is fawn made into un-dyed blankets, dressing-gown cloths, etc. *See Wool.*

**Camel Hair Brush.** The best paint brushes in this hair are made with a knot of camel hair securely tied and pulled into a tin ferrule, which is then in most cases fitted with a long handle of plain coloured or ebonised wood. Camel hair is of a soft, silky nature, and the end of the brush being pointed, the smallest quantity of anything in liquid form can be applied. To clean the brush after use, a little paraffin should be worked into the hair, the brush squeezed out and washed in warm water, and, the hair pointed with the fingers.

Camel hair pencils are made of knots fixed in quills

of birds' feathers varying in size between those obtained from the goose and the lark; the smallest sizes are found in a child's paintbox. Handles are supplied to fit into the quills.

Another use for camel hair is in the thin, flat brush made for damping paper for the letter copying press. The brush for painting the throat with iodine or other preparation is also composed of camel hair, the knot being pulled into a large quill, which is sometimes bent to facilitate reaching the inside of the throat. Care should be taken to see that the knot of hair is securely fastened, *See Brush*.

**CAMELLIA.** This evergreen shrub is generally grown under glass, but it is fairly hardy and may be planted out of doors in warm sheltered spots. In the greenhouse camellia is grown in large flower pots or in a bed of prepared soil. Thorough drainage is necessary, and a suitable soil compost consists of peat and loam with sand added freely. If grown in pots the plants should be set out of doors in the summer and replaced under glass in September. A temperature of 50-55 degrees is suitable.

Healthy plants have a habit of setting far too many buds. It is best to reduce the number, before the buds have developed, to not more than one on each shoot.

*Camellia. Flesh pink flower of the variety known as Lady Hume's Blush.*

After flowering, the plants should be pruned, but only sufficiently to preserve the shape of the bush. Crowding shoots may be thinned and straggling ones shortened.

Propagation is effected by means of grafting under glass in spring. If repotting be necessary it should be done directly the flowers are over, but should never be undertaken unless the pots are obviously crowded with roots. Camellias should be sponged occasionally for white scale, and fumigated for green fly if necessary.

Good varieties are alba plena, white; Comtessa Lavinia Maggi, white with deep rose stripes; fimbriata, white; Lady Hume's Blush, flesh pink; Mathotiana, glowing red; C. H. Hovey, crimson; Donckelaari, crimson and white; Reine des Beautés, rose; Thos. Moore, carmine.

**CAMEMBERT.** This is a popular variety of soft cheese. In France, its native country, it is usually made from whole milk of a quality similar to that given by Shorthorns. Often, however, separated or perfectly sweet skimmed milk is mixed with the new in proportion of 1 to 5. Usually made from Sept. to May, these cheeses are small; they weigh from 10 to 13 oz., about 5¼ gallons of mixed new and skim milk being required for each dozen. *See Cheese*.

**CAMEO.** This is a piece of relief carving in stone, such as sardonyx, chalcedony, agate. The layers of colour peculiar to these stones are utilised to form a background, after the front portions have been carved away. Cameos are also made from a variety of shell consisting of two layers, one of which is pink and the other white. The design is carved in the upper or white layer, while the lower or pink layer forms the background.

The value of the cameo depends on the beauty of its carving. A genuine cameo should be carved entirely out of one piece of material; many imitations consist of a badly carved subject cemented to a background of a different coloured material. Cameos may be cleaned by washing in warm soapy water and gently brushing with an old toothbrush.

## CAMERAS FOR THE AMATEUR PHOTOGRAPHER

Hints on the Choice and Use of the Best Modern Types

For the principles of Camera Work see Photography; their detailed application is described under Developing; Enlarging; Film; Plate; Printing, etc.

Other aspects are discussed under Cinema; Telephotography, etc.

There have been continuous developments in camera design since photography became a popular hobby, the general trend being towards greater compactness coupled with increased efficiency. Better lenses and more precise adjustments have made it possible to produce with the modern pocket camera crisp sharp negatives that will enlarge to any reasonable size. Cameras taking smaller negatives than the once almost universal ¼ plate (4¼ x 3¼ in.) are therefore now popular. The 3¼ x 2¼ in. is now the most popular size, but Vest Pocket (2½ x 1⅝ in.) is widely used. Other popular sizes are 4¼ x 2½ in. and Postcard (5½ x 3¼ in.).

Most modern cameras can be loaded in daylight. The majority of them take roll film; cameras primarily intended for glass-plates or flat films (which have to be loaded in a dark room) can be made daylight loading by fitting a film-pack adapter and using film packs. Daylight loading films are the most convenient form of material when a number of pictures are to be taken. Plates or flat films are preferred by those who wish to make only one or two exposures at a time.

With practice and intelligent application of the principles of photography good negatives may be made with the cheapest camera and the simplest lens. It is only necessary to realize the limitations of the lens, and not to attempt subjects which are not within its scope. The beginner who blindly snaps at a fast-moving motor-car, or even people walking in a street, with a cheap camera and its necessarily slow lens is making failure inevitable. The more expensive cameras are fitted with faster lenses, admitting more light, and therefore permitting shorter exposures, i.e. quicker snapshots to be made.

**Three Main Types.** There are three main classes of camera: box form, folding pocket, and reflex. Cinematographic cameras are dealt with in the article on the Cinema.

The box form is the simplest type, represented by the "Baby Brownie" (Fig. 1, to take pictures 6.5 x 4 cm.). A simple lens is fitted so that snaps can be taken only in fairly bright light, but the camera is so simple and solidly constructed that a very high proportion of good pictures results. Another simple box camera is the "Popular Brownie" (Fig. 2). It is fitted with a single lens and a Time and Instantaneous shutter. The pictures taken measure  $2\frac{1}{4} \times 3\frac{1}{4}$  in. Yet another example of modern box camera is the Coronet "Every-Distance" (Fig. 3) which, with a special type of lens gives sharp images at distances from 3 feet upwards without a portrait attachment. Equipment includes large brilliant finders and a Time and Instantaneous shutter.

*Camera. Figs. 1 and 2. Left, "Baby Brownie" Kodak model fitted with single lens and snapshot shutter. The viewfinder is of the metal frame type and folds into a recess. Right, Kodak "Popular Brownie" for pictures of  $2\frac{1}{4} \times 3\frac{1}{4}$  in. It is equipped with two ground glass viewfinders.*

*Camera. Fig. 3. Coronet Every-Distance-8 box camera. A 4-in.  $f/4$  lens allows close-ups and views to be taken without additional attachments.*

*Camera. Fig. 4. Leica Model IIIa precision miniature camera. Standard size cinematograph film is used giving  $24 \times 36$  mm. pictures.*

Folding pocket cameras are made in all sizes from the miniature type ( $24 \times 36$  mm.) to  $5\frac{1}{2}$  in. x  $3\frac{1}{4}$  in. (postcard pictures). Some are self-erecting, the lens front being automatically pulled into position as the baseboard is pulled down; in other types the base is pulled down and the lens front slid out on runners.

Various types of lenses and shutters are fitted to folding cameras, from the simplest to the most expensive. A good medium priced camera equipped with a  $f/6.3$  lens will enable snaps to be taken successfully even on dull days. Simple box cameras are fixed focus- only objects more than, say, 5 ft. away will be sharp unless a supplementary lens, a portrait attachment, is used. Folding cameras of the cheaper type usually have a focussing attachment; by setting a pointer at the appropriate distance on a scale the lens-to-film distance is adjusted.

Many folding cameras of the more expensive type have built-in range-finders.

**The Miniature Camera.** Cameras which are described as being of the miniature class have achieved notable popularity in recent years and, with the introduction of the Leica (Fig. 4) a new photographic technique came into being. Although there is no arbitrary limit to the size of "miniature" photographs it is generally accepted that all cameras producing pictures of  $2\frac{1}{4} \times 2\frac{1}{4}$  in., and less, fall into this class.

There is a large selection of these instruments on the market today, ranging from the box type costing a few shillings to precision models equipped with every possible refinement.

Some miniature cameras take pictures as small as  $1\frac{1}{2} \times 1$  in., and a large number use 35 mm. cinematograph film in roll form and give up to 36 exposures at a single loading.

Other miniature types are designed to give 16 exposures on standard Vest Pocket spools, and another class takes 16 exposures yielding a picture size of  $2\frac{1}{4} \times 1\frac{5}{8}$  in., on  $3\frac{1}{4} \times 2\frac{1}{4}$  in. film. Another type produces 12  $2\frac{1}{4} \times 2\frac{1}{4}$  in. pictures on standard  $3\frac{1}{4} \times 2\frac{1}{4}$  in. size film.

**The Stand Camera.** The types of cameras named above are primarily hand cameras, though most of them are fitted with a bush for attaching to a tripod when time exposures are to be given. The hand or stand camera is a type that takes plates, cut films or film-packs, and has a proper ground-glass screen for focussing the image when used upon a tripod, in addition to a pointer and scale for use when the camera is used in the hand. Most cameras of this pattern fold up small enough for the pocket, plates being carried in dark slides, or a larger number of flat films in a film-pack with adapter. The example shown in Fig. 10 will take plates, cut film, or film-packs of  $4\frac{1}{4} \times 3\frac{1}{4}$  in. size. It has a long extension with universal swing-front and an arrangement for using wide-angle lenses. The movement of the front enables the lens to be raised to the level of the top edge of the plate. The front is moved backward or forward by a rack and pinion, and there is a circular, spirit level fitted to the baseboard.

*Camera. Fig. 5. Kine-Exakta single-lens miniature reflex camera. Standard cine film loaded in cassettes is used, giving 36 exposures.*

**The Reflex Camera.** With the reflex camera (Fig. 6) focussing is done visually up to the moment of exposure on a screen at the top of the camera.

The general principles of a reflex camera are illustrated in Fig. 7. P is the plate holder; B is the revolving back for horizontal or vertical pictures; F is the focal-plane shutter; M is the hinged mirror which

swings to the dotted position during exposure of the plate; G is the ground glass upon which the object is viewed; H is the viewing hood; L is the lid to cover hood when folded down; R is the rising and falling front; S is the sky shade and lens cover; T are the sliding guides and racks; V is the focussing pinion.

The focal-plane shutter consists of a blind running close in front of the plate and having in it a slit, the width of which can be adjusted. The blind is wound with a spring, and when released passes very rapidly in front of the plate, giving an exposure which may be as short as 1/1000 of a second.

Camera. Fig. 6. Typical reflex type camera showing bellows extension, viewing hood, lens cover, and other main features.

Many miniature cameras are of the reflex type and are equipped with either twin lenses or a single lens. An example of the latter is the Kine-Exakta (Fig. 5). This instrument has a special focussing screen which magnifies the image two diameters and the focal plane shutter gives exposures from 12 sec. to 1/1000 sec. This camera takes standard 35-mm. cine film and allows 36 exposures to be made.

Fig. 7. Sectional diagram of reflex camera showing general arrangement. Parts shown include revolving back (B) and plate holder (P), focal shutter (F), viewing hood (H), and hinged mirror (M).

**Choice and Use of a Camera.** The choice of a camera depends upon the amount of money an amateur can afford, and upon the kind of work it is desired to do. The lens is the most important part of the camera. The best lenses are known as anastigmats, next to them come the rapid rectilinears (known also as doublet or R.R. lenses), and after them come the single lenses, the cheapest form, which do excellent work when properly used.

Camera. Fig. 8 (left). Kodak Six-20 folding "Brownie" taking  $3\frac{1}{4} \times 2\frac{1}{4}$  in. pictures. Fig. 9 (right). Ensign "Aurorange-20" folding camera equipped with rangefinder coupled to lens and shutter. This instrument takes either eight  $2\frac{1}{4} \times 3\frac{1}{4}$  in., or sixteen  $2\frac{1}{4} \times 1\frac{1}{2}$  in. pictures on standard  $2\frac{1}{4} \times 3\frac{1}{4}$  in. film.

If the would-be photographer wishes to do ordinary snapshot work he cannot do better than choose the best roll-film camera he can afford, deciding the size of original negative desired (always remembering that it may be enlarged), and the quality of the lens. Better use a small size with a good anastigmat lens than a larger size with a single lens.

Camera. Fig. 10. Ensign-Sanderson folding model taking  $4\frac{1}{4} \times 3\frac{1}{4}$  in. plates, film-packs or cut film.

In ordinary use in temperate climates cameras, either hand or stand, will last for years without needing any repair. The only care which they require is occasional wiping of dust from the inside of the bellows with a damp cloth.

In all the patterns of the hand camera which have been described, with the exception of the reflex, the user has to do two things in order to get a satisfactory picture. One is to hold the camera so that the exact picture required is seen in the finder. For this purpose it is best to use the direct-vision finder rather than the misleading "brilliant" finder.

The second essential is to obtain a sharp picture. With a tripod camera the actual picture is viewed on a ground-glass, and the lens moved in or out and adjusted by using a smaller stop until the necessary sharpness of definition is seen. With most hand cameras the distance of the principal part of the subject has to be judged by the eye, and the lens then racked in or out until a pointer on the focussing scale comes opposite the mark corresponding with the judged distance.

The smaller the camera and the smaller the stop in the lens the easier it is to obtain a sharp picture, even though the distance of the subject has not been quite correctly judged. With miniature cameras where considerable enlargement is necessary accuracy of focussing is ensured by scientific range-finders.

A cause of failure among many beginners is unsteady

holding of the camera. Most people clench the camera too rigidly; it should be held rather loosely, with the muscles of the arms or hands relaxed. Tight holding has the result of causing a certain muscular vibration, the effect of which in the picture is slight fuzziness. A very small camera should be pressed gently against some rigid support when making an exposure.

Even the cheapest hand cameras allow of much better pictures being taken if used on a light tripod. A longer exposure can then be given by using the time and bulb adjustments, marked T and B on the shutter scale. Set to T, the shutter is opened by pressing the trigger, and remains open until the trigger is again pressed. Set at B, the shutter remains open as long as the trigger is kept pressed. Fully exposed pictures may thus be taken, even in a very dull light and with the slow lenses fitted to the most inexpensive cameras. But the subject must not contain objects in movement.

**CAMOMILE.** This is a family of hardy rock and border plants. The flowers are white, silvery grey, and yellow, and the plants, which are mostly summer-flowering, do not need any special cultivation. *Anthemis Biebersteinii*, grey leaves and yellow flowers, 12 inches, and *macedonica*, white flowers, 6 inches, are suitable for the rockery. *Kelwayi* and *tinctoria* grow 2 feet high and are valuable border flowers.

**Camomile Tea.** The dried flower-heads of the camomile are sometimes infused at home to make camomile tea. It is made as follows: Soak 1 oz. of the dried flowers in a pint of boiling water in a covered pan for 15 min. Strain off liquid and add sugar to taste. It acts as a mild tonic and is good for sleeplessness. If given hot it promotes perspiration, and administered warm acts as an emetic. The infusion obtained from a chemist is of a uniform strength, and the dose is 1 to 4 oz. The drug is used in this way as a tonic and stomachic, as it is an aromatic bitter.

A camomile poultice is an old household remedy for inflammation and sprains. For this purpose the flower-heads are put in a bag and boiling water is poured over them. The oil, in doses of  $\frac{1}{2}$  to 3 minims, is a stimulant and antispasmodic, like other volatile oils.

**CAMPANULA.** Some of the most delightful hardy flowers for borders and for the rock garden are found among the bellflowers or campanulas: a few are suitable for the greenhouse. The border kinds flourish in sunny or slightly shady places and in ordinary soil which has been dug deeply and manured. Planting may be done in autumn or spring. The best perennial campanulas for the hardy flower border are *persicifolia* and its varieties *Telham Beauty*, blue, and *Snow King*, white, 2-3 feet; *glomerata*, blue, 18 inches; *Hendersoni*, mauve-blue, 12 inches; *lactiflora*, palest blue, 2-3 feet; *latifolia macrantha*, purple, 3-4 feet; *latiloba*, blue, 2 feet, and its white variety. These may be raised from seeds sown in fine soil in a frame in spring or by detaching and replanting rooted pieces in summer. *Lactiflora* may perish after flowering; it is

wise to raise seedlings every year or to take care of self-sown seedlings.

Left. *Campanula*. Bell-like flowers of *C. Allionii*, a rockery plant. Right. *C. carpatica*, grown as a pot plant.

The campanulas suitable for the rock garden thrive in moist, gritty soil in slight shade. The best are *pusilla*, blue, and its variety *Miss Willmott*, pale blue; *muralis*, purple blue; *G. F. Wilson*, purple-blue; *pulla*, purple; *garganica*, lavender-blue; *carpatica*, blue. The last named is more vigorous than the others, reaching a height of 12 inches when in bloom.

Some of the rock garden campanulas are difficult and must be grown in very gritty, thoroughly drained soil such as is provided by a moraine. Among them are *Allionii*, *cenisia*, *Rainerii*, and *Zoysii*. Seeds sown in spring in pots of very fine soil placed in a frame provide the best means of propagation.

The chimney bellflower (*campanula pyramidalis*) is a handsome plant, 3-4 feet high, suitable for planting out of doors or for cultivation in pots. Seeds are sown in March under glass to provide flowering plants the following year. *Campanula isophylla*, blue, and its white variety, *alba*, make charming plants for the room, window, or greenhouse; they should be grown in suspended pots, for they are of drooping growth. They are easily raised from seeds in spring and need a compost of loam, leaf-mould and sand.

The popular Canterbury Bells are varieties of *campanula medium*. There are single, double, and cup and saucer varieties in white, pale rose, purple, lavender-blue and other shades. The plants are treated as biennials: seeds are sown in boxes of fine soil in a frame in May. The seedlings are planted on a reserve border when large enough, and are put out in autumn or spring when they are to bloom the following summer. They are useless after having flowered. Plants which do not bloom in the year following seed sowing should not be disturbed: they will flower exceptionally well the next year. See *Canterbury Bell*.

**CAMPHOR.** Camphor is a pungent crystalline substance obtained by the distillation of the wood of the camphor laurel. The commonest preparations used in medicine are:

Camphor water—dose,  $\frac{1}{2}$  to 2 oz.

Spirit of camphor—dose, 5 to 20 minims.

Compound tincture of camphor (paregoric)—dose,  $\frac{1}{2}$  to 1 fluid dram. This contains opium.

Liniment of camphor and ammonia.

Rubbed directly on the skin camphor has a stimulating effect, dilating the superficial blood vessels,

and leading to an immediate feeling of warmth. As this passes off partial loss of sensation in the skin follows. It is for these effects that camphor liniments are so commonly used in chronic rheumatism, sprains, bruises, neuralgia, etc.

Internally camphor has a stimulating effect on the stomach, increasing both its muscular movements and the outpouring of gastric juices. It is also a heart stimulant, frequently prescribed when the pulse is thin and feeble. As it has a mild diaphoretic action on the skin, camphor is added to many cough and cold mixtures. The compound tincture of camphor was a common household remedy for colic and diarrhoea. It should not be forgotten that this preparation contains opium.

Spirit of camphor may be taken at the beginning of a cold, 10 drops on a lump of sugar. Camphor balls are used for rubbing on chapped skin. It is of service in relieving itching, and for this purpose the spirit may be dabbed on, or camphor water may be used as the basis of a lotion, e.g. zinc oxide 1 dram, glycerin 1 dram, camphor water 1 oz.; to be shaken well before applying.

**Camphor Balls.** Owing to its high cost camphor is comparatively little used in the home, but its efficacy in keeping away moths and other insects from clothing has long been recognized. Three or four camphor cubes about  $\frac{3}{4}$  in. square placed in the drawer or trunk in which the clothes are kept will preserve them from all the ravages of insects. To protect dried botanical specimens a little powdered camphor should be dusted between the leaves of the specimen book.

Camphor is useful in insect powders. Equal parts of camphor and boracic acid is an excellent powder for dusting on animals to prevent attacks by fleas. The addition of pyrethrum powder in the proportion of about three of pyrethrum to one of mixed camphor and boracic acid forms an insect powder which is good against practically all insects.

A cheap substitute for camphor, sold under the name of moth-balls, or carbon-balls, is not composed of camphor at all, but of naphthalene. A handful of naphthalene balls will protect stored clothes from moth, and the powdered form of naphthalene will take the place of camphor in insect powders.

**CAMPHORATED CHALK.** A popular dentifrice is made by mixing camphor with precipitated chalk in the proportion of camphor 1 oz. to chalk 9 oz. The camphor is first reduced to a fine powder in a mortar by rubbing it with a few drops of rectified spirits of wine or spirit of camphor. The spirit soon evaporates when the chalk is stirred in. It is advisable to keep camphorated chalk in a bottle to prevent evaporation of the camphor. *See Chalk; Teeth.*

**CAMPHORATED OIL.** This is another name for the liniment of camphor, which formerly was official, and consisted of 1 oz. of camphor dissolved in 4 oz. of olive oil. It is used as a stimulating liniment, and is especially useful for chest complaints in children. The

official liniment now contains ammonia, and is known as the liniment of camphor and ammonia. Camphorated oil is preferable for young children, however. Camphor in sterilised olive oil (camphor 1 part, olive oil 5 parts) is used as a heart stimulant in pneumonia, influenza, and other diseases. It is injected under the skin in doses of from 10 to 30 minims, and has proved most useful. *See Camphor.*

**CAMPINE FOWL.** Owing to its economical qualities this fowl is much esteemed by many poultry keepers in Great Britain. It is a prolific layer of good-sized white eggs, and when fattened makes a plump, though rather small, table bird. There are two colours, gold and silver. *See Poultry.*

**CAMPION.** There are both annual and perennial kinds of Campion (silene); they flourish in ordinary soil in a sunny position. The most popular annuals are varieties of *Silene pendula*; they are grown chiefly for spring bedding, as a groundwork to beds of bulbs. Bonetti, deep rose, and Double Salmon, pink, are two good ones. Seeds are sown on a reserve border in July, and the seedlings planted finally in October. Seeds may be sown in April to provide summer-flowering plants. *Silene armeria*, 12-15 inches, has rose-coloured flowers in summer; seeds are sown in April.

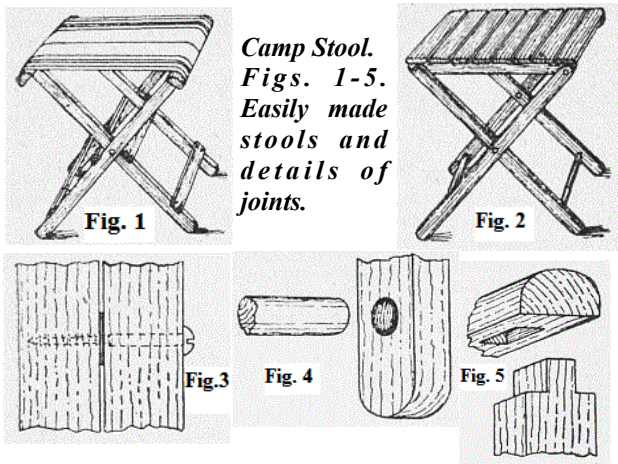

*Campion. Flower heads of Silene armeria, a pretty rose-coloured campion.*

Of the perennial kinds the most useful are *Silene alpestris*, white, 6 inches, and *schafta*, rose, 6 inches; both are suitable for the rock garden. *Silene acaulis*, which forms a moss-like cushion and bears rose pink flowers in April, is difficult; it is most likely to bloom if grown in gritty soil in the moraine. *Silene maritima flore pleno* is an attractive plant 6 inches high, which bears double white blooms in summer. Seeds sown in fine soil in a frame in spring provide an easy method of propagation; the stock can also be increased by division in autumn or spring.

**CAMP STOOL.** In the folding camp stool, types of which are shown in Figs. 1 and 2, the seat is usually of canvas and the legs are pivoted. The commonest type is that in Fig. 1. The canvas is stretched when the legs are open and folded when closed.

Fig. 2 has a wood seat, and the joints at the tops of the legs have to be made to suit, for the seat must fold over, instead of collapsing like the canvas stool. One pair of legs are pivoted to the seat and the other pair are detachable from it, so that it can turn over as if hinged. The pivoted joints generally swivel on a rivet. Another way is to use a screw, as in Fig. 3, instead of a rivet. The piece of wood nearest the head of the screw should be sufficiently slack to swivel without turning

the screw, and the thread of the latter should be immovable in the other piece of wood. The lower parts of the legs are united by cross pieces, varieties of which are shown in Figs. 1 and 2.

*Camp Stool.  
Figs. 1-5.  
Easily made  
stools and  
details of  
joints.*

Slats on the legs or back are screwed on. They are often a little longer than the actual distance over the legs, partly to avoid short grain beyond the screw holes and partly to avoid flush surfaces where one part shows end grain and the other side grain. Another reason is that the projecting ends act as stops for the folding parts.

The round rod connecting the lower ends of the legs in Fig. 2 is glued into a bored hole (Fig. 4), or may be secured by a wire nail. The hole is not bored entirely through the leg. In seats of the kind shown in Fig. 1 the tops of the legs are generally tenoned into the rail the canvas is tacked to (Fig. 5). The tenon may or may not go completely through. The wood is usually birch or beech.

**CAMSHAFT.** The shaft that drives the cams operating the valves (inlet and exhaust) of an internal combustion engine is known as the camshaft. Except in very large engines the cams are usually formed as part of the shaft. In the case of the overhead camshaft, it is so designed that one cam operates two valves. *See Cam; Motor Cycle; Valve.*

**CANADA BALSAM.** From this resinous substance, obtained from a Canadian tree, Canada balsam cement is made. It is used for mounting microscopic objects and mending broken glass. The cement is a thick, glassy liquid prepared by dissolving 3 oz. of Canada balsam in a bottle containing 3 oz. of benzol, the contents being shaken until the balsam has dissolved. The solution may be obtained ready prepared from most firms dealing in microscope accessories.

**CANAPÉ.** These may be either rounds or fancy-shaped pieces of bread and butter, cut very thinly, and served with savouries. Cut shapes in toasted or fried bread are sometimes known as canapés, but are more often called croûtons.

**CANARY.** In buying a singing canary it is important to make sure of two things—that one is getting a cock bird, and that it is young. A healthy singing pet should live at least 10 years, and may even reach twice that age, but its length of life will naturally depend on the constitution with which it starts and on the care it receives in the matters of food and housing. The best time to buy a singing bird is in the summer or autumn, when the young birds of the season's breeding are on the market. To be certain of the sex it is necessary to hear the bird sing; for, so far as appearances go, cock and hen canaries are so much alike that only expert fanciers can distinguish them, and even they cannot always be certain.

The plumage should be very close and neat, and the legs and feet quite smooth, with delicate claws; if the legs look rough and horny, owing to the projection of the edges of the scales covering them, and if the claws are long and coarse, the bird is either aged or has a poor constitution, the overgrowth of horn early in life being a bad sign. The bird should also be active and restless in its movements, and always ready to burst into song. The colour is quite immaterial, though most people prefer a pure yellow bird.

#### Best Singing Canaries

The smaller breeds of canaries are the best for pets, as they are more active and hardy than the large kinds, and their song is not so loud and piercing. In fact, the best singing canaries are the small Rollers. These have a beautiful soft running song, without the high notes, which are often rather too prominent in that of the ordinary canary.

*Canary.: four English breeds. 1. Lancashire Plainhead Buff. 2. Norwich. 3. Yellow Norwich. 4. Golden-spangled Clear-cap Lizard.*

To keep a canary in condition, one should buy as large a cage as space and funds permit, and this should be of the pattern with slips of glass round the bottom to prevent seed being scattered about the room. The best shape is oblong, and the cage should be hung in a room where the temperature does not vary much, placed well out of any draught, out of reach of the cat, if one is kept, and not above the gas.

The food should be canary and rape seed, and the latter should be the brown summer rape, at any rate for Rollers. A few grains of hemp may be given daily as a treat; but this is too fattening a seed to be given at discretion. A spray of millet to peck at makes a change. The only delicacies that should be allowed are green food or fruit, which should be given daily. In summer groundsel, chickweed, flowering grass, or dandelion

can generally be had; tender lettuce and watercress are also good, and a slice of ripe apple is much appreciated. But too much of this raw food should not be given, as if stale it is injurious; nor should any be used in a frosted state in winter. When the bird is moulting it may have a piece of stale sponge-cake daily, but not at other times.

Sand should always be available so that the bird can select the grit it requires for grinding its food; it is usual to cover the drawer of the cage with this, but as long as a teaspoonful or so of sand is put down whenever the cage is cleaned, the drawer can be just as well covered with sawdust or cedar litter. It is best to cover the drawer of the cage with paper before putting the litter on, and the cage should be cleaned out after the bird has had its bath, which it should have at least twice a week. A piece of cuttlefish bone should be stuck in the wires for the bird to exercise its beak upon and to give it lime. In warm weather the cage should be hung outdoors, but care should be taken to protect it against rain, wind, and scorching sun.

If it is considered desirable to breed canaries, the hen bird should be got before Christmas. A cock can be got at any season but hens which are on sale in the spring are often birds which have proved to be bad breeders, for the best birds are all booked up, so to speak, by that time. The cock and hen should be kept apart, if possible in separate rooms, till the middle of March at least, or the warm indoor atmosphere of a house will tend to make them nest too early.

The breeding-cage should be at least 2 ft. long and provided with two nests, and a bag of dry moss and chopped tow and wool for nesting material. The usual clutch of eggs is five, and the time for sitting a fortnight. Just before the eggs are due to hatch the birds should be supplied with egg-food, made by finely chopping hard-boiled egg and mixing it with crushed biscuit or stale breadcrumbs. It must be prepared cleanly, as it is most injurious if allowed to get sour. Green food must be given regularly.

#### Diet of the Young Birds

On these soft articles of food the birds will feed their young, disgorging the food from their crops. At three weeks old they should leave the nest, but will be fed by their parents for a little time still and should have egg-food till they are well used to cracking seed. As soon as they feed themselves they should be separated from their parents and put into as big a cage as possible. The old birds will nest several times during a season, but three broods are quite enough for them, and they should be separated after the last till the next-season.

Canaries will live and breed well outdoors in an aviary, but this must be sheltered from wet and winds, and the birds must be first put out in late spring, not in autumn. Moreover, in an aviary there should always be at least three hens to every cock, with a proportionate number of nests. If they are properly housed, they will bear the winter as well as British finches.

**CANARY: A White Wine.** Wine produced in the Canary Islands was formerly drunk in England under this name. The best is called Bidogne or Vidonia wine.

It is a dry, white wine somewhat resembling Madeira, but with less body and perfume. The name Canary was formerly applied generally to dry white wines, many of them mixed with sugar and cinnamon.

**CANARY CREEPER.** Grown as an annual, the canary creeper is popular for training over trellises, up porches and above window-boxes. The seeds are best sown under glass in spring, in pots or boxes, and the young plants set out in May or June. The plants grow fast in moist fertile soil, and soon come into bloom. The flowers are small and a bright pale yellow in colour, and are produced very freely. For rapidly covering fences, concealing ugly spots in newly formed gardens, this creeper has few equals.

*Canary Creeper. Sprays of flowers and leaves of the quick-growing creeper.*

**CANARY GRASS.** A hardy perennial, sanary grass or phalaris, of 3-4 ft. high, has various names in different localities. Thus it is known as bride's laces, French grass, gardener's garters, lady grass, lady's garters, lady's laces, painted grass, ribbon grass, silver grass, sword grass. It is a fickle waterside plant, which frequently reverts to type. It thrives in any soil which contains plenty of moisture, and can be propagated by division in spring. In a variegated form the leaves are striped with white or pink. The species *Canariensis* is not often cultivated. Its seeds are the well known shining canary seed of bird-lovers.

**Canary Seed.** When ripened and dried this is sometimes given, alone or forming part of a mixture, to canaries and other birds.

**CANARY PUDDING.** Well grease some small moulds, place 3 oz. each of butter and castor sugar in a basin, and beat them to a cream. Mix together 6 oz. of flour, one tea-spoonful of baking powder, and the grated rind of a lemon. Well beat two eggs, and then beat them into the butter and sugar. Add the flour, etc., lightly, also the strained juice of a lemon, and lastly 2 tablespoonfuls of milk. Half-fill the moulds with the mixture, cover them with a piece of greased paper, and steam them for  $\frac{3}{4}$  of an hour. Turn them out and serve with jam sauce.

**CANCER.** For malignant tumours of all kinds the general name of cancer is often used, such tumours having the characteristics of growing again when removed, of reappearing as secondary growths in

organs perhaps far distant from that attacked by the original growth, of leading to wasting and great general weakness, and of eventually killing the patient.

Cancer of the throat is said to be frequent in smokers, and these may have induced chronic catarrh by tobacco smoke. A jagged tooth may produce cancer of the tongue. In countries where the men eat their food hot cancer of the stomach is common, whereas it is almost unknown amongst the women, who eat their food cold. Cancer of the stomach occurs usually on that part of its lining which would be irritated by hot liquids.

The chief signs of cancer are a rapidly developing tumour or the formation of an ulcer, with a hard flattish base, and irregular, hard edges. Contrary to common belief, pain is not a common early symptom, though it may be very severe in the late stages. The treatment of cancer is the extirpation of the growth by operation, and if this is done early enough the likelihood is that the disease will not recur. Unfortunately too many people put off seeking advice about lumps or sores or haemorrhages till the disease has obtained a wide hold on the parts affected or has been disseminated to distant parts.

Radium and X-rays have produced good results, but, with the exception, perhaps, of rodent ulcer, the proper treatment of cancer is early operation. The other forms of treatment find their proper sphere in those cases which unfortunately have been allowed to get beyond a point where operation is of any use. They may prolong life, but can do little more.

**Relief of Cancer.** To mitigate the ravages of cancer much research work has been done, chiefly by the Imperial Cancer Research Fund, 8, Queen Street, Bloomsbury Square, London, W.C.1, and the British Empire Cancer Campaign at 11, Grosvenor Crescent, London, S.W.1. For sufferers there is a National Society for the Relief of Cancer, at 47, Victoria Street, London, S.W.1, and Cancer Hospitals in Fulham Road, London, S.W.3. and Nassau Street, London, W.1.

**CANDELABRUM.** A holder for two or more candles, the branches of the candelabrum may be attached to a bracket for fixing on a wall, or to a standard for placing on a table. The wall candelabrum with two or three branches has been extensively adapted for electric light, the bulbs being shaded by screens of silk fixed vertically.

*Candelabrum. Chased Sheffield plate example, with four lights, c. 1800-10. (Courtesy of Chapple & Mantell, London.)*

Brass candelabra are often lacquered, in which case they should be simply wiped with a soft cloth, and only sponged with warm soapy water; any attempt at polishing will destroy the lacquer. If medallions of

Wedgwood ware or china are let in, do not loosen the cement with which they are fixed by too hot water or much rubbing.

**CANDIED PEEL.** There are three kinds of candied peel, viz. citron, lemon, and orange, and the method of preparation is practically the same for each.

In the following S. American recipe for preparing candied peel at home, rinds left over from jellies, etc., can be utilised. Soak the rinds from 4 oranges or lemons in slightly salted cold water for 3 days. Then drain, rinse, and boil the rinds in fresh water until they are quite tender. Make a strong syrup by boiling together 2 breakfastcupfuls of white sugar and one breakfastcupful of water for 5 min., keeping the pan uncovered.

Put the cooked rinds into a basin, pour over them the boiling syrup, cover the basin and let it stand for 2 days. After that time strain off and boil the syrup. Put in the rinds again and boil them until they look semi-transparent. Probably they will need 15 or 20 min boiling. Take out the rinds, lay them on flat tins, put a little of the syrup in the hollow centre of each piece, turning them up like cups, sprinkle all over with castor sugar, and dry them in a cool oven. If they are not dried in one day, continue on the next. Keep the rinds in airtight tins, using them as required. Besides its use for flavouring cakes, puddings and other sweet dishes, peel can be cut into shapes for the decoration of shortbread.

**CANDLE.** The cheaper sorts of candles are generally made of paraffin shale wax. Others are of stearin, which is pure white, harder, and more opaque than the paraffin candle and burns longer, but is more easily broken. On the other hand it can withstand hot weather when the paraffin loses its shape. A medium grade is manufactured from an admixture of the two, and costs very little more than paraffin. Tallow candles, which are a dirty yellow in colour, are now chiefly used by plumbers and in engineering works, having been superseded in the household by the cheaper and more serviceable wax candle. Spermaceti, which is obtained from the cachalot whale, is employed in the manufacture of the most expensive candles.

For photographic purposes, carriage lamps, and invalid food heaters, the candles in use are similar in composition to the domestic wax candles, but are made with a special wick, which generates little heat; otherwise, being burnt in a small enclosed space, the wax would quickly dissolve.

Candles are sold by weight, the various size units, sixes, eights, 12's, etc., indicating the number of candles going to the pound. The usual sizes for domestic use are sixes to 14's. All sizes are equally economical, as the smaller the candle the smaller is the wick inserted, and therefore a given weight of candles of any size will burn the same time as a similar weight of any other size. Candles, it should be noted, improve with keeping; if the wax is allowed to harden, they will last longer and

give a better light.

**Decorative Uses.** Coloured candles are used in room and table decoration, in silver, glass, or other ornamental candlesticks. The best coloured candles are solidly dyed, and not surface tinted, and taper in shape. They may be obtained in many shades to tone with any colour scheme. Candles are often used for dining-table lighting in preference to other methods of illumination. Miniature candles in various colours are used to border a birthday cake.

Self-fitting candles are usual in white, but if a coloured candle will not fit the candlestick, immerse the end of the former in a cup of warm water, and while the wax is still soft, push it into the candlestick.

Candle grease may be removed from clothes by placing a piece of blotting-paper over the grease mark and pressing it with a hot iron. In obstinate cases fresh pieces of paper should be placed under the iron until all the spots have disappeared. *See Night Light.*

**CANDLESHADE:** How to Make. Silk shades may be made on wire frames with thin silk and necessary trimmings. Fluted or square shades are a change from the usual round shape; or the shield type of shade can be used when the candles are placed on shelf or bureau, or for electric candle lamps in wall lighting.

*Candleshade. Stages in cutting out parchment to make an ornamental shade.*

To make a round or square silk shade first cut narrow strips  $\frac{1}{2}$  in. wide, either selvedge, or crossway; if there is plenty of material available choose the latter. Cover the whole wire frame by tightly binding with the strips of silk; when starting a new strip, sew securely to prevent the material slipping. When the frame is completely covered, cut pieces of silk sufficiently deep to allow neatening at top and bottom. The length of silk depends whether it is to be perfectly plain or to be gathered or pleated on the frame. For the latter method, measure round the bottom of the frame, and allow about as much again for the gatherings.

*Candleshade. Left, candleshield consisting of orange silk stretched on a home-made wire frame, decorated with a daisy stencil and edged with gold galon.*

*Right, candleshade made from drawing paper.*

Mark the halves and quarters of the strips of silk with a contrasting cotton, also the top and bottom rims of the frame. Run a gathering thread at both top and bottom edges of silk, join to form a circular strip, and gather the silk and place it in position on the frame, taking care that the halves and quarters of the silk are made to correspond with those of the frame. Attach the silk to the covered wire by sewing, the raw edges being turned inside.

A good trimming is a tiny ruching (*see Bag*) of the silk sewn on the edges of the frame, or coloured wooden beads of different shapes may be threaded to hang from the frame in a kind of fringe, or a very narrow silk fringe to match the shade may be used on the lower edge. Such shades are suitable for electric candle lamps.

Silk shields may be plain or designs may be painted or stencilled on them. The edge should be fastened with a cord or narrow gimp. Mandarin inks are the best colouring medium to use for shades as they are transparent. Stencilled designs may be outlined in embroidery silks, as in the shade illustrated. Parchment shields can be bought cheaply, and decorated by means of oil-paint transfers.

When making round parchment and paper shades, the stiffness of the medium may render a frame unnecessary, and the shade, when completed, is placed on a holder with adjustable clip. Although the word parchment is used, real parchment or vellum is not often employed for shades, owing partly to the cost and the limited supply, partly to the fact that more skill is required to work on vellum. To obtain the pattern, use any suitable paper; pencil a circle round an ordinary meat-plate for outer circle and round a cup or small saucer for the small circle. The distance between the two circumferences gives the depth of the shade. Cut this wide circle in half, and there will then be patterns for two candleshades.

Amongst the simplest and cheapest kinds of candleshades are those fashioned of cartridge paper. These may have plain tops and coloured borders, or may be hand-painted with Chinese designs of dragons or birds, or illustrating the Willow pattern. The choice of colouring and design must be influenced by the room and candlestick. *See Lampshade.*

**CANDLESTICK.** In places in the country where neither gas nor electricity is available the candle is still the only illuminant for the bedroom, which is usually provided with standard candlesticks for dressing-table and mantelshelf. In addition a candlestick with a base for holding the matchbox is placed on the hall table early in the evening for each person in the house.

*Candlesticks in wood, that on the left of oak, the other being turned complete from a piece of cocus. (Courtesy of George Adams)*

Where candles are not a necessity, the candlestick is used for its ornamental quality, enhanced by coloured candle or shade. Very tall standards are made in polished or lacquered woods, or severe designs are carried out in metals, and faceted mirror glass. The older types in pewter had a base shaped like a bell and a grease tray half-way down the stem. Later models of brass, copper or silver had bases square, round or oval with columns surmounted with a capital to form the socket, or with grooved or spiral stems. These are particularly suitable for dining-table use and in crystal glass are also popular and sometimes adapted for electric lamp candles.

Wooden candlesticks of simple yet pleasing pattern are readily turned by the amateur who has a small lathe or a mandrel. Those shown in the previous page, worked in oak and cocus wood respectively, were made on a Verschoyle mandrel (*See Lathe*). The larger of the two is 10½ in. high; the base (turned separately) is 4¾ in. across. The other pattern is turned complete from a piece of cocus. It is 8 in. high, the base measuring 3¼ in. *See Mandrel; Wood Turning.*

*Antique examples. Left, Fig. 1. English, late 18th century candlesticks, that on the left being of silver gilt, the other two of silver.*

*Fig. 2. Right. Brass church candlestick, early 16th century.*

**Bedroom Candlesticks.** Portable candlesticks of plain coloured pottery with a screening back are a good choice for bedroom use, as they protect the wick from draughts, and also serve to arrest grease splashes. Candlesticks in silver or other metal which have no special fittings such as these should possess a wide tray to catch any grease as it falls. A good deal of trouble in cleaning is saved if a flat glass disk, with a hole for the insertion of the candle, is placed on top of the candle stick.

*Fig. 3. Left. Flemish brass double candlestick, 16th century.*

*Fig. 4. English patterns: on left, late 17th century; on right, Cromwellian. (1-3, by permission of the Director, Victoria and Albert Museum).*

**CANDY.** The accepted definition of this term is a sweetmeat made of boiled sugar, with numerous flavourings and colourings added. *See Sugar Stick.*

**CANDYTUFT.** The annual varieties of candytuft are favourite edging flowers for beds and borders. They are of various colours, crimson, purple, rose, lavender, etc. The plants are of the easiest possible cultivation, and make a brave show for several weeks. Seeds are sown in April where the plants are to bloom in summer and the seedlings should be thinned to about 6 inches apart.

*Candytuft. Flowers of the perennial Little Gem variety.*

There are some charming flowers among the perennial candytufts. They look best in the rock garden, where they will drape the boulders with sheets of bloom in spring. They flourish best in well drained soil and should be planted in autumn or spring. The best sorts are *Iberis sempervirens*, *garreyana*, and *gibraltarica*, all with white flowers. One named *Little Gem* is of compact growth and suitable for small rock gardens. Cuttings taken in June and placed in pots of sandy soil in a frame will soon form roots.

## CANE: THE MATERIAL AND ITS USES

**Hints on Making and Repairing Cane Furniture**  
Basket, Rush are other articles in this group. *See also* Armchair; Chair; Table etc.

By reason of its qualities of lightness and strength, cane has many uses in preference to wood, whether in the form of circular rod or split into strips. Large diameters of rod are used for the framework of light chairs and tables, for cricket bat handles, and similar purposes. Walking-sticks and fishing-rods are often of cane. Small canes are used similarly to willow for wicker-work articles. Naturally flexible, cane is still

more easily bent by soaking in hot or cold water, or by the application of dry heat, which prevents cracking and splitting when sharp bends have to be formed.

*Cane. Fig. 1. Principal varieties of cane used for furniture.*

The split cane is used for purposes where the whole cane would not be sufficiently flexible or would be needlessly thick. One of its chief uses is for the seats of chairs. It can also be very closely woven to form a kind of fabric. The hard outer skin gives great tensile strength to very thin and narrow strips. The interior, or pulp cane, is also strong, and is used in strips for winding round the nailed-together framework of cane chairs and other articles.

The woven fibre is manufactured into furniture, which shows to great advantage when coloured. Besides its use as garden furniture, woven cane of this type can be utilised in nurseries, bedrooms, and country living-rooms, as it can be procured or painted to tone with any colour scheme. The table illustrated is glass-topped in green glass to tone with shot green and gold paint used for the woven cane.

*Cane. Glass-topped coffee table in Lloyd Loom woven fibre, and procurable in many colours.*

Cane furniture has much to recommend it, for in addition to its durability it is easily and quickly cleaned. It does not collect dust so readily as upholstery, and may be washed with warm water and a scrubbing-brush, or with the garden hose. It is important that cane furniture should not be too springy, since the spring lasts only a short time, and in order to obtain it a good deal of strength has to be sacrificed.

The weight is another test of quality, the heavier furniture betokening a strong frame. When buying cane furniture special attention should be paid to the finish round the top and arms of the chairs, etc. In properly made cane all this is woven and has no plait or beading fixed on with tacks.

There are different varieties of cane, as seen in Fig. 1. The outer skin is retained for all purposes where strength is desired. The cane used for the back and seats of chairs is narrow strip, consisting chiefly of the outer skin, and can be bought from most basket makers and furniture repairers.

**How to Re-cane Chairs.** In the course of time chairs require re-caning, as the cane gets strained and slack and breaks in places. The new cane should be soaked in water for about 24 hours before using. This not only makes it more pliable, but it gets swollen by the water and dries and shrinks after the work is completed, and this strains it tighter than would otherwise be possible.

The work usually commences by removing the old cane from the seat. A portion may be cut out and kept as a pattern for reference in case there is trouble in lacing correctly. All round near its inner edge the seat has a row of holes, about  $\frac{3}{16}$  in. diameter, and  $\frac{5}{8}$  in. apart. In some of these wood pegs will be found wedging the cane, and these must be punched out. Commence the new lacing by putting in double strips of cane from back to front of the seat, the rounding or glossy side of the strips being kept uppermost. The strips pass beneath from one hole to the next. A steel awl and a number of tapering wood pegs are used for temporarily holding the cane at each hole, while it is strained across the seat to the next.

Then the lacing at right angles to this is put in similarly, except that it goes under and over alternately. This separates the double strips slightly. The next stage is to insert single diagonal strips. These also pass beneath the edge from one hole to the next. As seats are not square, it is not always possible to get geometrical accuracy around the edges, and canes must be put through the most convenient holes.

When all the lacing is done, alternate holes are permanently pegged, and an edging of wider cane is put round on top of the seat to cover the holes. It is pegged in at the corner holes, and tied down with cane at the alternate holes, which have not been pegged, the cane passing from one hole to another beneath the seat. Where lengths have to be joined the cane is tied with an ordinary knot.

**CANE SUGAR.** The sugar obtained from the sugar cane is also known as sucrose. It is found in various grasses, plants and trees.

It is an important food-stuff, not only from both the domestic and commercial points of view, but also because it is easily soluble, and, as a sweetening agent, renders foods more palatable and attractive. During the refining process molasses, treacle, and golden syrup are obtained, and at different stages the products are classified as loaf, castor, granulated, raw, moist or brown sugars.

Cane sugar is rarely adulterated, the most general addition to it being a colouring matter to tint white crystals to resemble Demerara sugar. Sugar candy is the purest form of cane sugar. *See Sugar.*

**CANKER: In the Garden.** This disease affects fruit trees, chiefly apples and pears. Predisposing causes are undrained soil, careless or late pruning, or the attacks of insects. Frequently where a branch has been torn off by the wind or sawn off roughly, the bark fails to grow over it, and an entrance is left for the fungus spores. Apple canker is evident around the fruit spurs and as soon as it is detected the branch affected should be cut far back from it and burned. The fruit of cankered trees is often cracked and worthless. *See Apple; Pear.*

The term canker is sometimes used synonymously

with roup in fowls, but it is in reality a development of diphtheritic roup in its last stages. *See Roup.*

**CANNA, or Indian Shot.** These handsome plants may be grown in pots in the greenhouse or in flower beds out of doors in summer. The broad foliage is green, brown, or bronze, and the flowers are of many colours. Cannas are not hardy, and need to be wintered under cover. The strong, thick rootstocks form large masses, which can be taken out of the beds in autumn with soil adhering and stored in a frost-proof place for the winter. These dumps can be divided in spring. It is usual to pot each division, and to plunge the pots in bottom heat, but they can be started in a warm frame or greenhouse. When they have begun to grow they should be hardened off in a cold frame, and planted out after mid-May.

