**Day-old Chicks.** Many chicks are sold when 24 hours old. It is a good plan to place them on arrival in a brooder heated to as near  $95^{\circ}$  F. as possible for an hour or two. If no brooder is available, the birds may be placed in a flannel-lined basket reasonably near a fire. They should then be given a feed of warm steeped oatmeal or biscuit meal, and a little warm milk to drink. If the chicks have travelled a considerable distance, the best results will usually be obtained by rearing them under broody hens, if available. One or two chicks only should be given to a hen at first, and if she takes kindly to these the remainder may be slipped under her wings. The hen should have been sitting on "pot" eggs for some days before the arrival of the chicks.

**Management of a Brooder.** The brooder or foster-mother is used when it is not always possible to make use of a sitting hen. The ordinary brooder usually consists of a heated chamber which is connected with one or more outer chambers or chicken-runs. It is of the greatest importance that the brooder should be so constructed that the temperature is always kept equable throughout, and should be completely free from fumes at all times. This latter specially applies to those corners of the brooder into which the young chicks are likely to crowd. Finally, it is essential that brooders should be kept quite free from damp.

In most brooders the heating medium consists of a lamp, and in some types this lamp is placed outside the heated chamber and is rendered fireproof by the provision of a jacket made of asbestos. In another type the brooding chamber is heated by means of a hot-water tank, or by a circulating hot-water tube, which is run all round the inner walls. In a third type of brooder a hot-air tank is fitted. This tank is heated by means of a lamp. The position of the lamp should in any case be so chosen that the fumes rising from it can be carried away immediately.

The heat should be generated in such a way that the floor is properly warmed. Otherwise, if there is not a proper provision for warmth at floor-level, the chickens naturally crowd together in order to keep warm, and the strongest will climb on the backs of the weakest and either crush or suffocate them. One way of making provision for such bottom heat is by means of a lamp which is placed in the centre of the brooding chamber. The inner roof of this chamber is made of metal and forms a radiator. The heat which rises from the lamp strikes this metal roof and is reflected down to the chickens.

The newly hatched chickens should not be transferred to the brooder until the latter has been properly warmed. The brooding chamber should be prepared for their reception by heating it for one or two days. This heating will get rid of any damp which might have accumulated owing to winter storage or from any other cause. Any dampness would mean a

large mortality in the young chickens. For the first week that the chickens are in the brooder the temperature should be kept as near 90° as possible. During the second week this temperature may be gradually lowered to 85°, and during the third week to 80°, while during the fourth and the following weeks it should be kept near 70°. Too much heat is as bad as too little. Apart from the use of the thermometer, it is generally possible to tell to within a small degree whether the temperature is too hot or too cold. If the temperature is too low the chickens will invariably huddle into the corners of the brooder or round the lamp and will utter plaintive cries; if the brooder is too warm they will gasp for breath and lie huddled about in a listless fashion on the floor. Overcrowding of the brooder must always be carefully avoided. As a general rule, it will always be advisable to keep well within the number of chickens specified by the maker of the appliance as its full capacity.

#### Benefits of Scratching for Food

The covered run adjoining the brooding chamber is usually converted into a scratching medium by littering the floor thickly with cut chaff, among which dry chick food is scattered. This is an important part of the rearing of chickens, since scratching for the food induces exercise, generates natural warmth, and so keeps the chickens in fit condition to withstand any sudden changes of temperature, which are not always possible to guard against quickly. On sunny days, when the chickens can be confined to the outer run, the brooding chamber should be opened up and exposed to the rays of the sun. As the season advances and the chickens outgrow the necessity for a heated brooder, generally at 4, 5, or 6 weeks, they may be transferred with safety to a cold brooder.

The ordinary cold brooder comprises nothing more than a sleeping compartment and a covered outer run. The sleeping chamber should be well ventilated, but it should be so constructed that no currents of air can play directly upon the inmates, and there should be just enough room to enable the chickens to huddle together comfortably for warmth. The floor of the cold brooder should be of earth, above which a good layer of cut chaff or peat moss litter is placed, and the floor of the outer chamber should be covered in a similar fashion.

**Feeding the Chicks.** Several systems of feeding are practised. Owing to absorption of the egg yolk before hatching food should not be given until the chicks are 2 days old. Then they can have fine chick feed, which will encourage them to scratch and exercise. Sawdust, sand, or peat moss litter broken up fine, laid on the floor of the coop, when they are moved into it, will greatly encourage them to scratch, and will prevent them getting cramp. A wooden floor is always advisable if there is danger from rats, and will also keep them dry.

From 2 days old they should be fed every 2 or 3 hours from dawn to dark, and fresh water may be given in a shallow pan, too shallow for them to drown themselves in. If there is any danger from cats, rats or other vermin, it is advisable to attach a small wire run

to the coop.

#### The Importance of Exercise

The hen should not be allowed to leave the coop at first, but the chicks can in this way obtain ample air and exercise without danger from vermin, or the possibility of the mother giving them too much exercise. It must be seen that the chicks have no difficulty in returning to their mother, and any difference in the height of the coop from the ground must be regulated by a brick or piece of wood.

The same care should be taken with the foster-mother or brooder, and in both cases the chicks should always be shut in at night. The coop must be cleaned regularly and all stale food and refuse matter removed. After the first 3 days an unlimited supply of fresh, clear water can be given. Special jars are obtainable which automatically regulate the supply of water, but make it difficult for the chick to foul it or drown itself. Fine limestone grit in small pannikins should also be given. If the weather is cold and damp and there is a tendency to diarrhoea, boiled rice once or twice a day will help to check it.

A grass orchard or small paddock or lawn is excellent for rearing chicks, as they will then have plenty of fresh green food, and ample shade in very hot weather. When possible, ground that has not had other poultry running on it for at least 6 months should be used. The young chickens will then be healthy and less prone to disease.

The feeding should be supplemented by coarser grain and chick feed as the chickens grow. Biscuit meal with a little meat meal may also be given. Some poultry raisers prefer to scald and give this slightly moist, whilst others—and this is the better method—dry it after scalding by mixing it with a little meal, such as Sussex ground oats. Dry feeding is much employed, i.e. a dry mash placed in pans or boxes, with a plentiful supply of fresh water always available. In a warm, dry season the chicks may be taken from the hen or foster-mother at 6 weeks old, but it is often better to leave them till 2 months old, unless the hen begins to lay again, when she may peck them.

**Pullets and Cockerels.** As soon as the sex of the chickens becomes apparent, e.g. from 2 to 3 months, according to the variety, they should be separated and kept in different runs. From then onwards they are termed cockerel or pullet, and though they reach maturity from 6-8 months, these terms are applied until they attain their second year. Frame, not fat, is the aim of all successful chicken-raisers, and especially is this applied to pullets, many breeders using only grain and green food for these until they approach laying, when a wet or dry mash may be used once a day. Cockerels thrive on tit-bits of all kinds, scraps of meat, etc. A mash of 1 part meat meal, 1 part pea or maize meal, 1 part supers and 1 part bran will be found very useful. Sussex ground oats, wet or dry, may be given as a change.

Wheat, oats, barley and buckwheat are the favourite grains for rearing, but it is better to give a feed of one variety, with periodical changes to others, than to give all varieties in one mixture. Maize or Indian corn is fattening and warming, and should be used when it is desired to supply these qualities. For further information consult Ministry of Agriculture Bulletin No. 54, also Advisory Leaflets Nos. 138 and 113.

**How to Cook.** Chicken may be cooked in many ways, roasting and boiling being the commonest. To roast, 35-45 min. should be allowed, and the oven must be hot for the first 10 min. of cooking, and maintained at a moderate heat for the remainder of the time.

Sausage-meat or veal forcemeat can be used for stuffing the chicken, and its addition makes the dish go farther. The breast of the bird should be stuffed with the forcemeat, and a greased paper placed over it.

The chicken should be trussed, and small slices of bacon laid carefully over the breast. It should be placed in a baking-tin in the oven, with some good beef dripping, and frequently basted while cooking. When half-cooked, turn the bird over and brown the back, then after 10 min. turn the breast uppermost again. While the bird is roasting, the liver and gizzard should be put to simmer in about  $\frac{1}{2}$  pint of well-seasoned stock for the making of the gravy.

When the chicken is cooked, skewers and string used in trussing should be removed, and the bird placed on a hot dish. The fat should be drained off the baking-tin, and the prepared stock poured into the tin and boiled up for a few minutes. It may be coloured with gravy colouring and more seasoning added. The gravy should be strained into a sauce-tureen, and bread sauce served separately, while watercress, washed and drained, may form a garnish.

### Improving the Flavour

To boil a chicken, first truss it, then rub it all over with half a lemon, and tie over the breast 1 slice of fat bacon, cutting a few slits in the latter to prevent it from curling up. Wrap the bird in a piece of buttered paper; then wash and prepare 2 onions, a carrot, a turnip, and 2 sticks of celery, cutting all these into halves and putting them in a large stew-pan, together with a bunch of mixed herbs, 3 cloves, and 4 peppercorns tied in a piece of muslin. Pour in enough hot water to fill the pan about half full, and put it over a moderate fire. When the stock boils, put in the chicken and let it simmer very gently for 1 to  $1\frac{1}{2}$  hours. Then take the bacon from the breast, remove the greased paper, and wipe the bird with a clean cloth to rid it of grease. Serve the chicken on a hot dish with egg sauce poured over it.

Chicken may also be fried, a good method being to cut the fowl into neat joints and remove the skin, afterwards dipping them into a mixture consisting of 2 tablespoonfuls of flour, 1 teaspoonful of salt, and a dust of pepper and cayenne. Melt 2 oz. of beef dripping in a small frying-pan, put in the pieces of chicken, and fry them until they are golden brown on each side. Keep them hot while 5 or 6 neatly cut pieces of bread are fried in the same fat; then slice three tomatoes, fry

them for a couple of minutes, and lay them on the slices of bread, placing a piece of chicken on top of each. Garnish the whole with small bunches of well-washed watercress and chopped parsley.

**Ideas for Re-cooking.** The remains of roasted or boiled chicken can be minced. To 1 lb. of finely chopped chicken allow 2 oz. margarine, 2 oz. flour, 1 pint stock, and some poached eggs. The stock can be prepared from the bones and trimmings of the chicken. Stir the flour into the margarine melted in a saucepan, add the stock, and simmer the whole for about 15 min. Seasoning should be added, and the chicken then placed in the stock. Leave the pan by the side of the fire until the bird is thoroughly heated, and serve it garnished with poached eggs, allowing one egg to each person, and one or two over. Finely chopped boiled ham can be mixed with the chicken if desired in the proportion of 4 oz. of ham to 1 lb. of chicken.

The remains of a cooked chicken may also be devilled for breakfast or supper, using a tablespoonful each of salad oil, tomato sauce, chutney, and vinegar, 2 shallots, peeled and finely chopped, and a dessertspoonful of lemon juice. Cut up the chicken into convenient-sized pieces, pour the salad oil (or oiled butter) on a plate, and dip each piece of chicken in it, sprinkling over them on both sides about a teaspoonful of pepper and salt mixed. Put the pieces on a gridiron, and grill them before a clear fire for 7 or 10 min., turning occasionally, and taking care not to burn them.

Put the shallots in a stewpan with the vinegar, and cook them over a fire for 10 min. with the lid off, then add the chutney, tomato sauce, lemon juice, about 5 grains of cayenne, and a saltspoonful of salt. Stir all together, and boil for 5 min. Serve the chicken arranged on a hot dish, with the sauce poured round.

**Invalid Cookery.** Specially suited for inclusion in an invalid diet is a gruel made as follows. Chop  $\frac{3}{4}$  lb. chicken meat very finely. Soak a little less than  $\frac{1}{2}$  lb. breadcrumbs in sufficient milk to cover them, and then rub them through a sieve into a saucepan containing the chopped chicken,  $1\frac{1}{2}$  pints chicken stock, and a little seasoning. Boil the gruel for a couple of minutes, when it should be very thick, and serve it immediately.

Another easily digested and nourishing dish is chicken jelly. A small chicken should be boiled until tender, the meat then sliced and placed round the sides and bottom of a mould. The bones and remains of the chicken should be put back on the stove with the liquor in which the chicken was boiled, and slightly seasoned. These should be simmered slowly over gentle heat for two hours. The stock should be strained and poured into the mould. When cold, the jelly should be turned out.

A suitable dish for invalids is chicken mousse made by mincing 6 oz. raw chicken, pounding it well, and adding to it  $\frac{1}{2}$  oz. margarine and  $\frac{1}{2}$  gill of thick white

sauce. Continue the pounding process, and add 2 eggs, one by one, mixing and pounding them well with the other ingredients. Season the whole, put it through a sieve, and then stir in 1 gill of unsweetened condensed milk. Grease a large mould, three parts fill it with the mixture, and then cover it with a greased paper. Place it in a steamer and steam it for about 1 hour, then turn it out on to a hot dish, coat it with white sauce and decorate it with parsley.

**CHICKENPOX.** One of the commonest fevers of childhood is chickenpox, which occurs chiefly in epidemics and is extremely contagious, so that immediate isolation of the patient is always necessary. It is commonest in children up to six years of age, but also occurs among older school children, and grown-up people may contract the disease if they did not have it when young. As a rule a person can only have it once.

The first symptoms are slight fever, pains in the limbs and sometimes sickness, occurring 11 to 19 days after infection. Within 24 hours a rash appears on the body, or on the face and scalp; the small, hard red pimples form blisters filled with clear, transparent fluid. In a few days these dry into crusts and drop off, rarely leaving any scar unless the child has been allowed to scratch or pick at them. The pimples or vesicles may break out inside the mouth in some cases and cause pain in swallowing.

The chief dangers to guard against are inflammation of the kidneys and broncho-pneumonia, so that the patient, after being isolated from the rest of the family or the school, must be protected from chills and draughts, and kept in bed till the crusts have formed. Custards, puddings and other light milk diet are the rule, but otherwise no special treatment is required. If the itching about the face is troublesome, the following lotion will give relief, and should be applied with a pad of cotton-wool:

Carbolic acid	1 teaspoonful
Glycerin	1 „
Rectified spirits of wine	4 tablespoonfuls
Water	$\frac{1}{2}$ pint

**CHICKWEED.** The mouse-ear chickweed (*Cerastium vulgatum*) is a common and troublesome annual weed which sows itself freely in gardens. *Cerastium tomentosum* (snow in summer) is a vigorous, low-growing, spreading plant with grey leaves and white flowers in early summer; it is very attractive in a sunny place, but must be kept in bounds by severe cutting back when the blooms are over. *Cerastium Biebersteinii* is similar, but has larger flowers.

**CHICORY** or *Succory*. The chicory plant is a hardy perennial bearing toothed blue flowers in summer. It thrives in ordinary soil, and the seed is sown in  $\frac{1}{2}$  in. deep drills, 8 inches apart, about midsummer to provide roots for forcing.

The seedlings are thinned to 6 or 8 inches apart. In autumn the roots are lifted as they are needed for forcing. If placed in boxes of soil, the tips just below the

surface, in a cellar or other slightly warm dark place they will start into fresh growth.

*Chicory. Head of a forced plant.*

As it contains both sugar and starch, the root of the chicory plant has a food value, and when ground it is widely used for mixing with coffee. The usual proportion is one part of chicory to four parts of coffee. It is also employed to darken the colour of soups and gravies. The green leaves are a useful addition to winter salad, or may be cooked for use as a vegetable. *See* Adulteration; Coffee; Salad.

**CHIFFON:** In Dress. This soft-finished, rather open-textured silk of light weight is used with lace or for fragile dresses and scarves, etc., in either plain colours or patterned varieties. Light and pliable silks of other descriptions are sometimes called by the additional name of chiffon. Thus there are chiffon velvet and chiffon taffeta.

**CHIFFONIER** or *Cheffonier*. Of French origin and descended from the cabinet, chiffoniers became popular in Great Britain in Victorian times and were chiefly made in rosewood or mahogany, fitted with knobs and handles of brass. They are still seen, usually taking the place of a small sideboard. The doors are well panelled, with brass beading along the edges, while the feet are often in the shape of claws. In the finer pieces sphinxes and other figures in gilded bronze serve for supports to the article. *See* Sideboard.

**CHIGNON.** Word used to denote a roll of hair in the nape of the neck. The ladies of the 18th century padded this roll of hair with a stiff cushion of false hair. It was then powdered and pinned in position with prong-like pins, and curls were attached to it. A century later women in dressing their hair threw it forward over their faces; they then pinned on the chignon pad and dressed the back hair over it, tucking the ends under the chignon. *See* Hair.

**CHILBLAINS:** How To Cure. Due to exposure to cold, chilblains painfully affect the fingers and toes in the form of purplish inflammation of the skin, sometimes running on to blisters and ulcers. As a rule, the sufferer's circulation is not very active, or he may be run-down. There is intense aching and tingling, with swelling and purpling of the skin. When blisters form and break, leaving ulcerating surfaces underneath, the chilblains are said to be broken.

The patient must see that gloves and boots are worn loose, socks thick and all-wool, and frequently changed. The feet should be placed in warm water at night and

dried briskly. A hot-water bottle in bed is not desirable, but if it is used it must not be placed near the feet. If the hands are cold, warm them by rubbing together or washing in almost cold water.

The circulation should be stimulated by regular outdoor exercise and a generous diet. Cod-liver oil should be taken, or cod-liver oil and malt. A teaspoonful of the syrup of the hypophosphates of iron, quinine and strychnia three times a day, after meals, is an excellent tonic for an adult. Benefit may accrue from taking calcium lactate in 15-grain doses (5 grains for a child) thrice daily for two or three days at a time. If the taste is objected to, add as many drops of the liquid extract of liquorice.

As soon as the redness and swelling appear the affected parts should be painted with tincture of iodine or camphorated alcohol rubbed in. They are then powdered with bismuth salicylate, 1 part, and starch, 1 part. If the heat and irritation persist it is well to apply zinc ointment or an ointment of ichthyol 30 per cent, in vaseline.

If blisters form and break, cover the whole part with a piece of lint, spread  $\frac{1}{8}$  in. thick with boracic ointment, and bandage tightly; or this ointment may be used: birch tar, 1 dram; zinc oxide,  $2\frac{1}{2}$  drams; vaseline, 5 drams. For washing the sores, especially if they are suppurating, there is nothing better than equal parts of hydrogen peroxide and warm water. *See* Boot; Foot; Hand.

## THE CHILD: ITS CARE AND TRAINING

### Dietary, Hygiene and Legal Status

The first year of life is dealt with under Baby. See also Adenoids; Croup; Measles and other complaints to which children are subject. Children's Party; Doll, etc., may also be read

All healthy young animals, the human included, are playful and active during waking hours, and need a large proportion of rest in consequence. During the second and third years 12 hours' sleep at night, say, from 6 p.m. to 6 a.m., with a couple of hours during the morning and another half-hour during the afternoon for the second year child, is a healthy allowance, though individual children vary a little in their requirements. As the child grows older and his interests increase, the daytime hours of sleep become shorter, but a rest after the midday meal should be encouraged up to 5 or 6 years of age. Early bedtime hours are most important throughout. Children from 10 to 13 years of age should have 11 hours' sleep, and from 13 to 16 or 18 at least nine hours.

From the earliest age they should be trained to sleep alone, in their own cots or beds. A hair mattress is the best, though during the second year, when control over the bladder is still imperfect, bran, which is easily and cheaply renewed, may be used. The bed-clothing should be as light as is compatible with warmth. Cellular blankets, being light and porous, are particularly good for children. Eiderdowns are not recommended. For

very young children it is permissible in winter time to warm the cot beforehand with a hot-water bottle, which should be removed when the child is put to bed. Light woollen or Aertex sleeping suits, with long sleeves, may be used for boys and girls during the cold season.

The importance of fresh air in the bedroom cannot be over-emphasised. Fresh, cool, circulating air has a stimulating and beneficial effect on the body, and as children spend such a large part of their time asleep, effective ventilation of the bedroom should always be secured. So long as the bed is protected from direct draughts, the bedroom window should always be kept well open. An exception may be made in very foggy weather. In very cold weather the air of the room may be maintained at a suitable temperature (about 50°-55° F.) by artificial heat, such as a fire or radiator. Winter and summer, whenever conditions are possible, a day-time sleep should be arranged for in the open air.

**The Child's Diet.** By the age of 2 or  $2\frac{1}{2}$  the first dentition should be complete, and to ensure this and help the teeth to grow sound and strong the child's powers of mastication should be encouraged as much as possible. Three meals a day should be the rule throughout early childhood, the last meal being the tea-supper.

Up to the second birthday the child should have one pint of milk to drink, apart from that used in cooking. This should be reduced to three-quarters of a pint after the second birthday. Too much soft food should not be given, but chewing should be encouraged by serving crisp packeted cereals, dry buttered toast, rusks, Vitawheat, Ryvita and suchlike. Small quantities of honey or home-made jam (without pips or skins in the case of young children) can be added. Fruit is essential, and is particularly good at breakfast time. It should be fresh (sieved or pulped when the child is very young), if possible. Dried fruits are excellent, also, and of the tinned varieties apricots and pineapple are rich in vitamins and iron. If fruit is stewed, only those varieties should be chosen which do not need excessive amounts of sugar to make them palatable. Well-cooked porridge, served with milk, is wholesome, but should not be given constantly. Meat or fish dishes are not necessary for the child under two, their place being taken at midday by vegetables in season (except onions), served with coddled egg, ground nuts or cheese. Raw, grated vegetables and salads should be introduced in small quantities, and gradually increased. Milk mixture, and later milk, is given to drink at breakfast and the tea-supper.

After the second birthday the child may have for the midday meal an increasing variety of simple, well-cooked dishes, but fried or twice-cooked foods should be avoided. Twice a week the child may have underdone meat or chicken; twice a week fish, preferably light varieties such as sole or plaice, or herrings in season: three times a week vegetarian dishes made with egg, cheese, nuts, macaroni, etc. Green or root

vegetables daily are important. Potatoes are best baked in their jackets. After three years uncooked greens, salads and root vegetables should be increasingly used.

All varieties of milk pudding, junket, jellies, steamed or boiled suet pudding with syrup, also baked apple or sieved stewed fruits, may be given from 15 months, provided the child is of average development. Beyond two years more variety may be allowed, also light homemade pastry. Fresh fruit and vegetables are always essential, and may be usefully served in the form of a finely shredded salad.

From 7 or 8 years onwards, when the child begins to go to school, the tea-supper will be given later in the day and will be a more substantial meal. Meat is not advisable, but soup, fish, or a well-made egg or cheese dish may be added, with milk pudding or fruit. This should be given at least an hour before bedtime. Tea and coffee are best withheld until after 9 or 10 years of age.

### Foods for Growing Children

From the age of 10 or 11 years onwards, a period of rapid growth and development, both boys and girls need a plentiful supply of wholesome food, but meat, if given, should not be given more than once a day. At no age should anything between meals be allowed except fresh fruit and water to drink. The best time for the latter is half an hour or an hour before meals. Drinking at meal times should be discouraged, and the habit of sipping between mouthfuls that some children are allowed to acquire is certainly a bad one. Highly seasoned dishes, sauces, pickles, vinegar, curries, or fried foods should not be given.

While food-faddiness should be discouraged, a small percentage of children display idiosyncrasies towards certain articles of food, such as fish, eggs, or some varieties of fruit. Skin rashes, maybe vomiting, with fever follow ingestion of these particular foods. If such be the case they should be omitted from the diet, and medical advice obtained if necessary.

**The Use of Aperients.** A word may here be said about the use of aperients. The child should be trained from infancy to empty the lower bowel daily, preferably after the first meal of the day. The stomach and intestines have natural, rhythmic movements of their own which need to be respected and cultivated. An unnecessary dose of purgative medicine may upset this delicate neuro-muscular mechanism for indefinite periods.

**Washing and Bathing.** For the first few years of life a daily warm bath, preferably at bedtime, is essential. If possible, this should be continued all through childhood, but where bathing facilities are restricted it may be given two or three times a week. From an early age, however, the child should be trained to the use of cold water. Unless contra-indicated on medical grounds, the body each morning should be sponged all over with tepid water, the temperature of the latter being gradually reduced until water from the ordinary cold tap is used. Rub briskly with a bath towel

afterwards.

As a general rule quite young children soon learn to appreciate this process, which has a stimulating and invigorating effect on the whole body, and no doubt tends to increase resistance to catarrhal infections. Provided the reaction afterwards be brisk, healthy boys and girls should take a cold or cool plunge bath each morning, followed up by simple gymnastic exercises for a few minutes. When the warm bath is not taken at night, exposed parts of the body should be washed before going to bed.

Teeth must be cleaned in the morning and after the last meal at night, the latter being more important. If particles of food, especially starchy varieties such as bread and biscuits, remain around the teeth during the night, fermentative changes take place and the enamel of the teeth is injured. Examination by a dentist at regular intervals—about once every six months—is most important. The hygiene of the nose is also very important. Children should be taught as young as possible to blow the nose and use a pocket-handkerchief. If the nasal cavities become blocked the child tends to develop a habit of mouth breathing which is one of the factors in the development of adenoids and their attendant evils.