*Canna. Brilliantly coloured flower spike and leaves of a garden variety of this handsome plant.*

Much the cheapest way to raise cannas is from seed, which is the size of a pea and very hard. Germination is hastened by soaking the seeds in water for 12 hours, then sowing in a warm greenhouse. The seed may be covered with half inch of soil.

When grown in pots the plant needs a rich, porous compost. A mixture of three parts loam, one part leaf-mould, and two parts decayed manure, with plenty of sand, suits it. It should be well watered, and when the flower spikes push up, liberal doses of liquid manure should be applied.

**CANNING.** The value of canned goods in the home and the importance of suitable crop-production for canning should be realized.

Canning is a twofold process: first, the fruit or vegetables are sterilized and preserved; second, they are partially cooked to reduce the work of preparation for the table. There used to be a popular fallacy that all the "goodness" in foods was destroyed; with modern safe methods this has now been exploded. It is accepted that Vitamins A, B and E at least remain uninjured; and doctors recommend canned goods.

**National Mark Canning.** Today, through the scientist's skill, the housewife may serve fresh green peas and strawberries in December or all the year round. Fruit and vegetables canned or bottled under the National Mark are graded to standards of quality laid down by the Ministry of Agriculture. The Ministry's Leaflet H.S.4 and Bulletin No. 45, on which these notes are based, give much information on the subject.

Fresh-picked English peas are a popular example: owing to our climate, they are particularly good. Often they are canned and cooked within a few hours of being gathered. They are shelled, minutely cleaned, graded for size, scalded for flavour and tenderness, examined,

sealed in brine, and cooked in steam at very high temperature, all by scrupulously hygienic machinery.

Appetising "stringless" beans, canned spinach, celery, beetroot, carrots, turnips, new potatoes and "macédoines" of mixed vegetables are other established varieties, to say nothing of the ever-popular "baked beans." Canned fruits include raspberries, strawberries, black and red currants, gooseberries, blackberries, loganberries, apples, cherries, and plums. Gooseberries are especially sweet, and make a good basis for fruit salads. Canned fruits are preserved in syrup.

**Fruit Production for Canning.** Related articles in this Encyclopedia should be consulted: the cultivation and food-value of fruits and vegetables are discussed separately. (*See Apple, Celery, Raspberry, Pea, etc.*) Home produce may be bottled for home consumption or, on a larger scale, supplied to a cannery under a definite contract. Some considerations are emphasized here.

Not all vegetables and soft fruits grown for the fresh fruit and vegetable market are suitable for canning. Some, such as the Victoria plum, the Sir Joseph Paxton strawberry, the Lloyd George raspberry, the Alaska pea, suit both demands; but in general crops must be grown specially for canning. Commercial canners want standardized grades of each product—quantity of unvarying quality. This should be remembered by both the home grower and the housewife who wants to buy reliable canned goods from abroad. A wide range of fruits is imported from Canada, Australia, South Africa and Italy. Note the preponderance of Empire crops; four-fifths of these are pineapples, peaches, pears and apricots. Berry fruits are mostly produced and canned in England. More canned home fruits will be eaten as the British housewife gradually realizes that they are as tasty and nourishing as foreign peaches and pineapples. Investigation shows that their popularity can be increased by good production and marketing.

English tomatoes are at present too juicy for successful canning, but breeding will probably alter this. Other experiments will eventually make most home fruits and vegetables "cannable." Meanwhile, canned "baked beans," peas and asparagus—besides such non-vegetable products as spaghetti—are ever-popular.

Plums are one of the most important home crops for canning. Victoria, Pershore and greengages are most suitable. Trees should be rid of pests according to the Ministry's Advisory Leaflets Nos. 34, 10, 302, and 367. Plums for canning should be picked in the "firm-ripe"

stage, as should also damsons and cherries. Cherries are not so good for canning; some tend to lose their flavour, and the chemical action of the juice on the metal container is a technical difficulty. White cherries are dyed red in canning. Canned strawberries are good, though the supply of the right kinds barely meets the demand; this problem, however, is being solved.

Raspberries are good for canning, loganberries even better. Lloyd George and Pyne's Royal are the best raspberries for the purpose. Special care is necessary in picking, as badly crushed fruit is useless for canning. Loganberries are extremely popular for home production and consumption. Keepsake gooseberries and Baldwin black currants are also coming to the fore. (General information on berry cultivation is given in the Ministry's Bulletin No. 4.) Canned apples are good for tart-making: already peeled, cored and sliced, they are particularly useful in restaurants.

**Vegetable Production.** Peas are the most popular home-produced canned vegetable, and can be used in many ways. The cultivation of beans is dealt with elsewhere in this Encyclopedia. (See also Leaflet 152 of the Ministry.) Keeney's Green Refugee, and the ordinary kidney bean are best for canning. For Asparagus, see Bulletin 60; the Washington variety is most suitable. Canned celery has recently enjoyed great popularity, both braised and stewed (consult Bulletin 47). Canned carrots are excellent: small carrots used for forcing and "French gardening" are most suitable for canning, as a tender, delicately-flavoured type is required. For canning whole, stump-rooted varieties are preferred. Other canned vegetables are gradually achieving recognition, and research continues unceasingly. *See also* National Mark; Sardine; Tinned Food, etc.

**CANTALOUPE.** A small ribbed variety of the musk-melon, it was originally cultivated at Cantalupo, near Rome, and so obtained its name. A good way of serving it is to embed it in crushed ice for 10 hours or more, then cut it in halves or thick slices, and remove the seeds, leaving on the rind. Serve with a lump of ice in each portion, and hand salt and fine white sugar, some people preferring to eat it with salt. *See* Melon.

**CANTERBURY BELL.** (*Campanula medium*). This is a great favourite among hardy border plants; if the dead flowers are picked off regularly the plants will bloom throughout the summer from early July. The Canterbury bell is useless after it has flowered, therefore a fresh stock of plants must be raised each year. Seeds are sown in May in a box of fine soil in a frame, and in due course the seedlings are planted on a reserve border; there they remain until October, when they are set where they are to flower the following year. Any plants which do not bloom then should be left undisturbed; they will form giant specimens the next year.

*Canterbury Bell. Spray of lily-like flowers of this vigorous and hardy garden plant.*

There are many varieties of Canterbury bell—single, double and cup and saucer flowers in purple, rose, lavender, white and other shades. All thrive in ordinary soil that has been well cultivated. Those who have no room for

raising seedlings may buy plants in autumn or spring.

**CANTHARIDES.** The drug known as cantharides, or Spanish fly, is prepared from a dried beetle found in Spain, Russia, and Southern Europe. The beetle is about  $\frac{3}{4}$  in. long and coppery green. Preparations used are the plaster, tincture, and an ointment.

Its intense irritant action makes the drug valuable for external use to produce redness or blistering of the skin, and so relieve deep-seated pain and inflammation, e.g. in such conditions as pleurisy and sciatica.

A mixture of one part of cantharidine ointment and two of soft paraffin is recommended as a pomade to stimulate the growth of hair. It should be discontinued for a short time if much irritation is produced.

In poisoning, give an emetic of mustard and water, and then white of egg. No fatty substances should be employed. *See* Blister; Hair; Poisoning.

**CANVAS:** Its Domestic Uses. Many different kinds are made, and the name is loosely applied to many rough, heavy plain cloths woven from hemp, flax, and cotton fibres. In packing-canvas nothing beats the old-fashioned hemp for durability, but it is so much dearer than jute-hessian that it is little used. Jute frays more easily than hemp and does not stand sunlight or damp so well.

*Canvas for embroidery. Left, single-thread canvas; centre, double-thread or Penelope canvas; both actual size. Right, canvas used as the groundwork for wool rugs.*

Green rot-proof cotton canvas, as used for cart and rick-covers, trunk coverings, boat and motor car covers, in addition to being waterproof is immune against insect pests, for its green colour is due to salts of copper. Sail-cloth and tent-cloth, both close-woven fabrics, and made from linen or cotton, are often called canvas; the linen kinds are the stronger and more expensive. What are known as tailors' canvases or paddings are used in basting, stiffening and inter-lining garments, and it is important that these should not shrink or stretch if the garment is to retain its shape. Canvases for interlining are made also in hair.

Artist's canvas is a special flax fabric made for oil paintings. Fancy cottons made in square and sometimes open-work weaves are described as canvases. Wool canvas is a rather open-textured fabric. Ordinary tarpaulin is a tarred canvas.

Double-thread canvas has two threads running vertically and two horizontally close together, so that there is a small square space between the threads. This canvas is employed for the coarser varieties of tapestry, and it is the chief groundwork for cross-stitch. When

stiffened it is used for tops of stools, and cushion covers, worked in silk and wool respectively. It is also used for bead purposes and bags. There are also two varieties used for homemade rugs, the first size with a mesh about  $\frac{1}{8}$  in. for ordinary rug wool, and the larger size canvas for cable wool. On the latter, though not much in use, home-made rugs can be made to resemble sheep-skin rugs. Finer embroidery is worked on single thread canvas. *See* Bead; Cross-stitch; Hessian; Waterproofing.

**CANVAS SHOES.** Canvas or stout linen is employed for making the uppers of a variety of shoes and also for cricket and sports boots. The soles of canvas shoes may be of leather, as in cricket shoes. In this case the canvas or linen drill should be of strong texture, and the soles should be made of well-tanned leather so that it will hold the spikes without bending or warping, a common fault with cheap-quality cricket shoes.

Canvas shoes for tennis and sports wear are soled generally with rubber, which is either attached by stitching or solutioned to the uppers. It is in this attachment of the soles to the uppers that the variation in the quality of plimsolls is most apparent. In a poor quality, cheaply made, the sole will frequently after a few days' wear part company with the upper, commencing by breaking away at the toe. It is a mistake to have canvas shoes tightly fitting. Not only does the canvas or cotton not stretch with the movement of the foot, as is the case with leather, but it actually contracts and shrinks when wetted. Rope-soled canvas sandals are worn for bathing.

In cleaning white canvas shoes the pipeclay should be wetted and a thin coating well rubbed in. Care should be taken not to soak the fabric too much or it will shrink in drying. They should preferably be dried in the sun.

**CAPACITY.** Electrostatic capacity is measured by the quantity of electricity which has to be transferred from one isolated conductor to another to produce a potential difference of one volt. The unit of capacity is the farad, and is the capacity of a condenser which requires a charge of one coulomb to increase its potential by one volt. A microfarad (mfd.) is one millionth of a farad. *See* Condenser; Dielectric.

Cape. *See* Cloak.

*Cape Gooseberry. Fruit and leaves of Physalis Franchetti.*

**CAPE GOOSEBERRY.** The true Cape Gooseberry is *Physalis edulis*, from South Africa, which provides edible fruits in that country. In British gardens other kinds are grown for the sake of their large orange-red ornamental "fruits" which cluster on stems about 2 feet high. These "fruits" are really

enlarged calyces within which the true fruits are found. They are popularly known as Chinese lanterns, and are most decorative in the garden and in vases indoors when cut. *Physalis Franchetti* and *Bunyardii* provide the finest fruits. Both are hardy perennials suitable for planting out of doors in well drained soil and a sunny place. They may be increased by division in early autumn or by sowing seeds in a box of soil in a frame, or out of doors in spring.

**CAPER.** This name is given to the small, dull-green, unopened flower-buds of a trailing shrub which grows wild in Greece, N. Africa, and various parts of S. Europe. It is cultivated to a small extent in Great Britain.

The bud is picked long before the flower is ready to bloom, and the further it is from that stage the more pungent the condiment.

After the buds have been picked and left in vinegar for a time they are sorted into sizes by sifting them through sieves with meshes of varying sizes, then bottled and named accordingly, being classified as nonpareil, capuchins, capotes, etc. Capers are used for garnishing purposes and for flavouring sauces.

**Caper Sauce.** This may be either white or brown. To make the white sauce, melt 1 oz. butter in a small saucepan, add 1 oz flour, and cook them together for about 3 min. over a slow heat without browning them. Next add gradually a pint of hot stock, stir it till it boils, then cook it gently for 5 min. Take 2 table-spoonfuls of capers, cut them in halves, add them and 2 teaspoonfuls of caper vinegar to the sauce. Season it to taste with pepper and salt, and it is ready to serve. If the sauce is to be served with boiled fish, use fish stock.

For the brown sauce, take 1 pint of any good brown sauce, season it carefully with salt, pepper and grated nutmeg, and boil for 15 min. with 2 tablespoonfuls of caper vinegar and add to it one tablespoonful of halved capers.

**CAPERCAILZIE.** This game-bird is also called capercailie, wood-grouse, or cock-of-the-woods. For roasting it is first prepared and trussed as for a turkey or fowl, and inside is placed 4 oz. of raw beefsteak, which is taken out after the cooking and may be used in the preparation of patties, mince, etc. A few slices of fat bacon are laid over the breast of the bird, with slits cut in the rind to prevent them curling. The bird is then put in a baking-tin and roasted in the oven or before a clear bright fire for about one hour, with frequent basting with milk. When it is about three-parts cooked, remove the slices of bacon—save them also for some cold-meat dish—dredge a light dust of flour over the bird, baste it, and let it thoroughly finish cooking.

To serve, remove the skewers, strings, etc., pour round a few spoonfuls of clear, hot gravy, and garnish the dish with tufts of washed watercress that have been seasoned with a few drops of salad-oil and a little salt

and pepper. Extra gravy and bread sauce (q.v.) should accompany the bird. A bird will be sufficient for about seven or eight persons.

**CAPON.** This term refers to a cockerel, specially treated when young and reared for the table, not for breeding purposes. It becomes specially large, and is plumper and better flavoured than ordinary fowls. Capons are trussed and cooked in the same way as directed for fowls. *See* Boning.

## CAPPINGS AND CORNICES

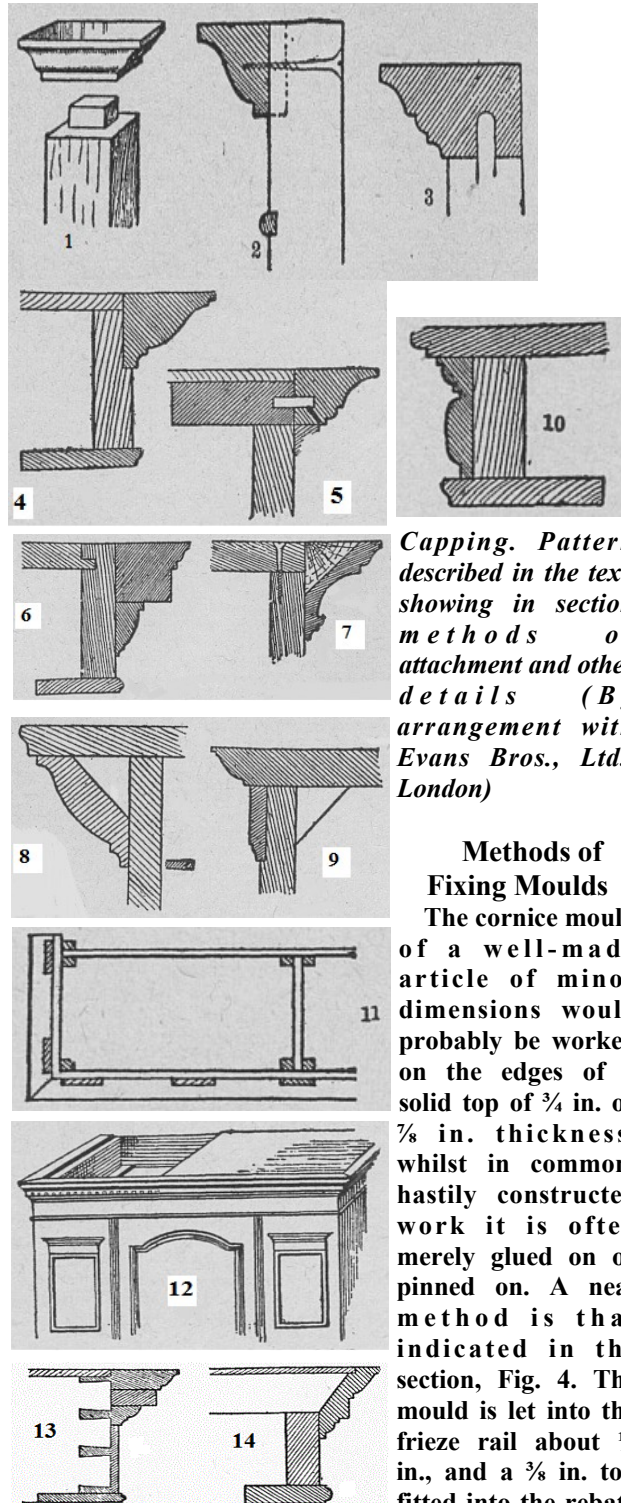

Some Typical Moulds and How they are Fitted  
Such entries as Bookcase; Cabinet; Cupboard may usefully be read in association with the one below.

See also Dowelling; Moulding

When setting out an article which is about to be constructed, special regard must be paid to the importance and finish that a suitable capping or cornice is capable of imparting to the assembled effect. Too frequently any section that may be ready to hand is worked in without the slightest attention to its suitability.

In fitting cappings, these may be finished with plain square edges, or the edges may be rounded, nosed, or thumb-moulded; or, again, the edges may be beaded or have a bevel taken off the upper or lower edge according as this is below or above the edge when fixed in position. Generally speaking, however, a three or more membered mould will give a distinctly enhanced effect. The simplest form of capping is that used as a terminal finish for posts, and frequently employed in the construction of bedstead ends. As indicated in Fig. 1, the caps on a 2 in. by 2 in. post finish about 4 in. by 4 in. square by  $\frac{7}{8}$  in. thick with a flat top. This portion is improved by a raised and rounded finish, for which purpose a 4 in. by 4 in. square of  $\frac{1}{4}$  in. thickness is glued on to the flat, or the detail can be finished from material  $1\frac{1}{2}$  in. thick net. These cappings are best fixed with a stub tenon cut on top of post to enter a corresponding mortise in capping, but three small dowels can be utilised instead. One dowel is a mistake, as the capping will be liable to twist out of the square.

The capping mould, often seen at the back of a hall table or dinner wagon or on the top of a washing-stand back, is sometimes fixed to the face of the rail, and in other instances (when below the level of the eye) is fitted to the top edge of rail. In the former case it may be glued and pinned into position, but is better screwed from the back (Fig. 2), and either mitred or returned on itself at ends with the chisel. Better work may have the section rebated into the face of rail, as indicated by dotted line. When fitted to top edge, the capping is dowelled on as Fig. 3, flush at back, and with a projection of  $\frac{3}{4}$  in. or  $\frac{7}{8}$  in. at front, according to the section in use. The bead grooved in below the capping mould in Fig. 2 is often added when a shelf is not provided above the tiles or marble panel of a washstand back. If well above the eye, the capping (Fig. 3) might be screwed instead of being dowelled into position.

*Capping. Pattern described in the text, showing in section methods of attachment and other details (By arrangement with Evans Bros., Ltd., London)*

## Methods of Fixing Moulds

The cornice mould of a well-made article of minor dimensions would probably be worked on the edges of a solid top of  $\frac{3}{4}$  in. or  $\frac{7}{8}$  in. thickness, whilst in common, hastily constructed work it is often merely glued on or pinned on. A neat method is that indicated in the section, Fig. 4. The mould is let into the frieze rail about  $\frac{1}{4}$  in., and a  $\frac{3}{8}$  in. top fitted into the rebate

formed by the rise of the mould beyond the top edge of rail. Another method is shown at Fig. 5, the mould being tongued to a lining slip behind it to form a rebate for a dustboard to drop in and be screwed. Either of these methods could be applied to a wall cabinet as well as to cupboards of larger size.

In some forms of cabinet work the cornice and frieze may be built up in the manner indicated at Fig. 6, the top being housed into the frieze rail, and the frieze mould mitred at corners out of slips about  $2\frac{1}{4}$  in. by  $\frac{1}{4}$  in., glued to under edge of frame. Stock moulds may be

obtained from the furnishing wood yards, the whole section of which, as at Fig. 7, is cut out of 1 in. material or less, to be glued into position on the cornice framing.

Such a section is sometimes completed by glueing a lining slip behind in the angle formed by the pitch of the mould; in other instances it will be held by angle blocks at intervals of 9 in. or so apart. The top is shown as screwed down to the framing, and the method with lining slip is suitable for an article such as a china cabinet. Below eye-level a solid  $\frac{3}{8}$  in. or  $\frac{1}{2}$  in. top to overlap had best be provided, to be glue-blocked under into position. The entry-holes of screws are unsightly, and, even when well-stopped, tend to show through the surface finish owing to shrinkage of the wood.

Another fixing for the upper mould is that given at Fig. 8, the top being made to project beyond the carcass sufficiently to cover the pitch of the section below it, which is glued into position above and below. Such a section would be suitable for a dwarf linen cupboard of Jacobean type, or could be adopted in the construction of a mantel.

An instance of a solid top mould is given at Fig. 9, the rail under being rebated to receive a lining flat of  $\frac{3}{8}$  in. material or so, thus extending the mould with a sort of frieze effect. Framing and top are glue-blocked behind, and the section is very suitable for an oak cupboard. In the section at Fig. 10 this method is developed, the arrangement being useful where it is desired to achieve a carved frieze effect after the Jacobean style.

#### Attachment of Loose Cornices

Loose cornices separately made to be easily detachable from bulky pieces of furniture (such as a wardrobe) are usually fixed into position by means of glued blocks on the upper part of carcass. Cornice and frieze moulds are mounted upon a separate framing. In cheap work the framing may be found to be merely mitred and nailed together at front and sides, with a glued block in the inner angle. A back rail is nailed and glue-blocked at back to hold the whole thing square, a stretcher rail being also similarly fitted in centre. The cornice mould is glue-blocked into position and nailed, and a dustboard is usually omitted, as indicated in the part plan (Fig. 11).

A sketch of a loose cornice is given at Fig. 12, showing it in position on wardrobe carcass as viewed from above. Height over all may work out at  $4\frac{1}{2}$  in. to 6 in., according to detail. The method of dovetailing front and side rails of framing is given at Fig. 13, and from this it will be seen that the mould is mounted higher than the front and side rails to form a rebate for the dustboard top. The side rails have the back rail fixed to them by means of a housed dovetail, and the stretcher rail between front and back rails by means of a dovetail into each. If properly done the whole thing should be thoroughly firm when glued up. The through-dovetailing is masked by means of facing slips of the hardwood in use ( $\frac{1}{4}$  in. thick or so), glued on after mitreing at corners. The width of these slips is determined by the height of the cornice mould which beds upon the top edge of them.

Another effective method is to pitch the cornice high

(Fig. 14) and rebate it to receive the dustboard.

When fixing a cornice mould, in cramping up after glueing it will be necessary to use a suitable block to fill the space caused by the pitch or projection of the members between the jaws of the hand-screw. Where the flat member, often dentilled, exists a square slip of necessary size will suffice, but in other cases it may be necessary to scribe the block to prevent it slipping when pressure is applied. It may be found that use can be made of a spare cut of the mould in use for that purpose, possibly with a layer of felt between to avoid bruising any points of contact.

**CAPSICUM.** This plant is grown for the sake of its red and yellow fruits, so much in demand for pickles and flavouring. It is raised from seeds sown in a heated glasshouse in March; the seedlings may be grown in 6-inch pots or planted out of doors in a sunny place in June. They flower in July, and yield pods ready for picking early in September. They are very ornamental when in full fruit.

Chilli or Chili pepper is obtained from capsicum, and cayenne pepper is the ripe fruit dried and ground. Fresh red or green chillies are procurable at certain seasons. Capsicums are sometimes stuffed with forcemeat and served as a savoury. (*See* Cayenne; Chilli.)

In medicine capsicum is valuable because it stimulates the flow of salivary and gastric juice, thus promoting appetite and digestion, and correcting dyspepsia. It relieves flatulence, and  $\frac{1}{8}$  to 1 grain may be given in a purgative pill to prevent griping. For these purposes the tincture may also be employed in doses of 5 to 15 minims, in a mixture.

For chilblains one may rub on either capsicum ointment or the B.P.C. stronger tincture of capsicum; but these preparations should not be used if the skin is broken. The liniment of capsicum may be used in painful affections like lumbago and sciatica. Capsicum wool and capsicum gamgee tissue act like thermogene and are warm and stimulating.

**CARAFE.** Glass water-bottles for bedroom use have a tumbler to match. Bottles or carafes of old green and wine-coloured glass, with old-fashioned stoppers, are obtained or copied for table use. For cleaning the carafe, shot, which may be bought at any oilshop, pieces of charcoal, or of raw chopped potato with warm water, may be shaken in the carafe. For rinsing, cold water must always be used. *See* Glass.

**CARAMBOLA.** This is the fruit of an evergreen tree widely grown in India. The fruit is yellow, about the size of an orange, and full of juice, but acid. It is eaten as a preserve.

Caramel. *See* Browning; Toffee.

**CARAMEL PUDDING.** Both the custard and the rice caramel puddings given here are popular with children, and very wholesome. To make the first, put  $\frac{1}{4}$  lb. lump sugar and  $\frac{1}{4}$  pint water in a small saucepan, and let them boil until the mixture turns a golden colour like toffee. Pour it quickly into a plain dry mould, coat the inside of it all over by turning the mould round, and then leave it until it is cold. Put 4 yolks and 2 whites of eggs in a basin and beat them, frothing them as little as possible.

Bring  $\frac{1}{2}$  pint milk to boiling point. When it has cooled slightly, pour it gradually on to the eggs, and add to the mixture a tablespoonful of castor sugar and a few drops of vanilla. Strain this custard into the mould, covering the top with buttered paper. Steam the pudding very slowly for about an hour or until it is quite set. The water should hardly bubble, for unless the custard is cooked very slowly, it will be full of holes and spoilt.

If the pudding is to be served hot, let it stand for a minute before taking it out of the saucepan. Then turn it very carefully on to a hot dish. If it is to be served cold, let it stand for an hour or more before turning it out. If preferred, 3 whole eggs can be used instead of 4 yolks and 2 whites.

Sugar, rice, milk and eggs are the ingredients for a more substantial caramel pudding. Make the same quantity of caramel mixture as is given in the first recipe, and with it line a plain mould thoroughly.

Put 2 oz. rice in a saucepan with a pint milk and let it simmer very gently for about an hour until the rice is tender and has absorbed the milk. Next beat up 2 eggs, add them and 1 oz. sugar to the rice. Turn the mixture into the prepared mould, twist a piece of buttered paper over the top, and steam the pudding for about three-quarters of an hour. Then turn it out on to a hot dish, when the caramel will run all round the dish like sauce.

**CARAMEL SAUCE.** Put 1 oz. loaf sugar into a steel pan, or one not lined with tin, and let it melt and cook till it is a rich brown. Add  $\frac{1}{2}$  pint water and 6 oz. more sugar, and boil these until a little forms a strong thread between the thumb and finger when tested. Flavour with vanilla, and stir in a teaspoonful of cornflour mixed thinly with cold milk. Stir and boil for five min., then strain it. It should be served with hot puddings.

**CARAT.** Carat is a term used by goldsmiths as a measure of purity of gold. Fine gold is 24 carats; 22 carat is 22 parts gold and 2 parts alloy, either copper or silver or both; 18 carat is 18 parts gold and 6 parts alloy, and so on down to 9 carat; 8 carat and 14 carat are not recognized in England.

**CARAVAN.** The horse-drawn caravan is largely used for holiday tours, while a lighter type is towed by a motor-car. Caravans used as permanent residences are in many places subject to special by-laws. *See* Holiday; Motor-Car; Sanitation; Tent.

**CARAWAY.** The seeds of the caraway plant, with their strong aromatic flavour, are used for flavouring cakes. The essential oil of caraway seeds forms important ingredients in various tonics, condiments, wines and cordials. *See* Seed Cake.

**CARBIDE.** The chief use of carbide of calcium is in the production of acetylene gas.

Carbide can be bought in  $\frac{1}{2}$  lb. and 7 lb. tins, and in iron drums or barrels holding from 28 lb. to 2 cwt. It greedily absorbs moisture, and will take it up out of the atmosphere. Hence, when a drum is once opened it is advisable to empty the entire contents at once into some form of special storage bin with an airtight lid. If the storage bin is not closed properly a white, powdery crust will form on the top of the carbide; this crust is, of course, so much waste.

As acetylene gas is explosive, and may be given off accidentally or without being noticed from a store of carbide, a licence to keep carbide must be obtained from the local authority if it is desired to store more than 28 lb. at a time. *See* Acetylene.

**CARBOLIC ACID.** The drug is generally used in the liquid form. It is used as an antiseptic, and at the same time relieves pain, but if employed as the liquid acid, or if lotions are too strong or left on too long, the skin and other tissues are destroyed.

Carbolic acid lotion may be in the strength of 1 in 20, 40, 60, or 100. If the lotion is made at home, hot water should be used in order to ensure thorough mixing; and the lotion should be kept in a poison bottle. It may be used for washing wounds or sores, but is also applied on lint or gauze which has been wrung out of it. When the dressing is to be covered with gutta-percha tissue or oiled silk only the weaker lotions should be used. The 1 in 100 lotion may also be used as a gargle in sore throat and usually brings much ease, but it should not, of course, be swallowed. This strength could also be sponged on the skin to relieve itching.

Carbolic oil is often used for burns, but to be useful it must be fresh. The glycerin of carbolic acid is better, and this is also a useful application in boils and carbuncles. A few drops of this instilled into the ear may be helpful in relief of pain.

Lozenges and pastilles may be obtained from the chemist for use in sore throat or septic conditions of the mouth. If a little cotton-wool be rolled on the end of a match and dipped in the liquefied acid it may relieve toothache if it is gently rubbed round a cavity in a tooth. Someone should do this for the sufferer, and should use cotton-wool or a rag to protect the cheek and gum.

**Poisoning by Carbolic Acid.** In poisoning there is intense burning of the throat and mouth, whitening of mouth and lips, and the characteristic smell of the poison. The doctor should be sent for, and in the meantime 1 oz. of Epsom salts dissolved in a tumbler of water may be given, with demulcent drinks later.

Sometimes symptoms of carbolic acid poisoning,

noted chiefly by a sudden darkening of the urine, may develop when large skin surfaces are being treated with carbolic acid antiseptic dressings. Here the treatment consists of the immediate substitution of some other antiseptic for the carbolic, and the taking of half a teaspoonful of Epsom salts in half a wineglass of water four times a day.

**Household Uses.** The chief use of carbolic acid in the ordinary household is as a disinfectant, and for that purpose it remains a favourite, although a good grade of coal-tar disinfectant is much more efficient, besides being relatively non-poisonous.

*Carbolic acid should always be kept in a labelled bottle and in a locked cupboard, owing to its poisonous nature.*

For use a 1 in 20 solution is convenient, and this is made by adding about 4 oz. of the pure carbolic acid into a  $\frac{1}{2}$  gallon of water, and shaking up well.

In cases of infectious illness, all infected bed-linen, blankets, and underclothes should be soaked in this solution for about 12 hours before being washed. The spreading of colds would be lessened if all soiled handkerchiefs were similarly treated before being washed.

The sheet hung over the door of the sick-room in cases of infectious illness is frequently moistened with carbolic solution. When required the fluid may be used in a scent spray for freshening the air of the sick-room. Floors which have been soiled with infected material should be washed over with the carbolic solution. For sweetening drains, sinks, and water closets, the solution should be swilled over the appliance, and allowed to remain in contact for two hours. *See* Disinfectant; Poisoning.

**CARBOLIC SOAP.** Carbolic soap consists of an ordinary soap to which a small proportion of carbolic acid has been added, but it actually contains so little of the acid that its disinfectant action is small and must not be too greatly relied upon. Carbolic soap has, however, a definite use. The smell is particularly wholesome and cleanly and will replace offensive odours.

**CARBONIC ACID.** Carbonic acid gas is given off in breathing, combustion, fermentation, and putrefaction. The proportion of the gas in pure air is about  $4\frac{1}{2}$  parts in 10,000; more than this can be tolerated, but if the amount in the air of a room exceeds that limit, drowsiness and faintness are produced. (*See* Ventilation.)

Aerated waters are charged with carbonic acid gas, which process gives them their piquancy.

Poisoning by carbonic acid gas occurs sometimes when people sleep close to lime kilns, when a charcoal or other fire is lighted in a room without a chimney, in the holds of ships, and especially in coal-mines by the after-damp or choke-damp. A condition of asphyxia is produced. Remove the patient to the open air without delay; practise artificial respiration, and if possible give

oxygen. If the patient recovers, the effects of the poisoning soon pass away.

**CARBONIC ACID SNOW.** This is one of the most successful agents for removing birthmarks, warts, and for the treatment of lupus and other skin affections. It is prepared from liquefied carbonic acid gas, and the snow should only be applied by a doctor.

**CARBONIC MONOXIDE.** Known also as carbonic oxide, this is a highly poisonous gas present in ordinary coal and water gases. It is also formed when any substance is burned in a quantity of air insufficient for complete combustion. Coke and charcoal stoves some-times give it out in dangerous quantities. A slight escape of gas in the house may gradually produce symptoms of carbonic oxide poisoning.

There is a considerable percentage of carbon monoxide present in ordinary coal gas, and the greatest care should be taken to see that all gas connexions and fittings are absolutely gastight. The action of the gas when breathed in is to form a compound in the blood which ultimately ends in asphyxia. The gas burns with the characteristic blue flame which is seen in a very hot fire or charcoal stove. The formation of carbon monoxide in this way, indeed, has been a very frequent cause of death where charcoal has been burnt in rooms which are insufficiently ventilated.

*No brazier or similar heating apparatus should ever be used in a closed room. For a similar reason, the use of a geyser in a bathroom is dangerous unless adequate ventilation is ensured.*

The gas is not readily displaced from the blood by oxygen; hence resuscitation by artificial respiration is sometimes very difficult. The symptoms are great weakness, a throbbing headache, nausea, and giddiness. Later there may be convulsions and then unconsciousness. Send at once for the doctor. Until he arrives practise artificial respiration. This may often have to be continued for several hours. *See* Artificial Respiration.

**CARBON PAPER.** Prepared with carbon, or other material, so that it reproduces on paper or other substances placed beneath it a copy of any design or outlines, it is chiefly used in typewriting to obtain a duplicate, and for a similar purpose when the writing is done with pen or pencil. Other uses include the transference of a design on paper to the surface of some other material such as wood, leather, or canvas, which has subsequently to be modelled, shaped or worked upon. The carbon paper used for typewriting purposes is not so sensitive as that for pencil use, as the force of blow struck by the type face is considerably greater than the pressure exerted in hand writing.

Pen copying carbon paper is very clean in use and produces excellent duplicates, when the original is written with a fairly fine or hard nib. The best results are obtained from carbon papers by keeping them flat and free from dust and excessive warmth, which tends to dry them up. *See* Typewriter.

**CARBON PRINTING.** This is a process of making photographs from ordinary negatives on sensitive tissue. This tissue consists of paper coated with a mixture of gelatine and a pigment, some 30 different colours being available. The tissues and other carbon materials are made by the Autotype Company. It is best for the amateur to buy the tissue ready sensitised.

In making a print, the tissue is exposed (behind the negative) to daylight. The negative must have an opaque border, made by pasting narrow strips of black paper round its edges. As the tissue is of deep colour, the action of light upon it cannot be seen; it is necessary to ascertain the required time of exposure by means of an actinometer. From the appearance of the negative it is fairly easy to judge how many sections of the P.O.P. must be exposed in succession to match the tint in order to give the correct exposure to the tissue under the negative.

*Carbon Printing. Three stages in development, the picture being then ready for hardening and rinsing.*

The action of the light on the tissue is to make part of the gelatine insoluble in hot water. Unfortunately, the action of light is chiefly on the surface of the tissue, which becomes covered over almost all parts with a skin of insoluble gelatine.

The varying amount of insoluble gelatine which, with the pigment held fast by them, will finally form the picture lie underneath this skin, together with all the soluble gelatine which is to be dissolved away.

#### Transferring the Tissue Coating

The tissue coating has just to be transposed to another piece of paper, so that the soluble parts are on the surface. This is done by soaking the exposed piece of tissue in cold water along with a piece of transfer paper, which is paper coated with hardened gelatine. After soaking for a minute or two, the dark surface of the tissue and the gelatine surface of the transfer paper are brought together under the water, then laid on a sheet of glass or other flat surface, and pressed together with a squeegee, which is a stout strip of rubber mounted in a wooden handle. The two sheets are then left for about 15 min., and the print is then ready to be developed.

The developer is simply water at a temperature of about 100° F. On soaking the pair of papers, which have been squeegeed together in this hot water the mixture of gelatine and pigment soon begins to ooze out from the edges. As soon as this is seen to be taking place the original paper of the tissue can be readily stripped away, leaving the picture, as yet invisible or very nearly so, on the transfer paper. On further soaking in the hot

water the dark coating of pigment dissolves away revealing the outlines and light and shade of the picture. It is best to assist the process of development somewhat by pouring hot water over the print from a cup. In this way parts such as heavy shadows may be lightened by extra treatment, or by using slightly hotter water. In all, development should not require more than 5 to 10 min. When the picture is seen to be of the correct depth and clearness in the lightest parts it is laid carefully, face up, in a dish of cold water, and is then soaked for about 5 min. in a hardening solution made by dissolving 1 oz. of alum in 20 oz. of water. A washing of 5 min. in running water is given before drying.

Owing to the transfer of the tissue coating to a fresh support the picture obtained from an ordinary negative becomes reversed. This may be overcome by making a reversed negative, or, in the case of film negatives, by printing with the tissue in contact with the plain side of the negative.

Carbon prints are of a very high degree of permanence, since only permanent pigments are used in making the tissues. Moreover, the only chemical, bichromate, is very completely washed out in the hot developing water. For good results on bought tissue, negatives of good contrast and quality are necessary. See Negative; Photography.

**CARBORUNDUM.** A manufactured article composed of silicon and carbon, carborundum is used as an abrasive in the form of wheels, flat slabs or stones, and in various other shapes suited to the sharpening of many kinds of tools and appliances. Carborundum powder is made in various grades, and is a splendid grinding compound.

It is also obtainable in the form of a sheet or cloth, the carborundum being applied to it in the same way as emery cloth. Long strips of this material, made in the form of an endless belt, are used for grinding small articles or cleaning the scale from a casting.

A carborundum combination sharpening stone is a handy form of oilstone, as it has a coarse face for rapid cutting on one side and a fine face for whetting on the other.

Carvers' slips for the sharpening of gouges and other carving tools, and the points, slips, and sticks of different shape are invaluable for finishing off dies or any small, accurate metal work, as they can be used as a fine file.

When using carborundum powder or cloth remember that it is an excellent abrasive; therefore, when the work is finished, every care must be taken to see that all trace of the powder is cleaned off the work.

**CARBRO PROCESS.** The Carbro process is a method of carbon printing which is very much simpler to work, yet yields results identical with those of the carbon process. In it pigmented paper of any of the large variety of colours used in carbon printing is exposed, not to light under a negative, but simply to

contact with a bromide print or enlargement after having been soaked in a certain mixture of chemicals.

The action on the coating of gelatine and pigment is that they are rendered insoluble proportionately to the silver in the bromide print.

This form of carbon printing has several very positive advantages. There is no need for daylight; the whole process, including the making of the bromide print, is done by artificial light. There is no reversal of the drawing of the picture, but at the same time a reversed picture can easily be made.

For working the process two stock solutions are required. The following is the stock solution A for the sensitising bath:

Potassium bichromate	..	..	..	1 oz.
Potassium ferricyanide	..	..	..	1 ,
Potassium bromide	..	..	..	1 ,,
Water	.....			20 ,,

The stock solution B for the acid bath is made up as follows:

Acetic acid, glacial	..	..	..	1 oz.
Hydrochloric acid, pure	..	..	..	1 ,,
Formaline, solution as sold	..	..	..	22 ,,

The sensitising bath is made by mixing some of the A solution with three times its bulk of water. The acid bath is made by adding 1 oz. of the B solution to 32 oz. of water. The sensitising bath may be used a large number of times in succession, but it is best to throw away the acid bath after each day's use. To make a carbro print, a sheet of pigmented paper is immersed in the sensitising bath and turned over once or twice in about 3 min. Meanwhile a bromide print should have been soaking in clean water. There is nothing special about the bromide print except that it should be printed with a white margin. If it is not made with this margin, the sheet of pigmented paper must be about ½ in. larger than the bromide print.

At the end of 3 min. the pigmented paper is drained from the sensitising bath and laid face up in the acid bath, where it is allowed to stay for a time ranging from 15 to 25 sec. The longer time of immersion yields carbro prints of less contrast. While the pigmented paper is in this bath, the bromide print is taken from the water and laid face up on a level sheet of glass. The sensitised pigmented paper is then taken straight from the acid bath and laid, coated side down, upon the bromide print. The two are immediately pressed into contact by means of a squeegee. The pair of papers is then placed between sheets of greaseproof paper and allowed to remain in contact for about 15 min.

### Special Method of Developing

During this time a sheet of transfer paper is soaked in clean cold water, and when the 15 min. have expired the pigmented paper and bromide print are gently pulled apart, and the former laid, coated side down, on the transfer paper, squeegeed into contact and left between blotting boards for about 20 min. At the end of this time the original sheet of paper which was coated with the pigment is stripped away, by immersing the

pair in water at about 100° F., leaving the picture on the transfer paper, though hidden in the mass of pigment. The further development of the picture is exactly the same as in carbon printing. The bromide print undergoes a bleaching action by contact with the sensitised pigmented paper. It is washed in several changes of water for half an hour, and then restored to its original state by placing it in an ordinary developer, such as M Q or amidol. After a further wash, the bromide print may be used at once for making other carbro prints, or be dried for future use. *See Carbon Printing.*

**CARBUNCLE.** The commonest sites for a carbuncle or local gangrene of the tissues underlying the skin are the back, the nape of the neck, the shoulders and the buttocks. A carbuncle may be an inch or more in diameter, is inclined to spread, and in the later stages has three or four openings in its surface leading down to the core.

A carbuncle is most likely to occur in one who is in a debilitated and generally run-down state of health, perhaps as the result of chronic disease or of living in insanitary surroundings or of insufficient food. A blow or a squeeze may be the exciting cause. A typical carbuncle begins as a hardish, painful swelling under the skin. Soon it becomes softer and doughy, and then later the purplish red skin gives way, and the core may be seen beneath as a greyish white slough.

A carbuncle requires immediate treatment at the hands of a surgeon. *See Boil.*

### CARBURETTER: Details and Working.

A carburetter is a device used on internal combustion engines to ensure a proper explosive mixture in the engine. Broadly speaking, for petrol an explosive mixture consists of one volume petrol vapour to twenty volumes of air. Should the mixture be too strong it will not explode rapidly, thereby creating loss of power in the engine, as well as causing the engine to get unduly hot. On the other hand, should the mixture be too weak, the resultant symptoms would still be the loss of power, but probably accompanied by popping in the silencer, caused by late firing of the weak mixture.

With few exceptions, the method of producing an explosive mixture is carried out by spraying the petrol from a fine jet, by drawing the air at a high velocity through a choke tube, in the centre of which this jet is placed. The suction is due to the fact that the pressure of the air at the restricted part of the passage, that is the choke tube, is decreased at the same time that the velocity is increased. The petrol as it issues from the jet into the stream of air is broken up into very fine globules. Fig. 1 shows the main parts of a simple carburetter.

To obtain perfect carburation at all engine speeds is not easy. A rich, slow-burning mixture is necessary for starting and slow running; a slightly rich, quick-burning mixture when accelerating, and a fairly weak mixture for fast running on the level.

mixture for fast running on the level.

**Carburettor.** Fig. 1. Part-section view of Solex carburettor showing float (F) in float chamber, needle valve (X), main jet (G), jet carrier (t), jetcap (A), choke tube (K) and butterfly throttle (V).

Carburettors, as a whole, may be said to be of either the single or multiple jet pattern. With the former one main jet is employed to serve the demands of the engine at all engine speeds, the pilot, or slow-running jet, only coming into operation when the throttle is closed. The necessary adjustment of the mixture to the needs of the moment with the single-jet type is usually provided for by means of the throttle, which is so arranged that more air is admitted at high engine speeds.

The multiple-jet carburettor is one in which two or more jets are so arranged as to be uncovered one at a time, by the opening of the throttle, as more power is wanted. Another popular type which may be said to be closely allied to the multiple-jet family is that in which the proportioning of both the air and petrol are automatically controlled, an ordinary butterfly throttle being employed to govern the engine speed. Briefly, this type has a tapered needle which fits into the petrol orifice, the base of the needle being secured to a piston valve; this valve also covers the air port of the carburettor, and is operated by the suction of the engine, which is so arranged as to create a vacuum at the back of the valve, thereby drawing it off its seating more or less as the engine speed varies.

Modern carburettors are of the horizontal, up-draught or down-draught type. In the horizontal pattern the mixture passes to the induction system of the engine through a horizontal passage, while in the up-draught or down-draught design the mixture is drawn into the engine via a vertical passage in an upward and downward direction respectively. Each type has its advantages which relate to accessibility, ease of attachment, fuel economy and running efficiency.

As a general rule carburettors fitted to motor cars are equipped with an air cleaner, the purpose of which is the filtration of the air before it enters the engine. The cleaner, having a felt or gauze element, extracts minute particles of grit and other foreign matter suspended in the air stream and so reduces wear in the

cylinders and minimizes the formation of carbon deposit. Frequently the air cleaner is combined with a silencer so that noise caused by the air stream as it enters the carburettor is materially reduced.

**Carburettor.** Fig. 2. Solex "self-starting" carburettor incorporating a separate carburettor for starting purposes. (Courtesy of Hillman Motor Car Co., Ltd.)

Some types of carburettor are equipped with a device for injecting an additional supply of fuel to the engine during the acceleration period, so that a rapid pick-up is obtained. The mechanism usually takes the form of a small plunger pump which works against the action of a spring. It is brought into action by the accelerator pedal to which it is interconnected. On depression of the pedal the pump forces fuel through a special jet into the air stream passing through the carburettor, and this extra supply gives additional power, and instant response from the engine ensues with rapid gathering of speed.

Carburettors which are known as the "self-starting" type are of normal construction, but have an auxiliary carburettor formed in the main body. Comprising a secondary mixing chamber with a petrol jet and air supply, this auxiliary carburettor is so arranged that it provides a mixture of sufficient richness and volume to ensure an immediate start from cold. This rich mixture, however, automatically decreases as soon as the engine is running, so that economical consumption of fuel is maintained.

When tuning a carburettor, the same results may be obtained by different methods. A weak mixture may be corrected by fitting either a larger jet or a smaller choke tube. Whether the former or the latter will result in giving as much power with petrol economy will be found by test. Broadly speaking, a change of jet is preferable to a change of choke tube, because the latter may seriously restrict the area called for by the particular engine being dealt with.

Further, as the air velocity would be much higher with a small choke tube than a large one at a given engine speed, it follows that the suction on the jet would also be greater. On the other hand, should the mixture be too rich, which is traceable by heavy petrol consumption and a hot engine, always try a larger choke tube first.

**Carburettor Troubles.** These are generally due to partial or complete stoppages caused by dirt choking up the gauze filter or the jets themselves; tracing and curing such troubles is a simple matter. Fuel supply from modern pumps with highly efficient filtering systems has greatly reduced the occurrence of dirt in petrol tanks and carburettors and its consequent troubles.

Water in the carburettor generally produces a complete stopping of the engine. Flooding at the jet may be due to dirt, wear of the needle, or a punctured float. *See* Bowden Control; Motor Car.

**CARDAMOM.** The small dark brown capsules of an E. Indian plant known as cardamoms are highly prized in tropical countries as a condiment for flavouring curries and also sweetmeats. In Europe they enter into the preparation of numerous curry powders, cordials, sauces, and for spicing cakes.

**Cardan Shaft.** *See* Propeller Shaft.

**CARDBOARD.** Strips of thin cardboard will serve instead of wood to light the fire. An old hatbox packed with hay, straw, or sawdust makes an excellent hotbox in an emergency.

**CARDOON.** Closely related to the globe artichoke, the blanched stalks and main root of the cardoon are eaten instead of the undeveloped flower-head. It is hardly suitable for small gardens, but in large ones it is often grown in trenches like celery, but given more room. The trenches should be larger, and be 4 ft. apart, with the plants 3 ft. apart.

The seeds may be sown under glass in March and the plants put out in May. Another way is to sow in the open ground in April for the current year's yield. The plants are generally strong enough for blanching in August, when the leaves are drawn together, bound round with straw to the tips, and covered with earth. They blanch in about two months. Recipes suitable for cooking celery (q.v.) may be used for the cardoon.

**CARDS:** For Visiting. Visiting cards should be stamped with a copper-plate die in script. A usual size is 3½ by 2½ in. for ladies, and 3 by 1½ in. for men. The name, placed in the middle of the card, is prefixed by the title (if any) or Mr., Mrs., or Miss. An address and telephone number may be put in the left-hand bottom corner, if desired, and should be in a smaller script.

Cards are not sent in upon arrival at a house for a visit, except in business interviews. On leaving after a call has been made, a lady may leave on the hall-table one of her own cards and one of her husband's, or of any male relative with whom she resides, e.g. her father or son. If her hostess is married or has a male relative living in the house, the caller may leave two of her husband's cards as well as her own.

When no call is made, cards may be left at the door upon the following occasions. After invitations to a formal dinner, dance. At Home, or any similar

function; if the lady of the house is not at home when a call is made; when one is inquiring in cases of illness; and to intimate a change of address.

Business cards may have the profession or trade in brackets under the name, with some essential details, which, however, must be few and as short as possible. The name of the newspaper, in the case of a journalist, or of the firm with which the owner of the card is connected, may be put upon a card.

A very narrow black edge may be used upon the card to indicate mourning; but this is no longer usual. *See* Call; Etiquette.

**CARDS, PLAYING.** Bridge, whist, poker, cribbage and other popular indoor games are played with packs of cards. A full pack contains 52 cards, but some games, e.g. bezique, are played with a smaller number, certain cards being removed. There is an excise duty of 3d. a pack on playing cards in Great Britain. *See* Bezique; Bridge; Cribbage; Nap; Poker; Whist, etc.

**CARD TABLE: How to Make.** For card playing tables are made in all the woods used by cabinet makers, and are covered with green baize. One type consists of a square of wood supported on legs which can be folded up, enabling the table to be put away in the minimum of space.

*Card Table of oak, veneered with walnut, of an early 18th century English make. (Victoria and Albert Museum, S. Kensington)*

There exist some fine specimens of antique card tables, chiefly of walnut and other light woods. The one shown in our illustration dates from the early 18th century. The top is of oak veneered with walnut, the carved walnut legs being graceful specimens of the long cabriole with ball and claw feet. The top is covered with green cloth, the under surface of the hinged portion being treated with green morocco leather. When open it shows a top of four equal sides interspaced by four oval concaves for money and counters, and a plain circular panel at each corner to hold candlesticks. The underframing is hinged so as to permit two of the legs to support the leaf when open, just as in the ordinary flap-leaf table of to-day.

Figs. 1 and 9 show a simple folding card table. A suitable size is 2 ft. by 2 ft., the finishing height being anything between 2 ft. 3 in. and 2 ft. 6 in. For a longer and narrower top a size 2 ft. 6 in. by 1 ft. 8 in. is of service.

Mahogany is the best wood for the top. Pine or oak may be used. Elevations of the opened table are given at Figs. 1 and 2. The top may be put together with hardwood tongued joints and clamped at ends with 2 in. clamps, the only finish to the edges being to round them, the corners also being slightly rounded, say 1 in.

by 1 in. on the angle. In another way, a deal top can be grooved and tongued up, and have the edges finished with slips of 1 in. by 1 in. material mitred and screwed or nailed on all edges and finally rounded off.

Diagrams show construction of a folding card table (By arrangement with Evans Bros., Ltd., London)

A better specimen of work would be to frame up the top, which could then be of material in lengths of 4 in. width, with the grain alternately reversed, and grooved into a framing 2 in. wide, the latter being mortised and tenoned together right through and wedged. The underside will be battened on with pieces 1 ft 9 in. by 2 in. by  $\frac{3}{4}$  in. or  $\frac{7}{8}$  in. net screwed on. As shown on the plan, Fig 3, the position for these battens may be 4 in. from outer edges of top, which will make them 12 in. apart.

The trestles are made of material  $1\frac{1}{2}$  in. by 1 in., finished with the edges slightly rounded. These are pivoted together (Fig. 2, B) either with a length of 1 in. dowel (hardwood) or with tapped and nutted  $\frac{3}{8}$  in. iron rod. An alternative method of pivoting is to sink a nut into the end grain of a tightly butted length of 1 in. by 1 in. wood (say, beech, birch, or satin walnut, if oak is not available), and enter the bolts, through the trestle lengths, into the nuts after the manner indicated at Fig. 8. For these trestles four pieces, to finish 2 ft. 10 in. in length, will serve, the pivoting point being found 1 ft.  $7\frac{1}{2}$  in. from lower end or 1 ft.  $2\frac{1}{2}$  in. from top end, and not in the middle of each length.

Two stiffening rails (A) are screwed to the crossed pieces, say,  $1\frac{1}{2}$  in. by 1 in., or 1 in. by 1 in. will serve, fixed at about 3 in. to 4 in. up, and the same may be done to the part above the pivot. At the top end of each

trestle pair a length of  $\frac{3}{4}$  in hardwood dowel is fitted to holes tightly, and wedged or pinned. The centres for these holes will be found by noting the position of the part at C, Fig. 2, the top end of trestle lengths being finished by rounding off the end grain.

In Fig. 9 a perspective view of the table opened out is given. From this it will be seen that the top is attached to the dowel rail at D by means of a pair of sockets, such as are used for a bolt to shoot into, two suitable kinds being indicated at Figs. 4 and 5, to be screwed to battens. These sockets serve as hinges to pivot the top and allow it to shut down on to the dowel rail at E, attachment being by means of a couple of hooked plates, as at Fig. 7, to be screwed on, or a couple of coat hooks, as at Fig. 6, will serve.

It would be possible to replace the dowel pieces D, E, with lengths of  $\frac{1}{2}$  in. brass tubes. If these are drilled each end for pinning, and with brass sockets and hooks, the effect would be smarter. In folding the table flat for standing against a wall the parts D and E approach F and G respectively, and the top lies upon them. See Bridge Party.

### CARD TRICKS FOR HOME AMUSEMENT

#### Some Examples Needing only Sleight of Hand

This article contains information that will usefully supplement that given under the headings Children's Party; Evening Party. See also Conjuring

The tricks described here require no apparatus, no conjuring skill, and yet will provide plenty of amusement.

A slight manipulation with a pack, or with a number of packs preferably, will enable any one to puzzle an audience completely. Prepare a pack of cards by placing all the odd cards together, the 1, 3, 5, etc. of each suit, calling the jack and king as odd, and all the even cards together, and place the two halves of the pack on top of each other. It is perfectly safe to show the cards to the company, for it is most unlikely anyone will see how they have been divided. Now ask anyone to choose a card, and note which half of the pack it is chosen from, the odd or even half. Return the card yourself, making clear you are not looking at it, but return it to the half from which it was not originally chosen. Then deal all the cards, face upwards, in rapid succession, announcing that you will stop at the chosen card. Naturally, it is the only odd card in the even half, or vice versa.

Another trick is absurdly simple, but its very simplicity baffles nine people out of ten. Six cards are laid solemnly on the floor, and the performer announces that he will make any one of the cards selected by the company disappear. A card is chosen, the performer turns up his sleeves and slowly picks up the cards. He holds them for a few minutes in his hands, and then slowly puts them back on the floor, when the indicated card is found to have disappeared. The explanation is rarely guessed by any who do not know the trick. In picking up the selected card the

performer runs his thumb, which he has casually moistened with his tongue, down the side of it, and the next card adheres to it. The cards when picked up should be carefully aligned up and given a firm squeeze before being laid down again, so that the two cards should stick firmly together.

The four knaves trick is performed in this way. The performer runs through the pack and picks out the four knaves, keeping up a running story of four knaves who are going to rob a house. The story is purely to distract the audience, and to hide the *modus operandi* of the trick. The four knaves are held out fan-wise in the left hand and the fact fully impressed on the audience that they are four knaves. The fan is closed and placed on top of the pack, face downwards. The performer then takes the top card of the pack, which is also the top card of the four, and places it, without showing it to the audience, about a quarter way down, telling a suitable story about this knave robbing the upper part of the house.

The next is similarly placed about half-way down, the third  $\frac{3}{4}$  of the way down, and the last left on the top of the pack. The performer then gives the cards a sharp double knock, which, he informs his watchers, has so frightened the three knaves in the pack that they have all hurried to the top of the pack to join the knave there. As he does so he turns over the four top cards and shows the four knaves. The explanation is that behind the back card of the fan of jacks are three other cards. Properly squared up with the jack they do not show, and when the fan is closed and placed on the top of the pack, it is these three cards which are placed, one after another, in the pack, leaving the four jacks in position.

It is always a good plan to prepare for the next trick while the audience is thinking about the last. During such an interval make a quiet mental note of the two top cards of the pack, and then ask anyone to divide the pack into three heaps, and announce that you will name the top cards of all three heaps. The usual method of dividing a pack into three heaps is by putting off about one-third to form one heap and dividing the remainder into two equal heaps. So, the two top cards of one heap are known, and the top cards of the other two are not. Let the known heap be called A, and the other two heaps B and C, and suppose that the two top cards in A are the ace of diamonds and four of clubs.

#### How the Trick is Performed

The performer calls out that the top card of heap C is the ace of diamonds, and picks it up. Without showing it to the audience he says "Correct," and states what the top card of B is. The card he names is the top card of C he already holds. He picks up the top card of B, calls out "Correct," as before, and names as the top card of A the card from B he has just picked up. As he picks the top card off A he holds all three cards, which have been correctly named, so that the audience can see them. The object of knowing the second card of the heap A is so that the trick may be repeated on demand to prove there is no trickery in it.

*Card Trick. Lay-out of cards, showing how the Four Aces trick is performed.*

The trick shown in the illustration almost explains itself, and its very simplicity usually

prevents the secret from being discovered. The four aces are apparently placed on the table as shown, and the rest of the pack dropped on top of them, and shuffled all thoroughly together. One of the company should be then asked to find the four aces. The ace of hearts is missing, and is produced from any place where the performer has previously hidden it.

The cleverness of the following trick lies in the fact that though the victim apparently chooses a card at random from out of the pack, the card is in reality chosen by the performer. The trick consists in clever question and statement by the performer, enabling him to eliminate every card in the pack save the one chosen. The performer knows the position of one card in the pack. It is immaterial whether it is the top or bottom card, or the seventh card down from the top, say, so long as he knows its actual position. For the sake of explanation, one will suppose he knows the top card—the three of spades. By question and answer he forces his victim to name it.

**A Series Of Questions.** The questions are similar to the following "Which colour do you prefer in suits, red or black?" If the other says "Red," the performer says, "That leaves the two black suits, spades and clubs," and continues as below. If he answers "Black," the performer says: "Very well and which of the two black suits do you prefer, spades or clubs?" If the victim answers "Spades," the performer continues with his questioning. If he says "Clubs," the performer replies, "That leaves spades," and continues, "And now which cards of a suit do you prefer, those cards from the ten to the ace, or those from the nine to the two?" If the victim chooses the nine to the two, the performer continues as below. If he chooses the ten to the ace the performer replies, "That leaves the nine to the two of spades. Divide them into two parts, the nine to the four inclusive, and the three and the two. Which will you have?" If the victim, as he most likely will, says the nine to the four, the performer replies, "That leaves only two cards, the three and the two of spades. Which will you have?" If the victim says the three of spades, the performer quietly asks him to turn up the top card of the pack. If he chooses the two, he says, "And that leaves the three, does it not?" The victim agrees, and the performer turns up the top card—the three of spades.

The end of the trick should never be explained, as it

always causes intense astonishment, to those who do not know it, how the chosen card should be on the top of the pack (or, of course, any other position known in advance to the performer). He is firmly convinced that he himself has chosen this one card out of the 52 in the pack. The whole essentials of the trick consist in taking or leaving each suit and each set of cards in turn or not, as necessary, according to the colour, denomination, and size of the known card.

**CARIES: In the Teeth.** Dental caries is a slow progressive destruction or rotting of the hard substance of the tooth, caused primarily by acid acting on the outer part of the tooth.

The foods which become decomposed in such a way as to form acid are sugars and cooked starches. These, known collectively as carbohydrates, encourage the multiplication of acid-forming parasites or bacteria, more especially in the crevices of, or between, the teeth or wherever the action of the tongue, lips and saliva does not easily remove them. The enamel beneath the carbohydrate and bacteria is softened or dissolved by the acid formed, and broken down. The destruction of the tooth generally proceeds more rapidly when the enamel is broken through.

For the prevention of caries it is particularly desirable that the food at the end of a meal should be of a cleansing nature, so that the mouth will be left free from the carbohydrates previously eaten. This means that artificially prepared carbohydrates, e.g. sweets, bread and jam, or sweet biscuits, should never be allowed to terminate a meal, but should be followed by some natural food such as uncooked fruit, or vegetables like celery. If these foods are undesirable, as, for example, with very young children, withhold highly sweetened foods altogether, and substitute hard, unsweetened foods, such as toasted bread or crusty bread and butter. *See Teeth.*

**CARMINATIVE.** Peppermint, cloves, allspice, cinnamon, cascarilla, bitter orange, alcohol, etc., used to relieve flatulency and intestinal colic, are examples of the remedies termed carminatives. By stimulating the stomach and the intestines into more forceful movements they help to expel the gas which has accumulated in the digestive tract.

For babies dill water may be used in teaspoonful doses, and a little bicarbonate of soda may be added with advantage. For others, peppermint water, which is more pungent, is useful, the dose being one to four tablespoonfuls, and here also bicarbonate of soda, perhaps half a teaspoonful, should be added; or soda mint tablets might be taken, *See Cascara; Indigestion.*

**CARMINE.** Being a particularly fine red colouring, carmine is much used for cooking and confectionery purposes. It is practically the same as cochineal, and both are valuable, not only on account of their colour, but because they are absolutely harmless and devoid of flavour. A small bottle of carmine will last an ordinary household a long time, as a few drops

give a good deep pink. Two or three drops at most are ample for a pint of cornflour blancmange. *See Cochineal.*

**CARNATION.** There are four chief types of carnation—the border carnation, which is grown in flower beds out of doors and blooms in summer; the perpetual-flowering carnation, which is cultivated in pots under glass and blooms all the year round, though chiefly in autumn, winter and spring; the annual carnation which flowers in summer from seeds sown in spring; and the Malmaison.

The border carnation is a fine old English flower of which many charming new varieties have been raised in recent years. It flourishes best in well-drained soil; on heavy land it is a good plan to raise the carnation bed 6 or 8 in. above the ground level, so that the plants are not waterlogged in winter. Well-dug soil with which a little decayed manure and mortar rubble have been mixed suits them. In most gardens planting is best done in September or October, in very cold districts the plants are wintered in a frame and planted in March.

*Carnation: three types.*

1. *Perpetual flowering carnation.*

2. *Bloom of the Malmaison.*

3. *Border carnation.*

Border carnations are propagated by layering the shoots in July. The layers will be well rooted by the middle or end of September, and may then be taken up and replanted at 15 in. apart to form a new bed of carnations; they will bloom the following year. Large plants can be obtained by leaving the layers undisturbed. It is not necessary to layer border carnations every year; they may be left untouched for at least two or three years. Such plants will bear large quantities of flowers.

Another way of raising a stock of border carnations is to sow seeds in a box of soil in a frame or greenhouse in March. When the seedlings are well developed they are planted out of doors, preferably where they are to bloom, at 18 in. apart. It is necessary to sow seeds of a really good strain to obtain a large percentage of double blooms. Carnations grown in this way yield more flowers than those raised fresh from layers each year. Border carnations can also be increased by

cuttings, though these are less certain than layers. Some of the best varieties of border carnations are: Crystal Clove, white; Royal Clove, pink; Bookham Clove, crimson; Margaret Keep, blush pink; and Steerforth, white marked with crimson. All the above varieties are fragrant.

Some of the best varieties of border carnations are: Crystal Clove, white; Royal Clove, pink; Bookham Clove, crimson; Margaret Keep, blush pink; and Steerforth, white marked with crimson. All the above varieties are fragrant.

Other border carnations of brilliant colouring are Mary Murray, yellow; Dr. Raymond Crawford, orange buff; Miss Josephs, old rose; Yvonne Thomas, lavender; Fair Ellen, white marked with lavender; Jessie Murray, white marked with mauve; Mrs. E. Charrington, white marked with lilac; Grenadier, scarlet; J. J. Keen, apricot and rose; Linkman, yellow and scarlet; Pasquin, yellow, pink and lavender.

Perpetual-flowering carnations are grown in immense quantities under glass to supply the florists' shops with blooms. These are long-stemmed, of many charming colours, and of great decorative value. Their cultivation is now quite an important industry. A sunny, well-ventilated greenhouse in which a minimum winter temperature of 45 to 50 degrees can be maintained is required for their cultivation. They need rather dry, airy conditions, therefore a span-roofed glasshouse in the open is better than a lean-to against a wall. The method of cultivation is to take cuttings in January, to repot the young plants as is necessary and finally to put them in 6-in. flower pots. The most suitable soil compost consists of loam (pieces of old turf), with which a scattering of sand and crushed mortar rubble and a little thoroughly decayed manure have been mixed. For the final potting bonemeal (one 6-in. flower pot of bonemeal to a wheelbarrowful of soil) or one of the special carnation fertilisers should be added. The greenhouse must be ventilated freely whenever the weather conditions allow; the carnations do not flourish in a close, moist atmosphere.

The cuttings form roots most certainly when inserted in a bed of sand in a propagating case placed over the hot-water pipes. The shoots near the middle of the stems of the old plants make the best cuttings. Perpetual carnations must be "stopped" twice, the last stopping not later than the end of June. Stopping, or removing the ends of the shoots, makes the plants, branch out.

Seeds sown in a heated greenhouse in spring will produce plants that will bloom the following winter. If the best seed is sown there will be a fair percentage of double flowers, but it is wiser to rely on cuttings taken from named varieties.

Beautiful varieties of perpetual-flowering carnations are: Purity, white; Laddie, salmon; Eileen Low, salmon pink; Red Laddie, red; Topsy, crimson; Wivelsfield Apricot, pink and yellow; Robert Allwood, scarlet; Achievement, apricot; Duchess of Gloucester, pink.

Malmaison carnations are little grown nowadays. They need similar conditions to the perpetual-flowering carnations. They are grown in flower pots 8 in. in diameter, and are increased by layering in summer.

**Annual Carnations.** Carnations which bloom the same year in which seeds are sown are useful as pot plants in the greenhouse and for filling summer flower beds. The best strain of seed yields a good percentage of double flowers of various colours. The seeds are sown in February-March under glass. When the seedlings are large enough they should be potted singly in 5-in. pots if wanted for the greenhouse, or they may be planted out of doors in May.

The chief pest of the border carnation is a grub which bores into the stem and causes its collapse. It is sometimes possible to kill the grub by using a hairpin, but, as a rule, a plant damaged in this way should be pulled up and burnt. Spraying with paraffin emulsion early in summer is recommended to keep away the flies. Birds often peck off the tops of the leaves in spring, though usually the plants grow freely afterwards. Black cotton tied to pegs among the plants will keep off the birds. Rust and leaf spot may do much harm to perpetual-flowering carnations under glass. Use sulphide of potassium, dissolved at the rate of 1 oz. to 10 gallons of water. It is better to use this as a preventive than as a remedy. It is important that all unhealthy foliage should be cut away.

**CARP.** Like all fresh-water fish, carp requires to be cleaned as soon as possible after it is taken out of the water, or it acquires a rank, muddy flavour. Carp is perhaps nicest if stuffed and baked, or it can be filleted and fried or plainly grilled.

To stuff and bake a carp, mix together 3 tablespoonfuls fresh white breadcrumbs, 1 tablespoonful chopped suet, 2 teaspoonfuls finely chopped parsley, and 1 teaspoonful powdered herbs. A little minced shallot may also be added. Add a seasoning of salt and pepper, and bind all with a beaten

egg. Press this stuffing into the cavity made by cleaning the fish, and sew the edges together with coarse thread. Brush the fish over with beaten egg, and dredge it well with crumbs.

*Carp. Stuffed carp ready for serving. It may be garnished as shown, or a fish sauce poured round.*

Grease a fireproof baking-dish, and curl the fish in it so that the tail can be fastened in the mouth with a skewer made from a pointed match. Put about 1½ oz. of butter or dripping in with the fish for basting purposes. It will take about an hour to cook. Serve it in the dish in which it was cooked, removing the string and skewer. A fish sauce can be poured round it, or merely the fish juice and butter in the dish can be used to moisten it.

Fried carp is also good. After cleaning it, with a sharp knife remove the flesh from the bones, and cut each fillet into convenient-sized pieces. To improve the flavour, lay the fillets to soak for an hour in a mixture made of 2 tablespoonfuls olive oil, 1 tablespoonful vinegar or lemon juice, 1 teaspoonful each chopped parsley and onion or shallot, and salt and pepper.

Turn the pieces now and then. Then drain them from the marinade, dredge well with flour, and fry them in hot dripping until well browned. Serve the fillets with a garnish of cut lemon, anchovy sauce, and any roe taken from them, which must be egged, crumbed, and fried separately.

**Carpentry.** This term refers to the constructional forms of woodworking, e.g. roofing, flooring, etc. *See Amateur Carpentry.*

## CARPETS AND CARPET REPAIRING

Selecting and Laying them to the Best Advantage  
See the articles on Bedroom; Dining Room and other rooms of the house; also Colour Scheme; Linoleum, etc., and the colour plate herewith

The first thing for the buyer to decide is the approximate amount he is prepared to spend on a carpet. This being settled, the choice of qualities is automatically narrowed down.

If a thick carpet is required, the purchaser will probably first turn to hand-knotted carpets, which may be either British, European, or Oriental. The cheapest hand-made carpets are Indian. Beautiful designs are seen in Oriental productions of good quality, especially in Chinese. Modern hand-made French carpets are flat, being woven after the style of the old Aubusson. If any doubt is entertained as to the knot, the intending purchaser should bend open the pile, across the width, when the tuft of yarn will be seen, firmly knotted, or, more strictly speaking, looped round the warp threads. Even this, however, is no guarantee that the carpet is hand-knotted, for there are power-looms capable of

imitating very closely the Oriental knot. This is not saying that such carpets are necessarily inferior to hand-knotted carpets of corresponding quality; indeed, they may be as good or better; only the buyer should not be put off with a machine-made carpet if he is seeking a hand-made one. The machine-made will be appreciably cheaper.

The carpet should also be examined to ascertain its pitch, that is, the number of tufts in any unit of length and width of the fabric. Hand-tufted carpets vary generally from 9 to 100 tufts to the square inch, though there are qualities even finer than the latter. Broadly speaking, the coarser the pitch, the heavier will be the fabric; also, the coarser will the design appear. The finer carpets, though lighter, will be more expensive, owing to the slower production and higher cost of weaving.

**Axminster and Wilton Pile.** Apart from hand-tufted carpets, depth of pile and luxurious tread can be obtained in many qualities of machine-made Axminster and Wilton. Axminster, with its comparatively thick woollen yarn, lends itself in particular to the production of soft and heavy qualities. The depth of the pile can be gauged not only by pressure of hand or foot, but also by opening up the pile between the rows across the width of the fabric, and noting the height which the tuft stands up from the back. Heavy qualities are also made in Wilton.

Below these in value comes a variety of qualities in Axminster, Wilton and chenille, which form the bulk of the average carpet dealer's stock, the retail prices of which will be within the means of the average householder. These comprise the standard qualities in the three fabrics mentioned, all of which have either a tufted or cut pile surface, and give a comfortable, if not luxurious effect.

In Axminster the pattern is formed by tufts of woollen yarn that are cut off and inserted double in the body of the carpet. It is practically unlimited in colour effect, and is made in all widths from 12 or even 15 ft. downwards, that is, both in seamless carpets, in body, border, and stair, and in sewn carpets made up in 27 in. breadths. The most typical and popular Axminster quality is about ⅝ in. thick., with about 45 tufts to the square inch.

Wilton is made of worsted yarns, the velvety surface being obtained by the cutting of the warp threads that form the pattern after they have been looped over the wires in the loom. This type of carpet is limited in colour, but is susceptible of finer effects of design than Axminster, owing to the greater closeness of pitch. A typical quality of this fabric is about ⅜ in. thick, utilising five or six colours, and with about 90 tufts to the square inch. It is made in widths up to 54 in., and also in seamless carpets.

In chenille Axminster the pile consists of chenille fur, which is inserted as one of the wefts and woven on to the body of the carpet. The design is apt to show a certain irregularity (not necessarily displeasing), and the pitch is coarser than in tufted Axminster or Wilton.

Chenille carpets are generally seamless, and a standard quality is about five rows of fur to the inch. They are to be obtained in excellent colourings.

**Loop-pile Carpets.** Below these medium qualities there are cheaper grades of Axminster, Wilton, and chenille, and there are also the Brussels, tapestry, and ingrain fabrics. Brussels is a loop-pile fabric, made in much the same way as Wilton, but with the loops left uncut. The clean but rather hard surface makes it a suitable floor-covering for some purposes; but, although the loops have a certain resilience, the fabric has not the same richness as Axminster and Wilton. Hair carpets are the best known loop-pile fabrics and are excellent in natural colour for stairs and as a background for Oriental rugs. These carpets are also a good choice for bedrooms and are obtainable in many shades by the yard and seamless.

*Carpet. Example of modern seamless Axminster, made in sizes 2-3 yds wide by any length in ½ yd. multiples. The design combines both "floral" and "geometrical" modern tendencies. (Courtesy of Waring & Gillow, Ltd.)*

**Ingrain Carpets.** Scotch, or art squares, are of a different class of manufacture, the design being obtained by combinations of the warp and weft threads. The surface of the fabric is flat, and even in the heavier qualities it cannot be regarded as a luxurious carpet.

What has been said so far applies to carpets with a surface composed of worsted or woollen yarns, combined with a backing of woollen, cotton, linen, or jute warp and weft. Carpets, however, are also made solely of jute. The lower cost of this material enables a carpet to be produced at a cheap price, but dyes are less satisfactory and the fabric lacks resilience. Coir, or coco-fibre, carpets are obtainable in attractive designs and colourings for bungalows or use on stone floors.

**Decorative Considerations.** Colour is often the first consideration with the purchaser of a carpet, and rightly so, as tiles, walls, curtains, etc., may have to be matched or pleasantly contrasted in the scheme of a room.

In the first place, the carpet should be regarded as the base of a decorative scheme, and in most cases should be darker in tone than any other part of the room, because it presents the largest mass of colour and because it forms a background to the furniture. This is not to be interpreted as ruling out all light-ground carpets; but such can only be employed with discretion, and in association with appropriate wall treatments and furniture. A well-lit room can stand a darker and

richer carpet than one with small or few windows, where a carpet with fairly light ground colour may be laid with the object of aiding the lighting of the room by reflection.

In most effective schemes three or four harmoniously contrasting colours are employed. A room decorated strictly on the self-colour or tone on tone principle, as, for instance, with a carpet in three or four shades of blue, blue walls, blue woodwork, and blue curtains, might be harmonious in a sense, but not pleasing. The proper use of semi-complementary colours is one of the secrets of an effective colour scheme.

The choice between a plain or self-patterned and a multi-coloured carpet is largely a matter of taste. In the case of the former the selection of a colour scheme is to some extent simplified. It is certain that it is not desirable to have too much pattern in a room; that, for instance, a figured carpet, figured curtains and figured wallpaper would be most difficult to harmonise, and unrestful. Broadly speaking, the prevailing colour of the walls and curtains should contrast harmoniously with the prevailing colour of the carpet, while there should be notes of some of the colours of the carpet in other details of the room.

The question of design may be of minor importance compared with the consideration of colour; but the right selection of a pattern is of high value in successful furnishing, as the adoption of a scheme in a room in which consistency and harmony are carried out in colour and also in design leads to perfection in interior decoration.

A definite and pronounced style, if adopted for the carpet, should be carried through the rest of the decoration. For instance, if geometrical patterns are liked, these go best with quite modern furniture, wall and window schemes. Carpets are obtainable representing every known period; and if a householder wishes to furnish his room completely in the Adam, Louis XVI, or in any Oriental style, he can do so by taking a little trouble.

Choice, however, is not limited to definite periods or to very striking designs. Many carpets of unobtrusive and harmoniously blended patterns and colourings tone perfectly with curtains and furniture of different styles, provided that the colour scheme is right. It may be sound advice to a householder who has to choose a carpet for a room with decorations of a nondescript or even a mixed character to select a plain carpet or one in a good Oriental style. Picture carpets are made in Axminster, or more expensive ones are hand-made, as seen in the illustration herewith.

**Care of Carpets.** One of the problems which may occur is whether to fit the carpet to the room, or to have a bordered square with a margin of floor between the edge of the carpet and the skirting. The former choice may be more cosy, and looks well with a plain

pile or hair carpet, but the latter is cleaner and more economical, enabling the room to be swept more easily, and the square can be changed end for end to equalise the wear. Oval and round carpets suit many rooms.

Carpets should be cleaned with a vacuum cleaner or brushed regularly with a carpet sweeper, or a broom that is not too hard.

**The Laying of Carpets.** The floor should be perfectly clean before the carpet is laid. After removing any old nails from the boards they should be scrubbed with soft soap and warm water, and allowed to dry thoroughly before the carpet is laid. This is an important point, and it is advisable when possible to do the scrubbing a few days beforehand, and to have a fire lighted in the room for a few hours to ensure thorough airing. If the carpet is laid over damp boards it is liable to rot.

The character of the surround must be decided upon, and it must be dealt with before laying the main carpet. If the surround is to consist of the plain boards, stained and polished, this must be done several days beforehand to ensure thorough drying of the stain. The width of the surround should allow for it to extend for 2 in. beneath the main carpet, and before applying the stain the exact width to be stained should be marked on the floor with chalk.

When the surround is made of linoleum it is a good plan to use an underlay of tarred paper. This prevents damp from rising through the linoleum, and it also prevents moisture from injuring the flooring.

The first precaution in laying the carpet is to put a suitable underlay in position. This keeps the carpet from direct contact with the floor, makes it wear very much longer, and also gives an impression of softness and comfort that is absent when the carpet is placed directly over the boards. The underlay can vary considerably in character, and is, as a rule, not fixed firmly to the floor, or only held in position by means of a few small tin-tacks. The best underlay is a plain and inexpensive grey felt.

Once the underlay is securely arranged the main carpet must be rolled and placed in position. A chalk mark should be made to indicate to where it must extend. In the case of a valuable or very thick pile carpet it is desirable to call in an expert, who has the tools necessary for stretching the carpet properly. Failing this, care must be exercised by the amateur to stretch the carpet well. Only a small portion should be unrolled at a time, and the roll used to pull and stretch the carpet after the free edges of one side have been fixed. The best kind of carpet nail is a patent brass nail which passes through the carpet and into a brass groove, securely holding the carpet in position. It is quite easily drawn up without tearing the carpet when the latter is removed for shaking.

**Fitted Carpets.** In the case of a fitted carpet completely covering the floor, the dimensions of the room must be carefully noted. If possible, an expert should be sent for to make exact measurements; but if this is impracticable for any reason, then a rough plan

should be made of the room. The outside measurements, by the floor along the skirting-boards, should be taken, also the measurements of fireplace, any recesses, etc. These dimensions, together with the measurement of the room diagonally from corner to corner, would enable a carpet manufacturer to make up a carpet in the exact size required. If an expert is not available to fix the carpet, care must be taken after fixing the underlay to stretch the carpet to its utmost and to fasten it down securely. To ensure this a wide brush such as painters use can be shorn of its bristles, and then used by pushing it along the surface of the carpet to press and stretch the carpet properly, so that it lies perfectly flat upon the floor.

Carpet nails as described above should be used at each corner and across the doorway. In other parts of the room the carpet will be held in position sufficiently by the weight of the various pieces of furniture.

Stair carpets need care in laying over under-felt or stair pads. Sufficient stair carpet should be bought to allow of at least an extra  $\frac{1}{2}$  yd. for each flight of stairs. This extra length makes it possible to rearrange the carpet about four times a year, so that the wear is distributed evenly over the whole length; without it, the carpet will quickly show signs of wear at the edge where the tread falls on each step.

The extra length of carpet can be folded up smoothly under the last step or under the tread of the carpet of the top landing at the head of the flight of stairs. In laying a stair carpet it is advisable to start at the top, securely nailing down the top edges. The carpet is then gradually unrolled, drawn down and fixed in position by means of the stair rods. Each step is gradually covered in this way and the carpet drawn taut, so that it lies perfectly even and straight over each tread of the staircase.

**Repairing Carpets.** When a carpet is in need of repair this work may be entrusted to the firm from which it was purchased; but if amateur workers should desire to attempt repairs themselves, the following hints may be useful. A supply of the raw material is necessary; cotton, linen, jute, and worsted or woollen yarns, the latter in the same shades and of approximately the same thickness as those used in the manufacture of the carpet, should be obtained, and stout needles of a suitable size.

If the back of the fabric has been destroyed, it will be necessary in the first instance to sew in carefully threads representing warp and weft. This done, the pile surface may be sewn on, in different styles, according to the nature of the fabric. Occasional stitches present no difficulty, but if a patch of even 3 or 4 sq. in. in a patterned pile carpet has been burnt, considerable care and skill will be required to restore the correct design and colour.

In the case of a Brussels or tapestry carpet the missing threads are replaced by others sewn round wires, which represent the original wires in the loom.

With Wilton or Axminster the tufts are sewn into the back, and cut off with scissors on a level with the existing pile surface. Tapestry velvet can be treated similarly.

Chenille Axminster occasionally suffers from breakage of the fine cotton threads which hold down the fur of the pile. If the fur is not lost or destroyed, it can easily be sewn down again; but if it is lost, it is hardly possible to obtain any of the correct pattern of the fur, and the next best thing is to sew in tufts as in Wilton or Axminster.

Repairs to a machine-knotted carpet, or to one which shows the pattern on the back, to be done correctly involves sewing the tuft yarn right through the body of the fabric. Repairs to the coarser types of hand-tufted carpets may also be made in this way, but repairs to a fine Persian carpet should not be attempted by the amateur. For cleaning carpets special soaps are used. See Soap. (See also page 360)

**CARPET BAG.** A carpet bag takes its name from the material of which it is made and is used for the transport of workmen's tools, cricket and sporting requisites, and other purposes. A simple form of carpet bag is made by cutting a piece of old carpet to the shape shown in the diagram; it is folded along the dotted line and sewn together at C D, using a cross-stitch.

The top is bound with a strong webbing band, bringing the end joint of webbing away from the sewn-up sides of the bag. The joins C D can then be covered with leather or webbing stitched in place. A canvas lining should be cut to a similar pattern and sewn to the top of the carpet prior to attaching the binding. Handles can be affixed where desired.

*Carpet Bag. Diagram showing pattern.*

Cricket and other carpet bags can be recovered by unpicking all the stitches, flattening out the old material and cutting a new piece of carpet to correspond. This is then sewn up in the same way as the old carpet and attached to the framework. In many cases cricket bags have a stiffener of card or leather; the purpose of this addition being to keep the bottom in shape.

**CARPET BEDDING.** Plants which are dwarf in habit, or are kept dwarf by clipping, are arranged in formal beds so that the diversity of colour of flower or foliage gives the bed a carpet-like appearance. The art of so arranging them is called carpet bedding. This operation is usually carried out by the aid of a wooden bench or form upon which the gardener can kneel or sit.

Clever gardeners can work out most intricate designs in the varying colours of bedding plants. The plants need continually clipping and cutting back, or the bed becomes ragged and loses its trim, neat aspect. The

chief kinds used are alternanthera, echeveria, mesembryanthemum cordifolium variegatum, herniaria, sempervivum golden leather, and sagina.

The diagrams on page 359 are typical examples of carpet bedding, and although the make-up of the beds is largely a matter of individual taste, the suggestions given may be accepted as giving a pleasing diversity of pattern and colour. Fig. 1 shows an ivy leaf; A, silver foliage with dot plants of dark-leaved nasturtium; B and C, vermilion and gold, rose and carmine, or mauve and purple. Fig. 2 shows a cornflower; A, maroon; B, gold or silver foliage with petals in two shades of blue. Fig. 3 shows tobacco blossom; A, gold; B, white; C, lemon; D, faint lilac; E, mauve; F, deeper mauve; G, dark purple; H, pink or silver. Fig. 4 shows A, deep red lobelia; B, white lobelia; C, golden feather; D, Iresine; E, Silene pendula compacta rosea; F, miniature sweet alyssum; G, gold violas.

Fig. 5 shows A and B, *Echeveria secunda glauca*; C, gold *mesembryanthemum*; D, penny royal; E, golden pyrethrum, lined with *Alternanthera paronychoides*; G, *Iresine Lindenii*. Fig. 6 shows A, scarlet nasturtium; B, golden nasturtium; C, sweet alyssum; D, blue violas; E, *Echeveria secunda glauca*; F, dwarf beet or *Iresine*. Fig. 7 shows a lily; A, silver green foliage; B, white; C, deep rose; D, blush; E, yellow; F, royal blue. Fig. 8 shows a maple leaf: A, dull gold with dot plants of scarlet crimson; B, Californian bluebell or pale blue violas; C, gold, scarlet-crimson, or deep blue. See Bedding.

CARPET: STANDARD IN BRITISH AND ORIENTAL FLOOR COVERINGS  
 IN GENERAL HOUSEHOLD USE  
 Direct reproductions from carpets lent by Messrs. Treloar and Sons.

**CARPET SWEEPER.** A carpet-sweeper consists of a circular brush enclosed in a wooden box on wheels and fitted with a long handle. The dust is collected in the box, which should have rubber corners to prevent damage to furniture.

A carpet sweeper will last for years, and do its work easily and effectually, if it is kept in proper order. Each day, after use, the dust and fluff accumulated in the box must be removed, and the brush itself kept free from hair, cotton, etc. In most kinds an automatic comb is fitted for accomplishing this. In time bits of hair, thread etc., will get wound round the axle of the sweeper between the wheels. When this is the case the framework should be drawn away from the axle, and the brush taken out so that the axle may be cleaned. *See Vacuum Cleaner.*

**CARRIAGE.** In general this word is used for any vehicle used for carrying, but more especially it means a vehicle drawn by a horse or horses and owned by a private individual. Carriages are called by different names, according to their shape, size, and other conditions.

**Carriage Licence.** In Great Britain a tax is charged upon carriages kept by private persons. For four-wheeled vehicles drawn by one horse this is 21s. a year, but if drawn by two horses it is 42s. Two-wheeled vehicles pay 15s. a year. Vehicles used for business purposes are charged nothing, but a tax of 15s. a year is paid by the owners of cabs plying for hire. Carriage licences can be obtained from any post office.

**CARRIER: Of Disease.** In medicine this is the name applied to persons who are found to be carrying in their bodies virulent micro-organisms which are capable of producing disease in other people if communicated to them. Thus diphtheria and cerebro-spinal fever carriers have the microbes of these diseases in their throats, and these people may not themselves have suffered from the disease which they carry, or only so mildly that it has been overlooked. Enteric fever carriers are persons who have recovered from the disease but who continue to pass the germs in their stools.

When a case of diphtheria (q.v.) arises all residents in the house should be examined to ascertain whether or not they are carriers.

**CARRIER: The Legal Aspect.** There are two kinds of carrier, the common carrier and the special carrier. A common carrier holds himself out to carry goods from one fixed place to other fixed places on payment of his customary charges. A special carrier undertakes special journeys on terms arranged for each journey. A railway company is a common carrier, a furniture remover a special carrier.

A common carrier is bound to accept for carriage and to carry all goods of the kind he professes to carry so long as he has room for them and the consignor will pay the usual charges. Apart from any special term, he

is liable for their safety and safe delivery, quite apart from his negligence, except for acts of God and the King's enemies. Thus, if they should be stolen by armed thieves, or damaged by someone else's negligence, he is liable.

Railway companies are only liable for goods sent at owner's risk if the goods are lost or damaged by the misconduct of their servants. *See Parcel Post.*

**CARRIER PIGEON.** Noted for its stately grace and dignified bearing, the carrier pigeon is held in high esteem by fanciers. No pigeon commands higher prices, as much as £200 having been paid for a show specimen. Possibly, on account of its name, many wrongly attribute to the carrier the characteristics of the homer; but although at one period it possibly possessed them, they are non-existent in the English carrier of to-day. *See Pigeon.*

**CARRIER WAVE.** A continuous wave of constant frequency which is radiated all the time broadcasting is being transmitted. The carrier wave is modulated or varied by sound vibrations picked up by the microphone in the broadcasting studio. *See Microphone.*

**CARRON OIL.** A soothing application for bums and scalds, first used at the Carron ironworks, Stirlingshire, received the name of Carron oil. It is prepared by shaking together equal parts of lime-water and linseed oil, when a thick cream is obtained. This is freely applied to lint or soft rags, and placed upon the burn or scald. Carron oil is improved by the addition of 1 or 2 per cent. of an antiseptic, such as carbolic acid or eucalyptus oil.

**CARROT.** This valuable root vegetable thrives best in deep, well-drained soil; but heavy land can be made suitable by cultivation and by adding sand, sweepings from garden paths, grit, and leaf-mould. Lumpy soil will produce ill-shaped roots. As the seeds are small, the ground surface must be well broken down with fork and rake before they are sown.

*Carrot.  
Right, early  
Gem carrots,  
a prolific and  
profitable  
variety.  
Left, bunch  
of Long Reds.*

The main crop of winter roots is obtained by sowing seeds thinly in shallow drills 10 in. apart in April. The seeds are covered sufficiently by passing the rake over the drills. The seedlings must be thinned out gradually until they are 6 in. apart: the final thinnings will be large enough to use in the

kitchen. During the summer months the soil between the rows must be hoed frequently to keep down weeds. In October or early November the roots are lifted and stored in sand or soil at the foot of a wall or fence. Often they are placed in boxes in a shed, but in such conditions their flavour deteriorates.

A sowing of an early variety in July will yield small roots of excellent flavour in autumn and early winter. To provide young carrots in summer, seeds should be sown on a warm sheltered border in March. By sowing on soil placed on a hotbed in a frame in November, and during the winter, a succession of small early roots is obtained.

On deep, well-tilled soil the long-rooted varieties, e.g. New Intermediate and Long Surrey, may be sown. For ordinary garden soil James's Intermediate and Scarlet Intermediate are more suitable. Of the small-rooted sorts for sowing in March and again in July, French Short Horn, Early Gem, and Scarlet Horn should be chosen. Varieties to sow in a frame in winter are Parisian Forcing, Early Nantes, and Inimitable Forcing.

*Carrot. 1. Insufficiently thinned and 2, a mply thinned plants. 3. How to sow*

*carrots: a, hole levered with dibber; b, hole filled with fine soil; c, seed sown on top and covered with fine soil. 4. Carrots stored away from frost in fine soil or sand.*

**How to Cook.** The carrot contains no starch, but a large amount of saccharine matter, and is of great value as a flavouring vegetable. Young carrots are most wholesome, and the fine colour of the outer portion lends a decorative touch to stews.

Carrots should never be peeled. After they are washed take a sharp knife and lightly scrape off the outer coating, scraping from crown to root. It is best

not to do this until the last moment, or the flavour is weakened. Young carrots require about  $\frac{1}{2}$  an hour's cooking, and old ones about 1 hour's.

If to be stored during the winter, put them, if possible, on a slate slab, covering them with sand. Carrots when used for garnishing purposes are cleaned and cut into various designs, after which they are boiled in slightly salted water. Grated carrots are often used in Christmas puddings and added raw to salads.

To boil carrots, cut off the green tops and rootlets of 2 lb. of carrots; scrub, then scrape the carrots downwards until they are quite clean, taking care to cut out all specks. Lay them in cold water, cutting them, if large, lengthways into quarters. Place them in boiling salted water, and boil them until tender. Pierce them with a skewer to make sure they are soft. Drain off all water, and serve them either plain with butter and pepper, or with melted butter sauce, or chop finely, reheat in the saucepan, and serve with 1 oz. of butter and a dusting of pepper. In the last case the mixture is pressed into a mould and turned out into a vegetable dish.

Young carrots, boiled whole, may be served with parsley sauce made from a lump of butter the size of an egg, half a handful of finely chopped parsley, the juice of half a lemon, and a little seasoning. Toss these ingredients in a pan over the fire for a few minutes, and then pour the whole over the carrots, serving at once.

Carrots with mint-glaze are excellent. To prepare them, wash and scrape about 3 or 4 medium-sized, well-coloured carrots. Slice these into  $\frac{1}{4}$  in. thick rounds, and boil them for 10 to 15 min. Then drain off this water and in its place put 2 tablespoonfuls white sugar and 2 oz. butter. Stir in 1 tablespoonful washed, finely chopped, fresh mint leaves, cover the pan, and let its contents simmer until the vegetable is tender and has a glazed appearance. Then arrange in a hot dish, pour over any juice, and add salt and pepper. A pretty dish is made if a border of cooked peas is added.

**CARROT FLY.** Carrots are frequently much injured by the larvae or maggots of the carrot fly which bore into and feed upon the roots, causing them to become brown or rusty, and finally rotten. In some cases the growth of small roots is entirely checked. It has been noticed that the pest is worse in dry seasons.

*Carrot Fly. A, adult fly. B. maggot. C. chrysalis. D. carrot showing ravages of the maggot (By permission of H.M. Stationery Office & the Ministry of Agriculture)*

In appearance the carrot fly is shiny black or dark greenish-black in colour and about  $\frac{1}{5}$  in. long, with a wing expanse of nearly  $\frac{1}{2}$  in. The maggot is yellowish, about  $\frac{1}{4}$  in. long.

The flies appear in spring, and may be seen upon the lower leaves of trees and bushes, especially near brooks

and streams. When the carrot roots are well established the flies lay eggs upon them just below the surface of the ground. When young, the maggots especially attack the outer parts of the carrot.

When it is noticed that the tops of carrots change colour prematurely, the roots should be examined and the infested parts forked up and destroyed. As a preventive measure spraying with paraffin emulsion is recommended. A paraffin emulsion may be made and applied as follows:

Dissolve 1 lb. of soft soap in 1 gal. of boiling water, and, while still hot, add 1 pt. of paraffin and churn the mixture thoroughly.

When required for use add 1 gal. of the mixture to 9 gal. of water, using rain water or water which is not very hard.

Spray the carrots soon after the seeds have germinated and immediately after they have been thinned.

Sawdust impregnated with paraffin laid alongside the plants helps to keep away the flies in early summer. Pressing the earth close round the stems after thinning the seedlings tends to prevent the flies from egg laying.

In localities where the attack of the fly is very prevalent, a supply of carrots can usually be maintained by sowing early varieties in a sheltered position in March, for early use, and again in July for autumn and winter.

**CARROT PUDDING.** Several puddings of which carrots are a constituent are sometimes known as carrot puddings. One of these is Victoria pudding, while another is made as follows: Mix together with a little milk 4 oz. of grated carrots, the same quantity of suet, flour, and currants, 3 large tablespoonfuls of golden syrup, and the grated rind of a quarter of a lemon. Steam the whole in a basin for 1½ hours, and turn out to serve.

**CARROT SOUFFLÉ.** An excellent soufflé is made with cold cooked carrots. Rub sufficient through a fine sieve to fill a breakfast cup. Melt 1 oz. butter in a saucepan stirring into it 1 oz. flour. When well blended, add the sieved carrots and stir the mixture over the fire until it boils. Cool it for a minute or so, then beat in the yolks of 2 eggs, and season all these ingredients carefully. A tiny pinch of powdered mace is an improvement.