As children approach the age of puberty it is desirable that they be given simple instruction about sexual life and its results. One of the parents is the most suitable person to do this; but if he or she feels unequal to the task there are excellent little books to be had dealing with the subject, or the services of a sympathetic teacher may be enlisted. Girls should also be told beforehand the nature of the menstrual periods, which usually start from 13 to 14 years of age.

**The Legal Side.** A father is the guardian of his legitimate children. But if the father and mother do not live together, and there is a dispute as to which of them shall have the custody of the children, the court will take account of the children's welfare. Unless the mother has been guilty of adultery, or is a drunkard, or there is some other reason why she is not fit to have the custody of them, children of tender years are practically always handed over to the mother. She may even be appointed their legal guardian and the father entirely ousted when he is unfit to be guardian, as if he has been cruel to them, or is a confirmed drunkard and wastrel, or is living with another woman, or brings his children into contact with immoral persons.

The father has a right to say in what religious faith his children shall be brought up. After the father's death it is usually assumed that he wished the child to be brought up in his own religion, but the court will regard the welfare of the children as the paramount consideration.

Any agreement before marriage as to the religion in which the children shall be brought up is worthless, for the father can still insist on all the children being brought up in whatever religion he chooses, subject to the qualification stated above.

A child's earnings belong to the child, not to its parents. A child earning money who lives with his parents is entitled to bargain how much he will pay for his keep, and the parent has no right to demand his wages and make him an allowance for pocket-money. A child's misdeeds are his own, and he alone is responsible for them. So that a father cannot be called upon to pay, for example, for windows broken by his son. The father (mother, if no father) is responsible for a child of school age attending school, and may be fined if the child fails to attend.

A father cannot be compelled to maintain a child capable of supporting himself or herself; but if a child of any age is, by reason of infirmity, whether mental or bodily, incapable of self-support and becomes a charge on the rates, the Poor Law authorities may summon the parent and obtain a magistrate's order that the parent shall assist in defraying the cost of maintenance. A father is bound to provide a child under 16 with sufficient food, clothing, and medical attendance; and if he does not, is liable to be summoned for neglect, and fined or imprisoned. The mother of an illegitimate child stands in the place of the father of a legitimate one.

**Baby Farming.** Any person who, for payment, takes charge of children under 7, apart from parents, relatives, or guardian, must notify the local authorities within 48 hours of so receiving any child. If the child dies, or is transferred elsewhere or if the baby-farmer changes her (or his) address, the fact must also be notified.

These local authorities can appoint inspectors to visit the homes and regulate the number of infants which can be kept in them. Persons are not allowed to keep children if their premises are insanitary, or if they have been convicted of previous offences.

**Child Labour.** In Great Britain local authorities have power to make by-laws restricting the employment of children of school age, and to regulate street trading by persons under 18. Any rules made can be ascertained at the office of the town, or urban, district council.

No child under 12 can be employed at all. Children under 14 may not be employed before the end of school hours, before 6 a.m. after 8 p.m., or for more than 2 hours on any school day; or on Sundays; or at any time in carrying heavy weights. No child under 14 may, without a licence, take part in any entertainment in connexion with which a charge is made, and no child under 16 may take part in any public performance involving danger to life or limb. Under the Shops Act, 1934, no person under 18 can be employed in or about a shop for more than 48 hours in a week except during periods of exceptional or seasonal pressure.

It is a legal offence for children under the age of 14 to be found on licensed premises, and for anyone to sell cigarettes to any person under the age of 16, whether for his own use or not. The police have powers to seize cigarettes or cigarette papers in the possession of any person, apparently under 16, whom they find smoking in a street or other public place. Any person who gives

any intoxicating liquor to any child under five except in case of sickness is liable to a fine of £3. No child under 7 must be allowed to be in a room with an open fire which has not a proper fireguard unless reasonable precautions are taken.

**Juvenile Courts.** These are held for the hearing of offences by children. Parents may be ordered to pay the fine imposed on the children. Children are prohibited from seeing certain cinematograph films unless accompanied by an adult, and in the case of other films are excluded altogether. The chief legislation on children and their protection is found in the Children Act of 1908, the Education Act of 1921, and the Children and Young Persons Act, 1933. *See also Cruelty.*

**CHILDBIRTH.** The expectant mother, besides making a sufficiently early arrangement with a doctor and nurse, must make other necessary preparations, for although childbirth is a perfectly natural and physiological process, it exposes the patient to the risk of infection by microbes. The room in which she is confined should, therefore, be thoroughly clean.

When there is a choice of rooms, let the one chosen be as large and airy as possible, and provided with a fireplace. The bedstead should be plain and easily cleaned, and should be placed so as to permit of easy access from either side, screens being used to prevent draught. It should have a good spring mattress and over this a clean hair one. A mackintosh or waterproof-sheet is placed over the latter, or, where this is not available, several layers of clean brown paper. Over this is placed a blanket and then a sheet. The bed is to be protected by putting a sheet of mackintosh below the hips and covering it with a draw-sheet, which consists of a piece of sheeting folded to the breadth of about a yard.

Labour takes place in three stages. In the case of a first baby the whole process occupies on an average 16 hours, but it may be shorter, as it usually is in subsequent confinements, or much longer. The doctor should always be summoned at the first symptom of labour.

It may be useful here to mention some of the more necessary things which should be procured in anticipation of a confinement: one or preferably two mackintosh or waterproof sheets, drawsheets, at least three abdominal binders for the mother, two or three dozen sanitary napkins of the largest size, 1 or 2 lb. of absorbent cotton-wool, some stout linen thread cut into lengths of about 10 in. or strong narrow tape, clean lint or linen, a bottle of lysol, large and small safety pins, a clean nail-brush, antiseptic dusting powder, a pot of vaseline, clean scissors, and two basins. Three or four lengths of thread are tied together at each end to form a ligature, and two such are required. They should be boiled for half an hour before use, or in an emergency

dipped in lysol solution. Lint and other dressings may be baked in a hot oven for half an hour, care being taken not to scorch them. Abdominal binders, towels, sheets, etc., should be freshly laundered and put away. *See Baby.*

**CHILDREN'S PARTY.** To be successful, a children's party requires an organized programme. It is easier to entertain children under 11 by themselves, as they like to play games and to have the undivided attention of sympathetic grown-ups, while older children often get bored with romping. It is usually a mistake to invite any child under five except to a real nursery party.

On the invitations, sent out about 10 days beforehand, the hour of leaving should be stated, to avoid any confusion in the fetching arrangements. Some hostesses engage a conjuror, a ventriloquist, or have a private cinema show, as a second part of their entertainment, finishing about 9.30, the older children staying on after that to conclude the party with dancing.

For a younger children's party beginning at 3.30, a room in which to play games should be cleared of everything except a gramophone or a piano and chairs. The more brightly this room is decorated the more quickly everyone gets the right spirit for a party. On arrival, most children are apt to be serious, and something must be done first to help them to get over their shyness. A jolly game such as musical chairs, or one of its variants, is a good start, while presents—trifles from a 6d. store—provided to send everyone away happy at the finish also make for success. The old-fashioned bran tub is voted rather messy for indoors, and the lucky dip has taken its place. This is simply a large laundry basket or box prettily disguised and filled with toys. A cloth is spread over the top, and each child puts a hand under this and drags out a parcel. Or the presents may be hidden about the room in which tea has been served, and the party end with a treasure hunt.

#### Making the Tea Table Attractive

Refreshments are most important at all children's parties. The table should be gay with a variety of cakes, fruits, and sweets. For small children there should not be too many rich things, but different layer and iced sponge cakes and varieties of fancy breads and buttered rolls. Fruit salad in pretty individual glasses always pleases. At a winter party crackers are an attraction. A large selection of coloured balloons are also useful, and can be given, one to each child, after serving as decorations, at the end of the party.

After tea all the old-fashioned games will go merrily. The great thing is to change a game directly it shows signs of flagging. When half a dozen children have been caught in blind man's buff it is well to start its variant. One person is blindfolded and given a stick to hold. The others take hands and dance round him in a circle until he bangs on the floor as a signal to stop. He then points the stick at somebody and says, Make the noise of a cat, dog, or any other animal that occurs to him. The person addressed has to take hold of the stick and obey the

order, while the blind man tries to identify the voice. If he succeeds in guessing rightly he changes places with that person. After this game may come musical bumps, hunt the slipper, or any other game that may be suggested. Most children will like some dancing to a gramophone. Competitions also, with prizes, always seem successful. A favourite is to give each child a balloon that has not been blown up, together with a short piece of tape; stand the children in a ring and at the starting signal they begin to blow up the balloons, a prize going to the biggest, after everyone has either tied up their attempt, or burst it in the effort to win the prize.

Illustrations of fairy stories and nursery rhymes can be cut out of cheap paper editions, the names removed, the pictures pasted on cardboard, and the child who guesses the most correctly is the winner. Where a hostess is specialising in a young children's party, a marionette or a Punch and Judy show, which can be hired through the entertainment department of a big store, will be sure to prove a great success as a finishing touch to a party of this kind.

For older children, at a later hour, there would be either a sit down or buffet supper. If the latter, it is well to have small tables, with chairs, scattered about the dining room to put glasses, etc., on. Most children delight in a stand-up supper; it has all the joy of the picnic, and boys feel pleasantly unrestricted as to what they may consume. After supper, should there be no entertainer, dancing is the rule; sometimes the party is a bigger success when the guests are in fancy dress. In some houses the children have a passion for charades, and love to get them up secretly with some of their friends before the day of the party. Any costumes that are to be worn should be put out ready in bedrooms beforehand, and a stage-manager chosen to superintend.

A summer party is pleasantly and quite easily arranged where there is a large garden, and all sorts of outdoor games can be played. Sports can be organized, with three-legged, wheelbarrow, obstacle, egg-and-spoon, and sack races. Tea is served either in the house or in a marquee, and in the evening there can be a dance with supper and an orchestra in a marquee lit by Chinesel lanterns. *See Charades; Christmas; Fancy Dress.*

**CHILL.** Exposure of the body to a draught of cold air or to dampness may bring on a chill. The patient feels shivery, may be nauseated or sick; there may be severe headache, a degree or more of fever, and he feels he is in for some illness. In a few hours all symptoms may pass off; on the other hand, congestion of some internal organ may follow, when the chill is said to have settled in the lungs or liver, etc. The commonest results of a chill are a cold in the head and bronchitis (q. v.). A hot mustard foot-bath, warm drinks, and hot-water bottles in the bed, the patient being put between blankets, are the immediate remedies for a chill. *See Cold.*

**CHILLI.** The dried pod of the capsicum plant is used in making curries, chutneys, and in pickling. In the green state it is eaten as a pickle. Chilli vinegar is used as a relish with fish. To make it 75 fresh chillies are used to 1½ pints of vinegar, the vinegar being boiled and, when cold, poured over the chillies. The whole must be tightly corked and left for two or three weeks, when it will be ready for use.

**CHIMNEY.** In building a new house it is well to remember how much the chimneys will influence its appearance, both at close view and at a distance when they become perhaps the most important detail of outline against the sky.

British architects are again taking an interest in chimneys and are not only designing them so scientifically in small houses that ugly pots and cowl are unnecessary to make the chimneys draw properly, but also with such an eye to decorative value that they may be now, as in Tudor times, ornaments which enhance the whole building. Elizabethan architects made such a feature of chimneys that they frequently designed them as part of the outer walls; the bases of such chimneys, when reproduced in modern houses, make provision in the interiors for inglenooks.

*Chimney. 1. Ornamental brickwork, typical of the Tudor period, used with good effect on the chimneys of a modern house. 2. Three chimneys brought into one stack. 3. Spiral stringing on a round chimney.*

Colour of brick used for the stacks is considered carefully. Dark red bricks may be selected for chimneys on a stone-tiled roof, a lighter shade of red on dark red tiles, and mellow tints for the plain brick chimneys suitable for thatched roofs.

Ornamental brickwork was also used with discretion in Tudor times. It is shown as adapted to a modern small house on the beautiful chimneys in Fig. 1. A good outline on a gabled roof is also achieved by bringing three chimneys into one stack, as in Fig. 2, while a round chimney is a charming architectural feature in Fig. 3, where the brickwork is enriched with spiral stringing composed of projecting bricks.

*Chimney Piece. Modern brick chimney piece, particularly effective design for a hall.*

**Smoky Chimneys.** An insufficient supply of air to the

fire is the cause of many a smoky chimney; it is discovered by opening a door or window, which is effective in curing the smoke nuisance by introducing a current of cold air. Remedies in such cases are to fit the ventilating bricks near the ceiling and through an outside wall to the open air. Another method is to fit a ventilating flue under the floor and terminating in a grating, provided with a regulating shutter, in the hearth or near to the fireplace.

The real trouble probably lies in the chimney itself or in the stove. The chimney may be choked with soot and broken pieces of mortar that have got loose and fallen down, and the services of the chimney-sweep are required. When the stove allows cold air to work into the flue or chimney it causes a down-draught. Being heavier than air, the smoke can only be carried out through the chimney if the draught caused by the heated air rising in the chimney is strong enough to carry it away. Therefore any excess of cold air must be stopped.

**Eliminating Down Draught.** This includes attention to the pointing of the joints in the brickwork, as the chimney must be airtight. Treatment may include the partial bricking-up of the flue, reducing the actual opening to not more than 9 in. square. If the new brickwork is so arranged that the flue makes an easy turn it will almost always effect a cure.

The most frequent cause of smoky chimneys is the shortness of the chimney stack. Surrounding roofs set up eddy currents in the air which nearly always have a tendency to blow down a chimney. A second advantage of a taller chimney is the extra draught it causes. All manner of shapes of pots have been devised; of them the louvre and bent top and certain other special type pots, as well as some of the revolving cowls, have substantial claims to success. When a considerable height is added to a chimney and a galvanised iron tallboy is used, light iron stay rods should be provided.

When every expedient in the way of extending the height of the chimney has proved a failure, attention must be given to the stove and its surround. The ordinary cast-iron register stove may not be fitting perfectly airtight to the brickwork at the back, and any leaks must be made good with cement or fire clay.

*Chimney. Double-coned cowl to check down draught. The air channel narrows at its centre. (Konkerwind Ltd.)*

Kitchen ranges are prone to this trouble as after lengthy use the mortar may have failed; when the brickwork is no longer a tight fit up to and around the stove back, it may be remedied in the same way.

### How to Deal with a Large Flue

Large open ranges can only be treated effectively by making a blower of metal or glass to restrict the opening. Dog grates and the old-fashioned open fires with a huge chimney shaft are very difficult indeed to correct. Perhaps the neatest method is to enclose the chimney opening with an iron plate having a small hole through it to accommodate an ornamental hood or bonnet. A separate soot door must be fitted to allow the chimney to be cleaned.

It is a legal offence to allow a chimney to catch fire. Various treatments are prescribed for dealing with a chimney on fire. The simplest and most effective is to close all doors and windows and to stop up the top of the chimney by means of wet sacks, bricks or anything handy that can be pressed into service. If the bottom of the chimney can be closed, this also has a retarding effect on the fire. It is customary to throw salt in large quantities on the fire in the grate or down the chimney from the top, while a patent extinguisher may be used when it can be brought to bear directly upon the fire in the chimney.

The best way to prevent a fire in the chimney is to keep the fire itself in moderation, to have the chimney swept at frequent intervals, and to avoid the burning of large quantities of paper that may be carried up the flue and set fire to the soot.

**Chimney Sweeping.** When a visit from the sweep is thought necessary, certain preliminaries are desirable. Begin by removing and putting away all white covers in the room. Take everything off the mantelpiece, as the sweep will need it clear to fix his black curtain. Sweep the hearth and grate perfectly free of all ashes and cinders, and spread a thick layer of newspapers all around the fireplace. The housewife knows from experience that some sweeps are tidy workers, and if such a man is coming no other preparations are necessary. But in the case of an untried man, it is advisable to take down white curtains and to cover all furniture with dust sheets.

While sweeping is in progress go outside and see that the brushes go right up the chimney and are visible above it. Some sweeps are careless about brushing right up, and neglect of this means that soot will fall later. When the sweep has gone take a hearthbrush and sweep out from the lower part of the chimney, just above the grate, the loose soot which falls from above and collects there. Then put the room in order again. *See Fire.*

**Chimney Bellflower.** *See Campanula.*

**CHIMNEY PIECE.** Since the chimney piece embraces the whole protective structure round a fireplace, from floor to ceiling, its decorative treatment is a matter of importance. One has to remember, in this connexion, that the grate is always an integral part of the chimney piece, and that one cannot design or alter the latter without considering the former.

*Chimney Piece. Old oak chimney piece beautifully carved and built up to match a Jacobean panelled room. (Courtesy of Gill & Reigate.)*

There are ways of converting a Victorian chimney piece into a modern one without great expense. The marble shelf can be painted after the surface has been well rubbed down and finished off with a final coat of egg-shell enamel. But this leaves the elaborate supports still visible, and on the whole the more effective transformation can be brought about by encasing the entire structure in wood. Next the grate has to be dealt with. The straight up and down lines of the wood encasement call for a more or less rectangular instead of a horseshoe shape, and this can be got by placing a piece of sheet iron, cut in the centre to the required form, across the opening, finished off by a plain moulding. Copper can be used instead of sheet iron with fine effect when dark oak is selected for the casing, or another idea is stainless steel, with a surround of black marble in place of a fender. The re-moval of the bars of the fireplace and the substitution of a barless grate will complete the work.

Where it is a matter of creating, not merely adapting, a chimney piece, there are certain general principles which should govern the choice of a design. In the first place, the size and character of the room should dictate the nature of this feature. In a small room the mantelshelf can be entirely dispensed with or restricted to 3 or 4 in. in width—sufficient, perhaps, to carry a pair of good candlesticks and one good piece of pottery or china. It should always be remembered that there is nothing more disturbing to the ensemble of a chimney piece than a mantel crowded with ornaments. When bricks are used the colour and design of the brickwork is of sufficient interest to hold the eye without disturbing detail above. The illustration of a modern brick fireplace suitable for a hall shows perfection of treatment. A mirror in an antique gilt frame or a good oil painting, either landscape or a flower-piece, inset as a panel can be usefully introduced in cases where space and surroundings permit.

If the house owner should be fortunate enough to possess a hall or a living-room with an inglenook, there is unusual scope for artistic treatment. Nothing looks better than a surround of good bricks at the sides and on the chimney breast. These should harmonise with the hearth, of which—since an open dog grate generally takes the place of the shut-in fireplace—a good deal will be seen. Tiles require careful selection. They look well in Chinese or blue delft designs in small fireplaces, and with amusing figures on them are a bright touch for the nursery chimney piece designed without a mantelshelf, the tiles being carried up to the

frieze. Lustre tiles in harmonious colourings, with hearth and kerb to tone, are also suitable for a flat treatment.

*Chimney Piece. Typical Adam style chimney piece, harmonising with the frieze, from Lansdowne House, London. (Courtesy of Country Life)*

The more architectural the chimney piece, the less need for overloading it with extraneous ornaments. For a panelled room the beautiful treatment of the Jacobean chimney piece illustrated gives some idea of richness combined with simplicity. The Tudor arch of the fireplace can also be adapted, in a room where panelling is not introduced, to a simple overmantel treatment of a plaster relief in a fine design.

Chimney pieces in the 18th century were the central interest of the rooms. Some were made in wood, but larger ones are in marble. Adam style fireplaces are adapted for rooms with classical decorative schemes, as in the one above. The Adam brothers employed Italian craftsmen to work on marble mantelpieces delicately carved in low relief or inlaid with coloured marbles. See Bow Ware.

## CHINA AND CHINA COLLECTING

### The Quest and Care of Old and Modern Pieces

Other entries to be consulted include Crockery; Faience; Pottery and those on the various kinds of china, e.g., Chelsea; Crown Derby; Sèvres, etc.

Modern china is so good decoratively that, whether required for ornament or use, many people prefer it to old pieces for their homes, as they can select it to bring out an exact note of colour desired in a room. There is also not the same worry over breakages. On the other hand, china collecting is an interesting hobby when the amateur does not think that any bit of old china, however indifferent, is better worth buying and hoarding than a beautiful piece of modern work.

Old English china, if porcelain be meant, covers a period of about a century prior to the Great Exhibition of 1851. But many collectors roam farther afield, and regard all the products of the kiln, in every age and place, as fit objects for study. More thrifty and practical lovers of old china, content to explore patiently the byways which still exist, may in time accumulate quite desirable and instructive possessions. Some may specialise in memorial ware recalling historic personages and events. Others may concentrate on blue-and-white, tracing the course of decoration and colouring from Nankin porcelain to modern Copenhagen. Others, again, may turn to special fabrics,

such as Wedgwood jasper or Staffordshire salt-glaze, two very distinctive forms of old English ceramic art.

**Clay Fabrics.** It is essential to learn to recognize the main features by which clay fabrics are classed. This knowledge does not come in a day, and for its acquisition a disciplined eye, a sensitive finger-tip, and a magnifying lens are indispensable aids. Unglazed pottery—fashioned of infusible, dark-coloured clays, fired once at a low temperature—has endured throughout the whole history of the art. The body may be fortified by white or coloured slip, or by fluid glazes covering the whole surface. Faience comprises earthenware which is not white, usually with decorative glazes, some of its supreme forms being the Persian polychrome faience brick bas-reliefs approximately of the period of Darius, and the majolicas of medieval Italy and Saracenic Spain. Delft is a variety of tin-enamelled faience, painted on the enamel in emulation of the achievements of Chinese ceramic artists. It is distinguishable from true china by the dark hue of the body, often perceptible beneath the roughnesses of the base.

It was the use by medieval Chinese potters of fusible felspathic rock, similar to china-stone, in conjunction with infusible china clay, that led to the invention of true porcelain. This is coated or glazed with a mixture of the felspar and lime, the whole being fired at a high temperature. It is vitreous and resonant, breaks with a shell-like fracture and cannot be scratched by steel. The secret of this hard porcelain was discovered in Europe 200 years ago at Dresden; in England its production was practically confined to Plymouth and Bristol.

The old Sèvres ware, on the other hand, was a soft-paste porcelain, employing artificial fusible frits, having a granular fracture, and a surface that crumbles under the file. This was the parent of Bow and Chelsea. A great advance was made in England by introducing bone-ash. When this was used with a mixture of china-stone and china clay, without the old soft-paste frits, there resulted the bone porcelain, of which, since about 1800, the best English china wares have been made.

An intermediate form, called stoneware, is partially vitrified by hard firing, and when thin may be semi-translucent. Its main defect is a tendency to crack with sudden changes of temperature. It was produced in the 17th century by John Dwight at Fulham. Out of it developed Staffordshire salt-glaze, and afterwards Wedgwood black basalts and jasper ware. With these fabrics may be classed ironstone china, semi-porcelain, opaque china, and other efforts to secure a durable material without incurring the risk and cost of intense firing.

In the 19th century the Great Exhibition of 1851 served as a turning point. Parian or unglazed statuary porcelain had just been invented, Mintons had reproduced Delia Robbia and Palissy ware, and Irish

iridescent porcelain was being made at Belleek. To the previous half-century belong many of the old heirlooms treasured in present-day homes, including examples bearing the famous names of Spode and Copeland, Davenport and Adams, Coalport, Swansea, and the Mintons, not to speak of the new wares introduced by factories established long before, such as Longton Hall, where Staffordshire porcelain originated.

**Old Chelsea and Bow.** To the 18th century belong many landmarks in the progress of the art. But among all the productions of that age lovers of old china are the fondest of Chelsea ware, because of its charm and historic appeal. Owing to its remoteness from our own day it is not abundant, and the homes of Chelsea and Bow china are no more.

Some 18th century factories, notably Worcester, Derby, Wedgwood, and Sèvres, are still active. No European ware earlier than the French soft-paste of the end of the 17th century ranks as porcelain. Such fabrics as Greek vases, Rhodian bowls, Samian ware, Persian glass-glazed dishes, ancient Egyptian faience, and neolithic pottery, are a collector's or student's separate studies.

Large quantities of inexpensive porcelain are turned out in present-day China and Japan for the export market, some of which are effective. Examples of the great periods of oriental porcelain, from the Sung and Ming dynasties to Kang-hsi and the 18th century emperors, together with Arita porcelain—commonly called Imari ware—and other fabrics of Japan, tend to become rare and costly.

**China Marks.** The various devices used by potters for identifying work, whether it be porcelain, stoneware, or earthenware, are usually painted, stamped, or incised upon the base before the final firing. They may denote the place of manufacture, such as Swansea, the master potter, such as Spode, the workman or decorator, such as G. T. for George Tinworth, or the date, as in some periods of Sèvres.

On Chinese porcelain the date-marks usually consist of two characters, meaning period made, together with two for the emperor's name, making a four-character mark. Sometimes two others, denoting the dynasty, are added, thus forming a six-character mark. Japanese wares differ from Chinese in usually having potters' marks, which are sometimes dated, and associated with armorial bearings.