Put the whites of the eggs on to a plate, and beat them with a knife to a very stiff froth. Fold these whites very lightly, but thoroughly, into the carrot mixture, then turn it either into a buttered fireproof soufflé-case or a greased pie-dish, or into some small fluted paper soufflé-cases. These must only be about two-thirds full, unless a greased paper band is tied round outside the mould to support the mixture as it rises. Bake these soufflés in a quick oven for about 15 min., and, when cooked, add a dust of finely chopped parsley over the top.

**CARROT SOUP.** In a good recipe for carrot soup only the red part of the carrots should be used. Melt 1

oz. of butter or good dripping in a saucepan, add to it 1 heaped breakfastcupful of the chopped red parts of raw carrots. Turn the pieces about in the butter for 10 min., taking care that they do not colour in the least. Next add 1 quart of stock, and boil the soup gently until the carrots are quite soft, which will depend on their age. Rub the soup through a hair or fine wire sieve, put it back into the saucepan, which must first be rinsed with cold water, and let it re-boil. Mix a level tablespoonful of cornflour smoothly and thinly with a little cold stock or water. Add it to the boiling soup, and stir it until it re-boils, then let it cook gently for about 15 min., removing all grease from the surface.

Season the soup carefully with salt, pepper, a few grains of nutmeg, and ½ a teaspoonful of castor sugar. Lastly, add about ½ a teacupful of carefully-boiled rice. Serve the soup in a hot tureen. If no stock is available use water, adding, if liked, a little meat extract. This is also known as Crécy soup.

**CARVERS.** This term is applied to the knife and fork that are used for carving food. They differ in shape and make according to whether they are meat carvers, game carvers or fish carvers. Meat carvers have long blades, 8 to 10 in. in length, a usual size for household purposes being 8 in. Carvers for ham and other cold meats are best with long narrow blades. The essentials are a good balance, a well-proportioned handle and a keen edge. The two former are provided by the makers; the latter can be developed at home with the aid of a table steel or sharpener.

Fish carvers are preferably made of silver, but cheaper patterns are made in electro-plate.

Game carvers are shorter in the blade than meat carvers, have longer handles and a different balance. They are usually made of good-class steel, either plain or rustless. The former take a very keen edge. For carving poultry and game, patent secateurs are also used. Fashioned like large curved-bladed scissors, they are equally effective for disjointing an uncooked fowl, or for carving at table. *See* Cutlery; Fork; Knife; Steel.

## CARVING FOR THE HOME TABLE

### Correct Ways of Cutting Meat, Poultry and Fish

See also the entry *Boning*; the usual cuts and joints provided by the retailer are given under the headings *Bacon*; *Beef*; *Mutton*, etc.

The correct carving for table of meat, poultry, and fish has considerable influence on the flavour, which may be spoiled by indifferent carving, and is also more economical.

For meat and poultry there are three necessary implements: a good sharp knife with a fairly thin blade, a strong, two-pronged fork, and a steel, which, however, is only required in case of emergency, for the knife should be well sharpened before it is placed on the table or the sideboard.

A good carver will consider the particular tastes of those he is serving, and also take care to cut the meat neatly so that it is not disfigured if brought for the second time to the table. The cook may make the carver's task easier by placing the joint or bird on a dish quite large enough, and also by refraining from filling this with gravy.

It is better when a dish is much garnished to remove the joint on to a flat dish, conveniently placed, to obtain full control for carving.

Figs. 1 and 2 show how, with a pair of forks, the centre bone is removed from a fried sole. It is not considered correct to fillet a fried sole, as the flesh adheres to the forks, but in the case of a grilled sole, by all means, yes. Always remember to cut the fins off with a pair of scissors before cooking. It makes the dish look much more appetising. When carving a salmon avoid breaking the flakes, and cut crossways. Run the knife along the backbone first, then right through the belly. Carve from the head in slices about 1 in. thick, until the middle is reached, when the slices should be only  $\frac{1}{2}$  in. thick. When the middle is past, again serve slices about 1 in., until the tail is reached. One side of the salmon is now clear. Take the knife and cut the backbone away from the head, then lift up carefully, using the fish slicer to keep down the fish, when the bone will come right off. Carve the same as before. The best part is the middle, but the tail portion is also liked, and this can be divided into four fillets, by cutting the tail end lengthways from the backbone. By dipping the fish carver in warm water occasionally, the carving is facilitated. Never use steel articles for fish.

*Carving. Figs. 1 and 2. Separating the backbone neatly from the flesh of a fried or grilled sole by means of two forks.*

For roast sirloin (Figs. 3 and 4), after loosening the meat from the chine, run the point of the knife along the bone. If the sirloin has the fillet or undercut on it, turn the joint on its back and cut the fillet longways.

York ham is simple to carve (Fig. 5). First cut an incision at the knuckle, remove surplus fat, and proceed to carve. When half-way up the slices should be cut alternately from right and left sides, or they would eventually become as large as a plate.

With a leg of pork the method is naturally similar to ham, but it is advisable to remove the crackling. Then

the slices can be cut as thin as required.

*Carving. Figs. 3 and 4. When carving a sirloin loosen the meat from the chine and then carve downward.*

*Fig. 5. For a ham, make an incision at the knuckle and carve towards it.*

*Fig. 6. For a leg of mutton, make an incision and carve fairly thick slices. Fig. 7. For the shoulder, remove fat and carve from blade bone to angle bone.*

Thicker slices of a leg of mutton (Fig. 6) should be carved than for beef. First make an incision at the knuckle. Continue until a bone at the top of the leg is reached. Then cut left and right sides alternately.

The best way to carve a saddle of mutton is to run the knife along the chine bone, and under the meat along the ribs. Cut down to the bone on the cross, then slices from the outside, which is called the flap. This will make the piece V-shaped. Two slices of cross-cut and a piece of fat are generally sufficient for a meal.

Commence carving a shoulder of mutton (Fig. 7) from the blade bone to the angle bone; this is called the long cut. Then carve the opposite side of the shoulder, giving a slice with the long cut, which will make a good portion. A small piece of the oyster should be served, this being regarded as a great delicacy. It should be remembered to cut down the bone in a rather slanting manner.

In dealing with hare or rabbit, separate the legs and shoulders, and cut the back part into portions. If a knife is inserted into the joint, and the back raised up, the operation is simple.

To carve a fowl, or a pheasant, hold the bird firmly on a dish by inserting the carving fork into its leg, then loosen the legs by cutting skin, following the natural curve of leg. Now turn fowl on breast and cut sharply through backbone. Remove legs from wing (Fig 8). Now cut wings in two-by inserting knife in centre (Fig. 9) and cutting towards and through the wishbone, then repeat operation: by following the first incision and cutting right through the breast the fowl is quartered. The portions can be increased by cutting the wings from the breast with winglets attached, making two portions, and dividing each leg into two. A small slice of the breast should be served with each leg. The fork should never be dug into the breast of the bird.

*Carving. Figs. 8 and 9. For a fowl, remove legs, leaving wings intact to enable the carver to quarter the bird.*

*Fig. 10. When carving a turkey, first separate a leg from the carcass and then carve slices from the breast. (Courtesy of J. Lyons & Co. Ltd.)*

Small birds, like plover, quail and snipe, are served whole. Woodcock, partridge, grouse, and pigeon are usually cut into halves.

The carving of a turkey is a similar operation to that for a fowl. Remove the leg (Fig. 10) place the bird on its back, and start carving from the centre of the breast towards the side. The legs should be cut into slices and served with pieces of breast and stuffing.

The carving of a goose is similar to that of turkey. With a roast gosling remove the legs as in the case of turkey, then cut the wings away, leaving the breast. Carve the breast crossways into four, serve one piece to each half of leg, which with the wings will make six portions.

To carve a duck, remove the legs, and, if desired, cut them into two. Then remove the wings. A small portion of the stuffing should be served to each person.

**CASCARA.** By reason of its gently laxative action cascara is very useful in medicine. In chronic constipation cascara sagrada is much used. The commonest preparations of this drug are the dried extract, dose 2 to 8 grains, the liquid extract, dose  $\frac{1}{2}$  to 1 teaspoonful, and the aromatic syrup of cascara, dose  $\frac{1}{2}$  to 2 teaspoonfuls. The dose of each preparation varies in individual cases, but it should be just sufficient to ensure one motion each day, and when fixed it should be adhered to. The dry preparation may be taken in tablets.

As cascara also has a bitter principle which makes it more or less of a carminative, it is a valuable drug in cases where constipation is accompanied by much flatulence. In habitual constipation a single dose of 5 or 6 grains of the dried extract, or a teaspoonful of the liquid extract, may be taken at bedtime, or smaller doses, 10 to 20 drops of the liquid, or a grain of the dried extract, may be taken before each meal, 3 times a day.

The aromatic syrup may also be used in appropriate doses. To cover the exceedingly bitter taste of the liquid extract it may be mixed with an equal amount of liquid extract of liquorice and taken with a little tincture of orange or chloroform water. *See* Aperient; Constipation.

**CASCARILLA.** This dried bark has aromatic bitter properties, and two medical preparations are made from it. The infusion, dose  $\frac{1}{2}$  to 1 oz., which does

not keep well, especially in warm weather; and the tincture, dose  $\frac{1}{2}$  to 1 dram. It stimulates appetite and digestion and makes a useful tonic in convalescence from an acute illness. A tablespoonful of the following may be taken thrice daily in a wineglassful of water, at or after meals: Tincture of cascarilla, 6 drams; tincture of orange, 3 drams; syrup of orange, 4 drams; chloroform water to 6 oz. *See Appetite; Diet.*

**CASE HARDENING.** This process consists in increasing the carbon content of the surface of a steel relatively low in carbon, so that by being heated and then quenched it can be hardened like other steel. Simple case hardening may be carried out by any amateur. As an example, suppose a new cone has been made from ordinary mild steel, and that it is desired to harden the surface. When sufficiently heated and surrounded by carbonaceous material, mild steel will absorb carbon, and the longer the time the steel is in the carbonaceous material, the deeper becomes the case hardening effect.

Having obtained a metal box, take some clean old bones, crush them up as finely as possible, sprinkle a layer of the bone dust on the bottom of the box, place the cone in position, and pack it all round until it is buried in bone dust. Fix on the lid by means of a catch, or wire it on with steel wire. If a very hot fire can be raised in the kitchen stove, this may be used as a furnace wherein to heat the box thoroughly and its contents. This must be kept glowing red-hot for half an hour or so, when it may be removed from the fire, the lid knocked off, and the contents dropped on to the hearth. The cone can then be picked up with a pair of tongs or pliers and dropped into cold water.

If several pieces are to be case hardened, it saves much trouble to purchase one of the ready mixed carburising compounds sold for the purpose. *See Hardening.*

**CASEIN.** Organic substance contained in milk and cheese, being the essential ingredient of the latter. Casein can be desiccated and prepared as a substitute for eggs in baking, as the basis of an enamel paint, and as a substitute for glue in the making of cement. *See Cheese.*

**CASEMENT: Of the House.** In domestic architecture the casement is a window in which the sash is hung upon hinges to open like a door. The expression, the casement, is generally understood as referring to that part of the window that opens and shuts. By casement window is meant a window of the cottage type, and as a rule made with multiple panes of glass.

Commercial casement windows are made in a wide variety of patterns and sizes; those commonly in use measure 20 in., 39 $\frac{1}{4}$  in., and 58 $\frac{1}{2}$  in. in over-all width, and either 3 ft., 4 ft., or 5 ft. 1 $\frac{1}{2}$  in. in height. The total area in square feet of all the casement windows in a room should never be less than 10 p.c. of the floor area; and preferably more than this for efficient lighting and

ventilation. Various combinations of the windows enable requirements to be met. By having one casement to open on the left hand and another on the right hand, with possibly a transom or top hung casement, at least one window can be open in any weather (Fig. 1). The one that opens with its back to the wind or rain very seldom permits the weather to enter the room.

*Casement. Fig. 1. Metal casement window.*

The modern tendency is to use the casement window in preference to the sliding sash type; it is made either in wood or metal. The latter has many advantages, for metal windows are wind and weather proof; they are not affected by moisture, and they never jamb or stick in their frames. Another advantage is the greater glass space in a frame of given size, metal framing not being so wide as wood.

*Casement. Figs. 2 and 3. Fastener and stay for wooden casement.*

Existing window openings can often be converted for casements by removing the old frames and setting the new ones in concrete. For this purpose the metal casement is provided with lugs or flanges, which are embedded in the concrete. In the case of a wooden framework, or when fitting a metal casement to a wooden dwelling of the bungalow type, the metal frame is simply screwed to the framework, and the joints

made good on the outside with a fillet of wood, and on the inside by boarding up the jambs and finishing the work with an architrave or moulding.

Wooden casement windows sometimes give trouble by swelling and jamming in their frames, the best remedy is to remove the sash and plane the edges until it can close easily. Should the window have warped, the beading or stopping around it should be removed and re-fixed. To ensure a close fit, shut the window and, when refixing stopping force it closely against the window sash.

Casement fit-tings include fasteners to keep the sash tightly closed, and stays to adjust the amount of the opening (Figs. 2 and 3). Those made of malleable iron are cheap, and some good patterns are on the market, but unless the joints be well lubricated they soon suffer from the dampness, and then exhibit signs of rusting. Brass fastenings are preferable, as they are not affected in this way. It is important when fitting the fastener that it should draw the sash closely against the stopping, for which purpose the rubbing plate is generally made tapering or wedge-shaped. When newly fitted the fastener should draw the window up tight when the fastener is just at the bottom of the wedge-shaped part. This allows for future wear.

Fittings that have been in use for some time may have worn, and the fastening is then insecure, allowing the window to rattle and admit a draught. This is remedied by resetting the fastener, recessing it further into the frame, or by packing out the rubbing piece. *See Blinds; Burglary; Curtain; Window, etc.*

**CASEMENT CURTAIN.** These curtains are made of the same depth as the casement, and drawn along rods fixed to the frame. They are provided with rings sewn on to the base of a hem about 1 in. deep, and made with a drawtape, which allows a perfectly even distribution of the fullness.

The rods should be accurately measured and have proper brackets. The rings should be threaded twice with a cord, so that they can be drawn or undrawn. Each casement will have its own curtain, and if, as is usually the case in a bay-window, there is a row of lights above the casements, these should be provided with curtains. In this way light can be regulated more easily than by the single pair.

The use of these curtains is not confined to casement windows, they are employed in place of blinds for small sash-windows, and also in full-sized sash-windows, one pair of curtains being allowed for each sash. They are made of various washing materials of casement cloth, cretonne, shantung or Bolton sheeting. The term casement curtains is sometimes loosely used for any short curtains, but here it applies only to curtains as shown in Fig. 1 on this page, which are fixed within the window frame. *See Curtain.*

**CASHMERE.** Real cashmere is a superlatively soft wool or hair forming the under coat of the Kashmir goats of Tibet and the Central Asian plateau.

Many goods made not from goat hair, but from fine

wool, are customarily known by this name. Cashmere stockings and socks are ordinarily made from fine-spun merino wool. Cashmere suitings and dress materials are made from the finer qualities of worsted. The real cashmere wool is used in high-grade knitted wear. *See Shawl.*

**Cash on Delivery.** *See C.O.D.*

**CASSAREEP.** The juice of the cassava-root with the addition of several native spices, yields the condiment known as cassareep. It is introduced largely into a West Indian pepper-pot, and enters into the composition of many sauces.

**Cassava.** *See Tapioca.*

### **CASSEROLES AND CASSEROLE COOKERY** **An Economical Method which Conserves the** **Flavour of Food**

*See Beef; Chicken; Game and also the articles on allied methods of cooking, e.g. Braising; Stewing*

This process is slower than that required by ordinary utensils, but, on the other hand, less fuel is required, the food is cooked evenly, and none of the valuable juices are allowed to escape in steam. It is on this account the most wholesome form of cookery. Owing to the elimination of waste, even inferior cuts of meat can be used with advantage. French cooks were the first to realize the advantages of casserole cookery, and it is extensively used in that country. Braising is carried on to perfection in a casserole.

Quite a number of dishes can be cooked in a casserole, and are best brought to the table therein. This saves re-dishing, ensures the food being served really hot, and reduces the labour of washing up. Also, it is a most convenient method of cookery for the busy housewife, as the food is cooked without constant attention and can be kept hot for a long period for any late comer to a meal.

A useful casserole which can be placed on a gas boiling burner, turned low to a blue flame, has an outer casing with a turned-in rim, forming a cavity into which heat ascends until the food inside the casserole is cooked.

**Casserole of Chicken.** Fowls cooked in this way can be successfully made tender and succulent even when they would be otherwise tough. Cut a fowl into neat joints and season each with pepper, salt, and a pinch of pounded mace. Put some slices of bacon at the bottom of the casserole and lay the chicken or fowl on these. Having sprinkled over them a finely-minced onion, pour over all half-pint of white stock. This done, the casserole can be covered and placed in a moderate

oven for an hour, or it can be placed on the hot-plate of a range and the contents simmered for an hour. If a gas stove is used a thin iron plate or an asbestos mat put over the stove will enable the casserole to simmer thereon. This recipe can also be used for other poultry

or for game. The casserole illustrated (Fig. 1) is of glass with a plated silver mount for table use.

*Casserole. Fig. 1. Casserole of chicken, for cooking a tough bird.*

**Ways With Meat.** One of the beef dishes that can be cooked in a casserole is the shin. Take 1 lb. of this and, after wiping it, cut it into small pieces and add four slices of fat bacon. Then place it in the casserole with two finely-minced onions, a scraped carrot cut into small pieces, some mushrooms or mushroom ketchup, and a pint of stock. Bring it to the boil and let it simmer for three or more hours. Strain the gravy and add a dessertspoonful of flour smoothly mixed with cold water, or, if preferred, with a glass of claret. The beef can then be returned to the casserole and again allowed to simmer.

*Casserole. Fig. 2. Beef casserole served in an earthenware dish.*

Fig. 2 shows this dish ready to be served in the casserole. Oxtail is also an excellent choice for casserole cooking. Having cleaned the tail and cut into pieces, fry them in 2 oz. of butter or dripping. When the pieces are a rich brown, put them into a casserole, and cook in the remaining fat 1½ oz. of fine flour, then, by degrees, add 1½ pints of good brown stock, and let all boil together, stirring till smooth. Pour this over the tail, and add 2 carrots, 1 turnip, and 2 onions, all prepared and cut up small.

*Fig. 3. Casserole of oxtail, to which carrot, turnip and onion are added, the whole cooked in a china dish.*

*Casserole. Fig. 4. Appetising breakfast dish of fish, haricot beans and eggs, served in a glass casserole.*

A bouquet garni and a

little spice, with a few peppercorns, should be tied in a muslin bag and put in with the vegetables. Simmer gently over the fire or in the oven from 2 to 2½ hours, pouring in a little more stock if required. Before serving, the gravy must be cleared from fat and the spices and bouquet removed (Fig. 3).

**Cod with Artichokes.** Among the fish that can be cooked in a casserole are cod, haddock, hake, plaice, salmon, sole, turbot and whiting. A good way with cod is to flake 1 lb., peel 4 Jerusalem artichokes, and put them into the casserole with ¾ pint milk, 1 oz. butter, a dessertspoonful minced onion, pepper and salt to taste. Cook gently in the oven until the artichokes are soft, then add sufficient melted butter sauce to cover, bring to the boil, add a squeeze of lemon-juice and garnish with finely-chopped parsley before serving in the casserole.

**Earthenware for Vegetables.** As regards vegetables, cabbages, cauliflowers, spring greens, spinach, turnip tops, green peas, celery, brussels sprouts, and French beans can be cooked in a casserole, preferably an earthenware one. For a medium-sized cabbage 1 gill of water and 1 oz. of fat should be placed in the casserole, which should then be covered. Corresponding amounts of water and fat should be used for other vegetables. The vegetable should be cooked gently and stirred now and again until it is tender. It should be seasoned with salt and pepper, and served very hot in the casserole. Celery is particularly good braised in a casserole. First par boil the celery for 10 min. in salted water and then drain it. Place in the casserole with sufficient boiling brown stock to cover the celery and put in the oven till tender. Serve with chopped parsley and a chopped, hard-boiled egg sprinkled over the top. Fruit cooked in syrup, to be afterwards served cold, is better stewed in a casserole, as not only is the flavour conserved better, but also the colour and shape.

Before being used, a casserole, if of earthenware, should be toughened or seasoned by filling it with cold water to which a handful of salt has been added. Bring the water slowly to the boil, and then leave it to cool in the casserole. Another method is to melt some fat in the pan, smear it well all over the inside and out, and bake it in a cool oven. A casserole is best used in the oven or on the hot-plate of a kitchener, and should never be placed directly over a fire or a fully-turned-on gas-jet. Glass casseroles should be used in the oven only. The food in these is cooked not only by the hot air of the oven, but also by radiation of the glass.

Breakfast dishes are appetisingly served in glass ware. A good recipe is made from 1 lb. of left-over cod or haddock, two boiled and mashed potatoes, 1 lb. haricot beans, boiled and pressed through a sieve, and four poached eggs. Make ½ pint anchovy sauce, place with flaked fish in casserole, add potato and put beans on top of these, also several dabs of butter. Heat slowly in oven and before serving place poached eggs on top

(Fig. 4).

To clean casseroles, wash them inside and out with hot soapy water to which a little soda has been added, and rinse them with warm water. In case of very dirty pans, fill them with cold water containing a little soda and place them on a hot-plate to heat the water and so loosen the dirt. Stains may be removed with sifted ashes or silver-sand.

**CASSIA.** A group of trees and shrubs of which only *cassia corymbosa* is commonly grown in British gardens. This is an evergreen shrub, 6 ft. or more high, which bears yellow, pea-shaped flowers freely in summer; it is not hardy and must be kept in a warm greenhouse for the winter. It will cover the back wall of a greenhouse if planted in a border of loamy soil, or it may be grown in large pots and used in flower beds in summer. Propagation is by cutting under glass in spring.

Oriental varieties of the same shrub provide the purgative senna leaves of commerce. Further species include the Hashish, or Turkish dream drug.

The bark of the cassia used in cookery resembles cinnamon in appearance, smell and taste. *See Cinnamon.*

### CASTING IN IRON, LEAD AND BRASS Methods and Equipment for the Amateur Metal Worker

A knowledge of this subject will help materially in making many of the articles described in this work. *See also Lathe; Metal Work; etc.*

While casting in iron can only be done effectively in a foundry, the non-ferrous metals like lead and brass offer plenty of scope for the amateur who has provided himself with the necessary tools, which are neither numerous nor costly. Such work has a particular attraction for many, and it is quite unlike any other mechanical process. For casting in lead, one or two iron ladles, a wire skimmer or spoon for removing the dross and a few simple modelling tools are all that are necessary. The lead can be purchased from most ironmongers or plumbers, as can the fine plaster of Paris used for the moulds. For casting in brass or aluminium a furnace is necessary. The addition of a few plumbago crucibles, a pair of crucible tongs, moulding sand, and flasks or moulding boxes, complete the equipment.

**Casting in Lead.** For first attempts at casting the amateur will be well advised to use lead or type-metal. Wooden moulds can be used, and the lead melted in an iron ladle over the kitchen fire. Cast lead panels or plaques can be modelled in wax or plasticine, and cast in plaster moulds, the lead casting being carefully scraped wherever any rough edges or faulty places develop. Almost any simple article can be made after first planing up some soft wooden blocks of appropriate size.

In making a wood mould of an article to be cast,

some skill in woodworking is required, since the mould must be a replica of the article itself in reverse, and a core must be provided if the article is hollow. The following system avoids a great deal of this trouble and produces excellent results. The first thing required is a replica of the desired casting: this can be an existing object, such as a toy soldier, or the article can be modelled in wax or plasticine. However it is made or obtained, the remaining processes are the same. The object is rubbed over with vaseline, then slightly warmed to ensure the vaseline flowing into every crevice, and the surplus is wiped off. Next stand the object on a piece of glass, a tile, or a smooth board, well greased, and make up some plaster of Paris into a thick paste. This is best done by putting some cold water in a bowl and sprinkling the plaster on to it, stirring the water gently all the time and always in the same direction. Continue adding plaster until the mixture is thick and sticky (like clotted cream, but not so thick).

Heap the plaster up and around one-half of the model, keeping the plaster in place with a temporary wall of clay or plasticine which has been previously built up. Allow the plaster to set, which will take about twenty min. or less, remove the clay and the model, and clean up the surface of the plaster to a flat face, using an old table-knife. Drill two or three holes into the body of the plaster, and fix into it little wooden pegs with rounded ends. These should protrude about  $\frac{1}{2}$  in. from the face of the plaster, and enable the two halves of the plaster mould to be put together in proper register. Replace the model, vaseline the face of the plaster, and well vaseline the pegs. Then build up the other half of the mould with plaster as before. The result is as in Fig. 1.

*Fig. 1. Plaster mould for casting a toy soldier. Left, a hollow half mould, right, the other half, with the casting in place.*

To cast from such moulds, remove the model, wipe off as much of the oil from the vaseline as possible, and coat the interior with powdered blacklead. Then tie the two pieces of the mould together with string and pour in the lead from what will be the bottom of the model. Some elaborate models will require the moulds in three, four, or more parts to enable them to be removed from the casting without being damaged.

When it is desired to make a hollow lead casting, it can be done in one of two ways. An ordinary mould can be made, the lead poured in, and immediately poured out again. As the skin or surface in contact with the mould is the first to chill and set, only the interior parts will be molten, hence a more or less hollow casting is the result. A similar method is used commercially for casting lead toys and for similar purposes. Disad-

vantages are unequal thickness in the casting, frequent distortion, and a tendency for holes to form in the outer surface.

A better plan is to make a rough plaster model, somewhat smaller than the finished model, then to coat the exterior with dental modelling wax, and shape this to the desired form with modelling tools. Three or four wires are then driven partly into the model in the least conspicuous places, and the composite model coated with plaster as before, except that the whole model is entirely covered, the only openings being the venthole for the exit of air and the gate or entrance for the molten metal.

When the plaster is quite dry it is placed in a dish in a hot oven with the gate downwards, the heat melting the wax, which flows out of the mould into the dish. The plaster core remains in position, as it is held firmly by the wires. A space must be hollowed out in the wall of the mould around the gate to form a trough into which the molten lead may be poured. The lead flows into the space hitherto occupied by the wax, and when cool the mould is broken open and the casting removed. The plaster, in the interior can be chipped out with a small chisel, and the holes made by the pegs closed up with a spot of solder.

It will be seen that this system requires an opening somewhere in the casting to enable the plaster to be removed; generally this can be arranged under the feet or at the back. When using plaster or metal moulds it is desirable thoroughly to warm them before introducing the molten metal.

**Casting in Brass.** A simple furnace suitable for melting brass or small quantities of iron is illustrated in Fig. 2, and can readily be made from bricks. The furnace is 18 in. square, built with nine courses of bricks set in cement on a concrete foundation 4 in. thick. The interior is lined with fireclay, poured in when wet, and is formed by means of a wooden core or box 6 in. square: the flue is similarly cored with a 3½ in. diameter wooden block. At the back of the furnace other bricks are set up to support the chimney, which is made from 4 in. diameter stove pipe, and is 24 ft. high, for, which reason it is desirable to place the furnace outside the house and against a solid brick wall to which the chimney is attached.

*Casting. Fig. 2. Simple brick furnace suitable for melting brass or small quantities of iron.*

The grate is made from a regular stock cast iron fire grate and is

supported on two bars of iron built into the brickwork. The top of the furnace is closed by a fire brick 12 in.

square and 2 in. thick. All joints are made airtight with fire clay. In use, a fire is made with gas coke worked up thoroughly hot, the furnace again filled with coke, and the crucible set in position on top of the fire. The lid is then placed on the furnace top and luted or made airtight with fireclay. A damper at the top of the chimney is a convenience in regulating the fire, and is operated by a long wire, as in Fig. 3.

*Casting. Fig. 3. Furnace damper.*

Such a furnace should melt 5 lb. of cast iron in ¾ of an hour, brass being melted in much less time. After every heat the fire grate must be pulled out and the slag cleaned away with a rake or scraper, as if allowed to cool off it will adhere to the lining of the furnace and be difficult to remove.

*Fig. 4. Simple gas-heated furnace.*

Where gas is available a very simple furnace can be rigged up by using the gas blow pipe as a heating medium. The furnace is simply built up from fireclay bricks, well jointed with fireclay and provided with a lid and a bottom of the same material, as in Fig. 4. The lid has a small and slanting hole about 1½ in. in diameter cored through, and a hole is left in the side of the furnace to receive the nozzle of the blow pipe. The gas is then turned on and lighted, the bellows operated steadily, and the gas adjusted until the flame entirely fills the furnace and flares out of the hole at the top.

Useful tools for handling the crucibles are illustrated in Fig 5, and can all be made from wrought iron. The tongs have curved ends to encircle the crucible, the two rakes are for skimming the dross off the top of the metal, and the circular tool with a handle is used to assist in holding the crucible while pouring the metal into the mould. A fine wire mesh sieve is needed for sifting the sand before mixing, also a small trowel and a few modellers' spatulas are useful to make good any damaged places on the mould.

Moulding sand can be bought ready for use, but some ordinary fine building sand obtained from a builder's yard can be used for early work. It is prepared by drying and sifting through a very fine wire sieve, then damping with water and thoroughly mixing on a piece of clean board into a moist mass. As a test of suitability take a lump of sand in the hand, squeeze it tight and on opening the hand if the mass

shows no tendency to crack or fall to pieces, it can be used for moulding, otherwise add 5 per cent, by weight of clean, thoroughly dried clay, which has previously been pounded with a hammer and sifted through the fine sieve. After mixing, damp the material to make it cling together. Moulding boxes can be made from wood 1 in. thick, just like an ordinary lidless box but with triangular corner pieces glued and nailed to the inner corners as in Fig. 6. The boxes can be any size to suit the work and are made up solid and then sawn asunder. The ends should have dowel pins or guides to make them register properly: the parts are kept together with a hook and eye on each side. Note the holes (A and B) drilled to act as a gate for pouring in the metal, and for a vent which allows the steam or gases to escape; when the metal overflows at this latter hole it indicates that the mould is full.

Fig. 6

Fig. 7

Fig. 8

*Casting. Fig. 5. Usefuo! tools employed in casting. A. Hardwood rammer. B. Crucible tongs. C. Sieve. D. Double-ended towel. E. and F. Skimmers or rakes. G. Crucible ring or hook. Fig. 6-8. Moulding box, pattern and core for casting an aluminium candlestick.*

In use, the wooden frame is laid on a wooden baseboard and filled with damp moulding sand

rammed in tight and levelled off flush with the sides. The model or pattern is now pressed into the sand until half the pattern is embedded, and the surface is then finished off level with the sides. Place the top box on the lower one, sprinkle the surface of the sand in the lower box with dry parting sand, that is finely powdered fire-brick dust, and then fill the top box and ram home the sand.

#### Preparing the Mould for the Metal

Separate the two, remove the model or pattern by rapping it with a stick, dust the surfaces with fine charcoal, cut a passage way to the gate, and another to the vent, also drive a knitting needle through the sand in one or two places from the cavity formed by the pattern, these to act as additional air vents. Replace the top box, and clamp them both together, then pour in the molten metal. The brass casting will come out much cleaner if a little powdered resin is sprinkled over the mould faces prior to replacing the top box.

The amateur can use new brass obtained from the metal merchants. Ornamental drawer handles, door fastenings, keyhole plates, and similar cabinet fittings may be cast in brass. A number of small models might be cast together in the same box, the cavities being joined by a channel to allow the molten metal to flow from one to another. The thin bonding piece thus produced is easily removed when the casting is cold. Aluminium is cast in much the same way, but larger pouring gates and ample air vents are needed. The metal should not be overheated and should be poured as soon as properly melted.

Plaster casts can be made in plaster or wood moulds. The plaster is mixed to the consistency of thin cream and poured in the same way as if it were metal. The moulds must be well oiled with lubricating oil prior to putting in the plaster. The surplus oil is poured out before casting.

Fig. 7 is a pattern of a short candlestick cast in aluminium. It should have the base recessed so that it will stand steadily on a surface that might not be quite flat; the top should be hollowed slightly, so that the melted grease will not run over the edge. If the pattern were made thus, however, it could not be lifted from the sand of the mould, so the preliminary pattern differs a little from the finished article.

In Fig. 7 the outline shows the pattern itself, and the heavy dotted lines show the details of recessing the base and candle holder. The candlestick is best finished by turning in a lathe, and therefore a piece is shown projecting from the base, to be held in a self-centring chuck, or for a carrier to be put on it and the candlestick held between the centres of the lathe.

The projecting piece at the other end is termed a print, and will not appear in the casting, as it produces the hole for the candle. The laces of both ends are slightly conical to allow the pattern to leave the sand easily.

A core is required, as shown separately in Fig. 7, and

in position in Fig. 8. It should be of the diameter of the print. Its length should be that of the projecting print plus the depth of the hole required in the top of the candlestick, shown by the dotted lines. This core can be made out of ordinary bath-brick sawn and filed to the required shape. When the pattern has been taken from the sand, the core is placed in the impression which was left by the print, and butting against its end (Fig. 8). The melted metal will flow round the core, and this will produce the hole for the candle. The print should not be made any shorter than shown, or the melted metal might float it up. When the casting is taken from the mould, a metal plug can be fitted to the hole, so that the work can be centred to run true in the lathe, and it can be turned all over. The base can be turned flat and recessed, and then with a pointed tool the projecting piece can be parted off.

**CAST IRON.** Although one of the cheapest metals, cast iron is of little use to the amateur worker, except in the form of small castings for the construction of little engines and other mechanism. It is widely used for all kinds of domestic appliances, from drain pipes to gas stoves, and, being brittle, must not be struck with a hammer. It can only be satisfactorily repaired by autogenous or acetylene welding. In drilling holes a hand-drill or brace and a sharp twist drill are employed, but no lubricant must be used upon the drill; if it shows a tendency to heat, it should be cooled with a few drops of water.

**CASTLE NUT.** This is the name that is given to an engineer's nut having a projecting portion which is slotted; it is secured by a split pin, inserted through a hole drilled in the bolt. The provision of six slots enables the nut to be tightened up to a nicety, 1/6 of a turn sufficing to bring a slot opposite the hole in the bolt.

*Castle Nut. Left, nut removed. Right, nut in place on bolt with split pin inserted but not fully bent over.*

To unscrew a castle nut, the split pin must first be removed by bending the ends of the pin and straightening them as much as possible with the pliers. The pin is pulled out with a pair of pliers or a split pin extractor. The nut can then be removed with a spanner.

**CASTLE PUDDING.** Whether baked or steamed, this is usually made in small moulds or cups. Choose two good sized eggs, lay them on the scales where the weights are usually put, and weigh against them first butter, then flour, and lastly castor or granulated sugar, the former being best.

Beat the butter and sugar to a cream and add the eggs one by one, beating each well in. Next add the flour and a good saltspoonful of baking-powder. Stir these lightly in; lastly add two tablespoonfuls of milk.

Turn the mixture into some well-buttered moulds and either steam them for about 45 min. or bake them, when they will only take from 25 to 35 min. Turn them out on to a hot dish, and make a little hollow in the top of each and put in a small spoonful of jam.

**CASTOR: How to Fix.** The kinds of castors mostly used comprise the socket, screw and plate sorts; to these may be added bedstead leg and truck castors and glides.

In dealing with a socket castor (Fig. 1) not only must height be carefully observed, but the diameter of the socket at its mouth, because any difference in this part will mean either packing for a size too large, or paring the wood if too small, in both cases inadvisable to attempt. It often occurs that a screw castor (Fig. 2) will break, and that the stump of the screw will remain in the wood, this should be removed by the help of a strong pair of pincers.

Plate castors (Fig. 3) are standardised into sizes, and made with either iron bowl or wheel, or wood, the last named being better for domestic use. These, being attached by screws in the plate, are easily fixed, and simple to attach to any chest or piece of furniture for the first time.

*Castor.*

*Fig. 1. Socket castor.*

*Fig. 2. Screw castor.*

*Fig. 3. Roller-bearing plate castor.*

*Fig. 4. Ball castor.*

*Fig. 5. Diagram illustrating how to replace the castor on the leg of a bedstead.*

**Fig. 5**

Ball-bearing castors may be procured in either socket or screw patterns, the object of such being to make movement more rapid and easy; but whether such castors are satisfactory is an open question. Glides are extremely useful if in the correct position, and can be driven home by means of a hammer with a piece of wood to protect the glide.

Glides are made circular or triangular but the former is recommended as being best. Fig. 4 shows a common

type of ball castor made in a number of sizes for chairs, tables, etc.

To replace a bedstead castor (Fig 5), first remove the old castor, taking care that the pin of the bedstead is straight and the edge of the burr at the end filed off before attempting to fix the new castor. If the chill or casting at the foot has been allowed to become worn so as to have spoiled the seating against which the castor is to work, it may be found helpful to place an iron washer under the castor to form a new seating, but this should not be done unless absolutely necessary. The castor being in place, add a small washer on the top and then rivet over the peg, which will, if sufficient turnover be given, retain the castor in its working position.

To fix a set of socket castors where none has previously been used will need careful and accurate use of chisel and gouge, taking precaution that the tapered wood end of the leg, be it either table or chair, is exact in the length of the taper, as well as being correct in the extent of its tapering. Use a screw gimlet for each screw hole so as to give every screw a good start, and be careful, especially in dealing with oak and mahogany, in both of which it is easy to get a split, to turn the screw gently and quite straight. It must also be remembered that the outside of the socket should be flush at its mouth with the wood of the leg as it enters when in place. *See* Armchair; Chair; etc.

**CASTOR:** For Table Service. A pepper castor is often called a pepper pot. Sugar castors are made of silver or electro-plate, or of glass with a silver sprinkler top. Remove the top from the pot when cleaning it, and if it is all silver, empty the sugar out. Caked sugar is removed from a glass pot by filling it with hot water and letting it stand. *See* Pepper Pot; Silver.

**CASTOR OIL.** This oil is a good purgative, especially for children. In doses from half to two tablespoonfuls it is often taken by adults.

Varying from 15 drops for a three months infant to a teaspoonful or more for a two or three year old child, castor oil is a remedy which can usually be prescribed with benefit at the onset of most infantile disorders. Instead of plain oil, the B.P. mixture of castor oil may be taken. The dose is one to four tablespoonfuls.

Where in a grown person there is diarrhoea, caused by the irritation of undigested food in the intestines, one to two tablespoonfuls of castor oil, to which has been added 10 to 15 drops of tincture of opium (laudanum), is sometimes a very effective cure.

To disguise the taste it may be taken floating on a layer of peppermint water, and covered with a thin layer of brandy. *See* Constipation.

**CASTOR OIL PLANT.** This is the common name of *Ricinus communis*, a member of the spurge family, which is grown for the sake of its large, handsome leaves and sometimes used in sub-tropical flower beds for the summer. There are varieties with leaves of different colours, e.g. *Gibsonii*, bronze, and

*cambodgiensis*, dark crimson. The plants are raised from seeds sown in loamy soil in a warm greenhouse in February, the seedlings being potted finally in 5-inch pots and planted out early in June. They may be placed in larger pots and grown for conservatory decoration. The plant correctly named *Aralia Sieboldii* is also called the castor oil plant.

**CASTOR SUGAR.** The highly refined form of cane-sugar known as castor sugar is a fine, white, glistening powder. It is much used in cooking and confectionery, being specially suitable for preparation of cakes, puddings, etc., or for sprinkling over fruit. *See* Cake: Sugar.

#### CATS: VARIETIES AND CHARACTERISTICS

With Hints on the Care of these Domestic Pets

Other articles in this group deal with Dog; Rabbit and other animals kept in the household

When only one or two cats are kept, no special accommodation need be set apart for them, but if catting on a more extensive scale is desired, a box-room or light and airy attic makes a suitable abode, while a substantially built wooden house makes an ideal garden, backyard, or general out-of-doors cattery. Cats stand any reasonable amount of cold, but damp and draughts are fatal to success, if not indeed to the animals themselves. A sunny room or a cattery situated in a sunny aspect is a big asset in cat-keeping, as felinity loves sunlight, and one of a cat's greatest pleasures is to lie on a shelf or other resting-place at the window, and while enjoying the sunlight, taking a keen interest in all that it sees outside.

Whether kept in a special room or cattery, or simply as a house cat, the animal should have its own bed, which may be a basket with a blanket in it, but a roomy box, raised a few inches from the ground, and thus above floor draughts, is preferable. A cube sugar-box makes an ideal sleeping-place. The lid should be removed, and the box placed on its side; the upper side then forms a roof which keeps off draughts, while if a broad spar of wood is nailed along what is now the front of the box at the bottom, the bedding will be kept in place and the lower draughts excluded. Neither straw nor hay makes suitable bedding material. Some layers of newspaper can be placed on the bottom of the box to break the hardness of the wood, and a piece of old blanket utilised as the actual bedding. An old pillow or not too coarse canvas bag can be filled with clean wood shavings, and if these are not too tightly packed, they make a cosy and comfortable bed.

Sanitary boxes or pans should be placed in an out-of-the-way corner, but always where the cat can get to them with ease. Well-broken peat moss or ashes from the ranges make the best sanitary earth. Sawdust alone is not to be recommended, as it sticks to the cat's paws and coat, is carried outside the box, and usually some is licked off the coat and swallowed. Sawdust mixed with the ashes makes a friable and absorbent material, but sawdust alone should be avoided. If the pans are

emptied and their contents renewed every day, they will never smell; apart from that, a cat will not use a dirty sanitary box, and it is the neglect of that necessary cleanliness which engenders bad habits.

As soon as it can leave the nest, even the tiniest kitten will seek instinctively for some earthy material, and if a shallow pan is placed close to the nest, and kept in the one place so that they know where to go, kittens will never give their owners any trouble in that respect. A pot or box of coarse grass should be grown, and with regular watering it will keep fresh indefinitely. Cats eat a lot of grass, as it acts as an internal cleansing agent, and is particularly necessary where long-haired cats are kept, as their swallowed fur is apt to gather in and stop up the intestines.

All cats indulge in claw sharpening, and for this purpose they should have a log or piece of rough wood into which they can stick their claws.

When house scraps do not suffice to feed the feline family, practically any of the proprietary dog foods can be requisitioned for the feline menu; that is, any of the broken-up or kibbled foods, and not the actual dog biscuits. Cod's head well boiled and sufficient of the liquid poured over it for the food to absorb without being sloppy, and then the flesh of the heads taken away from the bones and mixed up with the soaked food, make a nourishing and appetising meal. Or a sheep's pluck, namely the lights, liver, and heart, can be secured from the butcher, well boiled, the liquid poured over the food in the same manner as the cod's head liquid, and the flesh itself cut up and added. Rabbit is a size-making dietary, and horse-flesh is excellent, but the latter should be guaranteed pure.

Cow's milk is nearly always injurious to kittens because of the preservatives it contains, and for the same reason it disagrees with many adult cats. Both cats and kittens should be allowed abundance of clean water to drink.

**Varieties of Cats.** Cats are classified in two main divisions—Persians, or longhairs as they are usually called, and shorthairs. The latter include the various British varieties as well as Manx, Siamese Abyssinians, and Russian Blues.

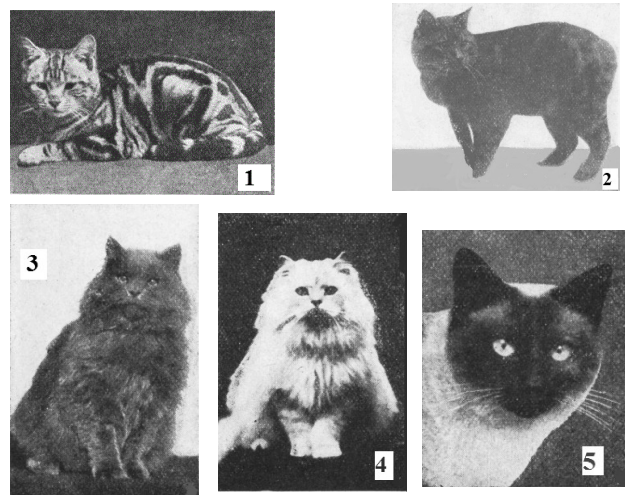

Blues are the most popular of all the feline tribe and the most remunerative for the average cat-lover. Any shade of blue is permissible, but soundness and evenness of colour are essential. There must be no dark patches, no tabby markings, and no white hairs. Blacks are jet-like cats, and the most difficult point is to get the colour a rich black to the roots of the coat. Blue and black kittens frequently have white hairs scattered over their bodies, and are often rusty or brownish in their top coats. These blemishes usually disappear with the kitten coats. Creams should be a rich cream or straw colour, the paler the better. Reds should be as rich orange or red as possible. All these varieties should have orange, amber, or hazel eyes. Some white cats have odd eyes: one blue and one orange, and these cats are quite good for breeding.

Chinchillas, which should have green eyes, should be one clear sparkling silver from nose to tail. Brown, red,

and silver tabbies should have orange eyes. Browns and reds have respective ground colours of sable and orange, with markings of black and red respectively, while silver tabbies have a ground colour of silver with deep black markings. The word "tabby" is often interpreted as meaning a female cat, but what it really stands for is the marked or striped cats, as distinct from the patched ones, which latter are tortoiseshell and tortoiseshell and white. Tortoiseshells should have patches of red, cream, and black, the richer the colour and the more distinct the patches the better; while tortoise-and-whites are tortoiseshells with white, but the white must not predominate. Both varieties should have orange, amber, or hazel eyes.

The British shorthairs are self-blue black, white, red, and cream, though creams and reds are very seldom seen. There are also brown, red, and silver tabbies, and tortoise-shells and tortoise-and-whites. The British shorthair is built on finer lines than the Persian, and is not so cobby, the head is not so round, the nose is slightly longer. The coat should be close and smooth and never woolly. Russian Blues are sealskin-coated blue short-hairs, lankily or snakily built, with long, narrow heads and faces and green eyes. The real sealskin texture and pile of coat is their first essential; a woolly texture means a cross with a Persian. Manx are tailless cats, with very cobby bodies, long hind legs, a round rump, big head with well-developed cheeks, and a rabbit-like coat.

Colour or markings are of no importance in Manx. Abyssinians or bunny cats are found in two varieties: browns and silvers. Siamese, or the royal cats of Siam, have pale cream-coloured bodies, with seal-brown faces, tails, and legs. Their eyes should be blue, and their coats have a woolly texture.

*Cat. Specimens of the principal Fancy Breeds: 1. Silver Tabby Shorthair. 2. Red Tabby Manx. 3. Blue Persian, male. 4. Chinchilla Persian. 5. Royal Siamese.*

**Care of Persian Cats.** Except that they require regular grooming if their coats are not to become matted and dishevelled, Persians are no more trouble to keep than are short-hairs. With the exception of the white variety being prepared for a show, washing is

never necessary. Groom persians with a long-bristled brush. White fuller's earth is the best cleanser for white or light-coloured cats. (See also page 376)

**CATALPA.** With its nearly heart-shaped leaves and clusters of summer flowers which are white marked with purple and yellow, catalpa bignonioides, or Indian bean, makes a charming lawn tree. It thrives well in town gardens. The yellow-leaved variety, aurea, is very attractive. Propagation is by seeds.

*Catalpa. Flowers of this beautiful hardy tree.*

**CATARACT.** Cataract is opacity of the lens of the eye, causing more or less blindness. It may develop from no apparent cause with the advance of age (senile cataract), usually after 50 or in diabetes, or may be due to accidental injury to the lens. Sometimes it is present from birth. See Eye.

**CATARRH.** Inflammation of a mucous membrane, e.g. the lining of the nose, the bladder or the gastrointestinal tract. See Bronchitis; Cold; Conjunctivitis; Cough, etc.

**CATERING:** For the Home. In the country, with most perishable commodities, so to speak, at the door, catering resolves itself into carefully thought-out menus, taking due consideration of the days when it is possible to get fish, to make a change in the planning of courses from poultry, eggs, vegetables, etc., and keeping an eye on the store room, which should always be kept well stocked with tinned and bottled food in case of emergency.

The caterer for a small family in a town, buying such provisions as fruit, cakes, bacon, fish, etc., may be well advised to carry them away in the shopping basket, because booked orders are often not dealt with until late in the day. Moreover, unless top prices are paid for special reserve stocks, the finest market value has been carried off by careful housewives, and only the second best is left. Other advantages of personal catering are that it enables the buyer to see the particular bargains of the day, and to get better service by tactful praise or complaint.

Some people find it answers to plan a week's menus in advance. Friday is a good day to choose for this scheme, because of the extra week-end shopping that is necessary anyhow.

When giving a party, a few days beforehand plan and write down the menu; then, taking each course in turn, make a list of things with the quantities of each that will have to be bought. The special things can be chosen at the caterer's convenience, and each item ticked off on the list as it is purchased, so that nothing

is forgotten. See Breakfast; Dinner; Luncheon.

**CATERPILLAR:** In the Garden. Hand-picking of caterpillars, killing of butterflies and moths, crushing of eggs which are found in clusters on the underside of leaves, are the surest means of riddance. Syringing or spraying with soft soap and paraffin solution, in the proportion of one gallon of suds to a wine-glassful of paraffin, is a deterrent; but care must be taken to spray the underside of leaves to make it effective. Fruit trees should be grease-banded at the end of September, in order to trap wingless female moths, which crawl up the trunks and deposit eggs at the base of dormant buds, whence caterpillars come in the spring, attacking growth with disastrous results. See Butterfly; Cabbage, etc.

**CATHARTIC.** Any drug known as cathartic is used to open and clear the bowels, which is done by increasing the peristaltic movements of the intestines and by rendering their contents more liquid. See Aperient; Constipation.

**CATHETER.** This is a long, hollow instrument used to tap certain cavities of the body through narrow passages. One form is used to draw off fluid from the urinary bladder. Of various sizes, catheters may be rigid, made of metal, or semi-rigid, of a varnished woven network, or soft, made of soft rubber. Frequently on account of enlargement of the prostate gland elderly men have constantly to use catheters.

**CATTLEYA.** One of the chief groups of hothouse orchids consisting of some fifty species and innumerable hybrids; many have large and particularly handsome flowers.

The labiata group of about 20 species has a single broad ascending leaf, and the flowers are large, usually lilac or rose-purple with a richly coloured lip and some yellow in the throat. The hybrids far outnumber the species. Cattleyas are easily grown in a suitable house. Artificial heat is generally required, except perhaps in the height of summer.

*Cattleya. Flowers of the popular hot-house orchid.*

Cattleyas differ in their time of flowering, especially in the C. labiata group, some of which bloom immediately the young growths are completed, others after a short rest in the autumn, while the remainder wait until the following spring; a little more water should be given as soon as the buds begin to push in the sheaths. See Orchid Pron. Cat'-le-a.

**CAUL.** A caul may be bought separately, or a piece  
(Continued in page 377)

## CATS: THE MOST POPULAR BREEDS

*Caught by the Camera in Various Moods*

The ordinary household black-and-white cat becomes a creature of sinister beauty in this close-up camera study. Note his fur, rubbed over with a short-bristled brush followed by hand grooming, his long whiskers, and the texture of his white throat

*Photo, A. H. Roche*

Here are two of the most familiar figures of the English fireside. Above: the long-haired brown tabby, leonine in appearance, with a thickish mane behind the ears. The ground colour is sable, the black occurs in stripes, and the eyes are orange. On the right: "Silver Penny," a prize silver short-haired tabby whose ground colour is silver. The black stripes are well defined, and the eyes are orange

*Photos, Ralph Robinson; Topical.*

A trio of Blue Persian kittens; a very popular and remunerative variety. Right: a champion of the English tortoiseshell-and-white species—patches rich in colour, eyes between amber and hazel. Other examples of fancy breeds are given in page 205

*Photos, Thomas Fall*

Kittens are notoriously difficult to photograph, but here are two successful attempts. Left: a Persian kitten with blue markings. Right: a remarkable group of Chinchilla kittens, such restless sitters that they must be exhausted by play before a good photo can be taken. Their fur becomes a much purer white as they grow up

of it should be sent with a joint of lamb. Pieces of caul are used in which to wrap cutlets that have been spread with some farce or forcemeat before they are grilled or fried. Chopped mixtures of meat, game, etc., are wrapped up in pieces of caul previous to baking them. The caul forms a protection to the food, and by the melting of the fat, of which it is mainly composed, the meat is basted and kept moist.

**CAULDRON.** Originally made in wrought or cast iron, cauldrons now survive in the form of coal receptacles. These are stamped from sheet iron. A coat of dull black paint speedily restores their appearance if worn. *See Coal Box.*

**CAULIFLOWER.** "What is the difference between cauliflower and broccoli?" is a question which is asked frequently. Both are varieties of the same species of wild plant (*brassica oleracea*), but broccoli is hardy, cauliflower is not. Cauliflower, which has whiter "heads" than broccoli, and is considered to be of finer flavour, is available only in the summer and early autumn, whereas broccoli is in season from autumn until late spring and early summer.

To provide the earliest crops in May and June, seeds are sown in a box of soil in August; the seedlings are potted, kept in a cold frame during the winter, and planted on a sheltered border in March. The frame must be ventilated freely in mild weather and covered with mats in severe frost. It may be necessary to protect the plants occasionally with bracken or straw should severe weather set in after they are planted out of doors.

Suitable varieties for sowing in August are Best of All, Early Snowball, First Crop, Magnum Bonum and All the Year Round. A sowing of these varieties in a warm greenhouse in January, the seedlings being planted out in March-April, will provide a succession of produce.

The chief sowing is made on a prepared seed bed out of doors in April or in boxes of soil in a frame or greenhouse in March. Before they become crowded the seedlings must be transplanted to a reserve border in rows 8 in. apart. In June they will be large enough to plant out finally at about 24 in. apart. Good main crop varieties to sow in March-April are Autumn Queen, Autumn Giant, Early Giant and Walcheren.

Cauliflowers need deeply dug, rich soil to ensure free development, and watering is necessary in dry weather in summer. Any check to growth is likely to lead to indifferent results. They are not a success in poor, shallow soil.

*Cauliflower. Three heads of the Walcheren variety with leaves cut as prepared for cooking.*

The cauliflower is subject to attack by club root, gall-weevil, and the

grub of the cabbage root-fly. In a blind plant no vestige of a heart appears, but in its

place there is a small cluster of pale leaflings. Such plants are useless. A check to growth, perhaps due to drought, is the principal cause.

**How to Cook.** To prepare a cauliflower for boiling, after trimming off the leaves and stump, notch the stalk deeply so that a piece can be removed from its centre. Lay the cauliflower in a deep basin with cold, salted water and a dash of vinegar. This soaking is necessary to extract any caterpillars.

After the soaking, to prevent scum settling on the flower, place it head downwards in a saucepan of boiling salted water. Select a pan that is sufficiently small to keep it in position; if too large it usually turns over so that the flower is uppermost.

Care is needed not to over-boil this vegetable. Test the flower by finger pressure or with a skewer. Time for cooking depends on age and size. A small one may require only 15 min., a large one as much as 40 min. A fish slice is useful for raising and draining the cauliflower when cooked, then place it in a hot vegetable dish, straining over it plain melted butter sauce, or else serve it plain with a small lump of butter on top and a dust of seasoning.

**Cauliflower au Gratin.** Put a hot, boiled cauliflower on a hot au gratin dish or a pie dish. Squeeze the cauliflower gently together in a clean cloth with the hands, so as to press it into a neat shape. Melt 1 oz. butter in a saucepan, stir ½ oz. flour smoothly into it, add 1½ gills milk, and stir over the fire until the sauce boils and thickens. Add 1 oz. grated cheese, and pepper and salt to taste.

Pour this sauce all over the cauliflower, sprinkle 1 oz. more grated cheese over the top, and lastly a few browned crumbs, with a few bits of butter here and there. Put the dish in the oven until the cheese is nicely browned, then serve it at once. This sauce will be sufficient for a small cauliflower.

The dish is as practicable made with the remains of a cold boiled cauliflower as with a fresh one. If the dish is required in a hurry, it can be browned under the grid. An alternative is to break the sprigs of cauliflower and place a layer to each layer of cheese sauce. Twice the quantity of the sauce is required for this method which makes a richer dish.

**CAUSTIC.** Caustics are substances which burn. Fuming nitric acid, glacial acetic acid, arsenic, nitrate of silver, carbonic snow, the electro cautery, and Pacquelin's cautery, a hollow metal point heated red-hot by benzine blown into it, are the chief caustics and cauteries used in medicine. Warts may be removed by nitric acid or glacial acetic acid, applied on the end of a match, otherwise the use of these agents should be left to the doctor.

**CAUSTIC SODA.** Being much stronger than ordinary washing soda, caustic soda is often used for

cleaning sinks, pots and pans, and for other domestic purposes. . It is a coarse white powder or in the form of pencils or sticks which become moist after keeping, and has a strong burning effect on the skin. For domestic use the proportion is 1 oz. in a pint of water.

In cases of poisoning, large draughts of water should be given mixed with acids such as vinegar, citric acid, lemon-juice or tartaric acid; then give white of egg and olive oil.

**CAVIARE.** There are several kinds of caviare, which is a delicacy made from the salted roes of sturgeon and other fish of the same family. It should be eaten fresh, when it is a greenish-grey tint, succulent, and in shape like small pearls. Those who appreciate caviare eat it quite plain with crisp, dry toast and salt, cayenne, and perhaps a dash of lemon-juice. It is not suitable for hot savouries, and is best kept on ice till required. It should never be touched with metal, bone spoons or wooden skewers alone being permissible.

**Caviare Prawn Croûtons.** These are made by stamping out a dozen rounds of bread, each the size of a five-shilling piece and about  $\frac{1}{8}$  in. thick. Fry them a golden brown in 1 oz. of butter, and leave them until they are cold. Place a teaspoonful of caviare on each croûton, lay a shelled prawn on top, and use a few thin shreds of gherkin as a garnish. Arrange each croûton on a tiny plate, and serve one to each person.

**CAYENNE.** Cayenne is a red, pungent, intensely hot powder, sold and used as cayenne pepper. It is prepared from the fruit of several varieties of the capsicum. *See Capsicum; Chilli; Chutney.*

**CEANOTHUS.** The mountain sweet or Californian lilac is a group of leaf-losing and evergreen shrubs of great decorative value. Most of them need the shelter of a wall; a few are hardy enough to be planted in the open garden except in cold districts. The flowers of most of them are of some shade of blue. The chief favourites for the open garden are hybrids between *Ceanothus americanus* and *Ceanothus azureus*: there they grow from 2-4 feet high and flower in July-August. The best of them are Gloire de Versailles, blue, Ceres, rose, Indigo, dark blue, and Rose Perle, rose. They should be pruned in spring by shortening the shoots or branches of the previous year's growth.

*Ceanothus. Flower clusters of the garden shrub.*

*Ceanothus veitchianus* is a beautiful blue-flowered shrub, in full beauty in May, for planting against a sunny wall, where it will grow 10 feet or more high. Others suitable for a sunny wall are *divaricatus*, *papillosus*, and *thyrsiflorus*, all having blue flowers in April-May. When the flowers are over these wall shrubs ought to be pruned by shortening the side

shoots of the previous year's growth to within a few buds of the base. They flourish in ordinary well-drained garden soil and are increased by cuttings set in a frame in July. Pron. Cē'-a-no'-thus.

**CEDAR: The Tree.** The cedar of Lebanon attains to a great age and size and forms a magnificent tree in time.

The Mount Atlas cedar forms a beautiful pyramid when planted with plenty of room to develop and with shelter while young. The foliage is less sombre than the cedar of Lebanon. The so-called blue cedar, *atlantica glauca*, is very handsome. The deodar cedar (*oedrus deodara*) is a most graceful tree for gardens. Cedars need plenty of room and thrive best in well drained loamy soil.

**CEDAR: The Wood.** Of the several varieties of cedar, the one grown in England is an ornamental tree the timber of which is seldom used, and is not of much value. The pencil cedar of N. America is the wood used for lead pencils. It is light reddish brown in colour, with a fragrant smell, and has close, straight grain, easy to work and easily split. W. Indian cedar is darker in colour, and has some resemblance to mahogany. The Himalayan cedar is a valuable timber tree in India.

Cigar boxes are made of cedar. It was formerly used a great deal for wardrobes, boxes and drawers, because moths and other insects dislike its smell and taste. It is used for some parts of pleasure boats; for, though soft and brittle, it is more durable than some woods when exposed to alternate wetness and dryness. The trunk of the cedar tree, owing to its low branches, decreases in diameter too rapidly to allow long planks to be cut from it. *See Wood.*

## CEILINGS AND HOW TO REPAIR THEM

### How the Amateur Worker can Make an Effective Job

Related articles include Cornice; Distemper; Moulding; Plastering. *See also Adam Style; Drawing Room, etc.*

In England the plaster ceiling, as we know it, was developed in Elizabethan times. The patterns of these ceilings are often rich in design, the monotony of the surface being broken by the ornament of slight or heavy projections, often elaborated with pendants. Towards the end of the 17th century the character of the ceiling began to alter. The constructional beams were no longer hidden, but were used in combination with crossbeams and curvilinear ribs of equal heaviness to break up the surface into a series of recessed divisions or bays. Ornament was concentrated on and near these beams and ribs, and its character became bolder and more massive. This style was succeeded by a reversion to the flatter surface decorated in low relief.

Ceilings are a feature in houses built by the Adam brothers, and some of these have been taken down and removed. The brothers seized upon the flat style then

in vogue, and perfected it by substituting an intelligible classic design for the somewhat confused essays of their contemporaries. In these, panels are suggested only, with slight lines and rings of leaves and arabesque. The moulds of the ornamental devices of Robert Adam are preserved and used for many modern ceilings.

Apart from such ornament modern decorators use colour in ceilings; sometimes to tone with the walls when these are in pale colours, or with the frieze only when the walls are panelled; sometimes in contrast, as for example when a ceiling is stippled in golden yellows to enhance walls of plain colour with mouldings enriched with gold metallic paint.

The inner covering or roof of a room is generally finished in plaster work, or may be constructed of boards, 3-ply panelling, or building boards such as beaver board and the like. Plaster ceilings are built up on a groundwork of laths, the boards being nailed directly to the ceiling joists or rafters; but it is frequently better to employ special battens so as to utilise the boards to the best advantage. A good ceiling should be artistic in appearance, homogeneous and dustproof, preferably finished white or in some light colour.

*Ceiling. Fig. 1. Diagram showing construction of a lath-and-plaster ceiling. A. Rendering coat. B. Floating coat. C. Setting coat. D. Cornice. E. Bracket. F. Ground. G. Ornamental work cast in pieces and fixed to F.*

**Lath-and-Plaster Ceilings.** A lath-and-plaster ceiling is formed by nailing laths to the underside of the joists, as in Fig. 1, with a space of approximately  $\frac{3}{8}$  in. between one lath and the next to form a key for the plaster, which should be pushed up through the spaces and grip the edges of the laths. It is important to have straight-grained, well-seasoned laths in order to avoid breakage or rotting after fixing. Rent laths, shaped by cleavage of the wood, are better than sawn, since they contain more continuous fibres, and are, therefore, stronger. Usually, however, sawn laths are employed, and those known as "lath and a half" in thickness should be obtained.

In commencing the work, some 10 or 12 laths, 4 ft. long, are nailed in position, then a similar number of 3 ft. laths, and so on. This is to prevent all the joints at the lath ends coming upon the same joist, as they would be more liable to tear away from their nails, and allow the ceiling to crack in a straight line from side to side of the room. In a new house the partitions running in the same direction as the joists are left incomplete

wherever possible until the lathing has been carried from end to end of the building. By this means a great deal of lath cutting is avoided. Partitions running at right angles to the joists are built to the required height in the first instance, and are generally used as structural supports to the joist ends. The laths run parallel to these latter partitions, and do not have to be cut for them.

### The Three Coats of Plaster

The plastering is applied to the ceiling in three coats, all composed of lime and sand, but mixed in different proportions. The lime is pure chalk lime, and is prepared by slaking lumps of quicklime in tubs containing excess of water, and then straining the liquid.

The first coat (Fig. 1, A), known as the scratch, pricking-up, or rendering coat, is made of coarse stuff composed of one part of lime with three parts of sand by measure, with 9 lb. of long, clean ox-hair to every cubic yard. In good work the floating, or second coat (B), is applied after the pricking-up coat is thoroughly dry, to avoid breaking the key of the mortar, i.e. the connexion between the mortar below the laths and that pricked up into the spaces between them. Floating and pricking-up are sometimes performed in one coat, but the attention devoted to obtaining a level surface (floating) detracts from the effort necessary in forming a good key by vigorous trowel work.

The third finishing, skim, or setting coat (Fig. 1, C), is of fine stuff composed of lime putty (q.v.) and washed sand in equal proportions, and is applied after the under coats have dried and settled into position. A setting coat of gauged stuff is sometimes used containing plaster of Paris mixed with the lime putty to hasten its setting properties. The proportions of lime-putty and plaster vary considerably at the discretion of the plasterer, but one part of plaster might be added to three of putty. No extra sand is added for the plaster of Paris, and in some cases the gauged stuff is left free of sand altogether, since plaster of Paris and other hard-setting gypsum plasters are not able to work with such large quantities of sand as lime mortar.

The employment of sheets, of asbestos compounds, compressed wood pulp or three-ply boards, beaver board, and the like, permits of ceilings being formed without the delay involved in waiting for plaster to set and dry out. The sheets are cut to the required sizes, and nailed at their edges to small wooden battens fixed in position at suitable distances on the underside of the floor joists. The exposed surface of the ceiling sheets is usually whitened or distempered, and the joints covered with slats of wood, arranged to form panelled patterns of ribs across the surface.

Ceilings in country houses are frequently made with the plaster in narrow strips between the floor joists in order to present an old fashioned appearance by contrasting the colour of the wood with that of the plaster. Small rough strips of wood are nailed to the sides of the joists to receive the ends of the laths, and after the plastering is complete small moulded strips

are sometimes fixed to the joists to cover the joint between the wood and the plaster.

Where plastering has to be applied to a broad wooden surface, special precautions have to be taken to ensure a key. In cheap work the beam is roughened with a great number of small gashes made with the corner of a broad chisel, an adze, or a hatchet, in such a manner that the chip is not detached, but is forced to stand out from the surface. As an alternative, broad-headed or clout nails are partly driven into the beam. If laths are used they must not be fixed direct to the face of the beam, but to rough battens nailed upon it in such a manner as will keep the back of the lathing from  $\frac{1}{4}$  to  $\frac{1}{2}$  in. from the beam to allow room for the key of plaster which oozes round the lath.

Lathing should never be fixed direct to the underside of a boarded floor, but always to the joists, otherwise the spring of the flooring boards will crack the plaster. The laths must be supported at every 15 in. of their length, or the plaster will be apt to crack.

**Repairing a Ceiling.** Among the tools which will be found of use in making or repairing a ceiling is the hawk, a wooden board about 12 in. square with a short handle projecting beneath it, used for holding a supply of material preparatory to depositing it on the ceiling with a trowel. The setting coat is applied with a wooden hand float, which works better if it is kept thoroughly clean and wet, free from lumps of dried plaster. The angle float is used for working in the corners between the wall and ceiling. A lath hammer is useful if much of this work is to be done, as by its aid the laths can be trimmed to length. The amateur will probably feel disposed to tackle the repair of an existing ceiling before launching out on new work. Fig. 2 shows a typical hole in a ceiling. Certain precautions are desirable, including the following. First break away all loose plaster around the damaged part. Then examine the lathing, and if any of it is broken, cut the laths out by chopping them off with a chisel, half-way across a joist, to provide a fixing for the laths which are to take their place. These can then be cut and fitted (Fig. 3). Next prepare the coarse stuff, and thoroughly brush away any dust and loose pieces of plaster, especially around the walls of the hole. Thoroughly damp the laths and the surrounding plaster work and then apply the coarse stuff with a trowel. The plaster has to be thrown at the laths rather than merely put up against them, the object being to force some of the coarse stuff through the spaces between the laths so that it can grip securely (Fig. 4).

The finishing coats (Fig. 5) are then applied. When applying the first force it up hard against the existing work and keep it damp for some hours by brushing it with water. When a moulded ceiling has broken away from the laths it can often be made good by strutting it up with uprights of wood, bearing upon boards placed on the ceiling, the whole driven up tight with wedges under the feet of the struts. Screws with large washers about 1 in. in diameter can then be driven into the joists about 10 in. apart. These will draw into the plaster work, and can be covered with plaster of Paris.

*Ceiling. Figs. 2-5. Stages in mending a broken ceiling, the laths being repaired and covered with two coats of plaster, one rough and one fine.*

A better plan is to get up into the roof, brush off all loose and dirty material from the back of the ceiling and pour over it sufficient water to saturate the back of the ceiling. Then immediately apply a grouting of liquid plaster of Paris, pouring it all over the damaged parts. It will set very quickly and make a sound key to hold the ceiling in place. This method depends for success upon the complete removal of all dust and loose stuff from the ceiling. The strutting must not be moved until this plaster has thoroughly set, and is dry and hard.

Cracked ceilings are best repaired by scraping out the cracks with a chisel or scraper to enlarge the hole sufficiently to take the plaster or lime-putty which is used to make good. The edges of the cracks must be saturated with water to ensure a sound joint. Spots and dirty marks on ceilings can be removed with a weak solution of starch and water, painted on, allowed to dry, and afterwards rubbed briskly with a coarse flannel.

The embellishment of an existing or a new ceiling can be carried out with fibrous plaster ornaments obtainable ready-made, and only requiring to be secured in place with strong plaster. Cornices and mouldings are generally worked in plaster.

**CELERICAC.** Turnip-rooted celery, as it is sometimes called, finds less favour in Great Britain than in the other countries of Europe. The edible part is the enlarged base of the stem which is well shown in the illustration. The plants are raised from seeds sown in a heated glasshouse in February-March: the seedlings are treated as advised for celery and are planted 18 inches apart in June in rich soil. In August the roots are covered lightly with soil, and in early autumn they are lifted and stored in soil or sand until required.

To cook celeriac, wash and trim a root, put into boiling water and boil till tender, skin it, cut it into

slices and serve with white sauce.

*Celeriac. stalks and roots of the turnip-rooted celery.*

## CELERY: FROM GARDEN TO KITCHEN

### The Culture and Cooking of a Favourite Vegetable

This article contains also recipes for special celery dishes and information on celery pests. See further Fertiliser; Trenching

Celery stands almost alone among vegetables in being equally palatable either when cooked or in its natural condition. There are two types in common cultivation, the red and the white. Opinions differ, but the white has perhaps the advantage in being earlier, the red in vigour and flavour, so that it is customary to grow both. Good white varieties are Giant White, White Gem, and White Queen. Al, Superb Pink and Standard Bearer are some of the best red varieties. Early celery may be planted between rows of peas; late celery may follow early peas and broad beans. Those who want celery in August or September should sow in gentle bottom heat in February or put the pans or boxes on a shelf in a mildly heated house. A fine surface compost is desirable. A covering of half an inch will be ample. The seedlings must be transplanted at 3 inches apart in boxes filled with a mixture of loam and leaf-mould. When nicely rooted they are hardened off in a frame and planted out of doors in May.

Seeds to provide the main winter crop are sown in boxes of light soil in a slightly heated greenhouse or frame in March. When the seedlings are large enough they are planted in a bed of rich soil at 4 inches apart in a frame and from these are transferred to the open garden in June.

**Trenching.** Trenches are not essential, but they provide a convenient means both of feeding and blanching the plant. To prepare a trench, remove the top soil, break up the under soil, and liberally interlard it with decayed manure.

A trench for one row of celery may be not less than  $\frac{1}{2}$  a yard wide, and for two rows 2 ft. wide, the plants in this case being set in opposite vacancies. If the plants are grown in single rows in a series of trenches, the latter should be 4 ft. apart, and run north and south.

The depth of the trenches when finished should be 9 or 10 in., allowance being made for returning just enough of the top soil to cover the roots.

The Cuthill method of trenching, which has produced the finest celery in the world, consists in digging a trench two spades deep and 5 to 6 ft. wide, banking up the mould on either side. Fill in with a foot in depth of strong manure, such as decomposed cow dung, and cover it over with three or four inches of mould for planting in; or, if the ground is very rich, half the quantity of manure.

Fine celery, especially for early supplies, can be obtained without trenching, being merely planted in a slight hollow in rich, well-tilled soil. The blanching is mainly done with brown paper, or with special blanching bands, but a little earth is generally drawn up to the base. The trench system is better for winter celery.

*Celery. Diagrams illustrating method of culture. 1. Trench properly prepared; a. sloping sides; b. good soil; c. manure; d. cast out soil, with catch crops growing at e. 2. Good method of tying. 3. First earthing-up. 4. Final earthing-up.*

If there is plenty of ground available, the trenches may be made a month or so before planting, and as soon as the ridges have been formed at the sides of the trenches lettuces may be planted on them. As the celery grows, any sucker shoots that spring up should be picked put. The plants will grow the faster if water and liquid manure can be supplied.

When the plant is half-grown, 1 oz. of nitrate of soda in a gallon of water,  $\frac{1}{2}$  oz. phosphate of potash in a gallon of water, and  $\frac{1}{2}$  oz. each of superphosphate and nitrate of soda (or sulphate of ammonia) in a gallon of water, used alternately, will work wonders. Another good change is 2 oz. Peruvian guano per yard of trench, dusted on the soil in showery weather.

When the plants are a foot high, a loop of raffia may be slipped around them, and when they have grown another 6 in., a second added, fixing one near the bottom, and one, not very tightly, near the top; in this

case this should be done before the earthing, in order to keep the soil out of the centres. For earthing up, the soil should be just damp, not sodden or moist at the top and dry below, or running to seed may follow.

The earthing should be thorough, even though it is not completed in one operation. When several rows are grown in each trench, temporary divisions will have to be made with boards of the width of the trench while the earth is being packed among the plants. If there are slugs about, lime should be used freely. By the time earthing is completed—and that should be in advance of severe frost—the earth should be level with the topmost tip of leaf. Celery blanches in 6 or 7 weeks from time of being earthed.

*Head of Celery.*

**How to Cook.** Celery should be carefully washed, the outer stalks should be pulled off, and all the green tops, except the very young ones, cut away. When to be served raw, the head should be split lengthwise into four or more pieces, or every stalk separated, and served in a celery glass half full of cold water.

For cooking purposes, celery may be dried and stored. The sticks are cut in strips 1 in. long, left in a cool oven for a day or two until hard and crisp, then packed in airtight bottles, and when required for flavouring crushed to a powder with a rolling-pin. Celery seeds are also used for flavouring.

*Celery. Successful method of blanching celery grown on the ground level by wrapping the stalks in paper collars which exclude the sunlight.*

To stew celery, the sticks are simmered in slightly salted water for about 45 min. They are then drained and served with white or brown sauce. Cooked celery is also good when dipped in batter and fried. Cardoon (q.v.) may be cooked in the same way.

In order to make celery and macaroni stew, 1½ heads celery and 1 oz. macaroni should be boiled for 35 min. in separate pans each containing salted water. They are then drained and dropped piece by piece into 1 gill hot white sauce. A sprinkling of pepper and salt is added, and the whole allowed to simmer for 20 min. Prepared in this way, but cheese sauce substituted for white sauce, celery and macaroni, or celery alone, are also excellent au gratin. (See Cauliflower.)

Another good way of utilising celery is in a sauce for serving with boiled poultry. In this case wash and chop 2 small heads of celery, putting the pieces in a saucepan with sufficient cold water to cover them. Cook these

slowly for a little less than ¾ hour, stirring frequently; then add some white sauce made from 1 oz. butter, 1½ oz. flour, 1 pint milk, and a little pepper and salt, and stir until the mixture boils.

To make celery soup with a large head, 2 pints of white stock or water and ½ pint of milk are required. The white part only should be used. Two rashers lean bacon, two onions, 1½ tablespoonfuls flour, 1 oz. margarine, with salt and pepper, are also needed.

The bacon is cut into pieces 1 in. long, and the onion and celery sliced finely. The vegetables should then be fried in the margarine in a large saucepan. The bacon, stock, and seasoning are added, and the whole simmered for about 45 min. until the celery is tender. The contents of the pan should be rubbed through a fine sieve and the puree returned to the pan, the milk added, and the whole brought to the boil. The soup is then thickened by the addition of the flour, mixed to a paste with a little cold milk, and the whole cooked for about 5 min., stirring all the time.

**Celery Diseases.** The most troublesome disease to which celery is liable is leaf spot or blight; one cause of the prevalence of this is bad seed. It is wise to buy seed of the best strain which has been treated in the way advised by the Ministry of Agriculture as a means of preventing leaf spot. If any doubt exists the seeds should be steeped for three hours in a solution of formalin, one part in 600 parts of water. Holding a leaf up to the light and looking through it enables the grower to recognize this disease which gives rise to dark spots on the leaves and may eventually render the plants useless. Spraying with Bordeaux mixture immediately diseased leaves are noticed is advised. If only a small number of plants is grown all the diseased parts should be cut off and burnt.

*Celery Fly, the larva of which attacks the celery leaf; magnified.*

*Celery Leaf Spot or Blight: the chief celery disease. 1. Plant attacked by blight. 2.*

*Effect on leaf. 3. Infected fruits. (By permission of H.M. Stationery Office and the Ministry of Agriculture)*

The attacks of the celery fly usually begin in April and may last into December. The larvae live upon the juicy substance between the upper and lower skins of the leaf, which eventually shrivels up, with the result that the stalks and stems of the plant cannot grow and fill out properly. Parsnips suffer in the same way from these pests.

The best preventive measures are to spray the plants occasionally in late spring and early summer with paraffin emulsion for the purpose of keeping off the flies. Paraffin emulsion is made by dissolving a handful of soft soap in a little hot water, adding an eggcupful of paraffin and two gallons of water. Some good is done by cutting off those parts of the leaves attacked and burning them. It is most necessary that unused parts of diseased plants and those attacked by pests be not left lying about or thrown on the rubbish heap; they should be burnt.

### CELL: In Electricity.

This apparatus is used to generate a current of electricity by means of chemical decomposition. A simple cell is composed of two elements, a positive and a negative, immersed in a liquid known as the electrolyte. A single accumulator is also known as a cell. The so-called dry cell has the electrolyte in the form of a paste.

Cells are generally classed under two headings, viz., primary cells, which generate current, and storage cells or accumulators, *See* Accumulator; Battery; Daniell Cell.

**CELLAR.** The best situation for the cellar is on the north side of the house, and it should be partially or wholly underground if advantage is to be taken of the non-conducting properties of the earth in preserving the cellar from heat in summer. Houses built on soft soil may have cellars economically formed in the basement between the foundations of the walls. The maintenance of an equable and low temperature is important when a cellar is used for storing. *See* Coal Cellar; Wine Cellar.

**CELLARETTE.** Some sideboards have a drawer lined with zinc or other metal and divided into compartments, one for each bottle of wine, etc. Originally the cellarette was distinct from the sideboard, and was placed beneath it. Fine examples were made of rose wood and mahogany, some being oval or octagonal in shape. They were bound with brass bands and, in addition, had a receptacle for ice.

**'CELLO:** How to Play. The violoncello is the bass member of the violin family, and for orchestral purposes is usually supplemented by the double-bass, an octave lower. Its beautiful tone makes it a favourite instrument for amateur players, and a capable performer is always in request. In appearance it resembles the violin, but it is played from between the knees of the performer its lower end being supported on a stem sufficiently long to prevent the bow touching his body when either of the outer strings is played.

The four strings are tuned in perfect fifths, thus:

The strings are of gut, the two lowest being covered with silver or copper wire. They are played with a bow, which is drawn across them at right angles about an inch from the bridge. In piano playing it should be rather nearer the finger-board, but in the opposite direction in forte playing. For crescendo increase the speed and pressure of the stroke, the process being reversed for diminuendo. Besides the F and G clefs, the C clef, on the fourth line, is used as for the bassoon.

A start should be made by trying to produce a good, steady tone from the open strings. To this end it is necessary to pay chief attention to the use of the bow, which should be firmly grasped by the fingers, yet so as not to interfere with the freedom of the wrist. When a satisfactory tone has been acquired, the study of stopped notes follows, by practising different intervals, 2nds, 3rds, etc.

Owing to the length of the strings and the consequently wider distances to be reached by the fingers, the principle of the fingering differs from that on the violin. Broadly stated, it consists in the use of the next finger for a semitone and of the next finger but one for a whole tone, though this procedure is not invariable, especially in the higher positions, as will be seen by the exercises given in tutors for the instrument.

In order to reach the higher notes, the left hand is gradually shifted nearer the ribs of the 'cello. When the index finger is used to produce a second above the open note, the hand is in the first position; the second position is when it reaches a third above the open note, and so on. Thus on the A string the index finger will play B in the first position, and C, D, E, F, etc., in successively higher positions.

Sometimes a false nut is made by placing the thumb across two adjacent strings, and then fingering according to the method on the violin. This is useful for high notes; but players prefer the ordinary stopping, as the tone is stronger and more equal.

After use the 'cello should be wiped with a dry duster to remove any particles of resin from the belly, and it should be kept in its case, so as to preserve it from the dust, which otherwise will certainly find its way through the f holes, to the detriment of the instrument.

**CELLULITIS.** The term is used to describe a rapidly dangerous variety of inflammation of the soft tissues underlying the skin or lying between the muscles. The cause is always some pus-forming germ which either enters the tissue through a wound or is brought there in the blood stream, e.g. the microbe of erysipelas. It is more liable to affect debilitated persons, e.g. those suffering from diabetes or chronic kidney disease.

The first symptom is a rapid swelling of the whole part, with redness, tenderness, pain, and some fever. On pressing the finger against the skin a small pit or depression is formed which may remain for some moments after the pressure is removed. In the next stage the whole of the skin over the part involved becomes dark red, tense, and firm from the swelling of the tissues underneath.

The inflammation in cellulitis rapidly spreads, so that when beginning above the wrist, for example, within a day or two the whole arm may be hard, brawny, and greatly increased in size. Unless vigorous treatment is instituted the tissues under the skin become gangrenous, and the skin itself becomes purple or blackish, and then gives way. By this time the patient is usually in a very low state, with high fever, rapid, irregular pulse, and all the signs of severe constitutional disturbance. He should be under medical care at once.

**CELLULOID.** Largely used as an imitative substitute for ivory, celluloid is manufactured in rods and sheets, the latter more or less transparent. The material is elastic, readily machined and worked, takes a high polish and is capable of exhibiting very beautiful colourings; it frequently takes the place of tortoiseshell and other valuable materials. Celluloid is highly inflammable. The Celluloid and Cinematograph Act, 1922, deals with the storage of celluloid.

Celluloid can be turned in a lathe. Sheet celluloid can be moulded to any desired form by softening it in boiling water; it can be sawn with a fine tooth saw, or carved with chisels and gouges and generally treated by much the same methods as soft wood. For amateur purposes the solid rod and tubular celluloids in colours and the transparent sheet are most useful. The latter are sold in various thicknesses from a few thousandths of an inch upwards and about 50 in. by 20 in. in size. Ready prepared celluloid cement is obtainable from most electrical supply stores, and by its aid perfect joints can be made provided the two celluloid surfaces are perfectly clean.

Cellulose. Paints and Lacquers. *See* Enamel; Paints.

### CEMENT: ITS VARIETIES AND USES

Methods of Use Clearly Explained for the Amateur

This article may be read in association with those on  
Brick; Bungalow; Cottage; House, etc.

*See also* Concrete; Lime; Mortar

Materials known in the building trades as cement include numerous varieties of lime and Portland cement. The former requires different treatment, and is dealt with separately, the following notes referring to Portland cement, which in appearance is a greyish-green material in the form of a fine powder. It should be perfectly even in grain and free from lumps, the presence of the latter indicating that the cement has got damp and has deteriorated.

Cement sets or goes hard by the action of water, a process known as hydration. It becomes harder and

more durable in combination with certain other materials. Mixed with an equal or greater bulk of sand, the material is more practically useful, and is known as mortar. When the aggregate is in comparatively large pieces, such as broken brick or gravel, the resulting mixture is known as concrete.

It is vitally important for good work that the cement be uniformly distributed through the sand or aggregate, and that the water be uniformly applied and dispersed. While cement imperfectly mixed, is thus a source of danger, when properly handled it is one of the finest of building materials, and has great possibilities for the amateur constructor. It can be cast in moulds, or worked up with a trowel on existing brickwork or lathing; a whole house can be built with it, and all kinds of garden seats, rollers, sundial columns, ornamental figures, etc., either cast or moulded while the cement is workable.

Cement can be purchased in small quantities at an ironmonger's, but it is more economical to purchase a sack of cement from a builder's merchant. This weighs about 2 cwt. Buy only the best and strongest quality manufactured to comply with British Standard Specification No. 12.

The amateur may begin by taking a handful of cement and gradually damping it with a little water, stirring the powder about so that the water is evenly distributed throughout. At first the cement will be crumbly; a little more water added to it causes the mass to hang together, and to retain its shape if moulded with the hand. Continue the experiment by adding a little more water to the cement and keep mixing it until the material feels slimy or greasy. This state is known as a fat cement, and is the best state in which to work it with a trowel. Now leave the material for a few minutes, and it will be found to have set. It will not be dry; indeed, it takes several days or even longer for the water to dry out. The point to notice is that the cement has undergone a chemical change, and setting has reached its maximum strength. The whole purpose of wetting is to bring this about, and the cement is then left to dry out. If it is knocked about with a trowel before it has dried and more water added, the material will mix up and look very much as it did before setting, but its real strength will have gone.

**How to Mix Cement.** The best way to mix a small quantity of cement is as follows. Provide a strong solid board or table about 4 ft. square upon which to mix the materials. The grading or proportioning of the materials is known as gauging: the gauging is done by bulk, or measure, and not by weight. Suppose the cement is wanted in the form of mortar. Take one pailful of cement and empty it on one corner of the board. Then take a pailful of clean, well-sifted sand and spread it over the board with a trowel. Sprinkle about  $\frac{1}{3}$  of the cement over the sand, put another pailful of sand on the cement, and sprinkle another  $\frac{1}{3}$  of the cement over it. Finally, add the remaining sand, and

the rest of the cement. Turn it all over with a shovel, and rake it over until the grey colour of the cement is seen to be evenly mixed with the sand.

The complete mixing must be done dry, and a good result is obtained by using two mixing boards, shovelling from one into a sieve on the other, and sifting the mixture. When properly mixed, sprinkle with water from a watering can with a rosehead, and keep stirring until the whole mass is well mixed and in a workable condition. For casting in moulds use it moist; for bricklaying and rendering, or any trowel or moulding work, use it fat.

**Cementing Large Areas.** The application of cement to bricklaying is dealt with in the article Brick (q.v.). The repair of cracks in floors and walls, as well as the coating or facing of a wall with cement, known as rendering, is done generally as follows, using the mortar as described: For cement facings on brickwork, chip out all loose material, rake out the old mortar from the joints between the bricks with a chisel to a depth of  $\frac{1}{4}$  inch, thoroughly wet the wall, and then smack on the cement by a sort of throwing action, so that it is forced hard on to the brickwork; and smooth it over with the trowel, and keep the cement damp for some hours by spraying it with a little water to avoid cracks due to a too rapid drying. Floors are dealt with after the same method.

A new floor laid in cement is generally composed of several inches of concrete and faced with a 1 in. thickness of granolithic cement, made by mixing cement, sand, and fine granite chippings in equal proportions. When dealing with large areas it is a convenience to break them up into sections by laying battens of wood on the concrete about 3 ft. apart and filling in between them with the cement facing, removing the battens and filling in the gaps as the work proceeds. Considerable skill is required to trowel up and float off a flat floor. A long, straight lath resting on the tops of two adjacent section battens, and worked about in different directions, will greatly aid this work by producing a level surface, only needing floating off.

Cement can be applied in the form of a wash to the surface of brickwork, old cement or plaster work. It consists of a mixture of equal parts of cement and sand, and is applied in a liquid form with an old whitewash brush.

*Cement rendering on brickwork, showing how the hand float is used for applying evenly.*

Casting

**and Moulding.** The casting of cement is carried out in shaped wooden moulds; alternatively, those made of plaster of Paris can be used. The cement is rammed into the mould by hand in a damp condition, and the mould can be taken to pieces and removed from the casting as soon as the cement has set sufficiently. It should then be soaked with water and left to set hard and dry off. Very good results are obtained by using cement and sand in equal proportions. Moulding in cement is carried out more or less on the lines of clay modelling by shaping the material with sweeps or boards cut to a template, or by means of trowels of different shapes, and wooden or other modelling tools.

Keene's cement, made from alum and gypsum, is used in plastering (q.v.). It sets very hard and is useful for repairing damaged surfaces.

**CEMENT: For Mending.** For uniting the broken edges of china objects a cement such as the following is required: Soak 1 oz. of isinglass in 2 oz. of water overnight; then place the mass in an earthenware jampot; put this in a saucepan containing a small amount of water, and heat until the isinglass has dissolved. Next add 1 oz. of strong acetic acid, stir well, and pour the cement into small bottles.

For use, the bottle containing the cement is placed in hot water until the cement liquefies. The edges of the broken china object, having been warmed, are smeared with the cement, then brought together and kept in position until the cement has set.

For mending knife handles, mix together flowers of sulphur 1 oz., powdered resin 2 oz., kaolin 1 oz., and fill the hollow handle. Next heat the tang of the knife nearly to redness, and press it into the handle, holding it in position until it is cold.

For sticking leather patches on boots the following cement is used: Dissolve by continuous shaking gutta-percha raspings, 1 oz., in carbon bisulphide 5 oz. The surfaces of the leather patch and the boot are cleaned by means of fine sand-paper, the cement is spread upon the surfaces to be united and allowed to evaporate. Then the patch is placed in position and smoothed with a knife handle or rubbed with a warm iron. *See Canada Balsam; Crockery, etc.*

**CENTIGRADE.** This is one of the chief ways of measuring heat by a thermometer. On a centigrade thermometer freezing-point is marked 0 degrees and boiling-point 100. To convert centigrade degrees into Fahrenheit multiply by  $\frac{9}{5}$  and add 32. Thus 300 centigrade =  $\frac{9}{5} \times 300 + 32 = 572^\circ$  Fahrenheit. To convert Fahrenheit degrees into centigrade subtract 32 and multiply by  $\frac{5}{9}$ . *See Fahrenheit; Thermometer.*

**CENTIPEDE.** Millipedes and centipedes are found in all parts of Great Britain. Millipedes are injurious in the garden, feeding on roots of all kinds, while centipedes are harmless to plants. Of the latter the variety mostly found in the garden is long and slender and is common in leaf-mould. *See Millipede.*

## CENTRAL HEATING FOR THE HOME

**A Typical System and How it Operates**  
See Anthracite; Gas; also Boiler; Range,  
and other entries dealing with the heating  
apparatus of the house

The heating of a building by radiators or pipes supplied with hot water or steam from a single boiler is known as central heating. Several systems are in use. For domestic purposes the one- or two-pipe drop systems for low pressure hot water are probably the most satisfactory.

With a central heating installation only one fire requires attention, while a good boiler does not need stoking more than two or three times a day, and will remain alight all night. The heat transmitted by the radiators is healthy, mild, and agreeable, and there are no noxious fumes. The temperature can be regulated at will, and any individual radiator can be put out of action when not needed, or brought at once into service by merely turning a tap. The following notes refer to small domestic installations suitable for the average dwelling-house of six to ten rooms.

There are two distinct methods of low pressure hot water heating. The object of the first is to warm the whole house and to maintain it at an equable temperature. The second is designed for local heating; that is to say, the bulk of the heat is applied to the warming of one or two principal rooms, the others being warmed as required. Combination systems, where one fire suffices for cooking, hot water supply, and heating, are now available, and the type of kitchen range illustrated in Fig. 1 (the Ideal "Cookanheat") will

serve several radiators in addition to providing domestic hot water and ample cooking facilities for the average dwelling-house.

*Central Heating. Fig. 1. Combined boiler and cooking range, which also supplies bath water. (Courtesy of Ideal Boilers & Radiators, Ltd.)*

A central heating boiler may be heated by coal, coke, wood, oil, or gas. Anthracite and coke are the most satisfactory solid fuels. Central heating by gas-fired boilers may be found satisfactory from a cost point of view when consideration is given to the absence of fuel storage and handling, no dirt and no attention, as the boilers today are absolutely automatic. For small private houses the initial cost of the oil-burning plant is generally considered prohibitive, and in any case auxiliary power, such as electricity, compressed air or steam, is necessary for atomising the oil. The general magazine boilers and automatic stokers are to be recommended.

A typical boiler is illustrated below left. It consists of a number of sections, each providing complete

waterways, connected at the top and bottom by nipples. The fire and ashpit are surrounded by a water-jacket. This boiler, usually supplied with an enclosing jacket and finished in vitreous enamel, functions as a radiator and will warm the kitchen or living room where it is situated.

*Left, Fig. 2, independent "Neo-Classic" boiler for supplying a number of radiators. Right, Fig. 3, efficient type of radiator for central heating.*

(Courtesy of Ideal Boilers & Radiators, Ltd.,)

Dampers are provided to regulate the fire by controlling the entrance of air, the opening of the ashpit draught door increasing the heat of the fire, and vice versa.

The size of the boiler must be sufficient to maintain all the radiators constantly at full heat. When reckoning the size of an installation, allowance must be made for the geographical position of the house. A dwelling on a hill-top, exposed to the full force of a winter gale, obviously requires more heating than a building of identical size in a sheltered position. The area and position of the glass windows also play an important part, the loss by radiation through the glass windows being very considerable. Taking a fair average, the following sizes of radiators are required to maintain a temperature of about 65°. The figures represent sq. ft. of radiator surface:

	sq. ft.
Small bedrooms	12
Larger bedrooms	25
Passage way	10
Entrance hall	25
Dining room	50
Drawing room	50

The total may be put roughly at 200 sq. ft. of radiator surface. To this must be added an amount to cover the losses in the connecting pipes, which can be greatly reduced by lagging the pipes wherever possible with asbestos or other non-conductor of heat. In an efficient system the heat employed exactly makes up the heat lost by the rooms. The above hypothetical installation would require a boiler containing about 10½ sq. ft. of heating surface, and measuring about 36 in. high, 14 in. wide, and 28 in. deep.

Having decided upon the boiler, the radiators can be selected according to their capacity. The latest type of radiator has small fluted columns, as shown in Fig. 3. The smallest size may be a two-column 2½ in. wide or thereabouts, composed of 12 sections 24 in. high. The four-column pattern for larger bedrooms would measure about 30 in. high, and be composed of ten sections. For the largest rooms a six-column type can be chosen, having, say, eleven sections 36 in. high or 13

or 14 sections 30 in. high, according to the space available. A long, low radiator is sometimes more convenient than one of fewer sections but greater height.

Such radiators as those illustrated in Fig. 3 are made of cast iron, with the internal waterways formed when cast. The sections are connected by taper threaded internal nipples. Inlet and outlet connexions as well as a tapping for the air release valve are provided.

The pipe system has next to be planned. Desirable features are compact planning, minimum lengths of piping and gradual easy falls to all pipes. In the drop system (Fig. 4), the heated water ascends by the flow pipe to a cross-piece HP at the highest point of the system; branches are taken as at A B to the return pipes C D. The radiators are connected by short branches, as at H and J with a valve on the top inlet of the radiator. On the ground floor, when radiators are required on this level, they are connected by the down pipe F, then through pipe G. It will be seen that any of the radiators can be shut off by closing the valve, but without impeding the flow in the pipe. The pipe should be galvanised wrought iron, steam quality, or else of copper tube.

Central Heating. Fig. 4. Diagram showing low pressure hot water drop system. See text for lettering.

A smaller bore expansion pipe is connected to a small cast iron or galvanised expansion tank M, another pipe being taken from the top of the tank as an overflow on to the roof. A safety valve should, however, be fitted to the boiler and maintained in perfect working order.

Connexions are made where necessary by means of the standard elbows, tees, and bends, screwed on tightly and the joints made water-tight with red lead or other jointing material. Various types of valves are available for controlling the supply of hot water to the radiators. The air release valves are simple plug-cocks and are

screwed into the radiators.

The position of the boiler will be governed by convenience. Owing to the water-jacket, the risk of fire is very small; and in the majority of installations the boiler is placed on a tiled hearth. The need of carrying the smoke pipe either through the wall to the outside air or into a conveniently situated flue must not be lost sight of. Otherwise the boiler is best placed in the most convenient position in the house, whence the flow pipes can rise with as few bends as possible, consistent with an allowance for the expansion of the pipes when heated.