Much old work was unmarked, while, on the other hand, the presence of a standard mark on certain pieces may be actually proof of their being fakes. There are marks of indication, apart from trade devices, which connoisseurs regard as surer tests. Such are the grain of the surface, the tint and imperfections of the glaze, the roughnesses on the base, the glassy moons seen in Chelsea ware before 1757, or the substance itself, as revealed by fractures.

Often undecorated pieces, after being produced in a famous factory, have been sent elsewhere, either by their makers or by dealers, to be decorated and finished, and in such cases the marks, original or

copied, have led to much uncertainty. Thus Chelsea imported genuine bodies from China for completion, and Sèvres biscuit pieces were at one time sent to Coalport for the same purpose.

**China Marks.** 1, 2, 3. Bow, 1730-75. 4, 5, 6. Chelsea, 1745-69. 7. Derby, 1751-69. 8. Chelsea-Derby, 1769-80. 9. Crown Derby, 1780-1815. 10. Bloor, 1815-39. 11. Derby, modern. 12. Chinese 6-character mark, 1723-36. 13 and 14. Plymouth, 1768-72. 15 and 16. Bristol, 1770-77. 17, 18 19. Worcester, 1751-83. 20. Chinese dedicatory mark, meaning harmonious prosperity. 21. Chantilly, 1725. 22. St. Cloud, 1695-1773. 23. Sèvres, 1754. 24. Dresden-Meissen, 1716. 25. Copenhagen, 1772-74. 26. Japanese fabric mark, Imari ware, 1800.

**How to Wash.** In washing china, plenty of hot water, space, and clean, dry towels are essential. For ordinary household china a good soap powder should be used in a large bowl of hot water. If the china is greasy, a handful of soda should be thrown into the water. The water should be changed as soon as it becomes cool and cloudy or greasy. After washing rinse the china in clean water. The washing-up bowl must not be crowded with articles, as this leads to chippings and cracks. A dish-mop on a stick is the most suitable, appliance for washing plates and dishes. A dishcloth that is used in the hand is better for cups and small articles. A rubber scraper is useful for greasy dishes.

In the washing of china to which value is attached, a folded towel or thick, clean duster should be placed at the bottom of the bowl to protect the articles from the risk of getting chipped or cracked. Neither soda nor soap powder containing soda should be used when there is gilt or much red colouring on the china, as the action of the soda is sometimes injurious to such ornamentation. A few drops of ammonia or a dessert-spoonful of borax should be used instead. If the china is badly stained a little powdered fuller's earth should be applied on a cloth. For safety the fewest possible articles should be placed at one time in the bowl. A small hog's hair paint brush may be used to clean raised ornament or porcelain figures. Such articles should not be allowed to become really dirty, and should be rinsed after being washed, and then drained and dried. Tea stains can be removed from china cups

by being rubbed with crushed salt on the dishcloth. Flower bowls and toilet jugs that have become discoloured by hard water can be cleansed by rubbing fine emery-paper over the stains, and afterwards washing them with strong soda-and-water. In putting away china in the cupboard, saucers and plates should be stacked in separate piles that are not too high. Cups and jugs, when not hung on hooks, should have the handles facing outwards in order to avoid accidents.

**Packing of China.** When packing china no piece should be in direct contact with any other, or with the walls of the packing case, and the packing material should be resilient and shock-absorbent. There must not be any gaps in the packing material, which should fill all spaces between the china. These requirements are met by the use of sawdust, old crumpled newspapers, straw or felt. Complete the work by filling in all gaps with more paper and straw, and have a layer on top at least 2 in. thick. Finally nail or screw on the lid. Give the box a good shake to ascertain if the contents are safe. If a rattling or clinking sound is heard, it will show that some of the china has been displaced, and this will necessitate repacking.

When packing china or any other articles for removal, it is well to remember that the removal contractor will not accept responsibility for anything that is not packed by his own men.

**CHINA ASTER.** One of the easiest flowers for amateurs to grow, the China aster is a universal favourite in all gardens. Seedlings may be raised outside in April, but stronger plants are obtained by sowing in a frame or greenhouse in February or March, always provided damping-off is avoided. The seedlings are transplanted at 4 in. apart, in boxes, and are planted out of doors in May. Great care must be taken not to over-water the small plants. There are many types and varieties of the annual aster with single or double flowers. The prim double blooms of the Victoria aster are still popular for exhibition and bedding, but for decorative effect and for cutting the Ostrich Plume, anemone-flowered and Comet varieties are superior. The single China aster is also charming. In each type there are varieties of rose, purple, mauve, so-called scarlet and other shades. If sown in May in the open, potted in mid-Sept., three in an 8-in. pot, and placed in a cool greenhouse, Victoria and other dwarf types will bloom throughout the autumn.

*China Aster. Bowl of double blossoms of various colours, purple to pink and white. (Courtesy of Sutton & Sons, Ltd.)*

Asters attacked by the black-leg disease, which turns the base of the stem black, should be uprooted and burnt. If this trouble has been experienced grow the plants on a fresh site, lime the soil and spray them with liver of sulphur, 1 oz. in 2 gallons of water.

**CHINA ROSE.** The popular name China rose is given to *Rosa Indica semperflorens*, or the monthly rose, so called because of the continuity of bloom. In mild districts, if planted against a sunny wall, the old pink monthly rose will bloom more or less all the year. China roses do well in beds in a sunny place. They should be pruned lightly. The best varieties are Armosa, pink; Comtesse du Cayla, reddish yellow; Laurette Messimy, rose and yellow; White Pet, white. The variety Fellenberg, which is rose-red, is more vigorous and makes a good hedge. *See Rose.*

*China Rose. Blossoms of the pink monthly or China rose.*

**CHINA TEA.** There are about a dozen varieties of China tea, divided into two classes —green and black. It is paler in colour and less highly flavoured than Indian and Ceylon teas, and not infrequently it has a perfumed taste and aroma. It may generally be described as being a delicate, fragrant variety of tea. It is sometimes medically advised for people with weaker digestions. *See Tea.*

**CHINCHILLA: The Fur.** The fur of the chinchilla, which is soft and thick, from  $\frac{3}{4}$  to 1 in. long, is a delicate light grey in colour, darkly mottled on the back, and shading into dusky white below. As the chinchilla is becoming extinct and the skins are very small, they are very valuable. Because of its fragile nature, combined with its bad wearing qualities, chinchilla ranks amongst the most expensive of furs. *See Fur.*

**CHINE.** When trimming the broad piece of bone at the end of a loin of mutton or ribs of beef or pork, the butcher is frequently asked to chine it, or saw off the chine-bone. It should be noted that, as this piece of bone will have been weighed in and charged for, it should be delivered with the joint for use in the stockpot or stew.

A chine of pork is a favourite joint for roasting; it is the piece between the head and shoulder, and should be carefully jointed before cooking. Or, if liked, the chine may be slightly salted, boiled, and sent to table with a pease pudding and some green vegetable. It needs to be cooked slowly in plenty of water and skimmed thoroughly to rid it of any superfluous fat. Chine of pork should be salted for a few days before it is cooked.

**CHINÉ.** Satins, taffetas, ribbons, and also cotton materials are described as chiné when printed in a blurred and shadowy-coloured design. The printing is done upon the warp, or lengthwise, threads before the cloth is woven. The weft threads are not printed, and they half conceal the design, tone down the colouring,

and account for the softness of effect.

**CHINESE STYLE:** In Furniture. The three ornamental features used in Chinese furniture are the cloud form, the dragon, and the fret. All three may occur on the same piece of furniture; the commonest is the cloud form, and it may be found practically alone in chairs, settees, and joss tables. To the unpractised eye the cloud form looks more like a conventional spiral suggested by the snail shell. The dragon and the fret, much conventionalised, are more easily recognized in forms approximating to those their names would suggest. Chinese furniture is commonly made of dark rosewood polished to a patina resembling bone.

The Chinese style in English furniture became popular in England when Thomas Chippendale took it up and exploited it with his Chinese Chippendale furniture, examples of which are rare and valuable. This furniture contains what to English people appear as more typically Chinese features than those already mentioned, many of them obtained from architecture. The principal one is the pagoda form, which Chippendale and other cabinet makers of his day employed in carved chair and settee backs, cabinets, beds, and wardrobes.

*Chinese Style. Lacquered and gilt bedstead in the form of a pagoda; English, c. 1760*  
(Victoria & Albert Museum, S. Kensington)

The legs of chairs and tables of this style are fundamentally square in section, but nearly always cut up very elaborately into frets, these frets often having daylight through them, but quite frequently being applied by glue to the solid. Occasionally a conventional rendering of the dragon's head will be seen carved on the terminals of chair arms.

Much of the so-called Chinese furniture used in England in the late 17th and 18th centuries was made of lacquered panels imported into Holland and England and made up into cabinets on carved and gilt or silvered stands. This style had much influence on that of Chippendale (q.v.). See Decoration.

**CHINTZ.** Being a glazed cotton material, printed in several colours, usually 31 in. in width, and dust-resistant, chintz is suitable for bedroom upholstery. It may be used for linings for hanging wardrobes, and ottomans. Old English designs are best in this fabric with its suggestion of coolness and cleanliness.

Being a stiff material, chintz requires much manipulation in upholstery work, especially when making loose covers. Careful planning is therefore advisable before starting to cut it out. Instead of gathering or folding the surplus material into pleats, as in the case of thin cretonne, a dart should be made by cutting away the material where any fullness occurs and sewing the edges into a fine point.

In laundering chintz it is advisable to add bran water to the first washing water. Bran water is made by boiling for about half an hour  $\frac{1}{2}$  pint of bran (placed in a muslin bag) in a quart of water. This addition helps to stiffen the material and to revive the colours of the pattern. Chintz should be starched in boiling-water starch. See Upholstery.

**CHIONODOXA** (Glory of the Snow). A pretty spring flowering bulb suitable for planting in the rock garden or in grass. *Luciliae*, blue and white, and *sardensis*, blue, are the chief sorts. The bulbs should be set 2 in. deep in September. Pron. Cio"-nō-doksá.

**CHIP CARVING.** This art, which is done with a sharp-pointed knife, has nothing whatever to do with the shaping of the article, the pattern consisting of simple V-shaped grooves or excavations cut in the surface, just as lettering or figures may be cut in a flat surface of stone. Designs, which are usually geometrical, are produced in this way in order to ornament what would otherwise be plain surfaces.

Fig. 1:

Chip Carving. Left,

Various V-shaped cuts. Above, Fig. 2: Carved trenches and triangles adapted from the V-shaped cut.

Fig. 3. Geometrical design. Fig. 4. Chip carving knives.

Fig. 5. Circular bread board with carved border. Fig. 6. Detail of pattern which is used in the border.

Examples of various cuts are

illustrated in Fig. 2. Before commencing on actual work it is best to practise on waste pieces of wood. Draw pencil lines and try to follow them accurately with the knife or with a chisel. As seen in Fig. 2, the V-shaped trench may have square ends, sloping down at

the same angle as the sides, or may curve or narrow up to a point at the ends. In other cases the excavation may be a small triangle with its three sides sloping to a point at the bottom. A number of these are generally cut in a series forming straight lines of the pattern. Examples are shown in Fig. 1.

More elaborate forms of chip carving are shown in Fig. 3. The method is the same in detail, but the complexity of the design is increased. Two trenches side by side may have only a ridge between, corresponding with a single line on the surface, or there may be a flat between them necessitating two lines in drawing the pattern.

After the design has been drawn on the wood the lines are followed with the knife sloping, so that when at the correct depth the edge of the knife is midway between the surface lines. First one side is cut, and then the slope of the tool is reversed for cutting the other. Instead of reversing the knife it is often more convenient to turn the work round. In a long trench the chip can be removed when the second side has been incised, but in the case of a triangle, or square end of course, a third incision is necessary to release the chip.

Material for chip carving should be evenly grained, quite free from knots or splits, and soft enough to cut easily without imposing too great a strain on the hand while manipulating the knife. Lime and American whitewood are both excellent for the purpose; they are light in colour, pleasant to handle, and the white wood is particularly amenable to treatment with water stain. Articles adapted for chip carving include wall brackets, medicine and other cabinets, and occasional tables; the turnery department of any large store is a happy hunting ground for suitable subjects. Similar articles are also available with a design ready traced upon them. Varieties of chip carving knives are shown in Fig. 4, the one most commonly employed being that which is bent in relation to the handle.

A straight cut may run with the grain or across it or diagonally, and in either case the knife can travel along it in the direction which suits the grain. In following a curved line it may be necessary to reverse the direction of cutting once or twice to avoid tearing up the grain. In a diagonal cut the knife must travel one way on one side of the trench and come back the opposite way on the other.

The bread board shown in Fig. 5 is a simple example of chipcarving, and may be made by any woodworker. It measures 1 ft. 2 in. over all, and should be cut from  $\frac{3}{4}$  in. or 1 in. material, sycamore or beech being suitable. The full size design may be set out from the particulars given at Fig. 6, the main lines running to the centre as shown. It is transferred to the wood by means of carbon paper. The principal lines should be veined. The edges should be finished with a pronounced chamfer. See Fretwork; Woodcarving.

**CHIPPENDALE STYLE.** Thomas Chippendale, a cabinet maker, who died in 1779, gave his name to a style of furniture which has been generally admired for its beauty of design. Genuine specimens command very high prices, while good imitations are

valued.

*Chippendale Style. Left, portion of mahogany bookcase, showing use of fret. Right, typical armchair with cabriole legs and claw and ball feet (Courtesy of Waring & Gillow, Ltd.)*

One authority has laid down the following useful hints for recognizing Chippendale furniture: "Chippendale furniture is made most frequently entirely of mahogany with carved enrichment and no inlay. Its construction is sturdy but its ornamentation often exceedingly light and fragile. Most of it shows skilful exploitation of curvilinear forms. Fretted or pierced ornamentation is common, and in general the style of the decoration follows Louis XV models. In colour old Chippendale furniture is inclined to brown, often becoming deep chocolate with an almost metallic-looking patina. It is never a hot red."

*Chippendale Style. Mahogany hanging shelves showing influence of Chinese design, made c. 1750-60. Right, characteristic fret patterns used in furniture decoration. (By permission of the Director, Victoria & Albert Museum, S. Kensington)*

The following articles are found in old Chippendale: chairs, stools, settees, commodes, dining tables, side tables, bookcases, card tables, basin stands, wine coolers, mirror frames, writing-tables, brackets, wardrobes, bureaux, secretares, tallboys, candle stands, clock cases, china cabinets, fire screens, tea caddies, bedsteads, and chests of drawers.

As far as can be ascertained, Chippendale never made a sideboard, as we understand the term, and even his side tables rarely have a drawer in them. Spanish mahogany, which was carefully selected, was used by him for most of his pieces, but some of his designs were carried out in carved and gilt wood. Chippendale's chairs and tables had square or cabriole

legs, the latter not infrequently terminating in a claw and ball foot. Foliage and scrolls, trophies of musical instruments, and fretwork carved out of the solid wood and cut separately—not applied, as was the custom with reproductions—are some of the features which characterise his cabinets. Mirror frames were divided into compartments by scrolls. Figures and animals were introduced.

**Chinese Chippendale.** After the middle of the 18th century Chippendale varied his furniture designs to fall into line with the prevailing Chinese mode. We have the lattice work backs of chairs, pagodas on tops of bookcases and cabinets, fretwork of Eastern patterns, and other details which give the style to Chinese Chippendale.

Later in the century French designs came into fashion, and Chippendale's work accordingly became more rococo. We have the interlaced riband-backed chairs sometimes with a free treatment of the lover's knot ornament, and generally scrolls and foliage were carved with a lighter hand. *See Antiques; Chair; Chinese Style; Table, etc; also illus. p. 281.*

**CHIPS: A Potato Dish.** The secret of making chips lies in having the fat so hot that a blue vapour rises from the pan, and in well draining the potatoes before frying. After peeling the potatoes wash them well in cold water, as this washes away the starch and prevents the chips sticking together in the pan. Slice the potatoes lengthwise. Wipe them dry with a clean cloth, then put them in a wire basket, plunging the latter into a saucepan containing sufficient hot fat to cover the potatoes. Fry them until they are crisp and lightly browned, turning occasionally to make sure that both sides are cooked equally. Lift out the basket, and drain the potatoes in this for a minute before turning them on to a soft paper so that they may finish draining. *See Potato.*

**CHIROPODY.** The treatment of the feet in order to keep them healthy and comfortable is a very important detail of the toilet, and the instruments employed for the purpose must be scrupulously clean. Scissors, files, scalpels, etc., should be placed in boiling water and then soaked in a solution of disinfectant.

The toe-nails should be kept well trimmed, but they ought not to be cut too short. They must not be cut in a curve like finger-nails, but straight; if cut down at the corners they develop a tendency to grow in at the sides, which is injurious and painful. If an ingrowing toe-nail makes its appearance, a notch should be cut in the free edge of the nail. As the toe-nail grows this notch will fill up, and the pressure of the nail at the side of the toe will be relieved.

If the spot at which the nail is growing in is very painful, a little piece of cotton-wool that has been dipped in boric powder should be gently pressed under the nail. This must be renewed daily, and will raise the nail so that the edge does not cut into the flesh. *See Bunion; Corn; Foot. Pron. Chi rop-o-dy.*

**CHISEL: How to Use.** In woodwork chisels are

most important among the cutting tools. Those known as firmer chisels (Figs. 3 and 4) are most generally employed, and are sold in eleven sizes, from 1/16 in. to 1 1/2 in. wide, the most useful being 1/4, 3/8, 1/2, 3/4, and 1 in. and 1 1/4 in. wide. A variety of the same class is a long, thin paring chisel (Fig. 2), intended for paring or cutting across the grain and working in deep holes. Both are rectangular in section, and are also made with bevelled edges.

Mortise chisels (Fig 1) are extra strong, and made from 1/8 in. to 1/2 in. in width, for cutting mortises. A drawer-lock chisel indispensable for cutting recesses for drawer locks, is an all-steel double-ended tool.

Good chisels should be clean and straight, all bright parts of uniform colour and texture, and the bevelled end straight and evenly ground. The carver shape of handle shown in Figs. 3 and 4 is smooth in contour, and generally made of boxwood. The plain beechwood or ash handles, as in Fig. 2, are larger in diameter, and give a good grip. Mortise chisel handles are more tapered.

*Chisel. 1. mortise, 2. Paring. 3. Bevelled edge firmer. 4. Ordinary firmer.*

Before a chisel can be used it must be sharpened or set. This is done by first grinding the bevel to a uniformly flat surface and square at the end. When grinding a chisel the grindstone should be turned towards the operator. The chisel should be held firmly and squarely on the stone near enough to the top edge of the latter to allow the tool to be in a nearly

horizontal position, with the bevel lying flat upon it. Holding the tool too low, so that the handle points downwards, will cause the water from the stone to run on the hands of the operator. The chisel should be constantly moved across the edge of the stone to wear the latter evenly. It is then rubbed along the face of a good-sized oilstone, at a slightly steeper angle than that of the bevel (Fig. 7). This produces a shorter bevel, terminating in a clean, sharp edge (Fig. 9), but the pressure put upon the tool will have turned up a tiny ragged edge on the flat side. This is removed by placing the chisel flat on its back on the oilstone and rubbing it off (Fig. 8). A few strokes on both sides, putting on little pressure, will result in a perfectly clean and sharp edge. Chisels must be maintained in this state by rubbing on the oilstone from time to time as they become dull or blunt.

The quality of work done with a chisel depends upon the correct handling of the tool. However good a chisel or sharp the edge, no satisfactory work can be done unless the handle is properly held. Generally speaking a chisel should be used with both hands. The right grasps the handle and directs the course of the tool, and also supplies the energy for its propulsion (Figs. 5 and 6). The left is used to grasp the blade near to the cutting part further to control and direct the cut. By far the greatest amount of work is done in one of four ways. These are: chiselling with the grain of the wood, paring across the grain, paring across the end grain and at right angles, and by oblique cutting partly across and partly with the grain.

5. *Horizontal chiselling.*

6. *Vertical work.*

7. *Sharpening edge.*

8. *Removing rough edge after sharpening.*

Chisel. Fig. 9. *Enlarged view of the cutting edge when correctly set, showing the smaller bevel formed by rubbing the edge on oilstone.*

In chiselling with the grain the tool is held at a small angle and simply propelled forwards, taking care not to let it dig in, by making judicious use of the left hand. In paring horizontally across the grain, work from one side of the job towards the centre; reverse the job and work from the other side and finally clean up the surface flat and true, making diagonal cuts to aid in the flattening. Test the work with a square at frequent intervals.

When paring across the end grain the tool is held upright and the cutting edge applied near the end and side of the wood, starting the cut with a slight side-tilt on the chisel, and bringing it up straight as the cut proceeds. The right shoulder should be close to the top of the chisel handle, and the whole strength of the arm, shoulder, and back put into the cut. One should never attempt to cut off too much at a time, repeated light strokes produce better results. In oblique paring always work downhill—that is, cut with and across the grain. Do not attempt to cut against or up the grain, as the result will be ragged work and splits in the wood.

The art of using the chisel is only acquired by practice, and the amateur is advised to begin with simple jobs, such as the shaping of a hexagonal piece of wood, say 6 in. across the flats and 1 in. thick. If accurately chiselled to shape, and square and true on all its faces, this will be ample evidence that he has passed his novitiate. *See Amateur Carpentry; Bench; Wood Carving, etc.*

**CHIVE:** Its Culture and Use. The plant grows in a thick cluster of small bulbs with grass-like, hollow leaves. If an old clump is pulled to pieces in spring, and the separate plants are set a few inches apart in a line in a fairly fertile soil, fresh clumps are soon formed. Where no old clumps are available, seed should be procured and sown, as if for onions (q.v.). The clumps require to be renewed about every third year. The leaves are cut close to the ground occasionally in order to ensure a full supply of young ones.

*Chive. A plant of chives, valued for its mild onion flavour in salads and soups.*

**Use in Cookery.** The chive is a very useful variety of the onion tribe. Though small, it has an exceedingly powerful flavour and should be used in cookery with caution. The young leaves are often minced, and when freshly cut the flavour is delicate and forms an important ingredient in French salads. They are also used as a pot-herb, and chive sauce is much liked with roast meat or grills.

To make this sauce, put a gill of fresh breadcrumbs into a saucepan with 2 oz. butter. Cook them over the fire until a pale gold, when  $\frac{1}{2}$  pint stock and 3 tablespoonfuls finely minced chives should be added. Stir while it boils for 5 min., season it with salt, pepper and a tiny dust of grated nutmeg, and it is ready to serve.

**CHLORAL** or Chloral Hydrate. On account of its soothing effect on the nerves and power of inducing sleep, chloral or chloral hydrate is often prescribed. Nevertheless, it exercises a depressing effect on the heart, and must be used with the greatest caution; if taken for any length of time it may result in a chloral habit that will be very difficult to shake off. It should not be taken by anyone suffering from kidney disease, and never except on a physician's prescription.

**CHLORODYNE.** For relieving pain chlorodyne is a proprietary remedy very commonly used. It is useful in colic either with or without diarrhoea, and when this appears to be due to indigestible food a dose of castor oil should be given at the same time. It may also help an irritable dry cough. It should not be given to infants or children without medical advice. The

symptoms of poisoning are those of opium, and the treatment is the same. *See* Poisoning.

**CHLOROFORM.** This drug is widely used in medicine on account of its properties of inducing loss of consciousness and preventing pain and shock during surgical operations or in childbirth.

The compound tincture of chloroform and morphine is somewhat similar to chlorodyne, and is used in the same way. The dose is from 5 to 15 minims. Chloroform water is a pleasant diluent for other medicines, as it has a somewhat pungent odour. The dose is  $\frac{1}{2}$  fluid oz.

Chloroform liniment is frequently used as ABC liniment, which is a mixture of the liniments of aconite, belladonna, and chloroform. This may be rubbed on the part, or it may be applied on lint covered over with gutta-percha tissue. It may be used in muscular rheumatism or in neuralgia.

Spirit of chloroform may be used in flatulent dyspepsia, and may be combined for this purpose with a third of a teaspoonful of bicarbonate of soda dissolved in a little water. It is also used in cough mixtures. A single dose is from 30 to 40 minims; a repeated dose is from 5 to 20.

**CHLOROSIS.** Women and girls who follow indoor occupations are liable, under certain conditions, to suffer from chlorosis, which is a form of anaemia and is also known as green sickness. The patient becomes breathless on exertion, as in climbing stairs. The complexion may not show any marked change, but more frequently it has a greenish tinge. Constipation and digestive troubles are common. Examination of the blood shows a large diminution of its colouring matter, haemoglobin. The treatment consists in the administration of iron, a convenient form being freshly made Bland's pills, increasing from one to three, thrice daily, and frequent doses of Epsom salts. *See* Anaemia.

## CHOCOLATE MAKING AT HOME

### Recipes for Some Popular Varieties of Confections

Other articles dealing with Sweet-making include Fudge; Sweets; Toffee. *See* also Cocoa; Decoration; Icing; Sugar, etc.

With additional cocoa-butter and fine sugar carefully incorporated cocoa becomes chocolate. Without the sugar it is known as unsweetened block cocoa, of which only the best should be used. Table cocoa must not be used for sweetmaking.