**CENTRE.** Centres are used on lathes and other tools to assist in supporting the work, and to locate it truly on the centre line of the shaft. The centre itself is in various forms; the point centre is pointed in shape, the cup or hollow centre is inverted, and the vee-centre has a V-shaped slot cut across at right-angles. Many small bench drilling machines are provided with such centres.

**Centre to Centre.** This expression is frequently found in descriptions of "how to make" articles. It means that measurements are taken from the centre line of one part to the centre line of the other part. It is the most accurate way of marking out a job. For example, floor joists may be specified as being 15 in. centres, meaning that their centre lines are 15 in. apart. Such joists are frequently 2 in. thick, but as they are only rough sawn, it would not be satisfactory to measure the gap between two joists, as this would vary slightly one from another, and the ultimate result would be unsatisfactory.

The word is also used in connexion with the making of chocolates. See Chocolate.

*Centre. Implements used in lathe work; top, point centre; middle, vee centre; bottom cup centre.*

**CENTRE PUNCH.** A centre punch is one having a sharp-pointed end, made of tool-steel either hexagonal or circular in section. It is used for marking the centre of a hole, for dotting a line on metal prior to cutting it, and sundry other similar jobs. It is used by holding it erect upon the work, with the point exactly on the centre. A sharp blow is then struck with a hammer on the head of the punch; this makes an indentation in the metal and thus marks the centre. The point should be kept sharp by grinding.

*Centre Punch. How the tool is held and applied; above, types of centre punches.*

An automatic centre punch has a spring-actuated self-contained hammer which strikes the blow when the punch is pressed hard on the work. They are very convenient in use. Bell centre punches are handy for marking the centre on the end of a metal bar. A centre punch or several of different sizes are essentials to almost everyone desirous of working in metal.

**CERAMICS.** Under this general name are included the plastic arts of the potter and the worker in clay fabrics. Thus the name includes chinaware (porcelain), faience, pottery (earthen and stone wares) and terracotta. Ornamental bricks and tiles are also branches of ceramic art. Owing to the fact that great potters experimented with many clay fabrics in making their wares, china marks are sometimes used on both earthenware and chinaware. *See* China; Faience; Pottery.

**CEREAL.** Foods made from cereals, i.e. from grains such as wheat, barley, oats, etc., provide the starchy substances which are necessary for life and health. Besides supplying starch, wheat flour and oatmeal furnish a fair amount of proteid or flesh-forming food, and oatmeal also contributes a substantial amount of fat as compared with the meagre quantity contained in other cereals. Mineral salts are also represented in cereal foods, chiefly in the form of phosphates of potassium and magnesium; but the amount of these in fine flour is small as compared with that in wholemeal flour.

Rice contains little else than starch, and what little of the other food constituents it does contain are generally removed by boiling it. The proper way to cook it is by thorough steaming. Oswego, corn flour and hominy are obtained from maize by acting on it with caustic potash. *See* Barley; Bread; Diet; Flour; Oatmeal; Rice, etc.

**Cerebro-spinal Meningitis.** This is the medical term for the disease better known as spotted fever (q.v.).

**CEREUS.** Several species of cereus bloom at night, hence its alternative name of torch thistle.

Among the best sorts is the rat-tail cactus (flagelliformis), so called owing to its slender wiry growth; it bears pink flowers in spring, and is a desirable plant for a hanging basket or for growing in a window. Fulgidus, with its scarlet flowers in early summer, is good for a small house. Grandiflorus bears large white flowers, often nearly a foot across, and is fragrant on summer nights.

These plants require a very porous soil, and it is usual to add shattered bricks to the loam when preparing a compost for them. The pots may be filled nearly one-third with crocks for drainage. In summer they should have a light, sunny position in the greenhouse or window; in winter they must be kept under glass safe from frost and given very little water. They are propagated by inserting portions of the

matured leaves or stems in sandy soil in summer. *See* Cactus.

**CERTIFICATE.** Certain documents that are issued by public and other bodies, usually containing evidence about a person's status or proficiency, are known as certificates. Copies of certificates of births and marriages are required for various purposes, e.g. insurance. These are usually obtained where the birth is registered or the marriage celebrated; but if not they can be obtained from the Registrar General, Somerset House, London, W.C., or the Registrar General in Edinburgh.

As regards marriage certificates, copies can be obtained from the incumbent of the church in which the marriage was celebrated. Death certificates, signed by a medical man, are also issued and are necessary for burials and cremations, as they are for the proving of wills. Copies can be obtained for a small charge.

Certificates are given by various bodies, both those that examine in education generally, such as the joint board of Oxford and Cambridge, and bodies that specialise in one subject only, e.g. music. Certificates from medical men testifying to sound health are also required from applicants for various public and other positions. *See* Birth; Death; Marriage.

**CESSPOOL.** This is a receptacle for the sediment from a drain. Cesspools are of two kinds; those adapted for all kinds of drainage, and others intended for sink and bath wastes only. Many old houses in the country have nothing more than an open pond to deal with this class of sewage, but its presence is a menace to health and should be destroyed.

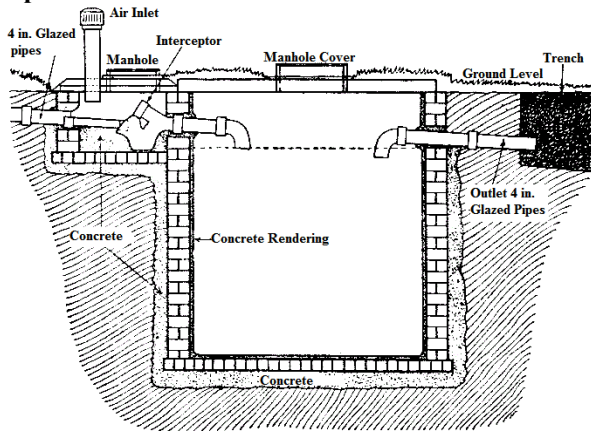

The drainage of the pond is generally accomplished by cutting trenches to conduct the water on to the land, previously filling in the trench with coke or gravel and covering with turf, if the land is pasture. The bottom of the pond should then be covered with unslaked lime, and a few days afterwards the sediment and soft material should be dug out, carted away and deposited in shallow heaps on the land as remote from dwelling-houses as possible.

The drains to the pool must be removed or stopped up with concrete, unless they are to be used for the new cesspool, in which case they must be tested before use. If the pond is to be used as such, the bottom should be cemented over, or covered with a layer of clay 6 in. thick, then a layer of straw, and finally another 6 in. layer of clay, well rammed and consolidated.

Points to observe in making a cesspool are to place it as remote from the dwelling as possible, never less than 70 feet, or any greater distance as prescribed by the local authorities, and equally remote from springs, wells or brook. The drain to the cesspool should fall gradually towards it. The outlet from the cesspool should fall as rapidly as possible, and discharge into an automatic distributor, or into trenches filled in with coke or gravel, and covered with turf.

The cesspool itself is preferably excavated to a depth of 6 or 8 ft. or more, the bottom made up with 6 in. of

concrete, the walls built of brickwork, filled in at the back with concrete, and rendered with a 1 in. thickness of strong cement mortar, gauged 1 of cement to 2 of sand. The top can be bricked over, or covered in with old railway sleepers and turfed over, leaving an opening large enough to admit a ladder and giving room for the ingress and exit of a man for cleaning purposes.

*Cesspool. Sectional diagram showing the correct method of lining and connecting a cesspool for house drainage.*

This opening should be covered with a cast iron manhole. To prevent any smell working back into the house, an interceptor trap and ventilating pipe must be built into a manhole formed between the drain and the cesspool. The outlet pipe from the cesspool should be 2 in. below the level of the inlet pipe, which should terminate in a downward direction by fixing a bend a little before the end. *See Brick; Cement; Drain; Sanitation.*

**CHABLIS.** A class of delicate, thin white wines, sometimes incorrectly described as white Burgundies, is known as Chablis.

This wine may be served with fish. A refreshing drink for hot weather is Chablis cup made from the following recipe: Dissolve 4 lumps of sugar in a  $\frac{1}{4}$  pint of boiling water. Put this into a bowl with a slice of lemon-rind, and after about  $\frac{1}{2}$  an hour add a bottle of Chablis, a wineglassful of sherry and  $\frac{1}{2}$  pint water. Mix well, and after straining add a bottle of soda or seltzer water, a sprig of verbena, and a few strawberries. Ice and serve in small glasses. *See Burgundy; Wine.*

**CHAFING.** Wherever there is pressure on the skin, or where two skin surfaces rub against one another, chafing may occur. Wash the part several times a day with warm, soft water and soap, dry carefully by dabbing the part with a soft towel, and dust the skin with powdered talc.

Where excessive perspiration is the cause of chafing, this scented powder will be found agreeable:

Oil of rose geranium	5 drops
Salicylic acid	1 dram
Powdered zinc oleate	$2\frac{1}{2}$ oz.
Powdered starch	4 "

*See Blister; Foot; Skin, etc.*

**CHAFING DISH:** How to Use. A dish in which light cookery can be done at table is useful at breakfast or for late suppers. Chafing dishes are usually made of silver or electro-plate and possess an outer vessel to contain water, an inner pan with handle and a cover, stand, and a heating stove. The last named is often a spirit lamp, but electric chafing dishes are obtainable with a disk stove with two heats.

#### *Chafing Dish.*

*Modern example of a spirit lamp chafing dish.*

*(Courtesy of Harrods, Ltd.)*

For frying and quick cooking, the inner pan of a chafing dish should be placed directly over the lamp; but when gentle heat is required, as, for instance, in the preparation of such dishes as scrambled eggs and stewed oysters, the hot-water pan should be placed beneath the cooking-pan. It is important that all utensils belonging to a chafing dish should be kept scrupulously clean, and the food served quite hot. When a spirit lamp is not in use, keep the cap on, otherwise the spirit will evaporate. A toaster is an invaluable adjunct to a chafing dish outfit. It is best to have all food to be cooked in the chafing dish prepared beforehand. Such food as sausages, fishcakes, rissoles, savoury haddock or kipper, can be ready cooked and reheated in a little butter or a suitably prepared sauce. *See Savoury; Supper.*

**CHAIN:** Its Home Uses. Chandelier chain is stamped from sheet brass by machinery and has many uses. Ladder chain is applicable to similar purposes, and can be used with small sprocket wheels for driving toy engines.

Jack chain is another machine-made form in brass, galvanised iron, or bright iron, and with single or double coils. It is useful for all kinds of light work.

**Bicycle Chain.** All the above chains are merely in the nature of a tether; but others are used to transmit power, like the bicycle chain, which consists of side plates or links, rollers and crossbars or rivets. There are several makes of such chains, of which the improved Renold is illustrated. This method of construction is applied to cycle and to motor cycle chains from  $\frac{3}{8}$  in. to  $\frac{3}{4}$  in. pitch.

*Chain. Component parts of improved Renold chain.*

To obtain maximum life and service from these, or any other roller chain, they must be lubricated freely. If the machine has an oil-bath chain case, make sure that a sufficient oil level is maintained to bring the bottom side of the chain into the oil; otherwise remove

the chain about every three months, thoroughly clean it by immersing in a tray of paraffin, wipe dry, and then immerse it in melted chain lubricant, working the chain about to get the lubricant into the bearings. An important matter with a chain is to run it at the correct tension. It should not be run dead tight, but when the top side of the chain is tight, it should be possible to move the bottom side up and down about  $\frac{3}{4}$  in. *See* Bicycle; Motor Cycle.

**Chain.** Measure of length. It is 22 yd. or 66 ft. in length and is divided into 100 links each of 7.92 in. Ten chains make a furlong.

**CHAIN STITCH.** In needlework there are three varieties of chain stitch—namely, machine stitch, embroidery, and crochet; all of these have the common purpose of linking together stitches that are comprised in the form of a chain. *See* Crochet; Embroidery; Sewing Machine.

#### CHAIRS: CHOOSING, MAKING AND MENDING

Advice for the Collector and the Craftsman

Related articles include Adam Style; Armchair; Chippendale; Dining Room; Drawing Room; Sheraton, etc. See also Baby Chair; Cabinet Making; Easy Chair

Most British households possess at least one chair, the Windsor, which expresses the development of this piece of furniture from stool to chair.

The two features which distinguish all Windsor chairs and are peculiar to them are the saddle-shaped seat and the fact that the back is structurally separate from the lower part. These two features are seen in no other chairs in the world. The Windsor is British and one of the very few pieces of furniture which is not a derivative from foreign sources. Old ones of undoubted authenticity can therefore be more easily obtained in England than anywhere else. Those made of yew are the best.

**Old Windsors.** A William and Mary Windsor has a crest rail with its upper profile bow-shaped. There is probably a crown in the middle. Some of the rails beneath the seat and the uprights of the back may be twisted or of barley sugar pattern. In a Queen Anne the centre splat of the back is probably fiddle-shaped and the legs cabriole. Later, this chair may show Prince of Wales's feathers. This type in varied forms appeared for quite 100 years. The arch back, which can be identified by its name, has horseshoe arms. The front stretcher beneath the seat is curved away towards the back legs.

Wheel back is a very common form, so called because the centre splat of the back contains a perforated shape resembling a wheel. It is probably derived from the well-known Hepplewhite feature. V-stretcher backs are so called because for extra strength two stretchers are put into the back of the chair in a V-shape, the point of which is formed by the stretchers

meeting in a specially made tailpiece of the seat. The other ends of the two stretchers are fixed into the crest of the back.

The chairs of the 17th century, genuine specimens of which are rare, but have been widely copied, are those belonging to the periods of James I, Charles I, the Commonwealth and the Restoration. In this category may also be placed those of William and Mary, but they are not so distinctively English as are the earlier ones.

**Chairs by the Great Makers.** Chippendale chairs are so called because they are in the styles followed by Thomas Chippendale, mostly adaptations from the French of the period of Louis XV.

The average collector may take it that Chippendale chairs were usually made of mahogany, with a wide seat in front narrowing towards the back; they stand on legs square or mainly square in section, have a bow-shaped crest-rail, and a perforated, decorative convex back. Many so-called Chippendale chairs have cabriole or club legs, with ball and claw feet; it is doubtful whether Chippendale himself made many chairs with such legs. The decoration was by means of carving. Inlay was rarely used. The mahogany was heavy and of close grain. Ribbon back, Gothic and Chinese Chippendale chairs are among the styles which are specially valued by collectors.

Hepplewhite chairs are also principally made of mahogany, and the wheat-ear is a favourite form of carved decoration. Many are painted, and the typical specimens have either a shield or heart-shaped open back and show the wave-line, a serpentine curve in furniture. The front line of his chair-seats is often bow-shaped, and the arms are held by curved supports. Sheraton chairs have thin, tapering legs, angular backs, and are rather small as a rule in the seat. They are often of satinwood and the decoration painted or inlaid. The crest rails are straight, or nearly straight, with slight breaks. Late in life Sheraton was influenced by the Empire period.

The chairs designed by Robert and James Adam are not within reach of the ordinary collector. They are both carved and painted and genuine examples usually fetch very high prices.

As chairs of any kind were not common in England before the reign of Charles II, it will be seen that numbers of so-called Jacobean chairs which are offered as antiques must of necessity be spurious.

The oak chairs of the time of James I have heavy framework, both legs and back being of timber square in section, and held together by rails simply mortised into the uprights. Panelled backs were common, and carved ornament had little or no modelling. Where chairs had arms they were simply scrolled, over supports which were continuations of the front legs, and were boldly turned.

The art of the carver developed at the period of Charles I. Numbers of cushions were used for the seats of chairs which were hard and without curvature. X-chairs (that is with supports in the form of an X) were

seen in great houses at this period, and the art of the upholsterer was encouraged. Chairs of the Cromwellian period had very little ornament.

The Restoration period has been more copied than any other of the 17th century. Typically, a Charles II chair will have a tall back with carved crest rail and twisted side supports, this twisted formation being also seen on the rails and legs. Cane panels were often used for the backs. In the time of William and Mary walnut was commonly used; and the twisted rails gave place to gracefully designed turning. A feature was the elaboration of the stretcher, one of the most important contributions to chair-making in this period.

Practically the whole Queen Anne period produced chairs in walnut wood. The stretcher work disappeared, the cabriole leg came in, and the knees were frequently carved with a shell. Backs were still high, and there was a concave centre splat resembling a fiddle in shape in the back. Many chairs of this period were upholstered. They were often inlaid as well as carved, and the ball and claw foot was first seen about the end of this reign.

**Making a Chair.** A change for the ordinary Windsor chair is that shown in Fig. 1. White deal could be used for a cheap variety.

The main dimensions are 18 in. from the floor to the seat, and 3 ft. 2 in. to the top of the back. In plan, the seat should be 1 ft. 2 in. at the back, increasing to 1 ft. 5 in. at the front and 1 ft. 3 in. from back to front. The rake of the back should be similar to that in Fig. 16 in the drawing room series, except that the lower portion is not curved, and does not diminish its thickness: the legs should finish 1½ in.

The front legs should also be 1½ in. square, and can be bevelled at the inner edge. All the joints are tenoned except those of the bottom rail, which are dovetailed

into the side rails. The seat rails should be of 1 in. material 2 in. wide, and the horizontal back rails the same thickness, 1½ in. wide. The panel and slats are ½ in. thick, the panel being 4 in. wide and the slats 1½ in. The seat should project slightly, and is screwed from underneath. It is cut away to fit round the back legs.

**A Bedroom Chair.** The design at Fig. 2 works out well in mahogany, and some extra interest is given to the panel by quartering up and shaping it. This chair would also look well in English walnut, whilst a good result is also possible in waxed oak. The chair (Figs. 2 and 3) has a total height of 2 ft. 11 in., height of back being 1 ft. 6 in., and of seat (at back) 1 ft. 5 in., the front of seat being ½ in. higher. Width of back at top is 1 ft. 2½ in., diminishing to 1 ft. 1½ in. at seat, depth (back to front) of seat being 1 ft. 1½ in.

In setting out the back legs the most economical method is to mark them out close together on a narrow board of a sufficient thickness to allow of cleaning up to the following detail dimensions. Total length finished 2 ft. 8¾ in. to joint of top rail, an additional 1 in. being allowed for the tenon here. The face should finish 1 in. in width throughout the back leg, but the thickness will vary between 1¼ in. net at the seat height and 1 in. net at ground. The upper portion of back leg can be lessened to 7/8 in. thickness with D section. The rake at seat height is 2¼ in.

The top back rail has broken corners, and in style will go well with furniture of Queen Anne or Chippendale character. This piece finishes 2¼ in. wide net, and should be carefully shaped to the outline indicated. In setting out, the best way will be to allow ½ in. radius for the quadrant internal breaks, and strike the parallel outer shapings at 1½ in. radius. The rail may be flat, but in practically all chairs of similar type the effect is improved by working to a curve, which in this case could be ½ in. spring (i.e. depth) only. The lower edge of rail will require mortising or grooving ¼ in. or so deep to receive the back panel or splat, the finishing thickness being 7/8 in. net. The lower rail of back is fitted 1 ft. 1 in. clear of top rail and, if curved, should correspond with the latter in depth, finishing size being a clean up from 1 in. by 1 in. and should be tenoned into position.

The back panel can be of ¾ in. thickness, or slightly less, and is 3½ in. wide, shaped back to about 2½ in., an extra ½ in. full being allowed in length for stubs top and bottom. The quartered effect indicated at Fig. 4 is well worth carrying out in veneer, and is not difficult to lay if the meeting edges are cleanly cut with the grain to match up nicely. A front elevation and side view of this chair are given at Fig. 3. The back, it will be noticed, tapers slightly towards the seat, and can be 1 ft. 2 in. to 1 ft. 2½ in. at top over all, narrowing to 1 ft. 1 in. or 1 ft. 1½ in. below. An enlarged set-out of the

back mapped in 1 in. squares is shown at Fig. 4. The seat is framed up of pieces  $1\frac{1}{2}$  in. wide by  $\frac{3}{4}$  in. net, usually dowed together, and is fixed to the back legs by notching and by a hardwood peg right through. The back rail of seat is often allowed a trifle extra width and is shaped. The seat is caned in the ordinary way. The legs can be worked from lengths of  $1\frac{1}{2}$  in. material to finish  $1\frac{3}{8}$  in. at top, tapering to  $\frac{3}{4}$  in., below which the swell for toe can be  $1\frac{1}{4}$  in. by  $\frac{7}{8}$  in. high, this latter projecting slightly more at front than at back of legs. A front rail between legs can be fitted at a height of  $10\frac{1}{4}$  in. from ground.

*Chair. Fig. 1. Simple kitchen chair. Figs. 2-3. Bedroom chair, with diagrams giving details and measurements for making.*

*Fig. 4. Showing how the back of the bedroom chair may be shaped and sized.*

**A Dining Room Chair.** Fig. 5 shows a serviceable and graceful type of chair for dining-room purposes. Oak is most suitable, but both beech and birch are serviceable if well stained so that they do not quickly wear white. Choose only

the pick of well-seasoned wood, fairly straight and regular in grain, and free from knots, shakes, and bruises that would tend to weaken its resistance to a strain that is often considerable. The general height for a standard chair-seat is fixed conveniently at 1 ft. 6 in., but is often found to be 1 ft.  $5\frac{1}{2}$  in. to top of front rail,

after levelling and a loose-pad seat, such as that shown at Fig. 12, if well stuffed, will add a trifle to this. Should it be desired to provide a stuffed or spring seat, the seat rail will need to be lower in order to allow for moulding up.

*Fig. 5. Example of single chair belonging to dining room suite.*

For the standard or small chair the width across the front is a full 1 ft. 6 in., and across the back it is from 1 ft.  $2\frac{1}{2}$  in. to 1 ft. 3 in. The depth of seat, front to back over rails, is 1 ft. 5 in. for the person of average height, but in special cases for a tall person a depth of 1 ft. 6 in. to 1 ft. 7 in. will be found more comfortable. A fairly high back is shown, height from seat rail to top of capping on back legs being 1 ft. 11 in., the top back rail entering the back legs 1 in. lower at a height of 1 ft. 10 in. The back may be made 2 in. lower without detriment to proportion. Width at top of back over uprights or back legs is the same as at ground level, 1 ft.  $2\frac{1}{2}$  in. to 1 ft. 3 in. Where armchairs are provided they are often termed carving chairs, and at times the seat is increased in height to 1 ft. 7 in. The width across front of seat is a full 1 ft.  $9\frac{1}{2}$  in., and at back is 1 ft.  $5\frac{1}{2}$  in. Depth, back to front over rails, should be the same as for standard chair. The height of back can be 2 in. in excess of that of the standard chair; width of back is uniform.

*Figs. 6, 7. Front and side elevations of dining room chair.*

The standard chair is shown in elevation (front and sides) at Figs. 6 and 7, with main dimensions marked. These will be of assistance in making a full-size set-out on lining paper which in all cases should be done, and to facilitate which a pencilled extract of following sizes will save constant reference to letterpress. The back is shown to enlarged scale at Fig. 9. The back legs (A) finish  $1\frac{1}{4}$  in. wide on face throughout, and thickness at seat height is  $1\frac{5}{8}$  in., which is tapered to 1 in. net at top

and at ground respectively.

The method of setting out this part of the work is shown at Fig. 8, A, plotted out in 1 in. divisions of width and 2 in. divisions of height, the height of seat rail being noted at 1 ft. 6 in., where the rake or depth of curve is  $1\frac{3}{4}$  in., measuring from a line touching top and bottom of back leg. Some economy of wood can be effected by setting out legs close together on the same board.

Fig. 8.  
Diagrams of framework  
of seat, and method of  
plotting design of chair  
back.

The top back rail (B) takes a piece 1 ft. 3 in. by  $3\frac{1}{2}$  in. including tenons and paring, and when finished will measure 3 in. wide. The lower rail (C),  $1\frac{1}{8}$  in. wide, finishes like the top rail  $\frac{7}{8}$  in. thick. Both rails can be flat, but the general appearance and comfort to back will be improved by working the rails to a curve in the manner indicated at Fig. 8, B, out of thicker material. The centre panel (D, Fig. 9) can be  $2\frac{1}{2}$  in. to 3 in. by  $\frac{5}{8}$  in. thick, stubbed into rails top and bottom, taking a length of 1 ft. 3 in. including joints. The narrow bars or uprights (E) on each side of panel finish  $\frac{3}{4}$  in. by  $\frac{5}{8}$  in. thick. By way of embellishment, three flutes can be worked on the back legs, and two scratched beads on the bars close to the edge will improve them. Height of rail (C) above seat-rail is a full 3 in.

The seat-frame rails, shown enlarged on plan at Fig. 8, C, finish  $2\frac{1}{4}$  in. by  $1\frac{3}{8}$  to  $1\frac{3}{4}$  in. thick, and will require careful tenoning into back and front legs. The joint is cut in line with the rails, and entered so as to give as long a tenon as possible, mitred to meet. A section of front and side rails is given at Fig. 8, D, showing a  $\frac{3}{8}$  in. rebate for seat-frame  $\frac{7}{8}$  in. or  $\frac{5}{8}$  in. deep with the outer edge rounded. The front legs should not be

less than  $1\frac{1}{2}$  in. by  $1\frac{1}{2}$  in. and might finish  $\frac{1}{8}$  in. larger for a firm chair. They are shown as tapered with the lower  $1\frac{1}{8}$  in. shaped to form a toe as a relief from plainness. In framing up it will be noticed that the back legs are joined square with the back rail, whilst the front legs finish at sides in line with the side rails of seat, but not quite flush with them—say  $\frac{1}{8}$  in. projection with the projection rounded away at edge.

Fig. 9. Back of chair.

#### Supports for the Movable Seat

The interior angles of seat are stiffened by the fixing of braces cut out in 1 in. material 3 in. by 3 in. to shape, and screwed into position flush with the bottom of rebate so that they give extra support to the pad frame.

An improved finish to the seat-frame is secured by moulding the top edges ovolo at front and sides. The back seat rail is not rebated.

The pad-seat is upholstered on a separate frame, and is indicated by dotted line on plan, Fig. 8, C. This frame should be preferably of birch dowelled together or bridled and screwed, and is made a full  $\frac{1}{8}$  in. smaller than the rebated opening to receive it, as an allowance for the covering material. Thickness of material should be that of the depth of rebate, and where the front legs project on the inner angles the pad-frame is notched at corners to fit. Upholstery of pad-frame could be carried out in hide, but a change would be velvet or mohair. Tapestry may also be used.

The underframing shows three rails, one high up connecting the two front legs, and one rail to connect each pair of front and back legs. The arrangement stiffens the chair considerably, and with the front rail as shown, has the advantage over the ordinary H-pattern framing of not tempting the sitter to put his foot upon it. No rail is necessary between the back legs, but it can be added if desired. Size for the rails may be about  $1\frac{1}{2}$  in. by  $\frac{5}{8}$  in., or the front one may be wider, say  $1\frac{3}{8}$  in.

**Drawing Room Chairs.** Since drawing room chairs are lighter in construction than dining room and other types, it is essential if the chair is to last any time that all the material should be sound and of good quality and that the maximum amount of strength be obtained by good workmanship and careful planning of the joints, etc. The best plan is to make a full-size drawing of the chair, giving side and front views and a plan of the seat (Figs. 11, 12, 16 and 18). The setting-out of the back legs requires careful attention to get the correct rake (notice that a straight, perpendicular portion is always left where the side seat rails join them).

The method to mark out the back on the wood is as follows: Prepare the wood the total length and thickness required, and wide enough to take the rake, and square up the front edge. At this edge mark the position of the straight portion required for the seat rail joint (the edge being already square and straight) and mark the remainder of the leg and back from this point. The chairs should be finished with french polish.

*Chair. Fig. 10. Light drawing room chair.*

Fig. 10 is a light chair to be made in mahogany with a loose seat (Fig. 12). This style would do equally well for any living room, the upholstery being varied accordingly. The main dimensions can be scaled out from Fig. 11, using the 3 in. squares as a scale (thus the height of the back is 3 ft., and two pieces 4 in. wide will be required from which to cut the back legs). At their widest part on the front side these should measure  $1\frac{3}{8}$  in., tapering downwards to  $15/16$  in., and upwards to  $\frac{7}{8}$  in.

*Figs. 11-14. Showing details of joints, back, and seat.*

**Fig. 14**

The front legs at the top are  $1\frac{3}{8}$  in. and taper to  $\frac{7}{8}$  in. Note that these are bevelled away to line up with the side rails, which are necessarily at an angle caused by the front of the chair being wider than the back. The front and two side rails are rebated  $\frac{7}{8}$  in. on the inner edge to take the loose seat and a moulding on the worked on the edge (see Fig. 14). The rebate is continued on the leg and the moulding worked on it after the chair is glued together. All the rails are tenoned into the legs and the joints strengthened with angle brackets (Fig. 12). The top rail of the back is mortised to take the uprights (Fig. 13) and the intermediate rails stub-tenoned.

The centre back portion is cut from a piece of  $\frac{1}{2}$  in. material, the triangular shapes being cut out. When glueing the chair up, glue the back and front first and allow to set before fixing the side rails. The loose seat can be made from any of the cheaper hardwoods and is either halved or mortised together. An allowance of  $\frac{1}{8}$  in. should be left all round to allow for the thickness of the material with which it is covered.

For a drawing room this type of chair looks well covered in striped material—either self-striped satin, or a vari-coloured taffeta. Brocade or damask is suitable, or a loose cover can be easily made to match those of other chairs, etc., in any living room. Rep is suitable for a dining room chair of this make, or any good fabric with a geometrical design. Damask may also be used if the other furniture in the dining room is of the light character with which this chair would be a good choice.

### Mahogany Chair with Stuffed Seat

Fig. 15 is a chair of similar character but having a stuff over seat and an under framing. It is set out and proceeded with similar to Fig. 10. A wide and shallow rebate is worked on the rails over which the material is tacked (Fig. 17). The front legs are easily rebated after glueing up. The lower side rails are of  $\frac{1}{2}$  in. material and are  $\frac{3}{4}$  in. wide, they are tenoned into the legs. Note that the shoulders of both joints will be at an angle. The joining rail is dovetailed into the side rails. When preparing the top back rail, which is dowelled into the uprights, the dowel holes should be bored before cutting the rounded portion, as it would otherwise be liable to split away (Fig. 19). Half-inch beech dowel is the best to use. The slats are stub-tenoned between the two rails, and are  $\frac{3}{4}$  in. wide at the top and taper to about  $\frac{1}{2}$  in. Use  $\frac{1}{2}$  in. material for these.

**Fig. 15**

**Fig. 16**

**Fig. 17**

**Fig. 18**

**F19**

**Chair Repairing.** This is often easily done. At Fig. 20 two common leg breakages are shown. Always repair such breakages before the fractured edges have got rubbed. The parts will then fit closely; whereas, if there is delay, the ragged edges may get injured and a neat joint may be difficult to effect.

The front leg is repaired by means of a long dowel inserted (Fig. 21). First cut off the small turned fragment which is attached to the top square block of the leg. Use a fine tenon saw, and cut across at AA. Warm the broken surfaces, glue the little part which

has been removed to the main body of the leg, and lay the work aside till the glue is set. Now bore both parts of leg (square portion and turned piece) for a long dowel (B), which should be of beech or oak not less than  $\frac{3}{4}$  in. in diameter. The dowel must go well up into the square block and at least 2 inches into the turned leg beyond the fracture. Glue everything well, and the leg will be stronger than before.

Chair. Figs. 20 - 30. Diagrams illustrating how various breakages can be easily mended. See text.

The back leg is repaired with screws, as at Fig. 22. If any of the splinters are loose, glue them down so that the parts will fit quite closely. Hold these together, and, at the angle indicated in the diagram, carefully bore holes for two screws, one at each side (*see CC*). Countersink for the heads. It is well to use a fine bradawl first, and then a gimlet. The screws must be of a fairly fine gauge, and either  $1\frac{1}{4}$  in. or  $1\frac{1}{2}$  in. in length. Try the screws, and, if all is right, warm the broken surfaces: apply thin hot glue and screw up. At the two ends of the joint (DD) insert a couple of needle-points. The holes countersunk for the screw heads are filled with a cement made with beeswax and resin. This is stained to the colour of the wood, and when trimmed off and rubbed over with polish the repair should be satisfactory.

#### The Repair of Frame Joints

Chair frame joints frequently work loose on account of the glue giving way. Seat rails are tenoned to the legs,

and when the tenons become loose the leg is unsteady. The inside angles of chairs are usually braced, either with a strut wedged in, as Fig. 23, or with a brace screwed on, as Fig. 24. If the bracing works loose the leg will probably be insecure. The joints of a chair with wood seat can be repaired with little trouble; but in the case of an upholstered seat, it is well to allow the repair to stand over until the chair needs to be re-upholstered. In this latter case it may be stripped, and then recovered after the joints have been repaired.

Knock the parts loose and scrape off all the old glue. As the tenons may have become a little too small, owing to shrinkage, they should be wedged in order to tighten them. As the tenons do not go right through the leg they will have to be blind-wedged, as Fig. 25. That is, two cuts are made in the tenon and narrow wedges inserted. When the tenon is glued and driven home with the mallet, the wedges increase its width and thus ensure a tight fit. The mortise holes in the leg may be gently pared to permit of the wedged tenon acting like a dovetailed joint. After the four seat rails have been glued up the braces or struts are glued and screwed in position. Work of this sort usually requires to be cramped up with a regular joiner's cramp, the method of using which is shown in Fig. 26. The cramping is very important, as the glue will not hold satisfactorily unless the parts have been put under heavy pressure.

Kitchen chairs, which are frequently used for purposes for which they were never intended, have a habit of falling to pieces, but if properly repaired they will be as good as new. Taking Fig. 27 as a typical example, the best plan is to knock all the parts separate, marking each, so that its correct place is known. Clean off the old glue, and, if any of the leg joints fit rather loose, take a paring off the ends, so that a thicker portion will make the entry. A broken stretcher rail may be repaired in the way already described for a back leg (*see Fig. 22*). It may, however, be less trouble to make or buy a new stretcher. Glue the rails to legs, and then glue and knock the four legs into the seat, using the cramp if possible. See that all four legs are level.

Coming to the back, if the tenons of the two outer uprights are loose they will have to be wedged (Fig. 28). The wedges are driven in from the underside. If the top pin which enters the shaped rail is broken, cut it off, and bore the upright for a beech or oak dowel pin as Fig. 29. The back parts, including the central and two intermediate slats, are first fixed to the seat. The holes in the top rail are then glued, and this part coaxed on with the mallet. It is usual to wait and see that everything is correct and in line before driving in the wedges used to strengthen the outer uprights.

The arms of kitchen armchairs often come loose owing to the breaking of the screw which holds them. Punch out the head of this screw. The other end may be withdrawn with the screwdriver if a nick is first made across it with a file. The new screw should be inserted so that the smooth shank will pass the line of joint (*see Fig. 30*). It will then run no risk of breaking, and the

countersunk hole may be filled with a stopping of some kind.

*Chair Bed, shown in two positions: open for use at night, and closed to form an easy chair. (Courtesy of Oetzmann & Co. Ltd.)*

**CHAIR BED.** This is usually an armchair, generally provided with an iron framework, which unfolds so that it can be used as a bedstead. The chair legs and seat remain in their normal positions, and the article is extended by turning over the upper part of the seat and lowering the back. The extremities of the extensions are supported on extra legs which fold. It is fitted with cushions, usually three in number, which serve as a mattress. It may be entirely of iron or may have wooden or brass legs.

The illustrations show another form of chair bed. When folded this has the appearance of an upholstered easy chair. The seat and back are folded down, as shown, to convert it into a bed. *See Bed Sitting Room.*

**CHAIR RAIL.** This is a wooden moulding fixed to the walls to prevent damage by chair backs. It can take the place of the dado, and if different shade or colour of wall covering is used above and below the rail, the result can be made very pleasing. The moulding can be obtained in the white, i.e. not stained or painted, and when ordering allowance should be made for waste in mitring corners. There will usually be at least 10 corners, and 2 ft. extra should be obtained.

Start on the longest lengths of wall first; the short lengths and odd corners can be fitted with the moulding left over. The mitres for the corners should be cut neatly with a tenon saw, and with the aid of mitre box or board. When making the joints for the fireplace and bay window corners, do not forget to cut outside corners, or some of the moulding will be wasted in recutting. If it is necessary to join some of the lengths, do not merely lay them end to end. Cut each end at an angle, of 45°, so that they can be overlapped. Such a joint will scarcely be noticed when glass-papered and painted.

Cut nails should be used to fix the rail to the wall, and a suitable height is 36 to 39 in. from the floor. Punch the heads of the nails well in and cover with plaster of Paris; putty is sometimes used, but it shrinks in drying, and is unsightly. The rail should be treated to match the other woodwork of the room. The moulding can also be obtained in oak, mahogany, or walnut.

**CHALK:** In the Soil. Chalk is not so good as lime for heavy soils, but on light, sandy land it is to be preferred, because of its slower action. For this purpose

it should be finely ground and put on the land in winter. Calcareous soils with solid chalk a few inches below the surface dry out quickly, and the best way to keep trees and plants flourishing in such land is to mulch the surface in early summer.

So far as soil treatment is concerned, a great deal can be done by breaking up some of the chalk with a pick or strong fork, and using rotting or charred turf, or burnt clay, if procurable, as freely as possible. A good deal of it should be packed below and around the roots of each tree. *See Gardening; Rose; Soil.*

**CHALK STONES.** These are gout stones or tophi, which form beneath the skin in gouty patients, frequent sites being on the ear or knuckles. They are composed of urate of soda. *See Gout.*

**CHAMBERMAID.** In a hotel the chambermaid's duties are similar to a housemaid's in a private house. She attends to the bedrooms and bathrooms, and the passages and staircases in that part of the house where these rooms are situated. She brings hot water if it is not laid on, draws the window blinds, and calls visitors. She makes the beds, cleans the rooms, lays and lights fires.

**CHAMBERTIN.** One of the most famous of all the red Burgundy wines is Chambertin. It possesses a fine, clear, dark red colour, and fulfils on the palate the promise held out by its charming bouquet. Soft and velvety, it is never sugary or "spirity." It is a warm, generous, and at the same time delicate wine. *See Burgundy; Wine.*

**CHAMFERING.** The object of chamfering may be either for decorative purposes or to lighten the appearance, or sometimes simply to remove a sharp edge. It is usually at an angle of 45° with the main surface, though it may be worked at any angle which the particular nature of the work requires.

The commonest form of chamfering and the quickest to carry out is when it is run along the entire edge without stopping (Fig. 1), in which case the work is done with an ordinary plane. In a type more frequently used the chamfer is run for a certain length and then stopped a short distance before reaching the end. Figs. 2 to 6 are typical examples of stops employed; Figs. 3 and 6 are more suitable for oak work. Frequent use is found on the inside edges of framings, such as panelling, and work for ecclesiastical purposes makes great use of chamfering.

In cases where the stop is flat, such as Fig. 6, the flat side of a chisel is used to cut the wood, and the reverse side for such as Figs. 2 or 3. As it is impossible to use an ordinary plane for the whole length of a stop chamfer, the ends have to be cut with a chisel or a bull-nose plane, which is capable of working very close to the ends, as there is only a very short distance between the cutter and the front of the plane. Where a great deal of

chamfering is to be done, a special chamfer plane (Fig. 7) is often used, the advantage of which is that it can work right up to the stops, and automatically regulates the depth of the chamfer.

*Chamfering. Figs. 1-6. Usual forms of chamfered edge and the principal stops employed for different purposes by the woodworker.*

*Chamfering. Fig. 7. Chamfer Plane, showing the correct method of holding this tool.*

When a very deep chamfer has to be cut, it is advisable to make several saw cuts at various points along the edge (not quite down to the finished depth), to obviate the tendency of the wood to split out when removing the bulk of the waste with the chisel; for should the wood start to split, the split cannot run farther than the next saw cut. The chamfer is finished off with a chisel and plane. Finally a scraper is used, and then glasspaper.

Sometimes the tool known as a chamfer shave is used for chamfering. In appearance it is like a spokeshave (q.v.), and used in the same way. It is capable of producing splayed and stopped chamfers.

**CHAMOIS LEATHER.** For cleaning windows and glassware, and as a polisher for metal ware generally, nothing is better than so-called chamois leather. It is really made from sheepskin, which after being freed from the wool is split into two layers. The top layer, or grain, is made into a variety of coloured leathers; the under layer, or flesh split, is used for chamois leather. It is treated with fish oil, and during oxidation the colour changes from white to dark yellow. The skins are pressed and washed to free them from excess of oil, and the leather is then bleached and finally buffed to give it a fine nap.

The two characteristics of chamois or oil leather are its softness and its resistance to the action of water. For this reason the name washleather has been given it, and washable gloves are made of it.

In washing these gloves a simple method is to wear them, while a good washing in warm, soapy water is given, working them about on the hands so as to remove grease and dirt. Wash again in clean, warm, soapy water, and if a little soap is allowed to remain in

them when they are hung up they dry more satisfactorily.

A cleaning leather is the better for frequent washing in soap and warm water with a little borax, afterwards rinsing in cold water. Then squeeze it, pull the leather out flat, and spread on a board or table. When almost dry, pass it through the hands and stretch it out until it is flat, repeatedly smoothing the surface. In this way the leather will dry soft. *See* Glove; Leather.

**CHAMPAGNE.** This sparkling wine requires to be looked after very carefully. If there be the least sediment or deposit the wine requires to be filtered into fresh bottles. The wine matures quickly, and is at its best after from 8 to 15 years, although there are instances of champagne having retained its excellence after 40 years. Champagne is known by the name of the shippers. Amongst the leading brands are Ayala, Bollinger, Clicquot, Goulet, Heidsieck, Irroy, Moët and Chandon, Perrier-Jouet, Pol Roger, Pommery and Louis Roederer.

The champagnes shipped to Britain are generally dry, and styled brut or nature, which should mean that they contain no added sugar or liqueur. They are obtainable in half bottles, pints, quart bottles, magnums (double bottles holding 4 reputed pints), and jeroboams (double magnums). Champagne keeps better in bulk.

Ice should never be put into it as it spoils the flavour. The bottle should be placed in an ice pail for 10 to 20 min. before serving. At a dinner party where various wines are served champagne is usually given with game or entrées and after. The best glass for champagne is tulip-shaped with a deep stem cut at the bottom of the bowl. This shows the steady stream of bubbles and keeps the wine lively longer than a shallow glass. *See* Dinner; Wine.

**Champagne Cup.** To make this agreeable drink, take a bottle of champagne, a liqueur glass of brandy, ½ liqueur glass each of yellow chartreuse, curaçao and maraschino, and two bottles of seltzer, soda, or Perrier water. Add a lemon cut in slices, a few sprigs of borage, and ice and sugar to taste.

Another recipe is the following: Put a large lump of ice in a jug and add a bottle of champagne, a bottle of seltzer, soda, or Perrier, and a liqueur glass each of brandy, curaçao and abricotine. Stir well and add various kinds of fruit, borage, mint, and cucumber peel.

**CHANDELIER.** Consisting of a branched candle, electric or gas holder depending from the ceiling, the modern type of chandelier is of gilt, bronze or gunmetal, and is usually specially designed for rooms decorated in the fashion of particular periods. Thus in a room of Jacobean type might be placed a Flemish chandelier in brass. For large rooms of 18th century type, especially with French furniture, a chandelier

hung with glass lustres is effective, although it is difficult to keep clean, and has to be shrouded in dust-bags when the room is out of use. For cleaning purposes the prisms must be taken down and laid on a tray in order, noting exactly how they were hung. When they have been washed and dried, they must be carefully replaced in their order after the brackets have also been cleansed.

There are also elaborate and costly chandeliers in gilded and painted wood, which are replicas of those of the William and Mary period. *See* Bent Iron Work: Candlestick; Electric Lighting; Gas.

**CHANGE OF LIFE.** The climacteric or change of life is the period at which women cease to bear children: and as the change frequently affects the mind as well as the body, especial care of the health is always called for. The age at which the change occurs is generally between 45 and 50, but may be either earlier or later in certain cases. The child-bearing period usually lasts about 30 years.

The manner in which the climacteric occurs is irregular. In some cases menstruation suddenly ceases, but in most it first becomes irregular, remains so for two or three years, and then finally stops. Excessive bleeding at the periods or bleeding in the interval should not be accepted by any woman as due to this cause alone without consulting her doctor.

Amongst the symptoms common at this time perhaps the most unpleasant are flushings of the face and limbs, frequently preceded by chilly sensations, and followed by profuse perspiration. Some women are prone to corpulence while others become thin. Osteo-arthritis is another of the evils to which women are exposed. Nervous symptoms are frequent, while headache is rather common, but often due to the need for glasses. Other symptoms are backache and indigestion.

The first thing necessary for a woman who is suffering from the troubles incident to the change of life is to realize that they are natural, and that they will pass away in the course of a few years. This will ease her mind. At the same time, however, she should realize that some increased attention to her health is advisable for a few months, or even years. The following aperient is useful:

Confection of senna      1 oz.

Confection of sulphur   1 „

Mix well. Take one teaspoonful at night when necessary.

As an alternative, one to three grains of cascara or a liquid preparation of cascara may be taken at bed time. The following simple dinner pill may be tried:

Aloin                              12 grains

Extract of nux vomica      6 grains

Alcoholic extract of belladonna   3 „

Make into 12 pills. Take one pill after the evening meal when required.

If the appetite is poor, a tonic may be useful. Strong tea, indigestible foods, and alcohol in any form must be avoided. Warm baths at bedtime, two or three times a

week, are soothing to the nerves.

Many women are prone to be emotional; they should strive constantly to control themselves and, generally speaking, to take a cheerful view of life, which does so much to banish worry and anxiety. The troublesome flushings are often relieved by bromides, and the following may be taken:

Potassium bromide	45 grains
Arsenical solution	20 minims
Syrup      „      „	6 drams
Cinnamon water (enough to make)	6 oz.

Make into a mixture. Take two tablespoonfuls after the midday and evening meals when required.

It has to be pointed out that bromides are only to be taken when really required; if their frequent use is necessary, it should be under the eye of the doctor. Flushings are also helped by taking ichthyol. Beginning with a tablet of 2½ grains, the dose is increased gradually till in about three weeks time four tablets are being taken thrice daily. If at any time there is a persistent taste of the drug in the mouth sufficient has been taken. Iron may be required in some cases where there is shortness of breath and want of general tone due to anaemia, and may be taken in the form of Blaud's pills or in a mixture. *See* Anaemia.

**CHAPERON.** Originally a hood worn by matrons, the word chaperon came to be applied to a married woman who took charge of an unmarried girl on social occasions. A hostess often gives dances and dinner parties to which it is understood that chaperons are not invited, the hostess herself acting in that capacity to any unmarried girls present. At important social functions girls are chaperoned at least during their first season.

**CHARACTER: The Legal Aspect.** It is usual for mistresses when engaging a servant to ask for a character, that is, something from a former employer about the antecedents and qualifications of the person requiring the situation. A character of this kind should never be given unless asked for.

Even if what a mistress says in giving a character is in fact untrue, yet if she says it honestly she will be protected by the law so long as she is not actuated by spite or malice.

Beware of giving a false character. If a mistress dismisses a servant whom she knows to be a thief, and out of good nature writes that she is honest, and in her new place she steals, her old mistress is liable to the new mistress. A servant who obtains a situation by a forged or false character is liable to fine or imprisonment. So is anyone who knowingly gives a servant a false character, by means of which the servant obtains another situation. *See* Servant.

**CHARADES: How to Play.** This game is suitable for any number of players above 7 or 8. Two persons

pick up sides, and one side then goes out of the room and chooses a word of two or more syllables, each syllable being a separate and complete word, e.g. selfish (sell fish). The syllables are then acted in two scenes, and the whole word in the final scene.

The usual method of procedure is for the syllable to be spoken by one of the players, though there is no need for the scene itself to give any direct representation of the word. Another method is for the syllable to be acted, though not necessarily spoken. Thus, in the example chosen, the first scene might show a shop, with a brisk trade, and the second might represent a party of fishermen coming home with their catch, while the whole word should not be difficult to act; two children playing could easily convey the necessary effect. At the end of the performance the audience has to guess the word chosen.

The game is more successful if a few words have been selected beforehand and a possible scenario drawn up, otherwise the time occupied in discussion by the acting party is apt to be wearisome to the members of the audience.

Historical charades is a picturesque variant of this game. The word to be guessed is the name of some person famous in history or fiction, and a short name is generally chosen, as upon its length depends the number of scenes to be enacted. Each scene depicts an incident in the life of some other celebrity whose initial letter occurs in the name selected for the charade.

No names are introduced by the actors that will give the subject away. About five people can comfortably take part in the scenes. No theatrical costumes, scenery, or other property are necessary; the house can furnish all that is required in the shape of a few shawls, scarves, sheets, hats, coats, and walking-sticks. *See Children's Party.*

**CHARCOAL: Its Domestic Uses.** Although charcoal has a limited use in the house, it has excellent deodorant properties, as well as the power of taking the colour out of certain solutions. It is produced by partly burning certain kinds of wood and bones, the former variety being known as wood charcoal, and the latter as animal charcoal.

Wood charcoal finds one of its chief uses in the garden. A few pieces mixed with the mould in which plants are potted keeps it sweet. For a similar reason a piece should be placed in the water of the glasses in which bulbs are grown. Stakes driven into moist ground resist decomposition for long periods if the ends are first put into a fire and so partly converted into charcoal. Similarly, casks charred inside resist fermentation better than uncharred casks.

Mixed with any foul material charcoal helps to destroy the odour. It has been found to absorb any smell that may arise when clothes are put away in a wardrobe or chest of drawers. For this purpose some moderate sized pieces should be placed among the clothes. Powdered charcoal serves as a tooth-powder, neutralising some of the effects of decay.

Some coloured liquids, e.g. red wine and fruit juices, lose their colour when filtered through powdered

charcoal. Charcoal should not be used to purify drinking water.

**CHARLOTTE RUSSE.** A jelly mould is lined with a little jelly at the bottom and when nearly set glacé cherries are pushed through it to the bottom or the mould and sponge cakes or savoy fingers placed round the sides. A dessertspoonful of castor sugar and half a dessertspoonful of gelatine should be dissolved in a  $\frac{1}{2}$  pint of milk over gentle heat. The milk is then strained and a few drops of vanilla essence added; also, if desired, a tablespoonful of sherry. Half a pint of cream should be well whipped and the strained milk stirred in when cool. The mixture is poured into the mould and left in a cool place or on ice until it has set, when it is turned out.

*Charlotte Russe, a delicious party sweet*

**CHARPIE.** Shredded linen used for the dressing of wounds is termed charpie. It is made of flax between layers of gauze, and used to form part of the first field dressing of the soldier; but gauze is now deemed to be sufficient. The shredding makes the dressing more absorbent and protective, but these purposes are usually achieved by the use of gauze or lint and absorbent cotton-wool. *See Bandage; First Aid.*

**CHARR: How to Cook.** Amongst fresh water fish charr is highly nutritious. It should be washed well and dried before cooking. To fry it, cut the fish into steaks, coat with egg and breadcrumbs, and fry in hot fat, or the fish may be first dipped in batter.

Charr may be broiled or grilled. Cut the fish into steaks about 1 in. thick, season with pepper and salt, wrap in pieces of oiled paper, and gently broil them over a clear fire. To grill charr with a gas fire, place it on a greased grid-iron and put this under the griller, which must not be turned on full. Charr cooked in any of these ways should be garnished with lemon or parsley, and served with melted butter sauce.

**CHARTREUSE.** There are three kinds of this celebrated liqueur. The white variety is the mildest; the green is the most potent and highly prized, especially in France; the yellow is the liqueur most widely used in all countries. Chartreuse is distilled from certain aromatic plants. *See Liqueur.*

**CHARWOMAN.** A charwoman is a worker who goes out by the day or hour to clean private houses, offices and shops. She may be paid by the week, day, half-day or hour, and her pay may include or exclude food.

A charwoman must be insured under the health

insurance scheme, but not against unemployment. If she works for a single employer he is responsible for the weekly payments. If, however, she works for a number of employers the one who employs her on Monday is, strictly speaking, responsible. In some cases, however, the employers agree to take it in turn to pay the employer's share of the premium.

If a charwoman is employed regularly—for instance, once a week, or once a fortnight or month—she is a workman within the meaning of the Workmen's Compensation Acts and the employer is liable for compensation if she is injured by an accident arising out of and in the course of her employment. It is wise, therefore, to include her as a servant when insuring against risks under this act. If employed only on odd occasions she does not come within the act. *See Insurance.*

**CHAUDFROID SAUCE.** A general favourite for coating meat made up into cold entrées, chaudfroid sauce requires skilful cooking to be of the right consistency. To make the white variety, heat up  $\frac{3}{4}$  pint white sauce, adding to it 3 sheets of gelatine, previously dissolved in a little white stock, and 2 or 3 tablespoonfuls of cream. Strain the whole through a tammy cloth, and use the sauce when it is just on the point of setting.

Brown chaudfroid sauce is made from  $\frac{1}{4}$  pint good brown sauce,  $1\frac{1}{2}$  tablespoonfuls liquid aspic, and 2 oz. meat glaze. The glaze is dissolved in the sauce before the aspic is added, and the whole strained and used when cooling. *See Sauce.*

**CHAUFFEUR.** The driver of a motor car is termed a chauffeur, and certain qualifications are required for the post. He must be in possession of a driving certificate, which should be free from endorsement, and in view of the responsible nature of his work he must be of good personal character. He should also have the technical knowledge required to do his own repairs and to keep the car in proper condition. He ranks as a skilled mechanic, and is generally an outdoor servant. Both men and women are employed.

The employer is liable for injury or damage to person or property caused by his chauffeur's negligent driving or handling of the car while on his master's business. But if the chauffeur takes the car out for his own purposes—e.g. to call on one of his own friends, or for a joy ride with the housemaid—and does damage while so engaged, the employer is not liable. The latter must always insure against accidents to third persons and property caused by his car when driven by his chauffeur.

A chauffeur must be insured under the national health insurance scheme and the employer is responsible for the weekly payments. Unless the chauffeur is a woman, the employer must take out a licence enabling him to keep a male servant. This costs 15s. a year. *See Insurance; Motor Car; Negligence; Servant.*

**CHEDDAR: A Mild Cheese.** This is one of the cheapest varieties of cheese. There are several methods of making Cheddar, besides the noted west of England way, other varieties coming from Ayrshire and Canada.

Cheddar cheese is usually made from morning's and evening's milk that has been ripened. The correct degree of ripeness is difficult to gauge, and the inexperienced maker can only determine it accurately by tests. One way of ripening the milk is to keep it at such a temperature during the night that enough acidity will develop to ripen the morning's milk partially when this is added. The other method is to add a ripening or souring agent, such as a starter, to the milk in the morning, and allowing it to remain until sufficient acidity is obtained. The former method is satisfactory with careful handling, but the employment of a good starter will give more reliable results.

## CHEESE AND CHEESE MAKING

### Some Practical Hints for the Small Dairy

Our Encyclopedia contains articles on the various kinds of cheese, e.g. Cheshire and Stilton. This entry is followed by a number of entries on cheese dishes. *See also Diet; Milk*

Cheese is a valuable food-stuff, more especially double cheese, which is made from whole milk, and contains a large percentage of protein and fat. Unfortunately it is difficult to digest. It should be eaten with bread or biscuit in order to ensure that it is thoroughly masticated and sufficiently broken up before being swallowed. Soft, fresh cream cheeses are more easily digested than most other varieties. Cheese is a more concentrated form of nourishment than the best beef. Lean meat has about 70 p.c. of water, whereas good cheese contains only about 30 p.c. Fortunately, for those with a tendency to indigestion, cheese can be eaten with impunity if grated or pulverised. Puddings and other dishes of milk, eggs, and grated cheese are extremely nourishing.

The standard English cheeses, such as Cheddar, Cheshire, and Derby, are too large for the smallholder to make, as he does not usually have more than 7 to 10 gallons of milk daily, and only a portion of this is available for cheese-making. The utensils for making the larger cheeses are expensive. *See Bulletin 43, Ministry of Agriculture.*

**Hygienic Making Conditions.** It is essential that the milk intended for cheese-making should be perfectly clean and in good condition. Almost any clean, airy, and well-sheltered building having a good floor is suitable for cheese-making purposes, and if a cellar is available in which to ripen the pressed cheeses, so much the better. If a dairy has to be built, it should be of brick, with a cement floor falling to a channel which leads to a suitable gully placed outside the dairy and communicating with a proper drain. If pressed

and ripened cheeses are to be made, a similar building, to be used as a curing-room, should be erected in line with the dairy, but sunk about 2 ft. in the ground, and provided with a floor of cement. A series of shelves, on which to place the cheeses, should be put round the ripening-room, and the walls of both rooms should be limewashed at least twice each year. When not required for cheese, the making-room would do duty as a butter dairy.

A suitable size for the making-room is 10 ft. by 8 ft., and for the ripening-room, 8 ft. by 8 ft. The roof may be of tiles, thatch, or galvanised sheeting, lined underneath with boards. All ventilators and windows should be made to open and close as desired, so that the rooms can be kept at a suitable temperature. In order to save expense, both rooms may be made of wood placed on three or four courses of brick to prevent rotting. If built of wood, the outside walls would need to be double, with an air space between. The making-room should usually be kept at a temperature of 62° F. to 66° F., and the curing-room from 58° F. to 62° F.

**Cheese-Making Requisites.** A table 6 ft. long by 2½ ft. wide, with raised sides and ends, and lined with tinned sheeting, is necessary. This table should slope to one corner, and be provided with an outlet and pipe to allow of proper drainage of the whey from the cheeses into a pail below. One or two well-made oak tubs in which to coagulate the milk are required; they should be of a capacity of 6 gallons each, and be provided with close-fitting wooden lids. The maker will need a large knife with which to cut the curd, a milk-strainer, curd-ladle, skimming-dish, and thermometer, cheese-moulds, boards, straw mats, measures, cheese-draining rack, set of wall shelves on one side of the wall, measuring-glasses, pails, and brushes; also weights up to 28 lb. with which to press cheeses, and a supply of rennet extract. The measuring-glass, 1 oz. size, should be subdivided into drams.

**Method Of Making.** A pressed cheese, which is creamy in texture with a distinct cheese flavour and very palatable when ripe, is quickly made. Six gallons of fresh, sweet milk are required for one cheese of standard size. The circular cheese-moulds should be 6¼ in. deep by 6¼ in. diameter, strongly made of tin, and perforated all round. In addition, the moulds should be provided with a circular tin disk and wooden follower.

The milk is first raised to a temperature of 90° F., and rennet, in the proportion of 1 dram to 3 gal., is added to bring about coagulation. The rennet is diluted with six times its volume of water, and then stirred into the milk. The milk is then stirred deeply from 3 to 4 min., after which the surface is kept gently moving to prevent the fat from rising, until coagulation sets in. The tub or vat is then covered with the wooden lid until coagulation is completed. The approximate time to cut the curd may be reckoned by multiplying by 2½ the time taken for coagulation to appear after the rennet is

added, thus: Time of adding rennet, 8 a.m. Time coagulation commenced, 8.15 a.m.— 15 min.  $\times 2\frac{1}{2}$  = 37½ min. Time to cut curd 8.52 a.m. The curd—as the coagulated milk is termed—is ready for cutting when it feels firm and springy, and splits with a clean fracture when a finger is inserted and lifted upward through the curd.

A large knife, long enough to reach to the bottom of the vat or tub, is taken, and the curd carefully cut in cubes ¼ in. to ½ in. in size, the horizontal cut being made with a skimming dish. After cutting, the curd is gently stirred by hand, care being taken to remove particles adhering to the vat.

The temperature is now raised to 106° F. If a jacketed vat is used this is done by passing hot water into the jacket. The temperature should not be raised faster than 1° in 3 min., and the curd should be kept stirred during the process. If the cheese is made in a tub or unjacketed vat, the following procedure is adopted: If there are 6 gal. of curd in the tub and the temperature is 86° F., it has to be raised 20° to 106°. This temperature is attained in 4 steps of 5° each. The first step therefore, is to raise each of the 6 gal 5°.

### Heating the Whey

A cheese cloth is laid over the vat and pressed down on the curd; a supply of whey is then ladled off into a bucket and the temperature of this raised by the immersion of the bucket in hot water. The temperature to which the whey should be heated is estimated thus: If 2 gal. of whey have been taken off, these 2 gal. must be raised 15° to 101°; if only 1 gal. had been taken, then the temperature would have to be raised 30° to 116°. The temperature of whey should never be raised above 120°.

When this heated whey has been returned to the tub, the mean temperature of the whole 6 gal. will be 91°, i.e. the first increase of 5° will have been effected. The three further stages in the process of raising the temperature to 106° are carried out in the same way. The stirring of the curd should be continued until the curd becomes tough and bright, and the particles, when pressed together in the hand fall apart and do not crush. The curd is then allowed to pitch and the whey is poured off through a straining cloth.

The curd is now spread evenly over the bottom of the vat, and salt in the proportion of 1 oz. to 2 gal. of milk is mixed into it. The curd is then carefully packed into the mould, which should previously have been lined with a cheese cloth, and put to press with 2 cwt pressure. It is turned the same evening and returned to press until the following morning. In the morning the cheese is taken from the press sewn in a calico bandage and again returned to the press for 1 hour after which it should be placed in a fairly dry draughty room for two days and then in the ripening room. It will be ready for use in about three weeks, when the weight will usually be about 6½ lb.

**Unsalted Cheese.** A cheese not unlike Welsh Caerphilly is quickly made and digestible but does not

keep well as it is unscalded. It is a popular cheese for consumption with salads in hot weather.

This cheese is made from mixed morning's and evening's milk. As the curd retains a large percentage of moisture (the whey), very little acidity is required, and, unlike the varieties requiring longer periods of ripening, it can be made in cold weather. Five gallons of whole milk will make a cheese weighing about 7 lb. The moulds for these cheeses should be flat, 9½ in. by 2 in., with removable bands which sink down as the cheese presses. Where a number of these cheeses are made they are piled one on top of the other when put to press, and only the top one requires a follower or board. Small moulds to make 1 or 2 lb. cheeses can also be obtained and are very convenient, as any number from 4 to 12 cheeses can be pressed at the same time with a large board placed between each layer.

When made without a starter the evening's milk is at once strained into the cheese vat or tub and well stirred to get rid of the odour of the cows and to lower the temperature slightly; in cold weather it is covered to maintain the desired temperature so that a certain amount of acidity will develop to ripen the morning's milk when added. In warm weather it is unnecessary to cover the evening's milk. When a starter is used, the evening's milk should be cooled down to 70° F. as soon as obtained, to check acidity, and stirred occasionally during the evening to prevent the cream rising. Next morning, when the temperature of the milk has been raised, a small quantity of starter may be added to produce enough acidity, so that when the morning's milk is added the milk is sufficiently ripened for renneting. If no test for acidity is available this must be judged, but care should be taken that the milk is not over ripe or the cheese will work too quickly.

The temperature may now be raised for renneting. This should be 84° to 86° F in summer and 86° to 88° F. in winter. Rennet is added at the rate of one dram (mixed with about four times its bulk of water) to every four gallons of milk, and the whole should be well stirred for 3 min. To prevent waste the cream should be gently stirred in just before the milk begins to curdle. The curd is ready for cutting when it breaks cleanly over an inserted finger, which is usually 40 to 45 min after renneting. It is now cut into pieces about the size of ½ in cubes, this process taking 10 to 15 min., during which time the whey should be stirred gently.

When the curd is evenly cut and well separated from the whey it should be allowed to settle for 15 to 20 min. The whey is now drawn off. With small quantities (e.g. 5 gal.) this is best done by pouring off the whey through a cloth (over another vessel) and then gently tipping the curd into the cloth and tying up into a bundle. It is now left for 20 min., and then cut into 3 in.

cubes and the whole moved and turned to assist drainage. It should then be tied up again for another 20 min, after which the pieces should be pulled apart and again tied up. This should be done at intervals until the curd has a slightly acid taste and smell, when it may be cut into slices 1 in. thick, and packed in the moulds lined with cheese-grey. A smooth piece of cloth is folded

over the top and the cheese put to press. Pressure is gradually increased to 2 cwt.

After the cheese has been pressing 1 to 2 hours, it should be taken from the mould, and well rubbed with salt and, after the cloth has been rinsed in cold water, put back to press again until next morning, when it is taken from the mould and put into brine for 24 hours. This brine is made from boiled water with enough salt to float an egg. The cheese should be allowed to drain, and removed to a dry, airy room and turned daily for a fortnight.

Typical cheese mould, with wooden follower and tin disks. 5. Glass for measuring rennet. 6. Enamelled ladle for collecting curds. 7. Cheese vat; A, draining tap for whey; B, draining tap for hot water; C, wooden rack; D, gauge for measuring liquid in vat. (1 courtesy of the Dairy Apparatus and Equipment Co., Ltd.; 2-7. courtesy of the Dairy Supply Co., Ltd)

**Soft Cheese.** A soft cheese which is usually designated Cambridge cheese is made from whole milk and is in demand during warm weather. Two cheeses can be made from a little more than 6 quarts of milk. It is unwise to make larger quantities than required for speedy consumption, as this cheese deteriorates quickly. The temperature at renneting should be from 92° to 95° F. About ½ dram of rennet should be added to the quantity of milk mentioned, and the cheese tub should be carefully covered. It is advisable to use a smaller tub when making not more than four cheeses. The rennet should be diluted and be stirred in for 4 min.

When the curd is set and the whey is on the surface, the curd may be removed with a skimming dish and placed in the moulds in thin slices, a portion of unbroken curd being set aside to form a smooth upper surface on the cheese. The moulds are in two pieces, the bottom portion holding a threaded straw mat, which

prevents the curd escaping, while the upper one is pierced with draining holes. They are about 7½ in. long by 5 in. wide and 6 in. deep, and should be made of elm wood. Moulds made of tin should not be used, as in these the curd rapidly loses heat, and drainage is thereby retarded. With tin moulds the curd settles into a flat cake, but with wooden moulds the curd adheres to the sides, causing the cheese to settle in the middle first, thus producing a curl in the curd.

These cheeses are not turned at all, and are ready for use when the wooden moulds can be removed without the cheeses losing shape, each cheese weighing well over a pound. They are consumed fresh, being sold along with the straw mat upon which they have been drained.

**Cheese Hopper.** Small yellowish-white maggots, known as cheese hoppers, sometimes swarm in cheese where care has not been taken for its protection against insects. They are the grubs of a tiny black fly (*Piophilidae*) which lays its eggs upon cheese. Maggots have the mouth formed for sucking, and to reduce solid food to a condition in which they can absorb it they have to discharge upon it a fluid that will dissolve it. In this process chemical changes take place that may be highly injurious to the human system. The part of the cheese attacked should be cut away and destroyed.

**Cheese Mite.** Flour, linseed, and other household stores, as well as cheese, are attacked by *Tyroglyphus siro*, or the cheese mite. It gets into cracks in the rind of whole cheese, or in air cavities of cut surfaces, and, reduces the food to powder. Some consider that the presence of the mites improves the flavour of the cheese. Under the microscope, the powder resulting from their activity is seen to consist of dead mites, cast skins, etc. The injured portions should be cut out and the sound part scraped thoroughly, to get rid of mites, the rind getting attention as well as the edible portion.

**CHEESE CAKE.** For the lemon-cheese filling these require 2 oz. sugar, 1 oz. butter, 3 oz. flour, 1 egg, 1 tablespoonful milk, ½ teaspoonful baking-powder, a pinch of salt, and a little lemon flavouring. Cream the butter and sugar, and add a well-beaten egg and the sifted flour. Beat well, and stir in the baking-powder and essence. Line some deep patty tins with puff pastry (q.v.), then put in each tin 1 teaspoonful each of raspberry jam and the mixture, and bake in a hot oven for about 15 min.

*Cheese Cakes made with puff pastry, the centres being filled with jam and a lemon-cheese mixture*

**CHEESE CROQUETTE.** Either vermicelli, macaroni, or spaghetti may be used for cheese croquettes. To prepare them, boil together ¼ pt. each of milk and water, adding 2 tablespoonfuls of spaghetti broken into short lengths. Boil these for about 10 min. or until the spaghetti is tender, and in a separate

saucepan melt 1 oz. butter, stirring into it ½ oz. flour, and then the cooked spaghetti and milk and water. Stir and cook the whole gently until it boils and thickens, then mix in 2 oz. grated cheese, and season it well. Turn the mixture out on a plate to cool, and when cold enough to handle form it into even-sized balls. Beat up an egg on a plate, brush some of it over each ball, and then roll it in breadcrumbs. Heat some frying fat in a deep pan, and when it begins to smoke put in the balls, a few at a time, and fry them a golden brown. After draining them, serve on a paper doily garnished with parsley.

**CHEESE FONDUE.** An appetising supper dish is prepared by mixing 3 tablespoonfuls of grated cheese and the same quantity of milk into 3 well-beaten eggs. Season the whole carefully. Thickly butter three little fireproof dishes and pour enough of the mixture into these to fill them about three-parts full. Bake these gently until they are lightly set and delicately browned, and serve them immediately in the dishes in which they were baked. Thin rolled brown bread and butter or thin fingers of dry toast should be served with this dish.

**CHEESE FRITTER.** Mix 3 oz. of flour with a dust of salt, and in a separate basin beat the yolk of an egg with ½ gill milk and 2 tablespoonfuls melted margarine. Stir these into the flour and beat the mixture well. Cut 6 oz. stale cheese into small strips or fingers, season with salt, pepper, and a few drops of vinegar. Beat the white of an egg to a stiff froth and fold it lightly into the batter, dipping the pieces of cheese in this and sliding them gently into a pan containing smoking-hot frying fat. Fry the pieces till they are golden brown in colour, turning them once to make sure that they are cooked on both sides. Drain them well, heap them on a hot dish, and serve them at once.

*Cheese Fritters. A method of using up stale cheese in an appetising savoury.*

**CHEESE PUDDING.** As this pudding sinks rapidly after leaving the oven, it requires to be served at once. To make it, stalk ½ lb. tomatoes, dip them for a few seconds in boiling water, and then peel them. Slice each tomato thickly and lay the slices in a greased pie-dish. Mix 6 oz. grated cheese with 3 oz. fresh breadcrumbs, and in a separate basin beat 2 eggs to a froth; mixing them with ½ pint milk. Stir these into the cheese and crumbs, adding as much more milk as is necessary to make the mixture the consistency of a thick batter. Season it carefully and pour it into the dish over the tomatoes. Bake the pudding in a moderately hot oven until it is set, well puffed-up, and browned.

**CHEESE SAUCE.** A sauce for serving with au gratin dishes, or with stewed celery or seakale. It is prepared as follows: Melt 1 oz. butter or margarine in a saucepan, stir in  $\frac{1}{2}$  oz. flour and, when smooth, add slowly  $\frac{1}{2}$  pint milk (or  $\frac{2}{3}$  pint milk and  $\frac{1}{3}$  water). Continue stirring until mixture boils, then add  $1\frac{1}{2}$  oz. grated cheese, preferably Parmesan, salt and pepper to taste, and, if liked, a little grated nutmeg. When serving an au gratin dish, mix a similar quantity of grated cheese with a tablespoonful of browned crumbs, sprinkle this over the sauce, add a few small pieces of butter, and bake the dish in a quick oven until the cheese melts and browns. *See Au Gratin.*

**CHEESE STRAWS.** These are frequently used as a savoury instead of cheese. Mix together 2 oz. flour, 3 oz. grated cheese—Parmesan if possible—and add a few grains of cayenne and salt. Into these lightly rub 2 oz. butter, and mix to a stiff paste with the raw yolk of an egg beaten up with 2 teaspoonfuls of cold water. Knead and roll out into a strip about 4 in. wide and  $\frac{1}{2}$  in. thick. Cut the mixture into narrow strips like large matches and bake them on a tin lined with greased paper in a quick oven till they are a delicate biscuit colour. They burn very easily, so need care; they are also very brittle and require gentle handling. They keep for at least a week in a tin, and can be re-warmed.

**CHEESE TOAST.** This savoury is made by boiling six almonds for 2 min., skinning and shredding them, and then frying them a light brown in a little salad oil. Coarsely chop 1 tablespoonful of chutney, put it into a small pan, and add to it the fried almonds, 2 tablespoonfuls grated stale cheese, and a little salt and pepper. Heat all these ingredients thoroughly and serve heaped up on small rounds of hot buttered toast. Small pieces of fried bread may be used instead of toast.

**CHEESE TURNOVER.** These can be eaten immediately after making, or reheated the following day. Mix together 1 oz. of boiled rice, 2 oz. of grated cheese, an egg, and 1 tablespoonful of thick cream, and season the whole with salt and red pepper. Make  $\frac{1}{2}$  lb. of pastry (q.v.), roll it out thinly, and cut it into six neat rounds. On each of these pile a tablespoonful of the mixture, damping the edges of one side of each and folding the pastry over to make semicircles. Have ready a pan of deep fat heated to boiling point, drop in the turnovers, and fry them to a golden brown, afterwards sprinkling them with salt and serving very hot.

**CHEF:** A Professional Cook. The chef is the principal cook of an hotel or restaurant, or of a house where a considerable staff is maintained. He must be a master-cook who has had experience in a first-class kitchen, and should be provided with a diploma from a recognized school. He—or she—must be able to compose a menu, and to take the principal part in or direct its preparation; he is expected to be capable of devising new dishes, and not to be entirely dependent

on the recipes of any cookery book.

It is possible to secure a complete professional training in the properties and qualities of different foods, and in the science of their preparation, at various places.

A chef's cap is made of white duck, twill, or linen. It is of no special size, and can be made by cutting a round of material 22 or 23 in. across, and pleating it into a band, 2 in. deep, and folded to the exact size of the head.

**CHELSEA BUN.** This is made from 4 oz. of flour,  $\frac{3}{4}$  oz. butter (melted), a little more than  $\frac{1}{4}$  oz. yeast,  $\frac{1}{2}$  teacupful of milk, and about 1 oz. sugar. Cream a pinch of the sugar and the yeast together, pour the milk over the melted butter, and mix all together with the warmed flour to a light dough, kneading it well. Leave it to rise, then repeat the kneading process, and roll the dough into a square. Spread it over with  $1\frac{1}{2}$  oz. currants and  $\frac{3}{4}$  oz. sugar, roll it up, and cut it into 5 or 6 pieces. Let these stand for a few minutes, coat with a little beaten egg, and then bake the buns in a hot oven for about 15 min.

**CHELSEA CAKE.** The ingredients required for a Chelsea cake are 10 oz. flour, 4 oz. butter, 6 oz. castor sugar, 5 eggs,  $\frac{1}{2}$  gill milk, and a teaspoonful baking-powder, and vanilla to taste. Sieve together the flour, baking-powder, and a pinch of salt, and cream together the butter and sugar. To the latter add the eggs, beating each in separately, then the flour, etc., and lastly the vanilla and milk. Put the mixture in an oblong baking-tin lined with two layers of buttered paper, and bake it in a moderately hot oven for about an hour.

In the meantime, prepare a filling for the cake by chopping up 2 tablespoonfuls of dried and shelled walnuts, and pounding them in a mortar with the same quantity of ground almonds, a tablespoonful of apricot jam, and a little lemon-juice and orange-flower water. Add enough sieved icing sugar to mix the whole to a smooth paste. Slit the cake into halves and put the icing between them.

Make a little white icing and pour it over the top and sides. Decorate with halves of walnuts and preserved rose or violet petals.

**CHELSEA CHINA.** True Chelsea is always soft-paste, easily marked by a knife, and as most imitations are in hard porcelain, the presence of a forged mark, either the triangle or the anchor, should not deceive.

Chelsea ware began with undecorated groups in translucent white, like skimmed milk, and passed thence to four-sided bottles and octagonal tea-ware, decorated with Aesop's fables or Japanese designs. After producing hexagonal jars, dishes in the form of birds and vegetables and the like, Sèvres and Dresden

influence introduced rich ground colours, especially pea-greens, turquoise, and the peculiar Chelsea claret, with panel paintings of pastoral scenes and Oriental birds. Besides the figures and groups, knife-handles, stick-knobs, scent-flasks, etc., were much favoured.

Careful imitations were formerly made at Coalport and Paris, and there are many inferior modern forgeries. These may often be detected by their gaudy colouring, the flesh tints of the cupids, and the tell-tale gilding of the anchor. *See* China.

*Chelsea China. Examples of the delicately coloured and gracefully fashioned old English ware. The characteristic figures represent: left, Justice, and right, Diana (Courtesy of Law, Foulsham & Cole, Ltd.)*

*For examples of Chelsea China see page 406.*

**CHELSEA PENSIONER.** The name is given to a prescription for rheumatism and gout which was obtained from a Chelsea pensioner. It has been subject to many alterations, but the following is probably the original prescription: Powdered guaiacum, 1 dram; powdered rhubarb root, 2 drams; cream of tartar, 1 oz.; sulphur, 2 oz.; and one nutmeg, grated. These powders are mixed together and then made into a paste or electuary by incorporating honey 12 oz. The electuary is taken in doses of from one to two teaspoonfuls, night and morning. *See* Rheumatism.

**CHENILLE.** The name is derived from the French word for caterpillar. Chenille trimmings and furnishing fabrics all have a certain velvetiness of appearance, and this is due to a method of manufacture which begins with the formation of a caterpillar of cut fringe.

Ordinary cloths are made by one weaving, but chenille fabrics are made by two. First of all a fabric is woven in bands of colour, and then that fabric is slit lengthwise into narrow strips, so providing the caterpillar—a furry coloured strip of fringe supported by lengthwise threads, arranged to hold the fur securely. This caterpillar is re-woven across a thinner set of threads, and the colours form the pattern seen in the completed cloth.

Chenille may be cotton, wool, silk, or other material. Cotton chenille is made into self-coloured window curtains, and their colour has a peculiar bloom, due to the method of making. Wool chenille is made into a variety of seamless Axminster carpet squares. Chenille in various colourings is also extensively used for embroidery, knitting, and crochet work.

The pile of chenille can be made either long or short.

The article is generally decorative rather than durable, although good wear is given by the best qualities if fairly treated. It should be realized that chenille is less able to stand severe treatment than velvet fabrics of more substantial construction, and the articles should be used with care, especially in cleaning. Rough handling is likely to break the light warp threads which form the support of the caterpillar or pull out the fur from its foundation.

Cotton chenille window curtains can be washed in a lather of good soap flakes; as the surface is bushy and rough, handling is to be avoided; it is advisable to steep them well, rinse thoroughly, and dry in a good current of air. Wool chenille curtains and table-covers can be dry-cleaned more safely than washed.

**CHEQUE.** A cheque is a negotiable instrument—that is, it can pass from hand to hand like cash unless it is marked "not negotiable." Thus, if a cheque is stolen or obtained by fraud, anyone who takes it in payment of an account or cashes it and does so in good faith without notice of the fraud or the theft, and before it is overdue, has a good title to it and can enforce payment. A cheque is overdue when it has been more than a reasonable time in circulation and a cheque over a week old may well be overdue.

A cheque may be made payable either to a named person or 'order,' or to a named person or 'bearer.' The payee of an 'order' cheque cannot transfer it to anyone else or obtain the money for it without writing his name on the back—'indorsing' it—but a bearer cheque passes from hand to hand by delivery without indorsement. If the person to whom a cheque is transferred is not paid by the person who transferred to him, he can sue the drawer.

If someone forges a man's signature as drawer of a cheque and his bank pays it, the bank must bear the loss, however clever the forgery; but if a man makes a cheque payable to Jones or order, and someone forges Jones's name and cashes the cheque the bank can charge it against the drawer's account. The bank is supposed to know the signature of its customers, but not the signatures of persons in whose favour its customers draw cheques.

**Crossed Cheques.** A precaution frequently taken in writing out a cheque is to cross it by drawing two parallel lines across it, thus \/. A cheque so crossed may be indorsed by the payee in the usual way; it cannot, however, be exchanged for cash at the bank, but must be paid into a banking account. If in addition the name of the payee's bank is written between the lines of the crossing the cheque can only be paid into that bank. The addition of the words "payee" to the crossing means that the cheque cannot be indorsed to any third person by the payee.

Another method of protecting a cheque is to write on it the words 'not negotiable' either with or without a crossing. If a cheque so marked is indorsed by the payee to some third person, that person and any

subsequent indorsee can have no better title to the cheque than the person from whom he received it. Thus if such a cheque is stolen or obtained by fraud, the holder cannot recover on it, even though he took it in ignorance of the theft or fraud and for value.

Always present a cheque the same day it is received if possible. A banker is bound to honour (i.e. pay) a customer's cheques drawn on him so long as he has money enough in his account. If the bank dishonours a customer's cheque when there is money to meet it, the customer can recover damages, which may be very heavy if he is engaged in trade or business.

Cheroot. See Cigar.

## CHERRIES: THE FRUIT AND ITS VARIETIES

With Methods of Preparing Them for the Table

See articles on other fruits, e.g. Apple; Plum; and for cultivation Grafting; Pruning, etc. Other uses of cherries are described in the shorter entries that follow this main heading.

The cherry tree flourishes best on well drained land, on a subsoil of sand or chalk; there, in time, it develops into a large tree and is long-lived. It may, however, be grown on ordinary soil that is well cultivated. When cherries are planted in small numbers in gardens the difficulty of protecting the fruit from birds has to be considered, for unless the trees are netted the birds will spoil the crop. For this reason amateurs should plant bush or pyramid trees in preference to standards which take up a lot of room and cannot be netted conveniently.

*Right. Cherry clusters of small red morello cherries, much used in cooking. Left. Large bunch of white hearts.*

Another detail of importance is this: all varieties of cherries are considered to be self-sterile and unless several are planted together the blossoms will not be cross-fertilised, and thus the chances of a successful crop are remote. For this reason it is useless to plant solitary cherry trees unless there are a number of others in the immediate neighbourhood.

The matter is complicated by the fact that some varieties of cherry are inter-sterile, that is to say, the flowers can be cross-fertilised only by certain other varieties.

The result of experiments has been to classify most varieties into six separate groups: those in one group will not cross-fertilise others in the same group, but they will cross-fertilise those from any other group. When making a choice of varieties, therefore, it is wise

to choose one from each of the following groups rather than two from the same group.

A. Knight's Early Black, Black Eagle, Early Rivers and Bedford Prolific. B. Frogmore Bigarreau, Bigarreau de Schrecken and Waterloo. C. Emperor Francis and Napoleon. D. Governor Wood and Elton. E. Kentish Bigarreau.

Other cherries are less difficult of management, and if a mixed collection is planted satisfactory crops may be expected. Among them are Noble, White Heart, Black Heart, Florence and Geant d'Hedelfingen.

Bush and standard cherry trees are grown in the open garden, standards at 30 ft. apart, bushes at 12 ft. apart. Fan-trained trees are suitable for planting against a wall facing south, west or east: they should be 18 ft. apart.

The sweet cherries, which comprise all those varieties named above, bear their fruit chiefly on spurs—short, sturdy shoots bearing blossom buds. The principal pruning is done in early August when summer laterals or side shoots which are likely to crowd the tree are stopped at about six leaves from the base. These shoots are again shortened in winter.

As cherry trees become older fruit spurs usually form freely and little pruning is needed. In fact, severe pruning does harm and may lead to an attack of "gumming."

Standard cherry trees need less pruning than bushes or pyramids; the branches are thinned out in autumn to prevent overcrowding. The growth of cherry trees on a wall must be limited and the summer and winter pruning of the side shoots is necessary. Cherry trees which grow luxuriantly but do not produce fruit should be lifted and root pruned early in November; that is a better practice than pruning the branches severely.

The morello cherry, which is so valuable for cooking purposes, flourishes best on a west or north wall. It needs quite different pruning from the sweet cherries. This takes place in late summer as soon as the fruit is gathered, and consists in cutting out parts of the old shoots to make room for those of the past summer's growth.

**Pests and Diseases.** Black fly usually infests the leaves of cherry trees in early summer. They should be sprayed frequently with an insecticide immediately the pest is first seen. Gumming is a malady which is difficult to deal with. Its presence is indicated by an exudation of a sticky gum-like substance from the branches. Planting in wet, heavy, ill-drained land and severe pruning are pre-disposing causes. If the silver leaf disease, recognized by the silvery grey appearance of the leaves, attacks a cherry tree it ought to be uprooted and burnt.

**How to Cook.** The cherry, whether it is fresh, preserved, or crystallised, is a favourite fruit with cooks, and may be used in a variety of ways. It is best

stoned before being cooked. If a cherry-stoner is not at hand, the fruit may be stoned by pushing a smooth, thick quill through each cherry from the stalk end. In this way the stone is pushed out and the fruit left intact.

To stew cherries, let them simmer gently until tender in an enamelled pan or casserole, with, to every pound of fruit,  $\frac{1}{2}$  pint water and  $1\frac{1}{2}$  tablespoonfuls sugar.

Stuffed cherries make pretty dessert sweets, and are prepared by rolling some almond paste into neat little balls, making a slit in the cherries, and inserting a ball in each. The cherry is then rolled in the hand to make it round, sprinkled with castor sugar and put into a tiny paper case.

Owing to their decorative appearance, cherry sweets are liked for parties. Cherry jelly is a favourite. To prepare this, wash and pick 1 lb. cherries, remove the stones, and put the fruit in a saucepan containing  $\frac{3}{4}$  pint water and 6 oz. sugar. Simmer these until the cherries are tender, then strain and add water to make up to the original quantity. Put in the strained juice of half a lemon, together with  $\frac{3}{4}$  oz. gelatine, and stir the whole over the fire until the gelatine has dissolved.

Strain all the juice into a basin, and when it is cold and nearly setting, add enough cochineal to produce a pretty pink colour. Put the cherries into a glass dish, pour the liquid over them, and then leave the jelly to set in a cold place. This may be decorated with cream, angelica, crystallised violets and cherries. A good blancmange for children's parties is made from a quart of milk, 4 oz. each cornflour and cherries, 6 oz. sugar, and a little vanilla essence. Put the milk into a saucepan and boil it, then add the cornflour mixed to a smooth paste with a little extra milk. Keep the whole over the fire until it thickens, and cook it very gently for 5 to 8 min., stirring all the time, then add 4 oz. sugar and a few drops vanilla essence.

*Cherry Jelly, covered with cream and ornamented with pieces of angelica.*

Stew the cherries in sufficient water to cover them until they are tender, adding another 2 oz. sugar. Rinse a mould with cold water, and arrange a few of the cherries at the bottom; then pour in some of the cornflour mixture, and lastly the rest of the cherries mixed with the remaining cornflour. Leave the blancmange to set.

Another decorative party dish is made from 1 lb. cherries, 3 gills water, the juice of  $\frac{1}{2}$  a lemon, 4 oz. sugar,  $\frac{3}{4}$  oz. gelatine, 1 gill cream, and a little cochineal or carmine. Remove the stalks, wash the cherries thoroughly, and then cut them into halves and take out the stones. Put them in a pan with the water, sugar, and lemon juice, and simmer the whole until tender. Then strain off the juice and measure it, and if it is less than 3 gills make up the amount with water, afterwards putting it into a pan with the gelatine, and stirring it over a slow heat until it has quite melted.

Add a few drops of cochineal or carmine, put the cherries into a border mould rinsed out with water, and strain the juice over them, leaving the whole in a cold

place to set. Turn out into a glass dish, and fill the centre with whipped cream, sweetened and flavoured with vanilla., A few whole cherries may be placed round the top of the mould.

**CHERRY BRANDY.** This is a cordial which is good when home-made and when the best materials are used.

A simple method is to fill a bottle  $\frac{3}{4}$  full with cherries, not overripe and using half morello and half black cherries; pour in brandy to the neck, cork it up well, and let it stand for a month. *See Brandy.*

*Cherry Cake, cut in half to show the glacé cherries and candied peel with which it is flavoured.*

**CHERRY CAKE.** By those who do not care for currants cherry cake is generally appreciated. To make it, sieve together  $\frac{3}{4}$  lb. flour and 2 level teaspoonfuls of baking-powder. Beat  $\frac{1}{2}$  lb. butter or margarine and the same quantity of castor sugar to a soft cream, using less butter if a plain cake is desired. Into this mixture whisk 3 beaten eggs, then fold in the flour lightly, adding 1 oz. chopped candied peel and 2 to 3 dozen glacé cherries cut into halves or quarters and well floured. Stir in about 3 tablespoonfuls milk, and bake the cake in a tin lined with greased paper in a moderately hot oven for about  $1\frac{1}{2}$  hours. This mixture might also be baked in small fancy patty pans for about 20 min. *See Cake.*

**CHERRY CIDER.** The ingredients required are  $\frac{1}{2}$

lb. stoned, ripe cherries, a pint of boiling water, and a thin piece of lemon rind. Bruise the cherries, pour the boiling water over them, and then add the lemon rind. A few bruised cherry-stone kernels will be found to improve the flavour greatly. Soak the fruit in this way for 4 or 5 hours, then strain and sweeten the liquor with 2 oz. of sifted sugar before bottling it.

**CHERRY JAM.** As it is deficient in pectose, the substance that forms jelly, jam made with cherries requires the addition of apple or red currant juice to make it set. To each lb. of sound fruit allow  $\frac{3}{4}$  lb. of sugar, 1 gill of red currant or apple juice, and two shredded sweet almonds. Put the sugar and the fruit juice in the preserving pan, and let it dissolve slowly by the fire.

Boil the mixture for 5 min., add the ripe, sound fruit, removing the stalks and as many stones as possible, and lastly add the shredded almonds. Boil the jam gently until the fruit is tender, and the juice jellies when tested on a plate. Keep it well stirred and skimmed during the boiling. When cooked, pour off into dry, warmed jars, and tie down at once.

Cherry Laurel. *See* Laurel.

**CHERRY PIE** or Heliotrope. A non-evergreen shrub with fragrant lilac-coloured flowers, the cherry pie or heliotrope grows fast from seed sown in heat towards the end of winter, and can therefore be used in beds the same season. The seed may be sown in a box or pan put in a warm glasshouse in February, and the plants pricked off and hardened in a cold frame, then planted out in June. Any fertile, friable garden soil suits them.

Cuttings can be made of the young shoots in spring, inserted in sandy soil and placed in heat. Curing the winter the plants need very little water, but must be given air.

Young plants bought in small pots in June should be planted in a sloping position about 18 in. apart, and the side shoots pegged down from time to time as they extend.

The greenhouse culture of cherry pie is easy. A suitable soil consists of loam with a quarter of leaf-soil, a quarter of spent hotbed manure, and a fair amount of sand. Propagation is either from seed or by cuttings of the young shoots in spring.

When planted on a warm greenhouse border, cherry pie will very quickly cover considerable space on a wall, and it will scent the whole house. All the attention it will need will be judicious watering, periodical tying-in, and occasional pruning. Standard plants can be secured by depriving the main stems of strong plants of all lateral shoots, and growing on until the plant has reached the requisite height.

*Cherry Pie. Plant of heliotrope, of the Miss Nightingale variety, in full flower.*

The following are some of the best varieties: Miss Nightingale, violet blue; Rose Glair, dark blue; White Lady, palest blue; President Garfield, mauve-purple; Lord Roberts, dark blue; and The Speaker, violet-purple.

**CHERRY PUDDING.** To make an ordinary cherry pudding, grease a small pudding-basin, sprinkling on the bottom of it a thin layer of brown sugar to form a caramel, and lining the basin with a good suet crust. (*See* Apple Pudding.) Remove the stones and stalks from 1 lb. cherries, and fill the basin with them, adding 2 or 3 tablespoonfuls of sugar. Pour in a little water to moisten the fruit, and then cover it with a layer of suet-crust. Bake the pudding in a moderate oven for 1½ hours, and turn it out of the basin before serving.

**Cherry Sandwich Pudding.** This is made by parboiling 1 lb. of black cherries in a syrup made by boiling 3 oz. granulated sugar in a saucepan, with a gill

of water.

*Cherry Pudding. A baked caramel-covered pudding made with cherries and suet crust.*

When the cherries are tender, drain them, and reserve the syrup. Then beat 5 oz. margarine and the same quantity of sugar to a cream, add a pinch of ground cinnamon and the beaten yolks of 2 eggs, and stir in 5 oz. breadcrumbs, 4 tablespoonfuls of milk, and the stiffly whisked whites of the eggs. Put a layer of this mixture in a greased pie-dish, and on this place a layer of cooked cherries, then some more mixture, and so on until the dish is full. Bake in a hot oven for ½ hour, then turn it out on to a hot dish, and pour the syrup over it.

*Cherry Sandwich Pudding served with the syrup resulting from parboiling the cherries.*

**CHERRY WOOD.** One of the chief uses for the wood of the cherry tree is in making tobacco pipes. It is valuable also for turned and fancy articles, and in small cabinet work. The colour of cherry wood is brown with a reddish tinge; it has a smooth and fine grain, easy to work, and takes a good polish. It is hard, but not very durable as it splits rather easily. *See* Pipe.

**CHERVIL.** The kind mostly grown is the common chervil, the aromatic leaves of which are used for salads and garnishes, particularly those of the curled variety, which are more crisped. The chervil is an annual, and thrives in any ordinary soil, producing leaves fit for gathering in about two months from the time of sowing. It may be sown successively from March onwards, and thinned to about 6 in. apart.

**CHESHIRE CHEESE.** Both as regards texture and flavour, Cheshire cheese possesses distinct characteristics, for while it is very open-grained it is yet mild, soft and full in flavour. It is perhaps the softest of the hard-pressed varieties. There are three types of Cheshire cheese, known as early ripening, medium ripening, and slow ripening. The cheese may also be coloured or uncoloured. *See* Cheese.

## CHESS: THE PIECES AND THEIR PLAY

### First Principles of an Ancient Game

The game of chess is played between two opponents, moving in turn, on a board of 64 squares, arranged in 8 rows of 8 squares each. These squares are coloured alternately white and black (at times other colours, but always conventionally called white and black); and there must always be a white square in the corner to

the right of each player. The opponents have 16 men each (also known as white and black) on the two rows of squares nearest to them, namely 8 pieces on the back row and 8 pawns on the row just in front. This is the position when a game starts.

The pieces on the back row are of five different kinds. The king and queen stand in the centre, the queen being on a square of her own colour; a bishop next each of them; a knight next each bishop; and a rook (or castle) next each knight. The pieces on the king's side of the board are known as king's bishop, king's knight, king's rook; the pieces on the queen's side of the board as queen's bishop, queen's knight, queen's rook. The pawns, who occupy the next row to the back one, are called after the pieces standing behind them—king's pawn, king's bishop's pawn, commonly written KP, KBP, etc.

The notation of the chess board that is current among English-speaking peoples is derived from the names of the pieces, each vertical row, or file, being called after the piece standing on it. Thus, in Fig. 2, white's extreme left-hand file is the queen's rook's, or QR, file. The squares on which the pieces originally stand are QR1 (or QR square), QKt1, and so on; the squares on the next horizontal row, or rank, are QR2, QKt2, and so on. From black's standpoint the figure is reversed, so that his Q side pieces are to his right, his K side pieces to his left. A move is recorded, in this notation, in the form K—K2, Q—QR4, P—K3, etc., indicating both the man moved and the square to which it moves.

*Chess. Fig. 1. Board set out with men placed in position ready to start the game.*

The theoretical object of a game of chess is the capture of the hostile king, which brings the game to a close. When the king is liable to be captured on the

opponent's next move, he is said to be in check; and if he cannot move out of check, he is said to be mated, and the game is over. Now and again situations arise where neither king is mated and the game has no decisive result.

All the chessmen alike capture an opposing man by being put down on the square occupied by that man, which is then removed from the board; but there is a considerable variety in the nature of their moves. The king has the shortest and simplest move, being one square only in any direction—horizontal, vertical, or diagonal. In Fig. 3, supposing the king stands on the square marked X, he can move to any of the dotted squares immediately surrounding it. As he cannot be captured, however, without ending the game, it follows that he cannot move into check and cannot stand on a square next the opposing king.

The queen's move is a prolongation of the king's move in each direction up to the edge of the board. Standing on X, she can go not only to each dotted

square, but also to any of the squares along the arrows shown in Fig. 3. The rook has the horizontal and vertical moves of the queen, but the bishop has her diagonal moves only.

Neither queen, rook, nor bishop has the power of jumping over a piece, whether friendly or hostile. The knight, on the other hand, can. The knight's move may be roughly described as one square in a horizontal or vertical direction, followed by one in a diagonal direction away from where he previously stood. Thus, in the left-hand section of Fig. 4, if the knight stood at X, he could move to any of the dotted squares in a circle round it, regardless of whether the squares immediately next him were occupied by friendly or hostile men. From this jumping power of the knight it follows that in the original position of the men (Fig. 1) the knights alone of the pieces can move, the others having to wait until the pawns have been moved.