Although impossible to make first-rate chocolate without machinery, a good eating chocolate may be prepared as follows. Put 1 lb. of unsweetened block cocoa in a small pan and place this inside another containing water. Slowly melt the cocoa over gentle heat, stirring well, and taking care that no water comes over. Add 1 lb. icing sugar, stir while this melts, and then thoroughly mix the two together. Run in 4 oz. melted cocoa-butter, and beat the mixture vigorously.

The contents must not be allowed to rise above blood-heat. Remove the pan from the warm water, add essence to taste, vanilla, kirsch, maraschino, etc., and

keep stirring and beating till the chocolate becomes almost solid. Allow it to stand for several hours, then remelt it as required, never letting it get much over 88° F. or 31° C.

If the chocolate is to be poured into tin moulds, these must be warmed to be of the same temperature as the chocolate, and should be clean and brightly polished to get nice glossy sweets. Once moulded, the chocolate should be cooled as rapidly as possible; otherwise it will be spotted and dull in appearance.

Milk chocolate is prepared as ordinary chocolate, but with the addition of 4 oz. full-cream milk powder to the amount mentioned above.

Hazel nuts, shelled, blanched, and well roasted in the oven, are used for nut chocolate. The hazels, while still slightly warm, should be stirred through the chocolate just before pouring, which in this case should be as nearly as possible at its setting point.

*Chocolate Confectionery making.* 1. The cream or other centre is dipped in liquid chocolate, and then, as in 2, placed on tin to be decorated with a whirl, made, as in 3, with a little chocolate twisted round with a sweet fork. 4. In making a truffle the chocolate and whipped cream are mixed; the sweet is then rolled in the hands and dipped in chocolate powder.

A great variety of chocolates are prepared by dipping sweets, known as centres, in a specially prepared chocolate. These centres, which may be either of a hard or soft nature, are made of fondant, variously coloured and flavoured, and also of fruit paste, caramel, nougat, marzipan, and other mixtures. Effective decorations can be devised from angelica, artificially coloured nuts and sugars, and crystallised flowers.

The prepared chocolate required for dipping is known as couverture, and it has to be melted down with the greatest care, for therein lies the secret of success. The correct temperature, too, when once attained, must be preserved throughout. With too hot a couverture, the sweets become grey; if too cold, the couverture is muddy, the dipping slow and tedious, the

coating heavy, and the finished sweet of unattractive appearance.

In dipping centres, wire forks or loops should be used. The pan with the chocolate, set in another containing warm water, should be in front of the dipper, with the centres on the left and highly glazed papers or brightly polished tins, on which to place the finished sweets, on the right. The centre is dropped into the chocolate with the left hand, and picked up with the fork in the right; the fork is tapped on the side of the pan to spread the coating evenly and remove any surplus, then drawn along the side to prevent "feet" on the sweets, and the covered centre laid on the paper or tin. Unless to be otherwise decorated, each sweet is ornamented with a twirl or line, made with the fork as the dipped centre is laid on the paper. All manner of centres may be dipped thus.

After each of the centres has been dipped, the chocolate in the pan should be well stirred, otherwise there will be layers at different temperatures and the sweets will be streaky. Couverture which runs very freely is too warm. It should set almost immediately the sweet is placed on the paper and show a gloss. The dipping should be done in a dry room, with a temperature of about 60° F. Only the best cocoa-butter should be used.

Almond centres are prepared by shelling ½ lb. sweet almonds and putting them on a baking-tin in the oven until they are slightly browned. When they are quite cold, dip them in couverture, and leave them on an oiled tin to harden.

Chocolate truffles are rich, soft chocolate centres dipped in grained chocolate or dark, unsweetened chocolate powder. For each ounce of chocolate allow one tablespoonful of cream and a teaspoonful of coffee or vanilla essence. Mould the truffles with two teaspoons and toss them in the grained chocolate until they are coated; finish by placing them in fancy sweet cases.

*Chocolate*

*Confectionery making.*

*Fig. 5. For a chocolate with marzipan centre, shape the marzipan, put it on a hatpin and dip in liquid chocolate, then*

*plunge quickly into dry chocolate powder.*

*Fig. 6. Home-made chocolate truffles. Fig. 7. Box of home-made chocolates of assorted shapes.*

Nougat centres are prepared by putting 6 oz. strained honey and 2 oz. glucose into a small pan, and setting the latter inside another containing hot water. Stir the mixture till it is quite hot. In another pan boil 1 lb lump sugar with ½ pint water, and also a pinch of cream of tartar, to 290° F. While this is boiling beat up the whites of three eggs to a stiff snow, which should just be ready when the sugar reaches the requisite degree. Add the

boiling sugar to the egg whites, stirring vigorously all the time.

Next add the honey and glucose, place all together in a double boiler (one large pan inside another will do), and keep on heating gently and stirring vigorously till it becomes quite stiff. Add a few blanched almonds and glacé cherries, warmed and cut up, and pour the whole into a tin or wooden frame lined with wafer paper. Cover it with wafer paper, place a board on the top, then a heavy weight; let it remain thus for 24 hours, then cut it up.

Orange cream centres are made by adding to the grated rind and juice of a carefully selected, deep-coloured orange sufficient icing sugar to make a stiff paste. Add to this a ½ teaspoonful of citric acid dissolved in a few drops of water, and mix all well together. Form the mixture into small balls, or other shapes, and dip them.

To prepare Turkish delight centres, dissolve very slowly together 1 oz. of ground gelatine, 4 oz. of glucose, 1 lb. of honey, the juice of one lemon, and a full ½ pint of warm water. Bring these carefully to the boil, stirring all the time, and boil for 10 min. Flavour and colour the mixture according to taste, and put it out into bright tins, rinsed out with cold water. When cold cut it up into squares.

Marzipan squares are made by dividing ¾ lb. of warmed almond-paste into three parts, leaving one white, and colouring the others pale yellow and pink. Flavour the white with vanilla, the yellow with lemon, and the pink with rose or raspberry. Roll them into sheets, and lay one above another. Cut them up into squares and set them out to dry before dipping.

**Fruit Centres.** To prepare fruit-paste centres, bring to the boil a little apricot jam, stirring it all the time. Remove it from the gas or fire, mix in an equal quantity of finely-cut preserved pineapple, and drop the mixture with a spoon in small drops on some glazed paper. When these are set, stick them together in pairs with stiff jam or jelly, and allow them to dry thoroughly.

Chocolate fruit dominoes can be made by finely chopping a cupful of shelled walnuts, half a cupful of figs, and the same quantity of stoned dates, and adding to them the grated rind of an orange, a tablespoonful of orange juice, and a square of melted, unsweetened chocolate. Turn the mixture on to a board sprinkled with powdered sugar, and roll it out to one-third of an inch in thickness. Cut the paste into the shape of dominoes, using a sharp knife; coat these thinly with melted chocolate, and decorate with small pieces of blanched almonds.

The ingredients required to make chocolate caramels are ¼ lb. chocolate (scraped fine), 1 cupful brown sugar, 2 cupfuls treacle, 1 cupful milk, and 1 piece butter the size of an egg. Boil these in a porcelain saucepan, stirring all the time, till the candy hardens when dropped into water. This should take about ¾ hour. Stir in 1 tablespoonful of vanilla extract when the

saucepan has been taken off the fire and the mixture has stopped bubbling. Pour in a shallow, oiled tin; leave candy to set and mark into squares.

**CHOCOLATE:** The Beverage. When possible, this should be made with a French chocolatière, which, by reason of a small beater device that passes through its lid, enables the chocolate to be easily whisked while cooking. A good drinking chocolate can be made by grating two large bars of plain chocolate into a pan, and adding to them 1 heaped tablespoonful of white sugar and a teaspoonful of the best cornflour or arrowroot. Mix these ingredients smoothly with a breakfastcupful of water, and let the whole boil gently for 5 min. Then stir in 1 breakfastcupful of milk, bring it to the boil, and serve it in cups, adding, if liked, a spoonful of whipped cream on the top of each. *See Cocoa.*

**CHOCOLATE BISCUIT.** These are excellent for afternoon tea. To prepare them, dissolve 2 oz. grated chocolate in a small tablespoonful of water. Put 2 oz. margarine in a basin, work it up with a wooden spoon, and add 3 oz. castor sugar, beating the mixture to the consistency of cream. Mix in the dissolved chocolate, beat in an egg, then add the vanilla and lastly 6 oz. sifted flour, stirred in lightly. Turn the mixture on to a floured board, and roll it out into a thin sheet. Cut it into shapes, and bake these on a greased tin in a moderate oven for 12 to 15 min.

**CHOCOLATE CAKE.** First of all  $\frac{1}{4}$  lb. each of butter and castor sugar are creamed together. Then the yolks of 2 eggs are beaten in, 3 oz. each of grated chocolate and flour, and  $\frac{1}{2}$  teaspoonful of baking-powder added, and finally the whites of the 2 eggs beaten to a froth. The mixture is baked in a moderate oven for 1 hour and may be covered with chocolate icing if desired, top and sides sprinkled with chopped nuts and centre decorated with pistachio nuts.

*Chocolate Cake, covered with chocolate icing and decorated with pistachio and other nuts.*

**CHOCOLATE CREAM MOULD.** A favourite party sweet is made from  $1\frac{1}{2}$  oz. grated chocolate, 2 oz. sugar,  $\frac{1}{2}$  oz. gelatine, and  $\frac{1}{2}$  pint of slightly whipped cream.

*Chocolate Cream Mould, set in an ornamental shape and turned out in a glass dish.*

Put the gelatine into a saucepan with enough water to melt it, and add the chocolate and sugar, together with a little milk, stirring the whole till dissolved. Whip the

cream slightly, mix it with the rest of the ingredients, after they have cooled slightly, and put all into a wet mould to set.

**CHOCOLATE ÉCLAIR.** These iced cakes are made with  $\frac{1}{2}$  pint water, 3 eggs, 4 oz. flour, 1 oz. sugar, 2 oz. margarine, a pinch of salt, a little whipped cream and some glacé icing. Put the water, salt, sugar, and margarine into a saucepan over the fire, and, when they boil, add the flour. Stir the mixture until it becomes a soft paste and leaves the sides of the saucepan. Then take the pan from the fire and add the eggs separately, beating each in well. With a forcing tube lay the paste out in shapes measuring about 4 in. long on an ungreased baking-tin. Bake these for 20 min. in a moderate oven, and when they are cold split them open at the side and fill them with whipped cream sweetened and flavoured with vanilla. Ice the top of the éclairs with glacé icing. This quantity is sufficient for about ten éclairs.

**CHOCOLATE ICING.** In making a simple chocolate icing,  $\frac{1}{2}$  lb. icing sugar and 3 oz. grated chocolate are mixed together with 2 tablespoonfuls of hot water or milk. A glacé for fancy cakes requires more sugar. Cook 2 oz. grated vanilla chocolate in  $\frac{1}{4}$  pint of water in a pan, then add 1 lb. icing sugar with 3 tablespoonfuls warm water. The mixture should be poured warm over the cakes.

**CHOCOLATE PUDDING.** A baked pudding requires 1 pint milk, 3 eggs, 2 tablespoonfuls each grated chocolate and castor sugar, a few drops vanilla, and 1 oz. cornflour. Put the grated chocolate in a saucepan with  $\frac{1}{4}$  pint of the milk, and boil the two together until they form a smooth paste. Then mix the cornflour with 2 tablespoonfuls of the cold milk, and add it, with the rest of the milk, to the chocolate, and stir the whole till it boils. Draw the pan to the side of the fire and beat up the 3 yolks of eggs and stir them into the cooled mixture, flavouring with the vanilla. Pour the whole into a buttered pie-dish, bake  $\frac{1}{2}$  hour, and then beat up the whites of 2 eggs to a stiff froth. Add half the sugar lightly, and heap it over the top of the pudding, sprinkling the rest of the sugar over all. Bake the pudding very slowly.

**CHOCOLATE ROLL.** Cream together 3 oz. each sugar and butter, and sieve together  $\frac{1}{4}$  lb. flour and 1 teaspoonful baking powder. To the former mixture add 3 eggs, beating each in separately, and lastly fold in the flour and baking powder, together with a little milk if required. Pour the mixture into a shallow greased tin and cook for 10 min. in hot oven.

In the meantime, put  $\frac{1}{4}$  lb. jam into a saucepan to warm, and when the sponge is ready spread it with the jam and roll it up immediately. When the cake is cool ice it with chocolate butter prepared with  $\frac{1}{4}$  lb.

butter, 9 oz. icing sugar, 2 oz. grated chocolate, 2 tablespoonfuls milk, and a little vanilla flavouring. Cream the sugar and butter and add the chocolate (dissolved in the milk) and a few drops of vanilla. Pour the icing into an icing bag and force it from a shell-shaped icing tube in straight lines from one end of the roll to the other.

**CHOKING.** One of the commonest causes of choking is when a fish bone gets stuck in the throat or when a morsel of food goes down the wrong way. Artificial teeth may get fixed at the back of the throat or in the gullet, obstructing the air passages; and fragments of children's toys have been a source of danger.

By taking a sudden deep breath when there is something in the mouth the object is sometimes drawn quickly into the larynx, or even farther, into the trachea or bronchi. The result is a violent choking fit, in which the face grows red and swollen, with violent cough and difficulty of breathing. A child so affected may be held head downwards to ensure that the foreign body shall not proceed farther down the windpipe. If this causes vomiting, no harm, but perhaps good, may follow; nevertheless, the accident is sometimes accompanied with real danger, and it may become necessary to send the patient to hospital to have the object removed by the aid of an instrument called a bronchoscope.

Unless the patient is unconscious he should be made to kneel on a chair with the head downward and the body weight supported on the hands on the floor. In this position he should attempt to cough the obstruction out of the windpipe, while at the same time he should be given a few smart blows between the shoulder blades. If these means are not sufficient to remove the obstruction, the mouth should be prised open by some hard object thrust between the back teeth, such as the handle of a spoon guarded by a handkerchief. Then someone should thrust his forefinger well to the back of the throat as far as possible, and sweep it across the base of the tongue in an attempt to dislodge the obstruction. If there is any difficulty in affording relief, the doctor should be sent for at once. Artificial respiration may be necessary if breathing has ceased. *See Artificial Respiration; Asphyxia.*

**CHOP: How to Cook.** The accepted meaning of a chop is a small cut of mutton, lamb, pork, or veal taken from the loin. Neck chops are very occasionally spoken of, but they are more correctly alluded to as cutlets (q.v.). When cut from the tail end it is known as a chump chop. The texture of the chump end is excellent, but the proportion of bone is greater. Chops cut from a very fat loin are wasteful, and as the price is high a good butcher will trim them carefully. They are best grilled or broiled. The method of frying them is much used, but it is less excellent in flavour. With grilled chops serve potato chips or straws, and maitre d'hôtel butter. Lamb chops are cooked as those of mutton; they are more delicate in flavour, but should be well done, while many people prefer a mutton chop slightly underdone. Stewed chops make a very savoury and

wholesome dish. Very little fat should be left on. For invalids, steamed chops are more suitable than grilled; serve simply, with their own cooking juice and a dust of seasoning. *See Grilling; Mutton.*

**CHOPPER.** Two types of chopper are in general use—the long, narrow pattern used for chopping wood, and a broader-bladed kind for chopping meat. A French kitchen knife, however, with its fine point and deep hilt, is better than the straight-bladed knife, and two or three of these are most desirable implements to have in the kitchen.

*Chopper. Shown is the broad-bladed implement used for chopping meat; below, the narrow pattern employed for wood-chopping.*

All that a chopper requires to keep it in good order is an occasional grinding. The edge can be kept in good trim by whetting it on an oilstone slip. A wipe over with an oily rag prevents the blade going rusty; a loop round the handle makes the chopper easy to hang up.

The correct method of chopping meat into small pieces is to hold the point of the chopper or knife firmly down on the chopping board with the left hand, and with the right work the handle up and down, now and then collecting together and turning over the food being chopped with the left hand, thus ensuring speed. *See Parsley; Suet.*

**CHOPPING BOARD.** Desirable qualities in a chopping board are rigidity, solidity, a smooth surface, and toughness to resist wear. It should, therefore, be made of a solid piece of hardwood, such as beech, birch, or maple. Convenient sizes are 14 in. long, 12 in. wide, and 2 in. or more in thickness. Four holes about  $\frac{3}{4}$  in. diameter drilled near the corners on the under side of the block and filled with ordinary bottle corks, leaving  $\frac{1}{8}$  in. protruding, ensure the board resting firmly and, by providing a certain amount of resiliency, facilitate the chopping.

**Chorea.** This is the medical name of the complaint known as St. Vitus's Dance (q.v.).

**CHOW CHOW.** A clever and kind-hearted dog, devoted to his owners and endearing himself to their children, the chow is a spirited guardian of the house and a distinct ornament to it. With his handsome coat of dark red, black, yellow, white, or blue, he wears a fur ruff around his neck, and the plume that serves for a tail is curled far over his back. His small, pointed ears are carried stiffly erect, his dark eyes are almond shaped, muzzle broad, and tongue blue-black. His weight is about 40 lb.; that of his mate a few pounds

less. *See Dog.*

*Chow Chow. Champion of the Chinese breed of dog.*

**CHOWDER.** Cod or fresh haddock may be used, 1½ lb. being cut up into small pieces with ¼ lb. each of peeled onions and potatoes, cut in ¼ in. cubes. Trim and cut 3 oz. of pickled pork into the 1 same sized pieces, and fry the pork and onions until they are a light brown. Put potatoes, fish, onions and pork in a casserole in layers, adding 2 sliced tomatoes and seasoning and powdered herbs between each layer. Potato should be on the top.

Pour in 1 pint of stock, cover it and simmer for 20 min.

Heat ½ pint of milk and break into it three water biscuits. Let these stand for 3 min. Stir into the chowder, boil it once, and serve it in the casserole.

**CHRISTENING.** This term is used, especially by certain Nonconformist bodies, for the religious rite more generally known as baptism.

**Christening Robe.** The usual length is 44 in., and 3 yards of double-width material is sufficient. An effective robe can be made by utilising a piece of Brussels or Honiton lace in panel form from the yoke to the edge of skirt. Tiny tucks and insertion finish the rest of the skirt. A beautiful gown can be made with self-embroidery—a fine spray of flowers extending the full width of the front, and tapering up to the yoke. Smaller sprays may be used in a running pattern at the foot of the skirt. An insertion of fine Valenciennes lace, to which is whipped a tucked and lace-edged frill 4 in. in depth, is a better finish than a hem. The robe will sit better on the infant if the skirt is gathered into a yoke 3 in. in depth. This can be self-embroidered, or trimmed with tucks, lace motifs, or insertion. The sleeves should be rather full and reach to the wrist, as they will then cover a woolly vest or small coat. They can be finished with a narrow beading or insertion edged with lace. *See Baby.*

## CHRISTMAS AND ITS MERRYMAKING

### Preparation of Seasonable Fare and Suitable Decorations

Further information will be found in such articles as *Artificial Flowers*; *Cracker*. See also *Children's Party* and entries on *Card Tricks*; *Conjuring*

Preparations for Christmas are a serious or joyous matter according to the spirit in which they are tackled. It is far better to give simpler presents, fare, decorations and general entertainment than to attempt expensive elaboration, which will not make for happiness owing to strained nerves or over-taxed resources.

Most children love assisting with anything to do with Christmas festivities; also they like preparing presents, secret shopping and doing up their parcels. In the latter connexion the continental habit of packing up gifts in special coloured and patterned papers, with tinsel or holly-sprigged ribbons and attractive seasonable labels and seals, is one which delights children, and these little extra bits of decoration cost only a few pence. Parcels sent out or arriving in Christmas wrappings with merry labels bearing the instruction "Not to be opened till December 25," are much more exciting than drab brown paper packages.

The modern child is apt to be incredulous of Santa Claus and of Father Christmas himself but is willing to do a little make-believe for the occasion. Therefore, in many households on Christmas Eve, when small people have given up the futile effort to lie awake until the arrival of Santa Claus, the stocking is filled and Christmas gifts are placed on the table by the bedside. This also has the advantage of keeping children busy until the elders are prepared to start the day: whereas, if the gifts are to be placed on the breakfast table, the whole house is astir before dawn. It is usual, especially where there are children, to have the Christmas dinner served in the middle of the day. This has advantages when evening refreshments have been cleverly planned to take the form of a help-yourself supper of ready-prepared dishes, as it allows the staff to have the evening off with their friends. If the Christmas party is a family gathering, probably after dinner games suitable to all ages will be included in the programme. Everyone enjoys a few conjuring tricks, if the host is able to do a short series of these. In addition it is well that a few records of popular dance successes should be forthcoming for the gramophone.

The Christmas menu may be simplified to grapefruit, consommé, flavoured and coloured by tomato and served in cups, roast turkey—chosen with due consideration for the size of the party—stuffed, with chestnuts in the body and sausage meat in the crop, accompanied by cranberry sauce, celery, a salad and baked potatoes, and followed by those essential features of a Christmas dinner, plum pudding, mince pies and special dessert. It is often found better to carve the turkey in the kitchen beforehand, arranging it nicely on a dish to be kept hot until served. Sometimes roast goose is preferred to turkey. If not too fat, garnish the goose with chipolata sausages and serve with apple sauce.

The table should be charmingly laid and decorated with as much colour in the scheme as taste permits. The big bowl of fruit, surrounded by scarlet or silvered candles, in glass or silver candlesticks, and by smaller sweet dishes with brilliantly coloured crackers interspersed, can be recommended where flowers are hard to obtain. A small frosted Christmas tree on a centre-piece of silver paper, outlined with holly leaves, or a snow man guarding a big bundle of crackers may be liked. If a tablecloth is used it should be a festive one, or mats of lace are always right, or an embroidered

runner is suitable for a long, narrow table. Place cards and menu holders carried out in seasonable designs add a finishing touch of gaiety.

**Christmas Decorations.** Some people like to decorate their houses throughout, others are content with an arrangement of evergreens in dining room or hall and sprigs of holly for the table.

*Christmas.*

*Figs. 1-3. How chains and festoons for decorations can be made of coloured paper.*

With many decorations about great care should be taken to see that there is no danger

from the fire or any candles. The latter should only be used for the table or high up on a chimney piece out of possible danger of being knocked over. Wall decorations have the advantage of not encroaching on the space for dancing or games.

Holly ropes are effective when hung in festoons along the picture-rail or swung across the room. The foundation of one of these ropes is a length of stout cord. Small sprays of holly are tied to it with fine string, the leafy end of one piece completely hiding the stalk of another. Such a rope should be fastened securely to the top of the picture-rail, for it will be heavy. Paper bells and ornaments of all kinds may be hung from the holly garlands. The effect is improved if a rope of tinsel is twisted and looped around it.

The simplest garlands to make at home are paper chains, three different kinds of which are shown here. Bundles of coloured paper, about 8 in. by 1-1½ in., can be bought to make them. The simplest chain (Fig. 1) is made by pasting one strip of the paper into a ring, running another through it, and pasting that also into a ring, and continuing thus until a chain of the required length is made.

Another chain is made by pasting a sheet of coloured paper about 8 in. wide to form a tube and pressing it flat, and then cutting it across into strips about 1-1½ in. wide, each strip being a flattened ring. In the middle of one put a small dab of paste, then press a second upon that; paste that also, and stick another flattened ring upon it, etc. Fig. 2 shows a chain made in this way, in which each ring has been placed exactly over the one before; Fig. 3, one in which the rings are made to lie across each other. Twelve rings thus pasted together will, stretched out, make a chain about 3 ft. long. These chains possess an advantage over those shown in Fig. 1, as they fold up into small space and thus can be put away without fear of breaking.

Paper garlands and festoons are also bright and cheerful, hung from wall to wall. The prettiest effect is obtained with "love-hoops," as shown in Fig. 4, made

with chains, bunches of coloured paper cut into strips and paper flowers. The hoops are small wooden ones twisted round with crepe paper. They are held up at intervals by wands, covered with twisted paper, topped by big brushes made of coloured paper cut in short strips. (See Fig. 5.) These decorations are in place of pictures that may be on the walls. A bunch of brightly coloured balloons depending from any central electric lighting fixture is effective. The paper chains and festoons can be held in place by drawing-pins. If the room is lit by gas or lamps the greatest care must be taken that no paper decoration is hung either directly over the light, or near enough to be swung towards it by a sudden draught. The entrance hall may be decorated with holly and a bunch of mistletoe hung from the central light.

*Christmas. Fig. 4. Wall decoration of paper-covered hoops joined by chains. Fig. 5. These are held up at intervals by wands topped by big brushes made of strips of coloured paper.*

An example of a paper figure for table decoration is shown in Figs. 6-7. Crinkled paper, paste, and flower wire are all that are needed to make it, and with a little ingenuity the costume can be amusingly varied. To make the head roll a ball of paper about the size of a hazel nut and twist over it a piece of paper 6 in. square. Paste a narrow strip of white paper round it to form the neck, and keep the twist tight. The loose end of the paper will form the body. Having cut a strip of paper, 2 in. wide and 4 in. long, the elastic way of the paper, twist it up very tightly to form a rope. With a stiletto or sharp-pointed scissors make a hole through the body just below the neck. If the rope of paper is inserted into the hole at one side and twisted, it will pass right through and form the arms. The legs are made similarly from a strip of paper the same width and about 5 in. long, and are run through the body 1 in. below the arms. The doll is then made as in Fig. 6, ready for dressing.

For the skirt, cut lengths, 9 in. by 4 in., of two colours of the crinkled paper. Paste the ends of each together and put one of the rings so made inside the other. Slit the top of both narrowly to a depth of about ¾ in. to form the fringe, then slip in the little figure and gather the skirt closely and evenly round it, so that the base of the fringe comes just below the arms. Bind it round firmly with a doubled strip of paper about ½ in. wide to make the belt. Press the fringe down so that the under colour shows, and stretch out the bottom of the skirt to its fullest extent. The top skirt should now

be cut up nearly to the waist, into strips  $\frac{1}{2}$  in. wide. All that is needed to complete the figure is a bow of narrow

paper pasted on the head and the face inked in. Such little figures made without legs can be mounted on sticks.

*Christmas. Figs. 6 and 7. How to make and dress a doll for Christmas tree or table decorations.*

**Christmas Tree.** For the children the most exciting decoration is often a Christmas tree. Sometimes this is of cut out painted plywood set into an imitation plywood tub. Toys, etc., are hung on the tree by means of tiny screwed-in hooks, and the tree is set flat against the wall. It obviates mess, but is rather a poor apology for the regulation fir.

With any candle-lighted Christmas tree there is risk of fire, for which season a long pole with a sponge at the end should be kept ready with a pail of water to extinguish the candles as they burn down. Because of this risk, many people prefer the tree lighted with coloured electric bulbs.

A fir tree standing about 6 ft. high takes two persons several hours to trim effectively. Ornaments made from silver, gold, and coloured paper should fill up odd spaces and trim the tub, or whatever the tree is placed in. Special shining ornaments are sold by the dozen and can be wired on the branches effectively, with chocolate animals in silver paper, baskets of sweets, little dolls, miniature furniture, crackers, and light wooden toys.

On the apex of the tree the Angel of Peace is symbolised as a fairy doll, with glittering crown and wings and spreading gauze skirts. A pretty touch is to let strands of tinsel fringing fall apparently from the doll's hands to festoon the branches. The girls generally draw lots for the fairy doll at the end of the proceedings. Large toys and presents, if to be given at the same time, should be placed at the base of the tree. The tree should be lighted up a few minutes before the children are admitted, and all other lights turned off. In many houses it is kept until New Year's Eve, when it is lighted up again about a quarter of an hour before midnight to welcome the New Year.

**CHRISTMAS CARDS.** There are not many households that do not send out and receive a few Christmas cards. They are often elaborate and beautiful, but the personal card with printed name and address of sender, either specially designed or chosen from stock patterns, is increasingly popular. Miniature calendars are also frequently used. If the envelopes are left unsealed, Christmas cards can be posted at printed paper rates.

**CHRISTMAS PUDDING.** The basin in which a plum pudding is boiled must be quite dry and well greased. Fill it up well and tightly with the pudding mixture, and tie down over it a scalded and floured

pudding-cloth, leaving a fold to allow for swelling.

A pudding for six or more persons requires boiling for at least 8 hours. Small ones require less in proportion, 3-4 hours sufficing for a 1 lb. pudding; but, in any case, long boiling does no harm. If several puddings are to be cooked in the same saucepan, put them into boiling water at intervals of a minute, so that the water is not cooled too much, and replenish with boiling water as it boils away. Puddings can be made months before use and stored in a cool, dry place; to re-heat them let them stand in boiling water for 2 hours or more.

*Christmas pudding turned out ready to serve and decorated with powdered sugar and a sprig of holly.*

The following is a recipe for a good rich pudding. Mix well together 4 oz. Flour,  $\frac{3}{4}$  lb. breadcrumbs, a small teaspoonful salt,  $\frac{1}{2}$  lb. chopped beef suet, and a flat teaspoonful allspice. Stone  $\frac{1}{2}$  lb. raisins, or use  $\frac{1}{2}$  lb. of seeded; wash and pick over carefully  $\frac{3}{4}$  lb. each of currants and sultanas, and stir them into the flour, etc. Add 3 oz. each of candied orange and lemon peel and 1 oz. citron, cut into thin strips, 2 oz. roughly chopped sweet almonds, and, if desired, 2 oz. glacé cherries. Mix in also  $\frac{3}{4}$  lb. moist sugar, and the grated rind and juice of  $\frac{1}{2}$  a lemon. Beat up 3 eggs, and mix with them 2  $\frac{1}{2}$  tablespoonfuls rum, 1 tablespoonful brandy, and 4 tablespoonfuls ale or stout. Pour this liquid on to the other ingredients, and the more thoroughly it is stirred the better. Leave it for about an hour, and it is then ready to be put in the basin and boiled. This will make a pudding which will be large enough for 10-12 persons.

For a plainer pudding, chop  $\frac{1}{2}$  lb. of beef suet very finely. Clean and pick over  $\frac{1}{2}$  lb. each of currants and sultanas, and stone and chop roughly  $\frac{1}{2}$  lb. raisins. Mix them in a large basin with  $\frac{1}{2}$  lb. moist sugar,  $\frac{1}{4}$  lb. flour,  $\frac{1}{2}$  lb. breadcrumbs, a little salt, and a saltspoonful of allspice. Peel and core  $\frac{1}{4}$  lb. apples and chop them finely, or put them through the mincer. Blanch and shred  $1\frac{1}{2}$  oz. sweet almonds, and cut 2 oz. mixed peel into thin strips. Add these to the other ingredients, with the grated rind and juice of  $\frac{1}{2}$  an orange and  $\frac{1}{2}$  a lemon, and mix well in. Beat up 3 eggs, strain them on to the other ingredients, and mix. Add  $\frac{1}{4}$  pt. of stout, and enough milk to make the mixture drop from the spoon. Let it stand for an hour, then put into basins, tie down, and boil. If made into one pudding, this will be enough for 10-12 persons.

To serve a Christmas pudding, turn it out on a very hot dish and pour over it brandy sauce, or hand round brandy butter separately. Alternatively, pour a little

brandy over the pudding just before bringing it to table, and set it alight. Decorate it, with a sprig of holly. Ready-made puddings are sold by most grocers and provision dealers, and all they require is a few hours' immersion in hot water. *See* Brandy Butter; Brandy Sauce.

**CHRISTMAS ROSE.** *Helleborus niger*, commonly called Christmas rose, is a member of the buttercup family. It is a hardy perennial which thrives in partial shade in deep sandy loamy soil. When transplanting becomes necessary it should be done in July; the clumps ought to be broken into several moderate-sized pieces. The finest variety is named *altifolius* (*maximus*). The blooms are protected by covering them with a handlight.

*Christmas Rose. Cluster of flowers and leaves of Helleborus niger.*

### CHRYSANTHEMUMS AND THEIR CULTURE The Characteristics of Many Different Varieties

In addition to the entries on Aster and other favourite flowers, consult general appropriate articles as Borders; Greenhouse, etc.; also gardening notes under headings of the various months, e.g. April

Few flowers equal the chrysanthemum in popularity, for even in small gardens beautiful displays of bloom can be obtained with very little trouble during the months of September, October and November. It will nourish in beds and borders, but still more under glass, where the flowering period is prolonged into winter, so that it is practically the last of the great plants to bloom. No plant better withstands impurities in the air, and consequently the chrysanthemum is successfully cultivated in town gardens.

There are many types of chrysanthemum; some of them are suitable for cultivation out of doors, others in pots under glass. Among them are several hardy border perennials, e.g. the shasta daisy or hardy marguerite (varieties of chrysanthemums *maximum* and *leucanthemum*) which bear large white blooms on long stems in summer, and the moon daisy (*chrysanthemum uliginosum*), a tall plant with *Chrysanthemum* greenish-white flowers in September. Japanese, incurved, decorative and single-flowered chrysanthemums are grown in pots to supply blooms under glass in autumn and winter. Early or border chrysanthemums flower out of doors from August to October. Annual chrysanthemums, of which seeds are sown out of doors in March, flower in summer.

The border chrysanthemum is hardy in all except cold districts, is easily managed and blooms profusely in late summer and autumn. It is a flower for every garden. Present-day varieties are innumerable, and every year fresh ones are introduced; they bear double or single blooms in crimson, rose, yellow, pink, orange,

bronze, and many other shades of colour.

*Chrysanthemum. Single variety.*

A start should be made by purchasing small plants in May and setting them out at 18 in. apart in a sunny place. Ordinary soil which has been well dug suits them; some decayed stable manure and a scattering of bonemeal should be mixed in. In a fortnight's time the top of each plant should be pinched off to make it branch out; the fresh shoots may be stopped early in June, but not after that month or the blossoming season will be too late. This treatment will ensure the development of well-branched plants that will bloom freely in early autumn. During the summer months the soil between the plants should be hoed frequently, and it will be necessary to stake the plants securely in order to prevent the shoots being broken or becoming misshapen.

*Left to right: Japanese "Mrs. George Monro"; anemone-flowered "Aphrodite"; another Japanese variety.*

*Chrysanthemum. Double variety of border plant.*

Although most of the plants will pass through an ordinary winter safely, especially if covered with old ashes, it is wise to lift a few of them, cut down the stems, and set them in boxes of soil in a cold frame; in early spring fresh shoots will grow, and these are used as cuttings to increase the stock. They should be severed slightly below the soil surface, trimmed just beneath a joint, and inserted in pots or boxes of sandy soil in the frame. If the latter is kept closed and the soil moistened occasionally the cuttings will form roots in 3 or 4 weeks. They will be ready to plant out of doors in May.

Border chrysanthemums may be left out of doors undisturbed for two or even three years if large plants bearing an abundance of bloom are wanted.

The following are some of the best varieties, flowering in August-September:

Afterglow, terra-cotta; Charlotte Harley, crimson; Cranford, yellow; Crimson Circle, red; Gold Dame, yellow; Guinea Gold, yellow; Mme. Desgranges, white; Miss Mattie, yellow; Mrs. Thorpe, terra-cotta buff;

Mrs. J. Pearson, bronze; Phoenix, red; Shirley Bronze, bronze yellow; A. McAlpine, bronze yellow; Harvest Moon, yellow; Red King, reddish.

#### Flowering in September:

Almirante, chestnut crimson; Crimson Marie Masse, Early Buttercup, yellow; Fee Parisienne, rose mauve; Goacher's Crimson, Golden Goacher, yellow; Horace Martin, yellow; J. McAlpine, rose pink; Leslie, yellow; Mme. M. Masse, lilac-mauve; Normandie, pink; Pink Delight, Polly, orange yellow; R.A. Roots, white; September White.

#### Flowering in October:

Bébé Blanc, white; Betty Spark, rose pink; Champagne, red; Cranford Yellow, Dragon, bronze; Ethel Harvey, yellow; La Garonne, reddish salmon; Pink Spray, pink.

Single - flowered chrysanthemums which bloom out of doors in early autumn are:

Delice, pink; Doreen Woolman, yellowish: Early Mary Richardson, buff; Maidenhood, primrose; Red Riding Hood, red; Shirley crimson; Snowstorm, white; Vicar of Shirley, bronze.

**Raising Specimen Blooms.** For the culture of large blooms the plants, grown in pots under glass, should be cut down immediately the flowers have faded, and the shoots growing through the soil will form the cuttings for new stock. Place the cuttings round the edges of pots containing a mixture of sandy loam, first dropping a pinch of silver sand into each hole. Put them under a handlight or propagator in a greenhouse temperature of 50° F.

Well-known growers who specialise in the chrysanthemum may be relied upon to supply excellent young plants in the spring. They must be given plenty of air, and they must not be grown in a temperature higher than 50°. Their proper place is in an airy house close to the light. A 3-in. pot may be used, and the compost should consist of four parts loam, two parts leaf-mould or well-rotted manure, and one part silver sand.

It is a good plan to make the potting soil fairly moist, and it is then unnecessary to water the plants for a day or two. By the beginning of April the plants will be well rooted, and should be put into 6-in. pots, the compost being rougher and a trifle heavier. The newly potted plants should be put back in the frame and kept fairly close for a day or two until the roots have begun to push out into the new material; but the pots must not be crowded. When the plants are again growing well give them a sheltered position in the garden, and do not allow to become dry.

The final potting, which is done in June, is a detail of importance. Flower-pots, 9 in. wide, are suitable for most varieties. The compost should consist of pieces of loam (old turf) two-thirds, well decayed manure one-third with a scattering of sand and crushed brick, and a sprinkling of superphosphate of lime or special chrysanthemum fertiliser. The compost must be made

firm with a wooden rammer and a space of about 1 in. left at the top when potting is finished. The best position for the plants is on a sunny gravel walk. Each plant must be staked.

Different varieties need different treatment in respect of stopping and taking the buds. Often the chrysanthemum produces a flower bud in May: this, which is known as the break bud, perishes and fresh shoots which will form the branches grow from beneath it. If this break bud does not form, the top of the plant must be pinched off to cause the development of other shoots. Usually not more than two or three of these are allowed to grow.

In August each one will bear a flower bud which is called the first crown. If the variety produces its best blooms from first crown buds, these are "taken" by removing the small shoots that grow beneath them.

If, however, the variety yields its best blooms from second crown buds, one of the small shoots beneath each first crown bud is allowed to grow; the bud itself will perish. Each of the new shoots will, in due course, produce a flower-bud—the second crown.

Amateurs will get the best results from most varieties by stopping the plants in April or May, and taking the first crown buds in August. If the shoots beneath the second crown buds are allowed to grow they will subsequently bear buds which are called terminals because they terminate the season's growth. Amateurs who grow for large blooms should consult the chrysanthemum catalogues which give the correct bud to take for each variety.

Booted cutting in small pot. 8. Later potting. 9. Rammer used in potting. 10. Dibber.*

(By special arrangement with "Amateur Gardening")

When the buds are developing the plants must be fed once a week alternately with weak soot water and with one of the special chrysanthemum fertilisers used according to the directions supplied. Towards the end of September the plants are placed under glass where

the blooms will open from November onwards. The glass house must be ventilated very freely in mild weather.

The Japanese varieties are grown to provide the largest blooms: not more than from one to three are left on each plant. The following are first-rate varieties:

Dawn of Day, reddish yellow; Duchess of York, rose-purple; Helena Margerison, pink; Lady Talbot, primrose; Louisa Pockett, white; Majestic, amber yellow; Marjorie Woolman, reddish bronze; Edith Cavell, bronze yellow; Mrs. B. Carpenter, rose; Mrs. R. C. Pulling, yellow; Peace, yellow; Princess Mary, yellow; Queen Mary, white; T. W. Pockett, silvery pink, very large; Viscount Chinda, yellow; W. Turner, white; W. Rigby, yellow.

Many new varieties are introduced each year.

Incurved varieties which need similar treatment to the Japanese are now little grown except for exhibition. A few of the best are:

Buttercup, yellow; C. H. Curtis, yellow; Lady Isabel, blush; Ondine, white tinged with green; W. Pascoe lilac pink.

Decorative chrysanthemums are splendid flowers for amateurs: they are double and of medium size. One plant will produce six or more blooms. The plants should be stopped in April or in June, the first crown buds being "taken." They can be planted out of doors for the summer and carefully lifted and repotted in September, though they do better if grown in pots throughout the season. They bloom under glass in late autumn. A few attractive varieties are:

Aldyth, crimson; Baldcock's Crimson; Blanche Poitevine, white; Cissbury Pink; December Gold, yellow; Dr. Enguehard, rose pink; Exmouth Crimson,

H. W. Thorpe, white; Jean Pattison, copper salmon; Mme. E. Roger, greenish; Mrs. R. F. Felton, crimson; R. H. Pearson, yellow; Wellington Wack, primrose.

These varieties can be grown to form large specimen plants, each bearing from 40 blooms upwards. Cuttings should be taken as early as possible in November or December. By stopping the shoots frequently well-branched plants are obtained. Stopping should not be done after June. The shoots must be staked and tied with great care. The final potting is done in June.

There are some beautiful single-flowered varieties which bloom under glass in late autumn; they need the same treatment as the decoratives. A few of the best are enumerated below:

Ceddie Mason, crimson; Exmouth Pink; Fusilier, bright crimson; Godfrey's Triumph, yellow; Mary Richardson, terra cotta; Phyllis Cooper, yellow; Sandown Radiance, chestnut crimson.

Other types of chrysanthemum are the pompon, anemone-flowered, and thread-petalled. The latest novelty is the cascade chrysanthemum, which is of somewhat drooping growth, bears small single flowers and makes a most decorative pot plant.

Aphis or fly attacks chrysanthemums, but can be destroyed by using one of the numerous proprietary insecticides. Earwigs may damage the buds; they should be trapped in small flowerpots filled with hay and placed, inverted, on the chrysanthemum sticks; the traps must be shaken over hot water every morning.

Rust and mildew are plant diseases which may damage chrysanthemums. On the first sign of infection the plants should be sprayed with liver of sulphur, 1 oz. in 2 gallons of water. The leaf mining maggot often disfigures the leaves by boring. Maggots can be destroyed by pinching the affected parts of the leaf between the finger and thumb. (See also pages 452 & 453)

**CHUBB:** The Fish. Casserole cooking is the best way with this freshwater fish, which somewhat resembles a carp. The fish should be washed in vinegar and water and then sliced; 2 or 3 small onions are sliced and fried in butter, and 1 pint fish stock added, with a dessertspoonful of mixed herbs and seasoning. The fish is allowed to simmer in this for  $\frac{1}{2}$  hour, then lifted out, and kept hot. Add 1 oz. flour mixed with melted butter to the liquid, and continue simmering until the sauce has thickened. The fish is served in the casserole and garnished with little sippets of toast.

**CHUCK:** Its Uses. In its simplest form this is a body piece adapted to screw on to the spindle of a lathe, or mandrel nose, as it is termed. Projecting from the end of the body is a tapered and coarse-threaded screw, on to which is screwed the piece of wood to be turned; such a tool is known as a screw chuck (Fig 1). When the work is long, like a baluster rail, and is supported at the other end by the tailstock, a prong chuck (Fig. 2) is the proper tool to

(Continued in page 454)

The varieties shown on this page are: 1. Bronze Early Buttercup. 2. Chrysanthemum Absolute. 3. Dawn. 4. Biterra. 5. Caroline. 6. Salamander. 7. Sylvia Superb. 8. Pink Topaz. 9. Golden Beam.

## CHRYSANTHEMUM: FOR THE GARDEN OR THE CONSERVATORY

Some beautiful varieties of this most satisfactory flower. General directions for their culture are given in p. 451.

use.

A drill chuck has movable jaws actuated by a screwed part of the body, a usual and cheap pattern like that illustrated in Fig. 3 being commonly found on hand drills, braces, and small drilling machines.

Chuck. Figs. 1-2. Showing construction of taper screw and prong chuck.

Chuck. Fig. 3. Goodell drill chuck. Fig. 4. Odd jobs chuck with four dogs in place. Fig. 5. Self-centring key scroll. (Courtesy of R. Melhuish & Co., Ltd.)

useful and inexpensive variety of chuck, known as a dog chuck, is shown in Fig. 4. The work is held by the short set screws; the posts, or dogs, in which they turn can be inserted in any of the holes in the body or faceplate. Such a chuck can be used on a simple lathe, and will also be found of service for holding work under a drilling machine, or while otherwise working upon it.

A popular chuck for amateur use is a three jaw self-centring scroll chuck (Fig. 9). This tool automatically centres the work. Two sets of jaws enable a wide range of internal or external work to be held very securely.

Chucks should always be kept clean and free from chips, especially the working parts, which may be lubricated from time to time with light machine oil. It is always necessary to clean the screw threads before screwing the chuck on to the mandrel nose, as any chips or dirt in the threads will make it jam or run out of truth. *See Centre; Lathe; Mandrel; Metal Turning; Wood Turning.*

**CHURN:** For Making Butter. One of the simplest churns consists of a glass jar or vessel with a nickel-plated screw cap, and a wooden beater actuated by means of bevel gears and a crank handle. It is readily cleaned and requires little attention beyond occasional oiling of the gears and spindle.

The barrel type of churn consists of a solid hardwood frame provided with roller or other bearings, on which is supported a steel shaft, rotated by a crank handle. A hardwood barrel with a removable lid at one end is attached to the shaft, and is rotated end-over-end when the crank handle is turned. The method of fitting and

securing the lid is of importance in this class of churn. In some, a number of screw clamps are used to press the lid home; in another, a cam actuation is used to hold the lid in position. Some barrel churns are supplied without a dash or beater; others have various forms of patent devices, such as the diaphragm.

Churns should be kept in a condition of scrupulous cleanliness, and preferably in a cool and equable temperature. There is virtually nothing to go wrong or to require special attention in a good churn. *See Butter.*

Left. Churn. End-over-end diaphragm churn. Right. Wooden box churn, with cover removed in order to show the dash or beater. (Courtesy of Thomas Bradford & Co., Ltd.)

**CHUTNEY:** The Condiment. Taken as a relish with hot or cold meat dishes, chutney is an Indian condiment, of which there are many varieties, such as Bombay, Madras, and mango chutneys. The ingredients include raisins or mangoes, cayenne pepper, ginger, spices, and lemon. Several kinds of chutney can be made at home with apples, tomatoes, marrows, etc., recipes for these being given under their separate headings.

*Cicatrix. See Scar.*

**CIDER:** How to Make. The apples should be gathered in dry weather, of as even a degree of ripeness as possible, but just before they are quite ripe. Decayed, damaged, or worm-eaten apples must be removed and the stalks picked off. Keep the apples about 14 days in a dry, well-ventilated place, and make the cider in cool weather. The making is done in three processes, the apples are crushed to a pulp or pomace, the juice squeezed out, and finally fermented.

For crushing, take a very strong, iron-hooped tub, about 18 in. in diameter, put in enough apples to cover the bottom, and pulp them by means of a heavy hardwood bruiser, not unlike that used by a street pavior. Pound a few apples at a time, and see that the bottom of the tub is well supported on the ground so as not to risk splitting it. The pulp should be continually removed from the tub as crushing proceeds.

For pressing, a strong haircloth or coarse canvas sheet—a cloth called netting shading is the best—3 to 4 ft. square is used. The pulp is spread evenly over about 18 in. square in the middle, and when about 3 in. deep the sides of the cloth are folded over the pulp; then

another cloth is placed on top of this and more pulp packed in that. In this way, a cheese, as it is called, is built up, the number of canvas sheets depending on the size of the press.

The simplest form of press consists of two hinged boards, the pressing leverage on top being obtained by using a stout pole; this is a crude way of pressing, but has been used by cottagers. Wooden presses are made very like those used for copying letters; so long as the bare iron does not come in contact with the apple juice, the latter might serve as presses for a small cheese. The press has to stand in a tray or tub to catch the juice, and from this tray or tub the juice is run into a cask.

If one man pounds the apples while another does the pressing they can between them make 10 to 11 gallons a day, and this amount will take about 180 lb. of apples, or less with a good press. It is not absolutely essential that the pulp should be pressed the same day as it is made; some keep it 24 hours, as it is said to improve the yield; but there is danger of vinegar acid forming by too long exposure to the air and, in any case, the extra yield is doubtful.

As a rule apple juice is left to itself to ferment, the yeasts present on the skin at crushing being sufficient, as in the case of the grape; but in small fermentations it is usual to start the fermentation with a little brewers' yeast. This is advisable, because it can never be foretold how long apple juice will take to ferment; sometimes fermentation is complete in 10 days, sometimes not under six weeks.

Having collected, say, 10 gallons in a cask, mix 2 oz. fresh brewers' yeast with 2 oz. honey and 1 oz. flour, place it in a muslin bag, and suspend the bag in the cask by a piece of string. The cask must be supported on a stand so that a tub can be placed underneath to collect the yeasty froth which works out of the bung-hole, and the cask must be topped-up occasionally to keep it full and allow the scum to overflow.

As fermentation ceases and the cider shows signs of clearing, it is run slowly and carefully into a clean cask, which is then bunged down and kept in a cellar at a temperature between 50° and 60° F. If the fermentation is very tumultuous, or if the cider is required sweet, the transferring to another cask (called racking) should take place earlier and be repeated two or three times, avoiding aeration as much as possible. This tends to stop fermentation and prevent the cider getting too thin. The rate of fermentation should be watched by using a saccharometer and the casks should be treated with a sulphur match after cleaning. *See Apple.*

**Cider Cup.** To make cider cup, slice 2 in. of cucumber very thinly, and put the pieces in a jug, together with 1 oz. castor sugar and a sprig of mint, pouring over them half wineglassful of sherry and a quart of cider. Then add 2 bottles of soda-water. Cover the jug, place it in ice or in a very cold place, and leave it for about 2 hours. Then strain out the mint and cucumber, and the beverage is ready for use.