The pawn's ordinary move is one square forward in a vertical direction. It does not however, capture an opposing man in this way, but by a move one square forward diagonally. Thus if a pawn stands at X in the right-hand section of Fig. 4, its ordinary move is to a, its capturing moves are to b or c. On its first move in the game each pawn has the privilege, at the player's option, of a double move, i.e. to d in the diagram. Both the single and the double move of the pawn are dependent on the absence of any obstruction in the path. There is also another limitation to the double move. If, in the diagram, a hostile pawn (but only a pawn, not a piece) stood on either of the squares marked e and f, then, in spite of the fact that a pawn on X moved to d, the hostile pawn could capture it on a, before it reached d. This is called taking en passant, or in passing. On reaching the further side of the board in safety, a pawn becomes promoted to queen, rook, bishop, or knight, at the option of the player.

*Chess. Fig. 2. Notation of the board usually adopted for describing moves in the game.*

The move known as castling is a joint move of the king and one of the rooks. It can only occur once in the game on each side, and then only if neither king nor rook has moved previously and no piece stands between them. This operation consists in bringing the rook up to the near side of the king, and simultaneously jumping the king over the rook to the square next beyond him. In this the king may not pass over a square where he would be liable to capture.

In power the queen is easily first; the rook is second, the bishop third, but only a little, and that not always, above the knight (which in certain positions, indeed, is the more powerful of the two pieces); while the pawn is the weakest of the chessmen, with the exception that its potentiality of promotion even to a queen gives it a force much above its normal. In the absence of a queen on the board, a pawn which cannot be prevented from queening is obviously most powerful as compared with the remaining pieces. Owing to the peculiar feature of the king, whose capture would end the game, his value cannot well be estimated.

Chess. Fig. 3. Diagram showing possible moves of the king, queen, rook and bishop from X. Fig. 4. Left, moves of a knight; Right, those of a pawn.

**Types of Opening.** There is no royal road to the openings at chess; and, though there are many excellent text-books, it is of little use to learn by heart the variations which they give, without understanding the principles of sound development. Now development means getting the forces into play where they will (1) have increased powers and (2) restrain the powers of the enemy's forces. The advance of the two central pawns releases both bishops and the queen. The knights can come out independently of the pawns, and so the way is cleared for the rooks to operate in the centre, the king being got out of the way by castling. Thus we might get such a system of developing moves for one side as P—K4, P—Q4, Kt—KB3, Kt—QB3, B—QB4, B—KB4, castles, Q—K2 (or Q2), QR—Q1, KR—K1, when every piece would be developed. But clearly both sides could not deploy their forces thus without coming into direct conflict in the centre of the board. The alternation of moves between the two must modify the development. A typical opening is brought about as follows: 1 P—K4, P—K4; 2 Kt—KB3, Kt—QB3; 3 B—B4, B—B4; 4 P—Q3, P—Q3; 5 Kt—B3, Kt—B3. This is a variation of the opening known as the Giuoco Piano, or Slow Game. It is optional now for both sides to castle, to bring out the Q and QB, and to move both rooks into the centre; but such procedure would not necessarily be the best.

A very different type of opening is seen in the various gambits. A gambit implies the sacrifice of a pawn, and sometimes more, in the opening. Here, for instance, is the Muzio Gambit, as illustrated in a game played by Morphy at the age of 20: 1 P—K4, P—K4; 2 P—KB4, P x P (i.e. P takes P); 3 Kt—KB3, P—KKt4; 4 B—B4, P—Kt5; 5 Castles, P x Kt; 6 Q x P, Q—B3; 7 P—K5, Q x P; 8 P—Q3, B—R3; 9 Kt—B3. White has given up a knight and a pawn for the sake of quick development and a very threatening attack, against which any slip by Black may lead to disaster.

Nowadays neither of these forms of the opening is in favour with the leading masters at chess; but they serve best as examples of two extremes in opening tactics. Modern practice devotes more attention to what are known as the queen's side openings, beginning with 1 P—Q4, instead of 1 P—K4; while among the king's side openings the Ruy Lopez (beginning 1 P—K4, P—K4; 2 Kt—KB3, Kt—QB3; 3 B—Kt5) retains a popularity which it has had for nearly half a century. Both of these methods of commencing the game are somewhat intricate. J. H. Blackburne recommends for the beginner the Scotch game (1 P—K4, P—K4; 2 Kt—KB3, Kt—QB3; 3 P—Q4, P x P; 4 Kt x P). The openings are intended to put the player in a good position for the middle game which, is the principal part of a chess match.

**CHESS BOARD: How to Make.** Fig. 1 shows a chess board which can be inexpensively made. The base of the board should be of three-ply wood surrounded by a fairly bold moulding; the base is rebated into the moulding, and the latter is mitred at the corner, while the face of the board is covered with the chequered playing squares.

*Chess Board.*  
Figs. 1-4. Diagrams of board completed and in process of making.

With the playing space formed with 1½ in. chequered squares the base will be 1 ft. square, in addition to which allowance must be made for rebating the base into the moulding, so that the piece of three-ply wood required for the base must be 12½ in. square, and it should be about ⅜ in. thick. The playing space consists of eight rows of chequered squares with eight squares in each row, sixty-four in all. Half of the

squares must be cut from a light wood, and the other half from a dark wood. Holly and ebony will give the best effect.

To cut the chequered squares accurately and quickly, provide five strips of light wood, about 14 in. long by 1½ in. wide by ⅛ in. thick, and four dark strips of similar

dimensions. The strips should then be glued up in the order shown at Fig 2. After the glue is dry, one end of the glued-up strips should be cut quite square, and from it eight strips 1½ in. wide are cut, from which the complete playing space may be formed. The chequered strips are fixed to the base with glue as shown at Fig 3, care being taken to glue the edges of the strips together as well

as to glue the strips to the base. When the chequered strips are arranged correctly it will be found that there will be a surplus light square at one end of one strip and at the opposite end of the next strip, and so on, but these must be removed before the strips are glued to the base.

The moulding, which is mitred around the base, should be 1¼ in. wide by 1 in. deep, and of a section similar to that shown at Fig. 4. Mahogany could be used for the moulding, and a piece of the section shown could be very easily worked by hand. A rebate or a groove is cut in the inner edge of the moulding, into which the base fits; the corners are mitred, and the moulding is fixed with glue. The best method of finishing the board will be by french polishing.

**CHEST: In Human Beings.** The important part played by the chest is sufficiently indicated by its position and the organs which it contains. Ailments of the chest are of common occurrence and injuries to it may involve the lungs or the heart, and call for surgical treatment.

In men chest measurement is regarded as a test of strength and stamina. Recruits for the army and navy, for example, must reach a certain standard in this respect. The chest measurement in most men varies from 33 to 40 in.

This region may be the seat of aneurism and of various tumours. Injuries of the chest may be slight and have no worse consequence than a bruise or a broken rib; or they may be severe and result in damage to the

lung, the heart, or the covering membranes. All severe injuries require the attention of a surgeon. Until he arrives it is important that the patient should be kept warm, and in a state of complete rest.

First aid consists in tying a broad-fold triangular bandage round the chest, the middle of the bandage being placed over the broken ribs. A similar bandage is then applied overlapping the first above or below, depending on the site of the fracture. A broad strip of flannel or a soft towel may be used instead, and these are fastened with safety-pins. The object is to restrict as far as possible the movements of the chest, but it is important that the bandage should not be firm enough to hurt.

Probably the most common cause of pain in the chest is flatulent indigestion, and this often erroneously leads the sufferer to believe that his heart is affected. It is a mistake for anyone to try to make his own diagnosis. The explanation of the cause of such pain must come from the doctor; in the meantime the patient should be placed at rest in the easiest position, and hot fomentations or a hot-water bag applied over the painful area.

**Care Of the Chest.** Besides indicating a good physique, a deep, well-expanded chest is a help to wearing clothes with distinction. Chest development by proper breathing can be augmented by the following exercises:

1. Stand with head bent forward, shoulders and arms relaxed; raise arms sideways and straighten back, letting the head go back with mouth open. The effort of the movement is concentrated *between* the shoulder blades, and the expansion of the chest. Repeat 6 times.
2. Kneel and sit back on heels with hands clasped behind, head well back and chest expanded. Still keeping head well back, bend the upper body forward until the chest almost touches floor in front of knees. Then relax upper body completely. Gradually straighten the back, the chest and head being the last parts to be completely raised, and finish with chest well expanded.

Exercise with a bamboo cane held behind the shoulder blades is helpful, especially if seated tailor fashion on the floor, as this position renders it impossible to hollow the back, and the shoulders must do their proper work in helping chest expansion. Send the cane to the right by straightening the right arm, and then to the left by straightening the left arm. Then raise the cane with both hands over the head and bring down to first position. *See* Adenoids; Bandage; Breathing.

#### CHESTS: ANTIQUE AND MODERN PIECES Information of Value to both Connoisseur and Woodworker

The reader may usefully consult the many entries that give practical advice to the amateur woodworker, e.g., Amateur Carpentry; Cabinet; Cabinet Making; Joint; Mortise

The chest is a development of the box, being really a large box with a hinged lid. In addition to their obvious use for holding clothing and other personal and household possessions at home and when travelling, chests were often, in the Middle Ages, used as seats.

These chests, however magnificent, were essentially boxes, but later they were raised from the ground by the addition of feet, and were used less than formerly for travelling purposes. Some were beautifully carved and ornamented with heraldic designs. Another class of chests, known as tilting coffers, were carved with representations of tournaments, or with figures of mythical monsters or heroes of chivalry. Examples are in the Victoria and Albert Museum, S. Kensington.

Existing antique chests are chiefly of the 16th, 17th and 18th centuries, although there are a few of even earlier date, at which time they were a common article of furniture, serving the purpose of cupboards. Some of them were marriage chests, of which there are magnificent examples inlaid with ivory and precious woods. English chests of the 17th century have often panelled fronts and sides, and are ornamented by carvings.

*Chest: three antique examples.*

1. Oak chest, English, 13th century, from a church in Hampshire.

2. Late 17th century oak coffer.

3. Heavily moulded oak chest, inlaid mother-of-pearl and ivory, dated 1660.

(1. Victoria & Albert Museum, S. Kensington; 2 and 3. courtesy of Gill & Reigate, Ltd.)

In many, architectural detail, especially of wainscoting, was followed; thus earlier chests were carved in linenfold pattern, while the Jacobean chests often reproduce the pilastered and recessed oaken mantelpieces of that time. The three antique chests illustrated are of oak, the wood chiefly used for them in the 16th and 17th centuries and earlier, while mahogany and walnut were the woods selected for chests in the 18th. Fig. 1 is a finely carved specimen of English work, dating from the 13th century. Fig. 3 is a beautiful piece of work. This oak is

heavily moulded and is inlaid with mother-of-pearl and ivory. Fig. 2 is a coffer of late 17th century make showing a plainer style. It will be noticed that it is well raised on feet, and also that in the lower part are two drawers, marking the development to chests of drawers (q.v.) which then were ousting the box chests.

**Making a Chest.** Fig. 4 shows a chest which can be made by the amateur, and will be suitable for the hall or for a dining room. The wood should be oak, stained to a rich nut-brown colour and oiled, waxed, or french polished to harmonise with the surrounding furniture. In a quieter way some suggestion of an old effect can be obtained: by finishing with red polish mixed with a small quantity of vegetable black. Those who prefer to make use of some other wood may be able to serve their purpose with birch or American whitewood, or something might be done with satin walnut, ash, or pine as substitutes. The length of the top is 4 ft. 3 in. by 1 ft. 10 in., and height over all a full 2 ft. Size of box is 4 ft. by 1 ft. 9 in. net. An elevation sketch of front and of end is shown at Fig. 5, and should be taken in conjunction with the sketch of parts at Fig. 7. The uprights (A) should finish 2 ft. by 3 in. by 3 in. if to be fitted as posts, but this part is frequently met with finished to a thickness of 1¼ in. to 1½ in. net. They will be mortised for tenons on front rails to enter well home and be pinned, and the corresponding rails on ends are entered in a similar manner. Between the mortises the uprights are grooved for panels ½ in. deep. The faces of uprights and rails (shown plain in Fig. 4) are often treated with scratch beads (Fig. 5).

The top rail (B, Fig. 7) is fitted from a piece 4 ft. by 4 in. by 1½ in. or ¾ in., to be grooved for panels and for the entry of the inner uprights. It has shouldered tenons at each end. The bottom rail (C) finishes 3 in. by 1½ or ¾ in. The two inner uprights (D) take pieces 1 ft. 4 in. to finish 3 in. by 1½ in. or ¾ in., and are stubbed to rails top and bottom. The three panels (E) are allowed a size of 1 ft. 4 in. by 1 ft. 2 in. by ⅝ in. net for fitting. These may be treated as plain or bevelled.

4

*Chest. Fig. 4. Simple dining room chest which can be made by following the instructions given. (For details see page 415)*

The detail for the panels shown in Fig. 4 is one that is easily mitred up of ¾ in. mould.

The two upper end rails (F) are fitted from pieces 1 ft. 9 in. by 4 in. by 1½ in. or ¾ in. The bottom rails (G) finish 3 in. wide to agree with the front. Both are tenoned to uprights and pinned with panels grooved in, taking 1 ft. 9 in. by 1 ft. 4 in. by ⅝ in. net. The back is rebated into position behind and screwed. It can be made up of three boards with the grain reversed and

glued up, or (preferably) tongued and glued, using hardwood tongues. The bottom is pieced up in the same manner and rebated to enter housings in front and ends. It may either be screwed or glue-blocked under.

The lid should be tongued together, if made up of lengths to the required width, 1 ft. 10 in.; a lining (Fig. 6) screwed on under can lap over the top edges of box at front and ends and serve as a stop for drifting dust. The top, however, is best framed up in the manner indicated with three panels at Fig. 8. For this the stiles (H) take two pieces 4 ft 3 in. by 3 in. by  $\frac{7}{8}$  in., and rails (J) four pieces 1 ft. 8 in. by 3 in. by  $\frac{7}{8}$  in. to be mortised and tenoned together and pinned or wedged. The framework is also grooved for the panels to be fitted flush, Fig. 9, allowance for panels being 1 ft. 6 in. by 1 ft. 3 in. by  $\frac{5}{8}$  in. Fig. 13 shows fitting of back, and Fig. 14 the jointing of front and end panels to posts and inner uprights. (*For working drawings see page 415*)

**A Simple Stand.** Those who would prefer to raise the chest above the ground, in order that the top may form an attractive side table, may construct a stand similar to that indicated at Fig. 10. The idea is useful, too, for anyone already in possession of a chest of which the lower part is dilapidated, or where the plinth or legs have been shortened, making the whole thing rather squat. Such a stand can be 12 in. high, and made with a wel top, so that the chest may drop in snugly. Details for making this stand with secure joints for the rails and legs, are shown in Figs 11 and 12.

Legs (or uprights) take four pieces 12 in. by  $1\frac{1}{2}$  in. by  $1\frac{1}{2}$  in., or may be finished  $1\frac{3}{8}$  in. if preferred. They may stand four square on the ground, but are indicated at Fig. 10 as with  $2\frac{3}{4}$  in. flat ball feet doweled in, of the type known as bun shape. The rails can be allowed 4 ft. 3 in. by 3 in. by  $1\frac{1}{2}$  in. for front and back, and 1 ft. 10 in. by 3 in. by  $1\frac{1}{8}$  in. for ends, to be dovetailed into uprights and be stiffened with braces in the angles as at Fig. 12. The brackets under provide some little finishing effect. They can be cut 3 in. by 3 in. by  $\frac{7}{8}$  in., to be doweled and screwed into position. The mould, forming a lip edging, behind which the chest (less its legs) will bed, can be a  $1\frac{1}{4}$  in. by  $\frac{3}{4}$  in. section, glued and screwed as shown in Fig. 12. The cutting list is given in the previous page.

## THE CHEST OP DRAWERS

### Construction, Renovation and Small Repairs

See further Cabinet; Drawer; Dressing Table; Tallboy; Wardrobe; also the preceding article Chest, and the entries dealing with the methods of the amateur woodworker

A chest of drawers is in essence a chest into which drawers have been fitted. For it the chest in ordinary use was made larger and the front cut away to admit the drawers.

The early chests of drawers were of oak, and of walnut, veneered on oak or pine, dating from the time of William and Mary and Anne. The beautiful effects of

the drawer-fronts were obtained by cutting and laying the wood in various directions. Later in the 18th century mahogany became fashionable for these chests, and many fine specimens are in that wood. They are made by Sheraton, Chippendale and other great designers.

Of the two illustrations of antique chests given herewith, the first is of pine and oak veneered with walnut and lignum vitae. It follows the conventional style in having two small drawers and two larger ones in the upper part of the piece, but the bottom is more elaborate than is usually the case. The chest has there a further drawer, and the whole is supported on five beautifully carved legs, three in front and two behind, which in their turn rest on a plinth or stand. On each drawer are brass escutcheons and drop handles. The second is an example of Dutch work of about the same date. The supports of old chests of drawers vary. Some are supported on a plinth and carved legs respectively, but others rest upon short legs of a plainer kind.

**A Man's Dressing Chest.** The type of chest of drawers illustrated in Fig. 3 requires only a small space, and will be of special use to the man who likes a convenient glass for shaving. The chest is 3 ft. 6 in. high, having a useful set of drawers ranging from 4 in. to 7 in. deep. The glass is thus at a suitable height, and the whole article is not only neat and compact, but easily made by those who have an average amount of cabinet-work skill. Oak is the most suitable wood to use, or, if mahogany be preferred, the lower corner brackets should be left out and the leg portion tapered.

The four posts should be prepared first. These are  $1\frac{1}{2}$  in. square, and are mortised to take the side rails and drawer rails, the top front rail being dovetailed as in Fig. 6. This diagram shows the top portion of a front leg with the top removed, the view being taken from inside the job. The posts are grooved to take the side panels, and the back legs are also rebated for the back as in Fig. 5. The ends are glued together first and allowed to set before glueing the remainder. If the job is to be stained a dark colour, it is advisable to put a little stain round the edges of the panels, so that in the event of their shrinking no white edges will become visible. The top dividing drawer rail is stub-tenoned between the two top rails, and all the rails except the bottom are grooved to take the dust-boards, as in Fig. 6. The bottom one is rebated to take the bottom board, and is 1 in. thick. The drawer rails measure  $2\frac{1}{4}$  in. by  $\frac{3}{4}$  in., and the runners  $1\frac{3}{4}$  in. by  $\frac{3}{4}$  in.

Having put the carcass together, the runners may be fixed. These are also grooved for the dust-boards, and are fixed at the front by stub-tenons fitting into the grooves of the drawer rails (Fig. 6), and at the back are screwed to the back posts around which they are cut. Note that these runners are in no way fixed to the side panels. To the tops of the runners the guides are screwed, being lengths of 1 in. squares, as Fig. 6 shows.

	Long ft. in.	Wide in.	Thick in.		Long ft. in.	Wide in.	Thick in.

## CHEST.

Figs. 5-14. Working drawings of the chest shown in Fig. 4.

### How to Make the Drawers

The drawer fronts finish  $\frac{7}{8}$  in. thick, and the sides and back  $\frac{5}{16}$  in., and all the parts are fitted separately to size. Fig. 7 shows the correct setting out for the dovetails. An important point to notice is that the groove for the bottom is contained within the lower dovetail, so that this will not show a gap when the drawer is together. The total width of the back measures from the top of the groove to the dotted line (Fig. 7), the top being rounded as shown. The bottom is fixed in a groove run along the drawer front, and at the side in grooved fillets with a rounded upper edge, as in Fig. 8; these are glued to the drawer sides. At the back, the bottom is screwed or nailed to the drawer back. It is usual to allow the bottom to stand out from the back, as shown, so that if the bottom shrinks the screws can be taken out and the bottom pushed forward.

The top is moulded at the front and sides, and overhangs 1 in. at the back to allow for the wall skirting. It measures 2 ft. 4 in. long by  $19\frac{3}{4}$  in. wide, and is fixed by screwing from underneath. The addition of the lower angle brackets (glued and screwed) completes the lower part of the chest. The mirror supports are  $1\frac{1}{8}$  in. square, and are tenoned into the top, the rail being dowelled into them; also the side brackets. The frame is mortised together and the glass fixed with wedges glued to the rebate (Fig. 9). The back board is screwed on, as shown. The glass swings on special brass movements made for this purpose. The handles of the drawers, if the job is in oak, should preferably be of the drop type.

**Converting a Painted Chest.** An old painted chest of drawers such as that illustrated in Fig. 10 is to be found in almost every house. If the paint has become worn, a practical plan is to strip the paint off and mount the chest on a stand, decorating the drawer fronts with mitred mouldings, and thus producing an attractive Jacobean chest (Fig. 11).

**Fig. 3.** Chest of Drawers.

*Fig. 3. Compact set for a man's room, the whole surmounted by a shaving mirror.*

*Figs. 4-9, Diagrams showing details of construction.*

**Fig. 7**

**Fig. 9**

**Fig. 8**

The plinth is usually attached with glue and nails, and strengthened underneath with corner blocks. These latter should be knocked off with a chisel before removing the plinth. The old handles, too, should be taken off. The paint should then be cleanly stripped off, using one of the well-known strippers. Every bit of paint should be got off, as when later the job is stained any paint left on would prevent the stain from taking.

Any necessary repairs may now be done to the chest, including filling in the holes left by the removal of handles, and the whole thoroughly glass-papered, finishing off with No. 1 1/2. Mouldings can be purchased at a cabinet maker's store; either oak or deal is suitable. For the chest illustrated about 60 ft. would be required. Mark out on the drawer fronts the position of

the mouldings, and at the jutting portions glue on small slips of wood  $\frac{3}{16}$  in. thick, round which the moulding is mitred (Fig. 14). The moulding is glued and pinned, and care must be taken to remove all surplus glue. The drawer stops must be removed and fixed further back to allow the moulding to stand only slightly forward from the carcass of the chest.

The stand may now be proceeded with. Allowance must be made at the front and two sides for the moulding shown (Fig. 13), inside which the chest stands. The stand is mortised together as in Fig. 12, using 2 in. stuff for the top rails and  $1\frac{1}{2}$  in. for the bottom rails. When this has been glued together and is quite dry, clean off the top and place the chest upon it in the required position, and fix the moulding round; this will ensure its fitting accurately. The moulding should be glued and pinned to the stand only, so that the chest is always free to be lifted off. The job is now ready for staining; dark walnut water stain is the best to use. Afterwards polish it with wax, and finally fix the brass drop handles.

**Repairing a Chest.** The illustration (Fig. 15) is an example of an old mahogany chest of drawers of the general type that any amateur might be called upon to repair. The chest top is veneered with one sheet of mottled mahogany, the grain of which runs lengthways of the chest. The veneer is laid upon a yellow pine top (or core, as it is termed), and this top has clamped ends similar to a drawing board. The edges of the top are cross-banded by glueing on  $\frac{3}{8}$  in. solid mahogany strips, these being afterwards rounded off to give a finish to the work.

The carcass ends are of solid mahogany of the straight-grained variety, commonly called bay-wood. The front of the chest immediately under the top shows a wide bearer rail, veneered with mahogany curl veneers, jointed up to obtain the necessary width across the carcass front. The drawers have their fronts veneered with mahogany curls, and small projecting cock beads have been fitted into rebates at the ends, but are simply glued on to the top and bottom edges. The plinth or lower part of the chest has been made in a separate portion, screwed to the carcass.

One of the commonest repairs to an old chest of drawers is the renewal of a cock bead which has accidentally been damaged by splintering a piece out of the drawer, or the replacing of a small portion which has been broken during removal operations. Fig. 16 (A) shows a new length of beading made out of a piece of old mahogany. It is ready to be glued to the bottom, and its mitred ends have been cut and tried in position. The lower edge of the drawer should be carefully scraped to remove all trace of the old glue. The necessary pressure to hold the bead in position whilst the glue hardens would be obtained by using two hand screws or G cramps, which would span across the drawer front. The edge of the bead should be bodied up with french polish before fixing in position.

At the top edge of the drawer (Fig. 16 B) is shown the method of letting in a small piece of new wood to

replace a bruised or damaged portion, where it is not thought desirable to fix a new bead on account of disturbing and re-fixing the lock, etc. The new piece is made to a dovetail shape and laid on to the existing bead: then a mark is scratched around it with a needle or sharp penknife point. This will give the exact size and angles of the new piece, and the recess may be sawn and carefully pared out with a chisel. The new piece should be made rather thicker than required, so that, after fixing, a shaving or two may be removed, thus leaving all flush. The top edge will then have to be glass-papered, stained and polished to the required colour.

*Chest of Drawers. Left. Example of English design, made in the late 17th or early 18th century. It is of pine and oak, veneered with walnut and lignum vitae. Right. Antique Dutch chest of drawers, with bowed front (1, Victoria & Albert Museum, S. Kensington; 2, courtesy of Our Homes & Gardens)*

Owing to constant friction, the lower edge of the drawer sides becomes worn away as indicated by the line drawn on the side of Fig. 16 (C). This allows the drawer to sag and throws the front out of truth with the face of the chest. This shows an unequal margin of the cock bead, and also causes the drawer to run badly. Drawers that have their lower edges badly worn should be turned bottom upwards on the bench and the worn portions planed away as indicated by the line at Fig. 16. The planing will not interfere with the drawer bottom, which stands clear of the lower edge of the side by anything from  $\frac{3}{8}$  in. to  $\frac{5}{8}$  in. A new piece, preferably of hardwood, is glued on to the existing drawer side and cramped in position. After, say, 24 hours, the surplus material may be planed off the newly-jointed piece, taking care to mark it out and make it parallel to the top edge of the drawer.

In other cases it may be found that the runner or piece that supports the drawer shows signs of considerable wear, and the remedy for this is to replace the worn runner with a new one. Runners are fixed in two ways, and it will be found that in most of the old chests a groove has been cut across the carcass end, as illustrated in Fig. 17, to receive the entire thickness of the edge of runner. This groove is generally about  $\frac{1}{4}$  in. deep, and the runner is simply glued into it. The end of the runner has a small tenon to engage the back edge of the front bearer. The partitions or dust-boards fit into the grooved edges of the bearer and the runners, and preclude any possibility of the runners working

out of the grooves cut in the carcass ends.

Fig. 14

Fig. 15

*Fig. 15. Example of an old mahogany veneered chest of drawers, a common type to require repair.*

#### Another Method of Fixing a Runner

The lower part of Fig. 17 illustrates the second method of fixing a new runner, and in this case no groove has been cut in the carcass end. The tenon on the runner is glued into the bearer groove, the opposite end notched out and prepared to receive a screw. A dab of glue is applied to the carcass end as indicated by the arrow. If the back edge of the runner be glued along its entire length, it does not allow for any contraction or expansion in the carcass end, and this will often cause a fractured or open end joint.

Fig. 18 shows such a fractured end, and, as it is practically impossible to knock the chest asunder and re-joint the end, it is necessary to glue into the crack or joint a small strip of wood with its end section wedge-shaped. If the fracture follows the general contour of the grain and a straight strip cannot be conveniently applied, the strip will have to be cut into short lengths of say, 6 in., so that they can be easily bent to the shape. Care must be taken to joint up the ends of the strips so as to leave no open joints. The job is then cleaned off level and polished.

Another common repair is a broken foot. Fig. 19 is a part sketch of a plinth which has been taken off the carcass and turned upside down. The repair is carried

out by cutting away the broken portion of the old foot, until the new joint is in alignment with the top of the straight portion. This will allow the bull-nose plane to be brought into operation, so as to plane up the major portion of the joint, after which the existing mitre and corner block are scraped by using a toothing plane blade which has been temporarily removed from its stock. A new piece of wood is planed true on its lower edge, and the end is mitred. This piece is glued in position and handscrewed down, whilst two ordinary screws are inserted from the back of the corner block to secure it. When the glue has thoroughly set, the new piece is cut to the desired shape with a bow saw, as shown by the dotted line. A fine sprig or panel pin may be driven in the edge of the shaping, as suggested in sketch, after the foot has been cut to shape.

Fig. 16

Fig. 17

Fig. 18

Fig. 19

Fig. 20

Fig. 21

#### Chest of Drawers.

*Figs. 16-21. Diagrams illustrating how various simple repairs can be effected.*

Fig. 20 shows how to effect a repair to a piece of broken veneer which has formed a cross-band on the wide top bearer of the chest. Using a steel rule as a guide to the penknife blade, a deep incision is made and the old piece of veneer removed. This may be accomplished by damping a piece of rag and placing it upon the damaged veneer. A hot iron is now applied to the rag, and the steam so generated will soften the old veneer and glue to such an extent that it may easily be peeled away.

A new piece of mahogany curl veneer is fitted to replace the damaged part and is laid by the caul method. The caul in this case may be a piece of yellow pine wood which has been planed up and rubbed over with raw linseed oil. It is heated in front of a fire, and a piece of clean white paper is placed between the caul and the glued veneer. The pressure is applied to the work by the handscrew, as shown. The work will in due course be levelled up with the steel scraper, after which it is glass-papered and polished. If old curl veneers which have been out for some years be used, it will save much time and matching up when the polishing is commenced.

Fig. 21 represents one corner of the chest where the cross-banded mould and the veneered top have been broken away. To repair this a cut is made across the corner and the old veneer removed by the method above described. A suitably grained piece of veneer is selected and laid in position by the caul and handscrew method. A day later, a piece is glued to the cross-banded edge, and in due course it is rounded off to shape with a block plane.

The polishing and colouring up of the repaired portions of antique furniture call for great care on the part of the worker.

**CHESTERFIELD SOFA.** Stuffed all over, back as well as sides, to seat two or three persons, this comfortable style of sofa is sometimes supplied with added loose cushions, which should be soft and resilient, while in some makes one end is adjustable to ensure greater length for reclining.

In selecting a chesterfield it is necessary to get a good quality guaranteed by the name of the firm to be of good workmanship, since it is not possible, even for an expert, to judge of the durability of the sofa in its finished state, but any basic faults will quickly show through. The framework of beech or birch, the bracing of the frame, the spiral springs, the webbing, all lie hidden beneath the upholstery, and it is upon these unseen parts that the lasting quality of the sofa depends. The frame must be of well-seasoned timber, birch being used in the best work; the spiral springs must be of well-tempered steel, and the workmanship should be of the highest standard.

The covering can be of various materials, according to the room in which the sofa is placed. For a lounge or living-room, velveteen, velvet cord, tapestry, a durable moquette, or a similar fabric of heavy weave, are suitable; for a drawing room, damask or velvet. This sofa is not suitably covered with any fragile material as it is usually selected for comfort and service.

*Chesterfield Sofa. Fig. 1. A comfortable sofa which can be made by following the directions given in this article.*

**How to Make.** Dimensions for the chesterfield shown in Fig. 1 may vary slightly in length for individual requirements, 5 ft. 6 in. over all when finished being about the smallest useful size; 6 ft. 6 in.

the size most frequently met with; and sizes up to 8 ft. or 9 ft. for halls, institutions or ballrooms. The length for framework (Fig. 2) in the present case is put at 5 ft. 6 in.; height to top of end posts, 1 ft. 10 1/2 in. or 2 ft., to include castors; height of front rail (seat), 8 in.; and depth of seat, front to back over all, 2 ft. 6 in. to 3 ft. for a large size. Settee frames of the chesterfield size vary in detail according to the character of the furniture they go with, but for a fixed end settee, the frame (Fig. 2), of which one half is shown, will be as simple as any to make. The woods generally used for frames are beech and birch, but pine or American whitewood could be used for parts, the show wood (in this case the legs) being in oak, walnut or mahogany, as an improvement upon staining to match existing furniture.

In making a start with the settee frame the front posts (A) will be cut from 4 in. by 2 in., the rounded or scroll portion being made up by an extension piece to project 1 1/2 in. or so, dowelled on. This post is flush with front of settee, but in some instances is shaped or set back a few inches from the front edge of seat rail, separate stumps (either turned or tapered) being jointed into the seat framing. The front rail of seat (B) is 4 in. by 3 in., preferably tenoned into position, but sometimes dowelled. It is shown as straight, but is often shaped to break forward as at X (Fig. 2). The end (C) and back seat rails can be somewhat lighter, 3 in. or 2 1/2 in. by 2 1/2 in., tenoned or dowelled at front; shaped portions at corner are separately worked and dowelled into position.

For the back legs (D) 2 in. by 2 in. material will be required, the legs being continued to the ground. If preferred they may finish into the back seat rail and have separate shaped legs dowelled or bridled into the seat framing. The top back rail (E), 4 in. by 2 in., has the centre upright at back (F) tenoned into it and into the seat rail, size for this and the centre stretcher (G) being 3 in. by 2 in., the latter being dovetailed and screwed to the seat rails from below. The stretcher is sometimes shaped with a dip or bend in the centre, or its place may be taken by one or two stout iron rods similarly shaped and screwed between the seat framing back to front. The stuffing or tacking rails (H) are made to finish 1 1/2 in. by 1 1/2 in.

#### How the Adjustable End is Made

A frame made to the foregoing sizes will be fairly stout for the size (5 ft. 6 in.) mentioned with fixed end. A chesterfield settee frame, however, is nowadays usually made with one or both ends adjustable to let down to the seat-level and serve as a lounge. In this manner the framing of Fig. 2 would have a similar upright to A built into the back framework, as shown in dotted line (J), and a separate head framing on the lines of A, E, H, hinged to let down. There are several adjusting actions on the market, some of which are obtainable through cabinet makers' sundries-men; but, as a rule, they are somewhat complicated for the

amateur to deal with. Details of one are shown which would be of assistance to the average worker in making his settee with drop end, the best way being to make a smaller model in thin wood, so that the method of action is clearly understood, before cutting up good material.

Fig. 3 gives a diagram of an adjustable head. The sectional view shows the head erect with dotted line of stuffing, together with a dotted line of head lowered to a reclining position. All that is necessary to operate the action is to lift the head slightly, which disengages it from a bottom stop-rod, and allows the head to revolve to a lower angle, where it is stopped by the extension piece bearing against a rail fixed for the purpose from side to side of the box seat. The wood from which these head scrolls are shaped should be about  $2\frac{1}{2}$  in. thick, preferably of hardwood, to counteract any undue strain. The seat frame should be boxed in at ends to a height of about 5 in. clear above ground, and with sufficient opening above to receive the base portion of scrolls, which revolve inside, in addition to clearance for the material with which the settee is covered to be turned in and tacked down. The bases of the scrolls will be portions of a 7 in. circle, and a radius of  $3\frac{3}{4}$  in. struck from a point about  $\frac{1}{2}$  in. above the box will indicate the amount of clearance required. These head scrolls are connected by the stuffing rails indicated on Fig. 3 at J and K. The sheet-iron brackets at L are screwed to the insides of box, and serve as rests for the head to pivot upon. The upper portion of the brackets can be shaped as the dotted line indicates, and is holed above and below for the entry of  $\frac{3}{8}$  in. gas pipe, to serve as pivot M and stop rod N, Fig. 4.

Figs. 2-5. Working diagrams, including details of alternative drop end.

The brackets are boxed in to prevent any possibility of interference with the upholstery at a later stage. The horn, or extension of the scroll lying over the bracket (as in section, Fig. 3), is therefore inside the box, and is mounted by means of a rip saw cut midway of the thickness for the bracket to enter. The outside portion of the scroll follows the compass line so that it tilts clear of the box opening previously referred to.

The end view of the framing of head seen at Fig. 4 shows pivot-rod and stop-rod in position. An indication of the method of lowering and securing the head, to an enlarged scale, is given at Fig. 5. The elongated hole for the pivoting rod at M (Fig. 5) allows of the lifting of the complete head clear of the stop-rod N; and, when thus free, it will pivot back till the horn is stopped by the rail O, which must be stout and well screwed home to afford a firm bearing. The dotted line shows the limit to which the saw cut for the passing of the iron bracket extends, and the latter must have the screw holes well countersunk so that the screw heads do not hinder free action. A tapered block, P, glued to the box end will serve as a guide for the horn to slip back to its position after being lifted.

An enlargement of the end view of the rods on the lower portion of the scroll (Fig. 5) indicates the stop rod N, bedded into the box sides to about two-thirds of its thickness, and the pivot rod M, passing through scroll and secured by burring over on a washer, which may be thin and slightly sunk. The position of sheet iron brackets is made clear at L, Fig. 5. By a little manipulation it would be possible to obtain an angle of adjustment for the head midway between the extreme points indicated by the foregoing, fixing being in the course of the dotted line near L, Fig. 5. *See Divan; Ottoman; Settee; Upholstery.*

**CHESTNUT (Spanish).** The Spanish or sweet chestnut, with green serrated leaves, grows up to 60 ft. in height. When ripe, the nuts are brown and glossy, but sweet and not bitter like those of the horse chestnut (q.v.). This tree likes a loamy soil with sand rather than clay. Propagation is by nuts sown in autumn or spring.

**CHESTNUT: The Wood.** There are two varieties of wood, differing very much in character, produced respectively by the horse chestnut and the sweet or Spanish chestnut. The first is a light, soft, spongy wood, which loses nearly half its weight and a considerable amount of its bulk in seasoning. It is used for turning bobbins and other small articles, for carving, packing cases and also for rough outdoor boarding where durability need not be considered.

The sweet chestnut is a more valuable wood, and is the one in general use, being easy to work. Comparatively hard and heavy, it sometimes serves as a substitute for oak. In rough carpentry it is employed for fencing, palings, piles, beams; also for coffins, door and window sills, in cabinet making and for fretwork. Ladders, small casks and hoops are amongst the innumerable articles that are made with the wood of the Spanish chestnut.

**CHESTNUT: In Cookery.** Of all cuts the chestnut contains the least oil, is probably the most digestible, and many dishes are made with it. It is also employed in stuffing for poultry and in sauce. To boil chestnuts, make an incision in the skin of each nut and put them into a saucepan of salted, boiling water. Boil

them for about  $\frac{1}{2}$  hour, drain, and remove the shells and re-heat the nuts in a little butter.

If chestnuts are boiled for a few minutes before being roasted on a shovel over a good fire, they will be cooked through to the centre instead of being done merely on the outside, as is so often the case with roasting.

A savoury dish is prepared by mixing one cupful of boiled chestnuts, mashed and sieved, with the same quantity of mashed potatoes, 1 oz. of butter or margarine, a teaspoonful of grated onion, and a little salt and pepper. Butter an au gratin dish thickly, fill it with the mixture, and sprinkle the top with breadcrumbs, together with 2 oz. of butter divided into small lumps. This quantity is sufficient for one or two persons only.

**Chestnut Sweets.** In order to make chestnut charlotte, cut some sponge cake into a round about 2 in. thick, spreading the outside edges with a little royal icing, and fixing around it about 2 dozen savoy finger biscuits. While these are setting, put 1 lb. chestnuts into boiling water, boil them for 10 min., then remove the outer shells and inner husks.

Break the nuts into pieces, put them in a pint of milk, together with 2 in. of vanilla pod, and stew them gently until they are soft. Then rub the chestnuts through a wire sieve, and mix the purée with a little castor sugar to taste, a gill of cream (whipped), 1 teaspoonful lemon-lemon-juice and 3 oz. matrons glacés each cut in about eight pieces.

Put the mixture into the prepared case, whip, sweeten, and flavour another gill of cream, and force it over the top of the mixture, using a large rose pipe and raising the centre well. Decorate the top with pieces of glacé cherries and crystallised flower petals.

Another attractive sweet for a party is chestnut trifle. The ingredients are 6 square sponge cakes, 1 lb. chestnuts, a little white wine, some apricot jam,  $\frac{1}{2}$  gill cream and some custard. Boil the chestnuts, skin and mash half, and mix them with 3 tablespoonfuls of apricot jam. Leave the remainder of the nuts in hot water. Cut the sponge cakes open, spread them with the nut and jam mixture, and arrange them in a glass dish, soaking them with two tablespoonfuls of wine, or fruit syrup may be used in place of wine.

Cover the whole with a good thick custard, and when the latter is set, shell the remainder of the nuts and press them through a large-holed sieve so that they fall like threads over the custard, leaving plain a round central space.

These give character to the trifle. The central space is then filled with whipped cream. *See* Christmas; Marron Glacé; Royal Icing; Sauce; Stuffing.

**CHEVAL GLASS.** The name is applied to a mirror swung between uprights which form a stand. The mirror frame is made of 1 in. stuff,  $1\frac{1}{4}$  in. wide including the moulding and is mortised together. The rebate for the glass is on the same level as the quirk of the moulding (Fig. 2), so that both the tenon shoulders will be level, the moulding on the mortised pieces being

cut away. When ordering the glass allow the size to be  $\frac{1}{16}$  in. small all round. Fig. 2 shows how the glass is secured by glueing wedge-shaped pieces to the rebate.

*Cheval Glass in walnut, Queen Anne style (Courtesy of Harrods, Ltd.)*

*Right. Cheval Glass. Fig. 1. Large swinging mirror which can be made by the amateur worker.*

Glue the frame together and clean up and prepare material for the back. The panels are  $\frac{3}{16}$  in. thick and the crosspieces  $\frac{5}{8}$  in., these being grooved to take the panels. The vertical rail is in two pieces, tenoned into the other at the centre, and both are screwed to the frame.

Fig. 2

Fig. 5

Fig. 4

Fig. 3

*Fig. 2. Showing fixing of glass.*

*Fig. 3. Back elevation.*

*Fig. 4. How rails are cut away to fit on frame.*

*Fig. 5. Side elevation*

As it is necessary for the panels to fit right on to the frame the rails are cut away, at the ends, on the underside, just the depth of the bottom flange, as in

Fig. 4. Screw these in position and fit the panels, rounding off the edges to give a lighter appearance, and mark on the inside their relative positions, so that they may be replaced in the same places.

The uprights, for the stand are  $1\frac{1}{4}$  in. square and are chamfered at the edges as shown, the top being cut to a finial shape. They are tenoned into the feet as in Fig. 5, the tenons being wedged from the underneath to give greater strength. The feet are cut from a block of wood each measuring 16 by 3 by  $1\frac{3}{4}$  in. The corner brackets are fixed after the uprights are glued, and fit into small grooves cut to take them. The rails joining the uprights together are tenoned; the length is obtained from the mirror frame, an extra allowance being made so that this will swing freely without touching. The small centre ornament is stub-tenoned into the rails and is glued just prior to glueing the uprights. The frame should be carefully polished before fixing the glass.

To fix the glass lay the frame flat on a table and put the glass in position, being careful that it is right down in every part. Glue the wedges all round about 3 in. apart (the wedges are each about 1 in. long) and allow to remain until quite dry. The mirror is hung upon special brass movements which screw to the frame and stand. By turning a thumbscrew the glass is made to remain in any position. *See Dressing Table; Mirror.*

**CHEVIOT CLOTH.** Scottish tweed manufacturers used to make their coarser tweeds exclusively from Cheviot wool, and in order to make softer tweeds and flannels they began also to get wool from Saxony. Thus, their coarser cloths became known as cheviots and their finer ones as saxonies; but cheviot has since come to mean not only cloth made from wool of the Cheviot hills, but any cloth made of wool less soft than Saxony, Botany or merino.

Cheviot tweed costs less than Saxony and often wears longer. Cheviot serges have a well-marked diagonal rib, and the surface instead of being bare has a short nap of fibre. *See Serge; Wool.*

**CHEWING GUM.** Introduced from America, this consists of chicle gum, sweetened and flavoured. Chicle gum is a substance resembling gutta-percha, obtained from the balata tree of S. America. The proportions used are chicle gum 1 lb., powdered sugar 3 lb., these ingredients being warmed and kneaded together and flavoured with cloves and cinnamon, wintergreen or peppermint. The mass is then rolled flat and cut into pieces.

**CHIANTI.** This Italian wine from the vineyards of Tuscany is light, dry, and easily digestible if properly matured. It has a fine bouquet and colour. It is best drunk in its own country, as it has a reputation for not travelling well. *See Wine.*

## CHICKENS: THEIR INCUBATION AND REARING

Advice on Raising Birds for Egg Production

### and the Table

Further information will be found under the headings Coop; Incubator; Poultry. See also Boning; Casserole; Curry; Egg; Fowl; Soup and other cookery entries.

In the incubation of eggs, whether naturally under a hen or artificially in an incubator, the first essential to success is strongly fertilised eggs. Where the number of chickens desired is not large the broody hen will suffice, but for more extensive operations an incubator is a necessity.

In the selection of a broody hen great care is necessary, as it does not always follow that because a hen clucks and takes to the nest she will prove reliable. Birds with non-sitting blood in their veins should be avoided. Pullets, too, are not always to be relied upon, and it is advisable to choose birds that are two years old or over. In sitting a hen nighttime should always be chosen. The nest should be made on the ground in a sheltered corner of a shed or outbuilding, and so placed that no other hens can have access to it. It is best made by scooping out a saucer-shaped hollow, pressing it evenly down and lining it with straw.

The number of eggs to be set will depend on the size of the hen. A small bird will cover 10; a large one 15. While sitting, the hen should be allowed off the nest once a day for food and water, regularly at the same hour every morning. Sometimes a hen will refuse to leave the nest, in which event she must be gently lifted off. After this has been done a few times she will act for herself. She may remain off for about 20 min.

The food of a sitting hen should consist of maize, clean fresh water and grit being always within her reach. Should any eggs get accidentally soiled they must be cleansed with tepid water, and the nest material, if similarly soiled, should be renewed. All being well, the chickens should make their appearance on or about the twenty-first day.

**Artificial Incubation.** This is a more complex proposition, everything, apart from the eggs, depending on the capabilities of the machine used and the care exercised in working it. In a small way a 50-egg machine may be quite large enough, but when it is desired to incubate a large number of chickens, one of at least 500-egg capacity will be needed. For the average poultry-keeper, however, a 100-egg machine will supply every need.

The mechanism and working of an incubator is explained in the article on Incubators. A good machine having been obtained, the first thing to be considered is where to locate it. A cellar offers many advantages; but wherever it is placed, the temperature must be even there must be no direct draughts and no fire. The machine should stand perfectly level and as firm as possible to ensure against vibration. The mode of working the incubator will vary according to the principle on which it is constructed, but every maker sends out full instructions. The temperature is the same in all cases, namely, for hens' eggs, from  $103^{\circ}$  to  $104^{\circ}$ ,

reduced to  $102\frac{1}{2}^{\circ}$  the last seven days: and for goose and duck eggs,  $102^{\circ}$  throughout. The eggs require to be turned regularly once a day, and it is as well to keep the large end uppermost. As the chickens hatch they are allowed to dry, and then removed to the brooder.

**Testing the Eggs.** In both natural and artificial incubation, the eggs should be tested for fertility by means of an egg-tester. An infertile egg will be perfectly clear, while an egg in which the germ has started to incubate and dried will appear thick and cloudy. A rotten or addled egg will appear black, but the fertile egg will exhibit small veins radiating from a dark red centre. The testing operation should take place on or about the seventh day, when all infertile eggs should be removed, and if in an incubator, replaced.

Immediately the young chick emerges from its shell, whether it is hatched under a hen or in an incubator, it requires air and warmth to dry completely its down and to expand its lungs. Unless the hen is very nervous and resents interference, the shells should be removed from the nest as the chicks hatch, as otherwise an empty shell may cover up the chipped air-hole of a hatching chick and smother it before it has time to free itself.

*Chicken. Oil-heated foster-mother or brooder, a useful appliance for rearing chickens when a sitting hen is not available. Adjoining the brooding chamber is a covered run.* (Courtesy of Spratt's Patent, Ltd)

There is not the same necessity for so much care with an incubator, as the eggs are less crowded, and in some cases there is an arrangement by which the young chicks in struggling towards the light drop into the drying chamber. In other makes the chickens will need to be lifted into the drying box or drawer shortly after they free themselves from the shell, and as soon as they are properly dry, and if they seem strong enough, they can be again shifted into the warm foster-mother or brooder. Chickens hatched under a hen may be safely left with her in the nest for 12-24 hours from the time they leave the shell, but if she is clumsy or nervous it may be advisable to remove them earlier.

A coop having been prepared and previously disinfected by lime-washing or other method, the hen and her brood may be carefully removed to their new home. The hen should be lifted from the nest first, and the chicks carried in that, or an old hat, basket, or even the loose pocket of a coat. In cold weather it is an advantage to use a small rather than a large coop, as the hen will have less room to scratch about, and will brood the chickens better. It should face south and be protected from cold winds by a hedge, fence or wall, if possible.