**CIGAR: Choice and Varieties.** It is not possible to judge a cigar by the outside. The outside wrapper is

very often made of fine leaf, and the inside filler of cheap leaf, or of scraps of leaf and stalk rolled up together. The only way to judge the filler of the cigar before smoking it is to cut through the cigar lengthwise. But if the cigar comes from a factory with a famous name, one can assume that the inside is of the same quality as the outside. Then the point to look for is an oiliness or glisteningness of the wrapper. Spots on the leaf are caused either by sunburn, or insect-bites on the leaf. They suggest by appearance that the cigar is not first rate; but, actually, they do not affect its smoking qualities at all.

If you place a cigar to your ear and crackle it, all that it tells you is whether the cigar is very dry or not, and the crackling may split the leaf! Some people prefer their cigars very dry, but the majority like them of medium, dryness. The smell of a cigar is a partial indication of its smoking quality; but a cigar which smells good does not necessarily smoke good.

As to the ash, if this remains firm for a long time while the cigar is being smoked, it means that the filler is composed of long leaves, neatly arranged and rolled. It indicates care in manufacture, but is not a guarantee of well-matured leaf. When the ash of a cigar is flicked off, the point should be sharp and bright, not ragged and dull. A sharp and bright point indicates a well-matured leaf.

**Keeping Cigars.** The proper keeping of cigars is important. Choice tobacco leaf is extremely sensitive to atmosphere, and to odours in the atmosphere, and will readily absorb them and affect its own taste. Paint, for instance, and especially wet paint, will ruin any cigar or tobacco placed near it. Salt sea-air will completely spoil a fine cigar. Therefore cigars must be kept in airtight boxes. Cedar-wood is the best material for the box.

If cigars are subjected to sudden heat they throw off their natural moisture and essential oils which give the character and bouquet to the cigar. In appearance the cigar is not changed; but in smoking quality it has become very different. That is why cigars have to be kept at a fairly even, medium, and dry temperature, in order to retain their condition. The best temperature is between 60° and 65° Fahrenheit. A fine cigar should be carefully lighted—lighted all round, so that it will burn evenly and not raggedly. When cigars burn down one side first it is usually due to careless lighting.

The shape of a cigar is a matter of individual fancy. Many people prefer the torpedo shape as a matter of appearance, or of comfort in holding the cigar between the lips; but in the shaping of such a cigar much good leaf has to cut away to waste, and this makes the cigar expensive in proportion to the amount of leaf it contains. A straight shape avoids this waste of cutting, and many of the finest Havanas are made in that form.

**CIGAR CASE.** The cases which are made to hold a few cigars for carrying in the pocket are usually either

of leather or of metal, the former being lighter and, generally speaking, more serviceable, while in a metal case the cigars are more effectually protected from getting crushed or broken. Some leather cases have the edges reinforced with metal, and others are padded to make them stiffer and less flexible. The most useful type in leather is made in two portions, one part containing the cigars, the other sliding down over the first, and so making the case practically airtight. Since this case does not require to be folded, the leather used can be much stronger, and a double thickness on either side lessens the risk of crushing and overheating the cigars.

A metal case affords complete protection, besides being airtight. The chief disadvantages are the size and weight. The lightest type is fitted with grooves to take three or four cigars. The hollowing out of the grooves makes for lightness, keeps the cigars separate, and so prevents the outer leaf from being damaged. A very small case is made to take a single cigar. Aluminium is of little use for a cigar case, as it is a good heat conductor, and may spoil the aroma of the cigars in a very short time. The ideal case is of silver, a metal which is lighter and harder than gold.

**CIGARETTE.** The main varieties of cigarette are Virginian, made from blendings of leaf from Virginia and Carolina; Turkish and Egyptian, manufactured from leaf grown in Asia Minor and Greece; and Havana, made from the cuttings of Cuban leaf used in the rolling of Havana cigars. Cigarettes are also made from Rhodesian tobacco. Mixtures of Virginian and Turkish are also sold, generally under the title of Turkish blend or Egyptian blend. Turkish leaf is considerably more expensive than leaf from Virginia and Carolina.

Cigarettes, like any other form of tobacco, are easily affected and spoiled by strong odours around them. They should be kept in condition in an airtight box, preferably of cedar-wood. The best cigarettes are rolled in very fine and pure rice paper, as thin as possible, so that no taste of burning paper shall spoil the taste of the tobacco smoke. Cheap cigarettes are rolled in inferior paper, to which saltpetre or other chemical is sometimes added to make it burn quickly. Many people prefer a cork tip, for the reason that it prevents fragments of leaf from entering the mouth.

Some smokers prefer to make their cigarettes, and this is quite simply and easily done by hand. All the outfit required is some light Virginia tobacco, which is mostly used, and a small packet of rice-paper, which is sold either with or without a gummed edge, some smokers preferring to dispense with the gum.

**Cigarette Holder.** The variety usually offered in cigarette holders is very wide, for they are manufactured not only in gold, silver, meerschaum, amber, and ivory, but more extensively in vulcanite, horn and bone, imitation amber and other compositions, or simply of wood.

Among the more expensive sorts is the plain tube of real amber of varying length, with gold rim, and the

silver-mounted meerschaum with amber mouthpiece. Ivory, tortoiseshell, and mother-of-pearl holders usually have gold mounts.

Plain holders are made of horn or bone in great variety as well as in polished wood, and the cheapest of all are of cardboard with a quill mouthpiece. Imitation meerschaum and amberette offer another variety, and compositions figure largely in the manufacture of many others, particularly the tube or trumpet-shaped kinds, which are produced in many colours. The length varies from 2 in. to 6 in., or even longer, the average being about 3 in. to 4½ in. *See Tobacco.*

**CIGARETTE CASE.** The metals employed in making cigarette cases include gun-metal, as well as gold, silver, and platinum. The outer surface may be plain, but is more often engraved. Silver is largely used, and many beautiful cases are made from tortoise-shell. Cheaper varieties are of nickel, white metal, or papier mache, frequently decorated with enamel pictures. Most cases are flat, but some, especially those made of silver, are slightly elliptical.

Cigarette cases are also made of leather, and many smokers prefer this medium, as a larger number of cigarettes can be carried in a flexible leather case than in the rigid metal one. This also allows of several kinds of cigarettes being packed into one case.

**CINCHONA BARK.** Quinine is found in the bark of the cinchona tree, which grows in S. America and elsewhere. The official dose of cinchona bark is 3 to 15 grains, and more in malaria cases. The powder form may disagree with the stomach. Common preparations are given in the following doses:

Liquid extract	5-15 minims
Tincture	½-1 dram
Compound tincture	½-1 dram

The action of cinchona is practically that of quinine. The liquid extract of red bark is recommended for inspiring in dipsomaniacs a distaste for alcohol. *See Quinine.*

**CINDERS.** The cinders from a coal fire need never be thrown away. First of all they should be sifted through a fine sieve. The fine dust that passes through can be dug into the garden soil, while the coarser cinders should be used again mixed with coal. If the fire is merely to be kept in till needed, a shovelful of cinders will keep it going. Pine cinders make effective garden paths; they lighten a heavy soil and make excellent drainage material in garden pots, and for the garden generally. Mixed with cement, a good concrete results.

In country districts where no proper drainage exists, it is useful to filter waste waters, such as those from the kitchen sink through cinders contained in an old perforated pail. The solid materials, such as grease, are

the cinders should be burnt and the pail replenished. See Ashes; Path.

**CINDER SIFTER.** The cinder sieve usually measures 12 in. to 15 in. in diameter, and is made with japanned metal or wooden rim and blacked iron wire bottom of fairly close mesh. A heavier make of about 18 in. to 20 in. diameter has an oak rim 4 in. to 5 in. deep and a straight mesh. In a superior make the strands are separately soldered to the cross supports. Apart from their use for cinders, such sieves are serviceable in the garden for sifting mould, earth and gravel.

## CINEMATOGRAPHY IN THE HOME

### A Modern Popular Hobby and How to Practise It

Other articles dealing with domestic amusements, both indoor and outdoor, include Billiards; Bowls; Conjuring; Croquet. See also Camera; Colour Photophone

The making and showing of motion pictures for home and general amateur use has now taken its place as a popular hobby, practised by many thousands of people throughout the world. A most complete range of apparatus and accessories is available for the amateur who wishes to take his cinematography "seriously"; yet for the non-technical man the matter may be simplified, more or less, to "button-pressing."

Standard cinema film of 35 mm. width, as used for the professional cinema, has been entirely superseded in the amateur world by "sub-standard" films, of which there are three recognised gauges, or widths: 16mm., 9.5mm., and 8mm. To arrive at a fair comparison between the cost of filming with these three gauges it is necessary to consider the total cost (including processing) of a finished film lasting for a certain time on the screen, and on this basis the average cost for a four-minute film is: 26s. for 16mm. film, 16s. for 9.5mm. film, and 10s. for 8mm. film. This compares with £5 or £6 for standard film.

*Cinematography. Fig. 1. The "Autokinecam," which can be used at three different speeds*

Four minutes is a much longer period of time than it may seem, and it is a fact that about 30 different scenes can be adequately dealt with in a film of this length.

All modern sub-standard cine cameras are motor-driven; the majority by clockwork motor, but a few by a small battery-operated electric motor. It is only necessary to load the camera with film, wind up the motor (if a spring motor), adjust the lens stop to give the required exposure, sight the subject in the view-finder, press the release button—and the film is being taken.

The film is supplied for daylight loading in all gauges; either on a light-proof spool or in a magazine

(according to the type of camera for which it is required), and in most cases the price includes free processing after exposure. Therefore, when the film has been exposed it is merely returned to the processors, who convert it into a positive ready for showing in the projector, and post it back mounted on a projection reel.

*Cinematography. Fig. 2, left: a Cine Kodak 16mm. camera with view-finder, direct-vision finder, and two-speed clockwork motor. Fig. 3, right: double-run 8mm. film being loaded into camera. Note simplicity of mechanism.*

Provided the exposure has been reasonably accurate the quality of screen picture derived from these small films—even the 8mm. film—is quite remarkable and compares creditably with the professional film of the public cinema.

The type of film which includes processing in, the price charged is known as reversal, or reversible film because, after exposure, the film is chemically "reversed" to give a positive instead of a negative image. Some brands of reversal film may be purchased without processing rights, but successful reversal processing is not a matter for inexperienced hands.

Separate negative and positive films are also available in the sub-standard sizes, but are not much used by the ordinary amateur. Who usually requires only one copy of each film and achieves better results on reversal than on positive printed from negative film. The chief advantages of "negative-positive" are that editing and titling can be effected on the negative from which a continuous positive, free of joins, can be printed; and also that any number of positive copies can be printed at any time from the negative, which is never subjected to wear in the projector. On the other hand, reversal films may also be duplicated provided the original has not suffered through use.

Most makers of cine cameras provide a choice of either fixed focus or focussing models: the former are more simple because the lens is permanently focussed to give sharp pictures of any subject beyond about 8 feet from the camera; for closer subjects a simple supplementary lens is slipped on to the camera lens. Focussing cameras enable subjects as close as 18 inches or 2 feet to be taken, without supplementary lenses, but the cameraman must always remember to adjust the lens for whatever distance is required. On the other hand, focussing cameras are usually provided with a "faster" lens, which means that filming may be undertaken in light which would be too poor for the

slower lenses.

The normal rate of film travel is 16 pictures (or "frames") per second, but some cameras are provided with a range of different speeds to allow for trick work or special effects.

### How to Use the Cine Camera

When the cine camera has been loaded with film and the clockwork motor wound, there is —assuming the use of a fixed focus camera— only one adjustment to be made by the cameraman before commencing to film, and that is to set the diaphragm, or lens stop, to give the correct exposure. When the light is poor the diaphragm must be opened wide; when it is brighter the diaphragm must be closed, more or less, according to the brightness of the subject.

Owing to the special system of compensated processing adopted by the leading makers of film a fair latitude exists for errors of exposure, but it is always to be understood that the best results can only be obtained by reasonable accuracy in exposure. Tables, calculators and meters of many kinds are available to assist the cinephotographer in exposing correctly, and the most satisfactory aid is the photo-electric exposure meter, of which there are many different makes.

The first efforts of the beginner at cine-photography invariably betray three outstanding faults: The camera is moved about, either to embrace a panoramic view or to keep some moving object within the view-finder; the "shots" are a succession of what are called "Long Shots" (i.e. general views and full-length subjects); and individual shots are held for too long.

Variety and movement (of the subject) are the soul of cinematography, and three or four short shots showing different angles or phases of an action are much better than one all-embracing shot which lays no emphasis on the interesting details of the action. It is all a question of camera position in relation to the subject.

A successful method of treatment is to take first a short general view of the subject and then to move the camera closer, ferreting out the interesting details to be shown "in close-up." Although the camera position should be repeatedly changed in order to maintain interest in the picture it should be kept perfectly still during the actual taking of each shot, and not swung round or to and fro; this is most important.

The most successful films are those in which a certain amount of planning has been done beforehand. If each shot is simply left to the inspiration of the moment it is almost impossible to achieve—what should be the aim of the simplest film, even *Baby on the Lawn*—a connected story. Distant scenes are generally disappointing; mid-shots and close-ups are the most interesting.

**Editing and Titling.** All films are vastly improved by being edited and titled. Simple editing involves the cutting out of all badly photographed sections, identification numbers, and "dead ends" (e.g., surplus frames at the beginning and end of each shot, where no action is taking place) and, perhaps, joining several

spools together to form a 300- or 400-ft. length. A splicer and film cement are indispensable to every amateur cinematographer.

*Cinematography. Figs. 1 and 2.*

*Above: The Cinecraft "Universal*

*Senior" Titling Outfit. The letters*

*can be obtained in cardboard, felt, celluloid and magnetic metal. Right: a popular "baby model" projector (Pathescope 200-B., 9.5mm.,) designed for use on all D.C and A.C. mains. The lamp-house is fan-cooled.*

Titling is an interesting part of the hobby, and a great variety of titling outfits is available to the amateur. The title is either drawn, stencilled or printed on card or paper, or movable letters may be purchased which cling to a suitable background. A titling stand enables the camera and title to be correctly set up so that the title is photographed, by artificial light, to form the necessary title strips of film, which are afterwards inserted in the appropriate places.

**Cine Work in Colour.** Cinephotography in natural colours is available in all substandard gauges, Kodachrome natural colour film being obtainable in 16mm. and 8mm. size, while Dufaycolor film is made in 16mm. and 9.5mm. gauge. No special filters or accessories are needed for these colour films, which are used exactly the same as black-and-white reversal films (except that a wider aperture or lens stop may be necessary).

Filming in the home by artificial light is easily possible with the fast films and reasonably priced Photoflood lamps now available, and even indoor colour films may be made by means of the Photoflood, Type "N," lamp. Special Kodachrome film is supplied for artificial light, while Dufaycolor needs merely the addition of a filter on the lens.

**The Home Cinema.** Projectors for sub-standard films are made in a wide variety of models, from simple low-power machines for projection in small rooms to high-class projectors suitable for use in halls. Each sub-standard gauge has its own range of projectors, while there are certain models which will project two, and in some cases three, different gauges of film. It is usual for the projector to incorporate an electric motor which drives it, and the models for home use may be connected to any ordinary domestic electric supply.

Operation is simplicity itself, and there is no danger of fire because all sub-standard film is "safety" film, which burns less readily than ordinary paper. In addition to personal films of one's own taking a wide

educational value of the cinema in the home is now a factor which is steadily gaining recognition.

*Cinematography. Fig. 3. A more elaborate projector, the Bolex G3, for films of three gauges. Silent running, no flickering, and enclosed geared mechanism are some of its advantages.*

Screens for home projection are generally of stout fabric mounted on a wooden roller, the surface of the screen being coated either with a medium containing aluminium bronze powder, or with an adhesive preparation covered with myriads of microscopic glass beads. The beaded screen is claimed to yield a better screen picture than any other type yet evolved.

Sound films and sound film projectors are now available in 16mm. and 17.5mm. gauge (the latter exclusive to Pathescope home talkies), and the presentation of sound films within the home now presents no difficulties other than a somewhat heavier outlay. Operation is simple, and no intimate technical knowledge is required, the results being comparable with those achieved in the public cinema. It is usual to hire, rather than to buy, sound films, and numerous libraries exist from among which the home sound film projectionist has an extensive choice of films.

Attempts have been made to popularise sound film-making for amateurs, and at least two makes of 16mm. sound film cameras are available for amateur use; but it is doubtful whether personal sound films will ever displace the personal silent film. Apart from the fairly high cost, the technique of sound film-making imposes heavier demands than the silent film, not only on the capabilities of the amateur cameraman-director, but also upon the histrionic abilities of the untrained "subject."

**CINERARIA.** This is one of the showiest of all greenhouse flowers, and is in full beauty in spring and early summer. There are large-flowered and small-flowered varieties in innumerable bright colours. The latter, of which there are star-flowered and cactus-flowered types, are very decorative; they form plants 2 ft. or so high which bear a profusion of bloom. The large-flowered sorts bear one large head of bloom and grow about 12 in. high. A new type, intermediate between the two other types, has now been raised.

Cinerarias are grown from seeds sown in May in pots or pans of light sifted soil in greenhouse or frame; the plants will flower the following year and are thrown away after the blooms are over, a fresh supply of plants being raised annually. When large enough to handle, the seedlings are put in 3-in. pots and later on into pots 5 in. wide. During the summer months they should be grown in a cold shady frame, the pots being set on ashes. They must have cool moist conditions. In September they are brought into the greenhouse: a temperature of 45° to 50° is high enough. If large plants are wanted repotting into 6-in. or 7-in. pots

should be done in February.

*Cineraria. Three blossoms of this large-flowered greenhouse plant.*

A suitable soil compost consists of loam two-thirds, leaf-mould and decayed manure one-third, with a free sprinkling of sand. The plants must be kept free from greenfly by fumigating occasionally, or by using an insecticide.

**CINNAMON.** The bark of a tropical tree, cinnamon is used as a condiment and stimulates digestion. Cinnamon water in tablespoonful doses half an hour after meals is sometimes used in flatulent indigestion; or compound cinnamon powder might be used in doses of 10-40 grains. The dose of the bark is 10-30 grains, and the powdered bark has been suggested as a prophylactic in German measles and measles, children exposed to infection being given as much as will lie on a sixpence or a shilling with the morning and evening meals. The dose of cinnamon oil  $\frac{1}{2}$  to 3 minims. It may be used, dropped on sugar, in catarrh and influenza. It is also used as an application for toothache and for warts.

Cinnamon sugar is useful in the kitchen. Put 4 sticks or rolls of cinnamon in a mortar with  $\frac{1}{2}$  lb. loaf sugar. Pound them finely and rub them through a coarse hair-sieve. Put the powder into a bottle and keep it tightly corked. Use it for adding to cakes, etc.

**CINNAMON BUN.** These are made with  $\frac{1}{2}$  lb. flour,  $\frac{1}{2}$  lb. barley flour, 2 teaspoonfuls cream of tartar, 1 teaspoonful bicarbonate of soda, 3 oz. sugar, 2 tablespoonfuls molasses, 3 oz. margarine, 2 teaspoonfuls ground cinnamon, and 1 gill milk. Mix together all the dry ingredients. Melt the margarine and the molasses, warm the milk, and blend the soda with a little extra milk. Add it to the milk and mix the whole to a stiff dough. Shape the buns quickly and then bake them in a hot oven for 20 minutes. This should make from 15 to 20 buns.

**CINNAMON CAKE.** Iced or plain, this makes a change for afternoon tea. To prepare it, beat up 2 oz. butter with  $\frac{1}{4}$  lb. sifted sugar, and when the two are well creamed, add to them a little less than 6 oz. flour,  $\frac{3}{4}$  teaspoonful baking-powder, 2 beaten eggs,  $\frac{1}{2}$  gill milk, 2 good saltspoonfuls each of powdered cinnamon and nutmeg, and a pinch of salt. Turn the mixture into a well-greased tin and bake for about  $\frac{3}{4}$  hour in moderate oven.

**Cinquefoil.** See *Potentilla*.

**CIRCUIT.** In electricity this is the path traversed by the electric current. If the positive and negative terminals of a galvanic battery or accumulator be connected by a wire, a circuit is formed, the current flowing from one terminal through the wire, back to the other terminal, and through the battery. *See* Battery; Bell; Burglar Alarm; Dynamo; Electric Lighting.

**CIRCUIT DIAGRAM.** This is a graphic representation of the internal or external connexions of a wireless receiver or other electrical apparatus, in which symbolic rather than pictorial methods of denoting the various parts are used. Some of the chief symbols are shown in the illustration. *See* Wiring.

*Circuit Diagram. Showing the principal symbols used in wireless and other diagrams, such as house wiring.*

**CIRCULATION: Of the Blood.** In the human body the blood flows continuously in a circle, being purified at one stage of the journey and then redistributed.

From the limbs, head, chest and abdomen it finds its way into the right upper chamber (right auricle) of the heart. When the heart beats, the walls of this chamber contract down, forcing the blood through a valve into the right lower chamber or ventricle. This ventricle has thick muscular walls, and when it in its turn contracts, the blood is forced into the pulmonary artery and reaches a network of thin-walled little vessels, called capillaries, threaded amongst the air cells of the lungs. Through the walls of these tiny vessels, or capillaries, there is an interchange of gases between the blood and the air in the air-cells of the lungs, carbonic acid gas passing out and oxygen passing in.

The purified blood is collected into the pulmonary veins and carried to the left upper chamber of the heart (left auricle). Here, again, at the start of the heart beat, the blood passes through another valve, flowing into the

left lower chamber or left ventricle of the heart. The walls of this chamber are very thick, and when they contract the blood is forced into the main distributing artery, the aorta, and reaches every portion of the body. The farther it goes from the heart the smaller become the branches of the arteries through which the blood passes, until finally it enters into the minute capillaries. The blood is then collected into veins which constantly increase in size and finally empty their contents into the right upper chamber of the heart.

The main bulk of the blood of the body is thus constantly moving through the circle. The blood of the walls of the intestines, however, after it has absorbed certain of the products of digestion, nutriment, etc., is carried by the portal vein to the liver. Here it passes again through capillaries, giving up certain of its constituents, and being collected again into a large vein, which in turn carries it to the right auricle or upper chamber in order to begin a new cycle.

Impairment of the circulation, may be general, and may be due to heart, lung, or kidney disease, or to anaemia amongst other conditions; or it may be local, as in piles, or chilblains, or Raynaud's disease. The person who always complains of cold hands and feet should keep his bowels freely regular, and take plenty of plain food, including fats. He should take open-air exercise, and should massage the affected parts. A sufficiency of woollen clothing should be worn. *See* Heart; Lung.

**CIRCUMCISION.** Wherever in infancy the foreskin is notably long, and cannot be retracted easily and thoroughly, circumcision should be performed. The operation is a minor one, and can be performed by the doctor in the baby's home. If this is not done, the secretions of the glands become dried and foul, causing local irritation, which may lead to other troubles.

**CIRRHOSIS.** Whenever the special tissues of an organ, such as the liver, kidney, or lung, are, as a result of disease, replaced by ordinary fibrous tissue, the condition is described as cirrhosis. Cirrhosis of the kidneys is the condition present in the small red kidney of Bright's disease (q.v.). Cirrhosis of the liver is a common result of prolonged over-indulgence in alcohol, or may be due to infectious diseases.

Nausea in the mornings, diminished appetite, a sour taste in the mouth, and a pallor of the skin, together with a gradual loss of energy and perhaps loss of weight, are the symptoms usually first noted in cirrhosis of the liver. The veins over the abdomen become engorged with blood and show through the skin as noticeable blue lines. Fluid escapes from the overcharged veins and collects in the abdomen, setting up dropsy. The patient has difficulty in breathing, through the pressure of the fluid in the abdomen

pressing upwards against the diaphragm.

No treatment will bring a cirrhotic liver back to its normal healthy state, but much can be done to retard the advance of the disease. The first step is to give up alcohol in any shape or form. The diet must be reduced to the simplest and most easily digestible form. Milk diluted with alkaline waters, vegetables, custards, etc., should be prominent in the diet, while heavy meats and all rich, highly spiced foods should be avoided. Plenty of plain water or mineral water may be drunk between meals, so long as there is no evidence of fluid in the abdomen. Constipation must be avoided.

Diarrhoea is often troublesome; but as much of the surplus fluid in the system is in this way got rid of, it should not be checked unless excessive, and not without advice. The following mixture is useful for the purpose:

Carbonate of calcium	$\frac{1}{2}$ oz.
Phosphate of calcium	$\frac{1}{2}$ oz.
Carbonate of bismuth	1 oz.

Mix thoroughly and take one teaspoonful every three hours, until the diarrhoea is checked. *See* Constipation; Diarrhoea.

**CISTERN: In the House.** As receptacles for water, cisterns are generally of galvanised iron, rectangular in form and open on the top. Usual stock sizes vary from 2 ft. in length, 16 in. wide and 15 in. deep, having a capacity of 20 gallons, to the 1,000 gallon tanks measuring some 9 ft. by 5 ft. by 3 ft 6 in. A durable cistern should be made of 16 gauge or 14 gauge steel plate, with closely riveted corners, and have strengthening angles at all corners and edges.

When fitting up a cistern it is well to bear in mind the very considerable weight of the water and to provide ample support. The cistern should always be placed as near to a wall as possible, if resting on the ceiling joists, and, further to distribute the load, should rest upon stout bearers of wood at least 4 in. by 2 in. and extending for 18 in. or so on each side of the cistern. *See* Ball Cock; Bath; Central Heating; Water Supply.

**Cistus.** This is a name of hardy and half-hardy perennial shrubs, also known as rock roses. *See* Rock Rose.

**CITRATE OF MAGNESIA.** Effervescent citrate of magnesia is a pleasant laxative and cooling medicine in doses of 1 to 3 drams. A solution of magnesium citrate, with the same properties, can also be obtained, the dose being 5-10 fluid oz. *See* Aperient.

**CITRIC ACID.** Obtained from the juices of fruits such as the lemon, citric acid in the proportion of about  $\frac{1}{2}$  teaspoonful to 2 tablespoonfuls of water makes a solution about as strong as lemon juice. The dose of citric acid is 5 to 20 grains. A weak solution increases the flow of saliva, and so is often useful in allaying

thirst in fever cases. Sodium citrate is frequently added to the cow's milk given to hand-fed infants, in the proportion of 1 grain to the oz. Tablets containing 5 or 10 grains may be obtained for the purpose.

Effervescing drinks are made with citric acid, such as the following. In half tumbler of water dissolve 20 grains citric acid; in another tumbler half full of water dissolve 30 grains bicarbonate of potash. Pour the two half tumblers of liquid into one large tumbler and stir.

A good home-made beverage may be prepared by boiling the peel of a lemon in a saucepan containing  $\frac{3}{4}$  pint water and  $\frac{3}{4}$  lb. sugar. When these have boiled for 4 or 5 min., pour on  $\frac{1}{2}$  oz. citric acid, adding the juice of a lemon when the drink is almost cold. Pour a tablespoonful in a tumbler and fill up with plain water or soda water.

**CITRON: The Fruit.** The fruit of the citron tree resembles a large lemon, with much the same flavour and medicinal qualities. *See* Candied Peel; Lemon.

**Citron: The Wood.** This is sometimes used by cabinet makers, and is that of the sandarac tree. *See* Wood.

**Clamp.** The word is largely used to describe the various forms of cramps used in many trades. *See* Cramp.

**CLAP BOARD.** This name is frequently applied to a feather-edged board used as a weather boarding. It is also given to an inferior quality of oak imported from Norway, white coloured streaks distinguishing it from wainscot oak. Both materials are inexpensive. *See* Board; Wood.

**CLAPPED BREAD.** Also called clap-bread, this is much made in Lancashire and Cheshire. Two wooden spoons and a girdle, or griddle, are the utensils required, and if a girdle is unobtainable a thick baking sheet must be substituted.

To make it, put about six tablespoonfuls of oatmeal in a basin with a small teaspoonful of salt. Mix these well, and add sufficient cold water to make a stiff paste, but it should not be dry enough to crumble. Shake a little oatmeal on the board, turn the paste on to it and pat it out with the two wooden spoons as thinly as possible. It is this patting or clapping that gives the bread its name, also its characteristic shortness. Dredge the paste with more meal if it sticks, and put the girdle on the fire to heat whilst the making is in progress. The cakes should be about the size of a breakfast plate.

When ready, dust the girdles thinly with oatmeal and carefully slip on a cake, one or more according to the size of the girdle. Bake them on the top of the fire until they are crisp, turning them occasionally. They may be served hot and buttered, or cold. They keep in dry tins, but need to be reheated. At first it is wise to mix only sufficient for one cake, as the meal dries so rapidly.

**CLARET.** A great proportion of the wine drunk as claret is but vin ordinaire, or the secondary wine of the country, for the prime growths fall far short of the demand.

All clarets need a full six months in bottle before they are fit to drink. Fine clarets will mature in bottle for 30 or 40 years. When maturing, the wine should be kept at an even temperature of 60° F., and not exposed to sunlight. Claret will not keep sound for

demand. All clarets need a full six months in bottle before they are fit to drink. Fine clarets will mature in bottle for 30 or 40 years. When maturing, the wine should be kept at an even temperature of 60° F., and not exposed to sunlight. Claret will not keep sound for more than 6 or 8 hours after being opened. It should be drunk at the temperature of a comfortably warmed room (65° to 70°). The best way is to place the wine on the dining-room sideboard or mantelpiece for an hour before meals, and then decant. At a formal dinner-party, where several wines are given, claret is served with the entrees or roast. *See Wine.*

**Claret Cup.** The following is a recipe for claret cup. Take a bottle of claret, a tumbler of sherry, a bottle of soda or seltzer water, the peel of a lemon, a slice of cucumber, and sugar to taste. These should be mixed together, and served iced in a glass jug or bowl.

**CLARIFYING.** Any pieces of fat left over from meat or bacon, or the fat that is skimmed from the surface of stock, can be clarified and utilised in various ways. Pieces of fat should be cut small and placed in an iron or steel saucepan with sufficient cold water to cover them, slowly brought to the boil, and simmered until they look dry and shrivelled. The liquid is then strained into a jar or basin, and when cold will be a firm white cake of fat.

The fat skimmed from the stock-pot should be covered with boiling water and left to cool. Any impurities can be scraped away from the underneath of the fat when it has solidified. Cold water should be poured over dripping left in the tin in which meat has been baked; when the fat has set it should be lifted and the water poured away. Fat that has been used several times for deep frying can be clarified by being poured while hot into a basin containing cold water, well stirred and left to solidify. Cooked or uncooked fats may be clarified and are best kept separate.

**CLARINET.** Generally made of cocus wood, the clarinet comprises five parts: the mouthpiece, the socket, the upper joint (fingered by the left hand), the lower joint (fingered by the right hand), and the bell. The tube is pierced with holes stopped by the fingers, and is fitted with keys which affect other holes. The number of the keys varies; it is usually 13, but with the Boehm system this is considerably increased. The compass is over three octaves, and is divided into three registers, each completely chromatic.

The reed should be of medium strength; if too flexible or too stiff, the tone will be either weak or harsh. Fix it carefully on the flat side of the

mouthpiece of the ligature. Place the two joints together, with the finger-holes in a straight line, and add successively the socket, the mouthpiece, and the bell. Behind the lower joint is a projecting rest, under which the right thumb is placed, so as to support the instrument.

The following is the basic fingering of the clarinet, and it should be committed to memory before trying to produce a sound.

*Clarinet on Boehm system (Barnes & Mullins)*

Right hand. 1st finger works keys 9 and 12 and stops hole 4; 2nd finger stops hole 5; 3rd finger works key 5, and stops hole 6; 4th finger works keys 3 and 4.

Left hand. 1st finger works key 11 and stops hole 1; 2nd finger works key 10 and stops hole 2; 3rd finger works key 8 and stops hole 3; 4th finger works keys 7, 1 and 2; thumb stops the hole at the back of the upper joint.

To play, draw the lower lip over the teeth so as to obviate their contact with the reed, put about half of the mouthpiece in the mouth, the reed gently touching the lower lip, and then draw the upper lip round the mouthpiece, in order that no breath may escape. Take the breath through the nostrils or through the sides of the mouth, but on no account through the instrument. Press the tongue against the upper teeth and pronounce the word "too," which will cause the breath to pass between the reed and the mouthpiece. Keep the pressure of breath steady. To get different sounds, study the table of fingering given in your instruction book, where also will be found exercises for the production of tone.

An inherent defect in the instrument is that many notes are difficult to get in tune. Correct intonation can only be acquired by steady, well-directed practice in controlling the breath. After use, with a soft duster remove from the interior any moisture caused by the condensation of the breath. *See Bassoon.*

**CLARKIA.** A showy hardy annual of which seeds are sown out of doors in March-April where the plants are to bloom from July onwards. There are two types: elegans, which grows 2 feet high and produces charming decorative flower sprays, and pulchella, which is shorter and more graceful. Each type is represented by varieties of rose, purple, salmon and other colours.

*Clarkia. Single mauve variety of this showy hardy annual.*

**CLARY.** The leaves of this aromatic plant of the sage family are sometimes used for flavouring soups and for seasoning, and the flowers for flavouring fermented drinks. The lower leaves are large, rough, crimped

toothed, and grey-green in colour. The clammy, quadrangular flower-stem rises about 2 ft. high, and bears pale blue or lilac flowers in small clusters. The plant is perennial by nature, but is best treated as a biennial. The seed should be sown thinly in spring, and the plants set out about 18 in. apart when 3-4 in. high. The first leaves will be ready for picking late in summer. Its use has almost vanished, but in old-world or historical plant collections it cannot be ignored.

**CLASP NAIL.** Used for general woodwork, the clasp nail is of cut steel from 1 in. to 6 in. long. Its shape is shown in the illustration. A smaller type, the wrought clasp nail, with the head and ears in the form of a barb, has considerable drawing power, holds firmly, and is difficult to withdraw. Clasp nails should be driven in with the wide part of the nail the same way as the grain of the wood.

*Clasp Nails*

**CLAUSTROPHOBIA.** A condition of uneasiness and apprehension is experienced by certain people when they are in closed spaces. Known as claustrophobia, it is one of the effects of neurasthenia (q.v.), and may be contrasted with agoraphobia, the term used for fear of open spaces.

**Clavicle.** *See* Collarbone.

**CLAW AND BALL.** In furniture this term is used for the terminations found in many chair and table legs of the early part of the 18th century. The way in which the claw grips the ball varies, and much of the interest and value of the pieces lies in the skill with which the modelling is executed. It is generally associated with the introduction of mahogany into the cabinet making trade, and is almost always found in this wood. *See* Cabriole Leg; Chair; Chippendale; Table.

**CLAWFOOT.** This is a deformity of the foot in which there is a marked increase in the hollow of the sole. The toes are also bent backwards towards the instep, and as a result of those changes the foot is much shortened. The condition often begins in early life, and should be thought of where a child is awkward on its feet and tends to stumble. The treatment recommended is perseveringly to bend up the foot several times on three or four occasions each day, till the angle in front of the ankle is less than a right angle. Care should be taken that a long enough boot is provided, and this should have a bar about  $\frac{1}{2}$  in. thick placed beneath the tread, to throw the front of the foot up. *See* Foot.

**CLAW HAMMER.** This is a hammer with a claw-shaped tail for extracting nails. The ordinary cheap kind has a malleable cast head, and is only adapted for very light work. The Kent or Canterbury is of solid steel, with forged side straps; a medium size weighing 1 lb. is suitable for household use.

**Claw Hammer.** *Illustration showing method of holding when extracting nails.*

**CLAY:** As a Soil. Clay soil is difficult to cultivate because in continued wet weather it becomes sodden and in prolonged dry weather it cracks. Yet most trees, shrubs and hardy plants flourish in well tilled clay soil.

The best way to lighten clay and render it friable is to dig it deeply in the late autumn, and leave the surface rough so that the winter frosts and moisture can percolate and disintegrate it. Clay land is greatly improved by adding burnt soil, lime, leaf-mould, sand, sifted coal ashes, wood ashes, road grit, old potting soil and strawy manure.

Clay is sometimes considered as being dangerous to build upon; but except on unsuitable or improperly drained sites a clay soil is quite satisfactory if the foundations are taken deep enough to be beyond atmospheric action. The whole area beneath the house should be covered with six inches of cement concrete. The great thing to avoid on a clay soil is waterlogged ground.

**CLAYTONIA.** These pretty little plants of the Purslane family are low in habit and suitable for the rock garden. *Sibirica*, rose and *virginica*, white, are readily grown from seed sown in spring. They thrive in shade in ordinary soil, if not stiff, but loam and leaf-mould suit them well. Other species are *caroliniana* and *perfoliata*, the latter an annual. *Claytonia* is sometimes described variously as the Cuban spinach and the Chinese chickweed, though it is related to neither.

**CLEAR COLE.** Before distempering wood or plaster the pores are first filled with a coating of medium strength size to which a little whiting has been added. This is called clear cole. *See* Distemper; Plastering.

*Cleats in common use. 1. Best quality cast brass. 2. Japanned cast iron. 3. Malleable iron or cast brass, on plate.*

**CLEAT:** For Fastening. A cleat is used for securing a cord or line by twisting it about its projecting horns. It is useful for many purposes in the home, such as holding a fanlight or greenhouse skylight cord. Cleats measure from  $2\frac{1}{2}$  to 6 in. long, and are simply screwed in position. They are made of cast iron, superior varieties in malleable iron; the best are of cast brass, burnished and lacquered or electro-plated.

**CLEFT PALATE.** This is a congenital deformity in which the roof of the mouth shows a cleft down the

centre. It may be associated with hare-lip. The only treatment is an operation, which may be performed between the third and sixth months after birth, though some surgeons prefer to wait till between the second and third years.

**CLEMATIS.** One of the loveliest of hardy climbing plants, represented in gardens by many species and varieties. If a careful selection is made, one or another will provide bloom from May until September.

The successful management of clematis depends chiefly on correct preparation of the soil and pruning. As clematis is long-lived, it is worth while making a hole 2 ft wide and 18 in. deep for each plant; well decayed manure and a free scattering of mortar rubble should be mixed with the excavated soil before it is returned to fill the hole. Clematis is grown in pots by nurserymen and may be planted at any time of the year, though early autumn and spring are the best seasons. If the roots are matted together they should be soaked in water to remove the soil; the roots can then be disentangled to some extent and spread out at planting time. Although the clematis loves the sunshine, the base of the plant should be placed among other low-growing plants.

*Clematis. Flowers of this very decorative climbing plant.*

There are several types or groups of clematis, and they need different pruning. Those varieties belonging to the Jackmanni and viticella groups should be cut down in February to within about 10 in. of the base of the previous summer's growth; they bloom from July onwards on fresh shoots of the current year's growth. Varieties which need this kind of pruning are:

Ascotiensis, lavender blue; Comtesse de Bouchaud, old rose, very beautiful; Gipsy Queen purple; Jackmanni, purple (and all other Jackmanni varieties); Kermesina, reddish; Lady Betty Balfour, purple; Mme. E. André, reddish; Mme. Grange, reddish violet; Mrs. Cholmondeley, light blue; Star of India, reddish; Thomas Moore, violet, purple; Ville de Lyon, carmine red.

Large flowered varieties of the other groups, which bloom in May and June, need quite different pruning. It is sufficient to look over the plants in February and to cut out weak, useless shoots to give more room to the others, especially those of the previous year's growth. Long, straggling shoots should be shortened, but there must be no severe cutting back, or they will bloom sparsely. Some of the chief varieties needing this treatment are:

Beauty of Worcester, violet blue; Crimson King, crimson; Duchess of Edinburgh, white, double; Fairy

Queen, pale flesh pink; Henryi, cream white; Edward VII, violet; Lady Nevill, lavender grey; Lady Northcliffe, lavender blue; Lasusturn, purple blue; Marcel Moser, mauve shade; Nelly Moser, pale mauve; The Queen lavender.

There are some vigorous and beautiful kinds of small-flowered clematis. All are rampant, and soon cover a large area. It is impossible to prune them systematically, but they ought to be thinned out occasionally after flowering to get rid of old, worn-out and weakly shoots. Clematis montana bears white flowers in May; flammula, which is in full beauty in August, has sweet scented flowers; vitalba Traveller's Joy or Old Man's Beard, exceptionally rampant, bears white flowers in summer followed by decorative fruits in autumn.

Clematis tangutica bears small yellow flowers in September; indivisa, white flowers in spring, is tender and suitable only for the greenhouse; recta is a bush clematis which bears white flowers in summer; heracleafolia is of somewhat shrubby growth and bears small blue flowers in summer.

The easiest way to increase clematis js by layering the shoots in July. Cuttings may be inserted in sandy soil in a frame in September. Most of the plants sold by nurserymen are grafted on clematis vitalba.

A disease which causes the sudden collapse of the plant sometimes attacks clematis. If all the stems are cut down, fresh growth may spring up from the base; if it does not, nothing further can be done. *See Climbing Plant.*

**CLERGYMAN'S THROAT.** Chronic inflammation of the tissues at the back of the throat, and perhaps of the vocal chords, is commonly caused by over use or improper use of the voice. In this condition, which is termed clergyman's throat, the lining at the back is covered with little elevations varying in size from a pin-head to a pea, or even larger in some cases. The irritation is aggravated by a dry cough, and the voice gradually becomes weak and husky.

In treatment, any defect of the general health should be remedied. If the granules at the back of the throat are prominent they should be destroyed by galvanocautery. The voice must be rested. The following gargle may be used four or five times a day.

Tincture of krameria	1 dram.
Tincture of myrrh	1 „
Compound tincture of lavender	15 minims
Glycerin of borax	4 drams
Water to make	6 oz.

**CLICK BEETLE.** Several species of click beetle

are found in gardens, and, though as beetles they are harmless, the females lay eggs from which are hatched the garden pests known as wireworms (q.v.).

**CLIMBING PLANT or Climber.** The uses of climbing, trailing, and rambling plants in the garden petiolaris, and the ivy, of which there are many varieties with green or variegated leaves. Rose, clematis, honeysuckle, jasmine wistaria, ornamental vine, passion flower (for sunny walls), Cotoneaster horizontalis, Ceanothus veitchianus and the firethorn (pyracantha) are some of the chief hardy climbing plants and shrubs.

Before planting, it is necessary to prepare the site thoroughly by making a large hole and filling it with manured soil: climbing plants on a wall must be watered freely in very sunny weather. Certain annuals make good climbing plants for trellises. Chief among them are canary creeper, climbing nasturtium, ornamental gourd, Japanese hop and sweet peas. Seeds are sown under glass in March, the seedlings being planted out in May, or seeds may be sown out of doors in April.

*Climbing Plant. Fig. 1. Trainers made of scantling with wire stretched vertically.*

*Figs. 2-4. Diagrams for making trainers.*

Favourite climbing plants for the greenhouse are abutilon, fuchsia, heliotrope, Clematis indivisa, the scarlet trumpet honeysuckle (*Lonicera sempervirens*), roses, lapageria, Cobaea scandens, bougainvillea and Cassia corymbosa. See Arch; Clematis; Fuchsia; Pergola; Trellis.

**Clinical Thermometer.** See Temperature; Thermometer.

**CLINKER: Its Uses.** A hard, rocklike residuum is obtained under the name of clinker from gasworks, brickyards, and other places where furnaces are in operation. It is cheap, and has many applications, especially for making garden paths and for inferior grades of concrete.

In large lumps clinker may be used for rock gardens; its black colour can be altered to some extent by coating it with cement wash. The finer grades, when sifted through a sieve, make a good aggregate for cement partitioning blocks intended for subsequent facing.

The clinker from brickyards being very thoroughly burnt is generally fine, and makes a good path for a garden when laid to a depth of 3 in. to 4 in. and thoroughly consolidated with water and a heavy garden

roller. A heavy clay soil can be lightened considerably by an admixture of fine clinker, but it must be used sparingly. A shovelful per square yard is sufficient. See Brick; Cement; Concrete.

**CLIVIA: A Greenhouse Plant.** Belonging to the amaryllis order, clivia is an evergreen, flowering plant, with reddish-yellow blooms in the spring. It is a greenhouse plant, and is raised from seeds sown in March, and potted in a mixture of loam and sand, with some well-rotted manure. The roots can be divided after flowering. A winter temperature of 45° to 50° is suitable. It is a good window plant.

*Clivia. The orange-yellow flowers of clivia, a fine window and green-house plant.*

**CLOAK.** These garments are always more or less in fashion. Cloaks for evening wear, or in waterproofed fabrics, are fairly simple for the home dressmaker to evolve with the aid of a good pattern service.

The simplest way to convert a Paisley or other shawl into a cloak without cutting the material is to adopt the burnous or Arabian style.

It may be made from 2 1/2 yards of material not less than 40 in. wide, a full length burnous requiring a 50 in. material. The shawl or material is merely doubled across to bring the two edges together, and one set of selvages are caught together at a point about a foot from the fold to form a hood, which hangs down the back, and shapes the neck sufficiently to make the cloak sit on the shoulders. The top front corners are turned back to form revers, and each point, as well as the hood, can be finished with a tassel. The fronts of the garment may be fastened with a clasp, or, in the case of a shawl with a surplus of material, the fronts are draped across and held in place by the hand.

A wide circular cloak, cut without a join and known as a cavalier cloak, is attached to each shoulder with a buckle of elaborate ornament. It has much fullness, which may be drawn across the front and over the left shoulder, and allowed to hang in folds down the back.

**CLOCHE: In the Garden.** Cloches are domed covers of thick glass, very useful in the garden, especially in French gardening, where they are used to cover lettuces, cauliflowers, and other plants which are grown under the system of intensive culture. See Bell Glass.

## **CLOCKS: FOR USE AND ORNAMENT**

**Choosing Them and Keeping Them in Good Order**

Subsidiary articles to the one below deal with Alarm Clock; Cuckoo Clock; Grandfather Clock. See also Watch

Chamber clocks, as the early 17th century examples were called when clocks first began to appear in English houses, were often referred to as lantern or bird-cage clocks. They had no pendulum, as it was not introduced until about 1658. A bell on the top was struck with a hammer as the hours progressed, and, after winding, the clock lasted a day, or not more than 30 hours. It was common for such clocks to have an hour hand only. These clocks were of brass and the earlier ones had thickly gilt dials. A decorative feature was the fretted ornament surrounding the clock above the dial, often containing a conventional rendering of the crest of the owner, and at the bottom the maker's name. One of the earliest makers was William Bowyer, who in 1642 presented a great chamber clock to the Clockmakers' Company.

*Adam style clock, with carved figure of Time with his scythe and surmounted by a vase painted with classical subjects.*

An idea of the size of these early English clocks may be gathered from the diameter of the dial, which was from 3 in. to 5 in., though larger examples are known, up to 7½ in. The bigger dials often projected each side of the frame or structural body of the clocks. These lantern clocks continued to be made for quite 100 years. A wooden hood was commonly used over the bell to protect the works from dust.

Clocks by Thomas Tompion (1638-1713) are the most desirable acquisitions, from the collector's point of view. His shop, with a sign of the Dial and Three Crowns, was in Fleet Street at the west top corner of what is now White-friars Street.

*Antique Clocks. Top. 1. Ebony bracket clock, late 17th cent. Below, 3. Early 18th cent. clock, with perforated metal top.*

Tompion was the chief watch and clockmaker of the time of Charles II. Fine examples of his clocks are to be seen in the Pump Room, Bath, the British Museum, and Windsor Castle. His name and date are usually on the dials of the clocks he made. Two other great clock-makers of the Tompion period are Daniel Quare and Joseph Knibb. During the reigns of William and Mary and Queen Anne, when walnut succeeded oak for clock cases, twisted or corkscrew columns were often

seen at the corners each side of the dial, supporting a horizontal moulding, sometimes finished with a pediment. When mahogany became comparatively

common in the first quarter of the 18th century, it was employed largely and walnut discarded.

Clock cases were made during the reign of George III in rosewood, chestnut, kingwood, pear, and other woods, while ebony, tulip, amboyna, and satinwood were used effectively for inlaying. Bracket or pedestal clocks were simply chamber clocks with enriched wooden cases. French clocks of this period were beautifully decorated often in the Buhl style with delicate inlays of metal and tortoiseshell.

*Fig. 2. Act of Parliament clock.*

*Fig. 4. Clock playing tunes, c. 1750-1760.*

*Fig. 5. Brass lantern clock with hour hand only, 17th-18th cent. (Courtesy of C. W. Shapland)*

The imposition of a tax upon users of clocks and watches in 1797 resulted in the making of what are known as Act of Parliament clocks. They were used by inn-keepers, who,

anticipating the probability of their customers being without watches, put up such clocks in their public rooms. They were, for the most part, very plain, and had a large dial of wood, painted black, with gilt figures, the face covered by a glass. They were hung on the wall, and had an extension below to give sufficient room for the movement of a seconds pendulum. The Act was so obnoxious that it was repealed in April, 1798.

The 18th century bracket clocks, with improvements in mechanism, are reproduced freely. Now that mantelshelves are often absent or so narrow that they do not admit of a large clock, the brackets solve the problem of accommodation. The cumbersome 19th century models in marble have given place to small lacquer-framed clocks with clearly marked dials and strut supports at back, or glass framed clocks.

**Mechanism.** Figs. 1 and 2 illustrate a type of English clock which is known as a fusee and chain pendulum timepiece. This variety is the most generally used where a timekeeper pure and simple is required. The plates or frames, A, Fig. 1, usually made of brass, are held together by four brass pillars, pivoted between which is the barrel, B, Figs. 1 and 2. Inside of this is coiled the mainspring, the outer end of which is hooked on to the rim of the barrel, and the inner hooked to the arbor, C, Figs. 1 and 2. This is pivoted between the two caps of the barrel so that the barrel is free to turn; the arbor is also pivoted between the frames, with one end coming through. This end is squared, and fitted

on the square is a ratchet wheel, D, Fig. 1, into which fits a click, E, Fig. 1, to prevent it running back. Round the barrel is wound the chain, F, Figs. 1 and 2, one end hooked to the rim of the barrel and the other to the largest end of the fuzee, G, Fig. 1.

The winding is done from the fuzee, which is pivoted through and keyed on to the mainwheel, H, Fig. 1, but can only turn one way, as between the fuzee and the mainwheel there is a click and ratchet. The arbor which carries the fuzee extends through the plates and the end is squared to fit the key or winder. When it is wound, the fuzee is turned, and the chain begins to wind round the spiral grooves. The other end of the chain, being hooked to the barrel, will pull the barrel round, incidentally coiling up the mainspring, which then has a natural tendency to uncoil itself. Thus it pulls the barrel back again and with it the chain. Since the fuzee is held by the ratchet, it cannot go back. It therefore pulls the mainwheel with it, and thus arises the motive power that keeps the clock going.

The fuzee is a spirally grooved pulley of varying diameter. Its object is to convert the varying force of the mainspring into a constant pressure on the train of wheels. Working on the small end of the fuzee is what is known as the stopwork, J, Fig. 2, which when the fuzee is wound full of chain is drawn into action and catches the hook at the end of the fuzee, thus preventing its being wound any farther.

The motive power is transmitted from the mainwheel to the centre pinion, JJ Fig. 1, which carries the hands. Fixed to the centre pinion is the centre wheel, K, Fig. 1, which in turn gears into the third pinion, L, Fig. 1. Fixed to this is another wheel, the third wheel, M, Fig. 2, which again gears into the escape pinion, N, Figs. 1 and 2, to which is attached the escape wheel, O, Figs. 1 and 2. From here the power is transmitted through the pallets, P, Figs. 1 and 2, by the way of the crutch, R, Fig. 2, to the pendulum, S, Figs. 1 and 2.

The pendulum controls the timekeeping. If it is raised from the point where it is at rest and then released it will, by the force of gravity, fall back to that point, and the momentum it gains in descent will carry it as far up the other side. If it were not for other factors, viz, the resistance of the air and the friction of the suspending spring a pendulum would go on vibrating indefinitely. The motive power supplied by the clock should only be sufficient to make up to the pendulum what it loses through this cause.

The escapement is the point where energy stored up by the mainspring escapes at regular intervals. The steel pallets swing with the pendulum and alternately release and catch a tooth of the escape wheel. They are so shaped that the forward movement of the escape wheel imparts to the pendulum by way of the crutch the amount of energy required to keep it vibrating.

The length of the pendulum used governs the ratio of the wheels and pinions necessary to show true time. The centre pinion carries the wheel to which the minute hand is attached by means of a sleeve over the extending part of the centre pinion, pinned down friction tight by means of a spring behind the wheel to allow the hands to be moved forward or backward.

This is the minute pipe (T, Fig. 1). Geared into this is another wheel of the same size and number, U, Fig. 1, which in turn is geared into the hour wheel, V, Fig. 1, at a ratio of 12 to 1. To the hour wheel socket, W, Fig. 1, is attached the hour hand; thus the minute hand travels round 12 times while the hour hand travels once. Thus the clock mechanism by way of the dial and hands indicates the number of vibrations the pendulum makes, and so, by the length of the pendulum and the ratio of the wheels the hands are made to register the time.

**Striking Clocks.** The fuzee and chain striking clock, as far as the timekeeping mechanism is concerned, is exactly the same as the timepiece. For the striking train it will be seen that an additional barrel and fuzee and train of wheels are used; the working of the barrel and fuzee has already been explained. The mainwheel in this case, A, Fig. 3, gears into a pinion, B, Fig. 3, carrying a wheel which is called the pinwheel, C, Fig. 3: driven into the web, and at right angles to the wheel are eight pins set at equal distances; it is these pins which raise the hammer, D, Fig. 3, to strike. This wheel gears again into the pallet pinion, E, Fig. 3, at a ratio of eight to one thus for each blow of the hammer this pinion turns once.

Attached to this pinion is another wheel, F, Fig. 3, which in turn gears into the warning pinion, G, Fig. 3, at a ratio of 7, 8, or 9 to 1, according to the speed the clock has to strike. On this pinion is fixed the warning wheel, H, Fig. 3, which in turn works into the pinion carrying the fly, J, Fig. 3. The fly acts as a sort of governor when the striking train is in motion. It will be seen that while the striking train is in motion it will keep lifting and dropping the hammer, which in its fall strikes the gong or bell. The mechanism shown here is the rack repeating system.

Screwed to the hour socket is a disk with 12 steps, called a snail, JJ, Figs. 3 and 4, each succeeding step being nearer the centre; this is what regulates the number of blows to be struck. Close by this and working on a stud is the rack, K, Fig. 4, on the outer edge of which is cut a series of inverted ratchet teeth. The distance of these apart in proportion to the distance from the centres corresponds to the steps on the snail. Extending from the working centre of the rack is a lever called the rack arm, L, Figs. 3 and 4. In the end of this and at right angles is a pin; when the rack comes into action it falls on to the snail, and according to the step it falls on, it allows a corresponding number of the rack teeth to come into operation.

To set the striking clock in motion the minute wheel, M, Figs. 3 and 4, has two pins; as this wheel turns once an hour, one of these pins will come into contact with the lifting piece, N, Figs. 3 and 4, every half-hour. This is a double arm lever which, when lifted by the pin in

*(Continued in page 469) (For images of fuzee and striking clocks referred to, see page 468).*

## CLOCKS

*Figs. 1 and 2. Front and back views of the works of an English fuzee and chain timepiece. (J. W. Benson. Ltd.) Fig. 3. Side and front view of English striking clock. (J. W. Benson. Ltd.) Fig. 4. Front view of English striking clock. (Courtesy of J. W. Benson, Ltd.)*

the minute wheel, in turn lifts the rack hook, O, Figs. 3 and 4, by means of a pin on the end. Attached to the extending portion of the pallet pinion which comes through the plate is the gathering pallet, P, Figs. 3 and 4, which is usually squared on and pinned across. When the striking train is at rest it locks on a pin in the rack, R, Figs. 3 and 4.

As the hour or half-hour approaches the pin in the minute wheel gradually lifts the lever, N, Figs. 3 and 4, which in turn lifts the rack hook. In doing this the rack is now free to fall, aided by a spring, S, Figs. 3 and 4, working on a small extension of the rack. In falling, the rack arm pin falls on to one of the steps of the snail. When the rack has fallen, the gathering pallet, and with it the train, would be free to turn, but the train is held in check by what is known as the warning, that is, an extension of the lifting piece passing through a slot in the plate, T, Fig. 4, and catching a pin in the rim of the warning wheel, H, Fig. 3. When the clock reaches the hour or half-hour the pin in the minute wheel reaches the end of the lifting piece, which then falls into its original position and clear of the warning pin and the rack hook.

Now the train is free to move the gathering pallet, turning once to every blow struck. On the gathering pallet is a small nib which as it turns gathers up one tooth of the rack, the rack hook by reason of its shape and position riding out and falling again behind the succeeding tooth. This is repeated until all the teeth are gathered up, when the gathering pallet will come to rest on the pin, R, thus again locking the train. So the number of blows struck depends on the step in the snail on to which the rack arm falls. At the half-hour only one blow is struck. This is done by means of the first tooth in the rack being cut shorter than the rest and the pin in the minute wheel for lifting for the half-hour being placed nearer the centre of the wheel. When it lifts it is only far enough to let go the first tooth of the rack, and therefore the clock will only strike one blow.

**French Striking Clocks.** These are cheaper than the English fuzee clocks, and on account of their small compass they can be offered in a large variety of cases. Here the fuzee and chain are not used, the mainwheel and spring barrel being all in one. A, Figs. 5 and 6, and the winding is done from the barrel arbor. This necessitates an extra wheel and pinion between the mainwheel and centre pinion on one side and between the mainwheel and pinion on the other, B, Fig. 5. The working of the other parts is fundamentally the same, except that the striking work is locked in a different manner. The gathering pallet in this case has no tail to it, the locking of the train being done by the rack hook, which is fixed to a detent, C, Figs. 5 and 6, pivoted between the plates with an extending arm which catches on a pin in the pallet wheel, D, Fig. 6.

This kind of clock is also fitted with what is known as a Brocot regulation, that is, a shaft passed from the front of the dial to the Brocot box, E, Figs. 5 and 6, which by turning forward or backward turns a wheel and moves up or down a small slide which lengthens

or shortens the pendulum.

**Pendulum Clocks.** When a pendulum clock stops, and, although it has been wound up and re-started, stops again almost immediately, the trouble is nearly always due to unsymmetry of beat. This is easily detected: if the beat is unsymmetrical, the intervals between the sounds of successive ticks are alternately a longer and shorter time, instead of being all equal.

The simplest remedy is to place a small pad of paper or the point of a wedge under the right or left hand side of the clock case, so that the clock is tilted over a little. If the beat is still uneven, but less so than before, some further raising of the same side will be necessary. If on the other hand the beat is more uneven than before, it is a sign that the block or wedge has been put under the wrong side of the clock case; it should be put under the other side and the procedure repeated.

In some kinds of clocks the works are enclosed in a drum-shaped metal case of the same diameter as the clock face, this metal case being a tight fit in the outer ornamental case but not being fixed immovably therein. In clocks of this type the beat may be adjusted by turning the inner case in the outer case by a small amount.

In the case of a clock not provided with the special facility described, it is still possible to avoid the unsightly appearance of the wedge, but the process is one of some delicacy. In many good class clocks the crutch or part which is slotted to receive the pendulum rod is a tight fit on the pallet spindle but is not fixed immovably. Consequently the crutch can be rotated by a minute amount relative to the pallets about the common axis. The procedure is similar to that used in the wedge method. A small adjustment is tried, and the clock re-started; if there is improvement but not yet equality of beat, more adjustment is required in the same direction, while if the first adjustment has made things worse, then the second adjustment should be made in the opposite direction.

In other clocks the crutch may be a wire which is firmly fixed to the pallet axis; in such a case the crutch can be slightly bent with the pliers to one side or the other till the clock is in "beat." It is not generally advisable for the amateur to attempt the cure of other troubles in pendulum clocks, or of any trouble arising in balance-wheel clocks; these are rather matters for the expert.

**Regulating a Clock.** In the case of a pendulum clock, the pendulum bob is usually held in its place on the pendulum rod by a nut underneath the bob. To make the clock run faster, the nut is screwed up a little, so that the bob is a little higher up the rod. Some pendulum clocks have a small square peg at the top of the clock face, with the letters S and F on either side of it. Such a clock can be regulated without stopping it, the procedure for making it run faster being to turn the peg with a key towards the letter F, and vice versa.

The regulator of a balance-wheel clock is a small

pointer at the back of the clock, which can be moved by hand over a graduated arc towards F to make the clock go faster or towards S to make it go slower. In clocks of French manufacture the letters S and F are replaced by R and A respectively. The balance is a small wheel with a bar across the centre connecting opposite sides of the rim. It is very delicately adjusted and is pivoted in plain conical bearings: it revolves backwards and forwards by the action of a fine spring, called the hair spring. In one movement the wheel winds up the spring; the second movement is caused by the impulse of the spring to regain its normal tension. The regulation of the balance requires great care and the pin should be moved very gradually.

Fig. 5. Front and side view of a French striking clock

Fig. 6. Back and side view of French striking clock

When setting a clock, if the clock either strikes or has an alarm, the hands must not be moved backwards, but instead must be moved forwards nearly 12 hours. Moving the hands backwards is permissible for other classes of clocks. The case of a clock should never be left open any longer than is absolutely necessary for winding, etc., or else dust will get into the works. If a pendulum clock is moved otherwise than with the greatest care it will be stopped, and may develop an un-

symmetrical beat. All members of a household should therefore avoid accidentally moving such a clock, and intentional moving in order to dust behind it should be forbidden.

**CLOCK GOLF.** The game of clock golf can be played in any garden when there is room to chalk out a circle of 4 to 6 yd. diameter, which is then marked with figures placed exactly as on the face of a clock. A tin, or small flower-pot is sunk for the hole as shown in the diagram, not in the centre, but nearer to some of the figures than to others.

*Clock Golf. How the numbers may be marked on the glass to be at unequal distances from the hole*

If there are only four players, the game can be one pair against the other; if more, each person scores for himself or herself. A golf ball is placed on the figure I, and the first player, armed with a putter or any other golf club, endeavours to get the ball into the hole in as few strokes as possible. When he has succeeded, the next player takes his turn, and so on until all have played. The player who succeeds in the fewest strokes wins the hole. The ball is then moved to the figure II, and the game proceeds as before. When all the players have played from each figure on the clock face, the game is scored by holes as in ordinary golf.

**CLOG.** Footwear with wooden soles and leather or fabric uppers, known as clogs, is used for a variety of purposes and in many industries. The English clog should not be confused with the continental sabot, for whereas the former is a wooden-soled boot or shoe, the latter is merely a block of wood, shaped and hollowed to admit the foot. The wood for the soles of a clog is usually either beech, ash, or alder. The first, being a close-grained wood, is less liable to swell and split when soaked; it is therefore invariably used in occupations which entail much standing about in wet places.

Clogs are more comfortable for garden work and on the allotment than boots. The iron-shod soles never wear out, and when in course of time the uppers become perished and cracked, they can be renewed at home. New clog uppers can be obtained at most leather and grindery shops. The clog upper is nailed round the outer edge of the sole in a rebate of about  $\frac{1}{8}$  in. To affix a new upper, first remove the welting or thin strip of leather which is used to hide the join between the sole and upper. If this is done with care, the welting may be fit to use again. After all the nails are removed the new upper should be lightly attached with a few tacks, and the old welting or a new strip cut to the same size, put into place and freely nailed. *See Boot Repairing.*

**CLOSET.** Originally the name given to a small private room, the idea of privacy has been retained in the present use of the word for an earth closet, chemical closet, or water closet. The portable chemical closet is convenient for indoor use where a water closet is not available, and is specially adapted for the caravan, boat or temporary building. *See* Earth Closet; Sanitation; Water Closet.

**CLOT: Of Blood.** The solidified state of the blood when it coagulates constitutes a clot. This is composed of a network of fine strands of fibrin, in which the blood corpuscles are enmeshed, the red blood corpuscles giving it a red colour. At first the clot includes the whole blood, but the serum is gradually squeezed out and the clot contracts.

When bleeding occurs inwardly the clot softens and disappears; if not, its place is taken by new fibrous or scar tissue. When a clot forms in the heart or blood vessels during life it is called a thrombus, and the process thrombosis. A clot of blood on the brain may mean that thrombosis has taken place. *See* Coagulation ; Embolism; Thrombosis.

**CLOTH.** In all woven cloths two sets of thread, crossing at right angles are interlaced with each other. Compound cloths can be woven with more than two sets, but not with less. Knitted cloths are made by forming a thread or threads into a succession of loops joined to one another. Animal, vegetable, and mineral materials are employed. Wool, hair, and silk appear in the first group; cotton, linen, jute, hemp, ramie, and artificial silk in the second; cloths woven from asbestos, spun glass, and metal wire come into the third.

Widths are limited only by the widths of the machines. Velvets are made as narrow as 16 or 18 in.; trouserings and handwoven tweeds are 27—28 in.; most cretonnes and many linings are 31 in.; dress serges are often 40 to 44 in.; various upholstery cloths are made in 50 in., and the nominal width of many wool cloths is 54 in.

Added width so often means a saving of length in cutting-out that a large proportion of goods are made in broader sizes. Narrow width is an ambiguous term usually implying 27-29 in., and double width 50-58 in. It is much better to specify the breadth in inches for clearness.

Cloth for Government service use is tested by special machinery, which applies tension, note being taken to the pound pressure at which breakage occurs. The ordinary test for wearing power is by the thumbs; when a cloth is so strong that the thumbs cannot be pressed through it, though tightly held and strength exerted, it is considered satisfactory.

**Yarns and Weaves.** Worsted can be distinguished from woollen by noting whether the yarn fibres are parallel or bunched crisscross. Combed cotton may be told from carded cotton by the evenness in the length of the fibre recovered. Linen differs from cotton in the much greater length of the individual fibres. Spun silk can be told from raw or thrown silk by the fact that the

one is made like worsted, from a large number of detached fibres, where the other is made by twisting more or less tightly together a few fibres of virtually endless length. This process does not afford final proof, but is informative so far as it goes.

Another point to be noted in examining detached threads is whether the yarn is tightly or loosely twisted. Tight twisting is favourable to wear, but makes the cloth harder and may militate against its graceful draping or the brightness of its appearance. Tight twisting is sometimes resorted to because the fibre is too short and poor for use otherwise. Hence it follows that cloths which feel very hard and substantial do not always wear well.

Double or two-fold threads are preferred to single for wear, and from a length of the yarn it is easy to tell by rolling one end between the fingers, while holding the other end, whether the thread is single or not. Single-strand yarn disintegrates forthwith into fibre, whereas two-fold splits into two individual threads.

Woven cloth, being composed of two sets of thread, is firmer and stronger the more efficiently these two are bound together. They are never more securely interlaced than in the plain weave seen in handkerchiefs. Cloths are made to feel thicker for being woven in twill or step formation. Their surface is made smoother and more lustrous by satin weaving, in which the thread, after passing under one of the opposing set of threads once, passes over the next five, six, or more. Under given conditions firm and good-wearing cloths can be made in these and in more fancy weaves, but it is not an advantage to the wear that there should be long unbound floats of thread lying on the surface. Woven cloth, on account of its structure, is firmer and less liable to stretch than knitted cloth. Knitted fabrics are used where elasticity is specially required. Cloths are knitted also when stockinette or jersey is in fashionable demand. *See* Braid; Serge; Tapestry; Tweed; Weaving.

**CLOTH BALL.** This is a compressed tablet, chiefly composed of precipitated chalk and magnesia, used for cleaning white and coloured fabrics, suède shoes, handbags, gloves, hats, etc. It can be obtained in white and in many different tints.

The white cloth ball is particularly useful in cleaning white furs, white satin shoes, and so on. The coloured balls are used for cleaning coloured nap cloths, coloured shoes, velours, hats, and velvet fabrics, pile carpets and rugs.

The methods for cleaning white and coloured fabrics is as follows. Brush well with a stiff clothes-brush, and free from dust as much as possible. The cloth ball is then rubbed vigorously into the nap or pile. Care should be taken that a good deposit of the cloth ball is rubbed into every part of the article, as neglected parts will spoil the effect of the cleaning. Fabrics should be folded carefully with the treated surface on the inside, and put away in a dry, warm place for at least 24 hours.

Shoes and other articles that cannot be folded should be covered to keep free from dust, and put into a warm place for a similar period. At the end of this time the cloth ball powder should be shaken and brushed out, and the article will be found to be almost completely restored to its original freshness and colour. In the case of articles that have been allowed to become very much soiled, a second application of the cloth ball may be necessary.

In suède shoes and suède goods generally, the nap in wear has a tendency to be rubbed down, and the article presents a shiny surface. This is particularly noticeable in shoes and handbags, the rubbed parts presenting a greasy, black appearance. If such is the case, procure a piece of fine sandpaper and gently rub against the nap until the surface is restored. Then apply the cloth ball in the manner already described. To avoid an uneven appearance, the sandpaper should be applied to the whole of the shoe upper, extra attention being paid to the soiled parts. See Fur; Suède.

### CLOTHES AND THEIR TREATMENT

**Care that Makes for Economy and Good Appearance**  
This article tells how both men and women can keep their clothes in good condition. See also entries on Darning; Mending; Pressing, and articles on Boot; Hat, etc.

It is not always realized that a small income does not preclude anyone from being turned out well groomed, since appearance depends less upon the extent of the wardrobe than the care taken of it. The chief enemies of woollen garments being dust, damp, and moth, it follows that no clothing should be put away for any considerable period without a thorough airing. If clothes are brushed thoroughly once a week, there is no fear that they will become a prey to moth. If it is necessary to pack clothes up for a lengthy period, either in a wardrobe or a trunk or other receptacle, there is nothing more suitable as a wrapper than a newspaper, the smell of which is particularly obnoxious to the moths that infest clothes.

Cloth is highly susceptible to the effects of heat and damp. When a man has worn a suit of clothes all day, and particularly if covered by an overcoat, it cannot fail to be somewhat creased, especially in the arms of the coat and the legs of the trousers. If these garments are carelessly thrown on a chair, they will assume permanent wrinkles instead of temporary ones. The chief damage is done during the first few hours after removal, so it should be a rule always to place the coat on a suit-hanger with a lower rail over which to place the trousers neatly folded. A trouser-press is a help, as by its aid trousers can be kept in good condition and their life prolonged.

When clothes become soiled they should be sent to a good cleaner, who will tailor-press them before sending them home.

#### Renovations by the Tailor

Early attention should be paid to any sign of wear at vulnerable points, e.g. bottoms of trousers and cuffs of

sleeves. If the damage is severe, take the garment at once to a tailor, who will present a new wearing surface by shortening the sleeve or trouser leg by a fraction of an inch.

Hats should be kept well brushed. Nothing is so damaging to them as dust, which eats its way into the felt, and speedily renders the hat too shabby to wear.

Neckties need careful treatment. Silk is a material which gives the greatest resistance to creasing, but silk ties are not composed entirely of that fabric. There is an interlining of swansdown, horsehair, wool, canvas, or some other material, and this interlining either becomes displaced or distorted through being re-tied day after day in exactly the same position. The only remedy is to have several ties in use, and to wear them in succession, placing them for a rest in a tie press or smoothing them out as much as possible after a period of wear.

Underwear should be changed frequently for airing, but not necessarily washed so frequently. These remarks may also be applied to socks and stockings—and it may perhaps be added that keeping the toe nails cut short prevents frequent darning. The practice of carrying loose change in the trouser pocket, or a heavy bunch of keys, speedily wears a hole in the undergarment. The stuffing of all sorts of articles in the pockets of the outer garments should also be avoided, as nothing contributes more to loss of shape. Boots and shoes, immediately they are taken off, should be put on boot trees. Here also the rule of having more than one pair in wear is highly to be commended. Where the heels have a tendency to wear on one side more than the other, the addition of a rubber tip will be effective. If a man follows the policy of constantly changing all the articles he wears, of keeping his garments well brushed, and of placing them in the best position after wear to recover the shape, he should save many pounds a year, and present a better appearance.

**Hints for Women.** Obviously the chief thing is to keep all your clothes well pressed and spotlessly clean. Damp, dust and moth (q.v.) are the greatest enemies to woollens and tweeds, and you should never put clothes away for any length of time without giving them a thorough airing. If you brush them well once a week there is no danger of moth.

As far as cleanliness is concerned, the main essentials are to keep all "undies" and washable silks and cottons frequently washed, and to send all tweeds and shrinkable silks to be regularly cleaned. To keep knitted woollens soft and in perfect condition never wash them in very hot water or dry them too quickly, as it hardens them. Ammonia added to the water will loosen dirt and grease.

To keep your undies fresh and fragrant keep them in Cellophane envelopes and add lavender bags to give a faint perfume.

Stockings are a great problem, as they always seem to wear out so quickly. However, here are a few useful tips which will help to prolong their life: When they are

new, always rinse them through in soapy water before wearing them; it greatly enhances their elasticity. A spoonful of vinegar added to the water takes away any ugly shine. Never wring them out, but roll them up in a towel to take away surplus moisture; then hang out to dry. Wringing them weakens the threads.

To keep white things a really good colour when they are washed always add either a little spirits of wine or some blue to the last rinse.

Always use a deodorant or sew dress preservers into frocks as perspiration leaves a very ugly stain. If any frocks do get stained you can remove the stain by covering the affected part with powdered borax, placing it over a saucer and pouring hot water through.

A really useful tip for keeping the backs of skirts in good shape is to sew a strip of silk, about half a yard long and cut to the shape of the skirt, into the side seams at the back.

All clothing should be periodically overhauled and mended whenever necessary. Keep all your clothes on hangers or neatly folded in drawers.

#### *How to Fold a Lounge Suit.*

1. Fold trousers, button to button at top and seam to seam in leg.
2. Place flat on table.
3. Fold vest, with lining inside and fronts outside.
4. Place vest on top of trousers.
5. Fold jacket, pushing out tops of sleeves.
6. Place on table, with sleeves straight, and fold over until lapels almost meet.
7. Fold again so that fronts meet and are straight, then place on vest.
8. Fold trousers over as far as possible, to prevent crease in legs.
9. Turn top of coat over as far as bottom of trousers will allow. (Courtesy of My Valet, Ltd.)

**Small Renovations.** In spite of proper care wear and tear are bound to have their effect eventually, and there comes a time when some form of renovation is

necessary. Coats grow shiny; collars begin to look greasy and stained, and garments require pressing.

To remove shine from a black coat rub the latter gently with some fine sandpaper, afterwards sponging it with a solution of common washing blue and water. Press the coat while it is still damp, but if it requires freshening, first brush it and clean it with benzine, afterwards sponging it with a quart of water containing a table-spoonful of ammonia. Coat collars are best renovated with a mixture comprising 1 pint benzine,  $\frac{1}{2}$  drain chloroform, and 1 dram alcohol. Apply this with a soft rag, or, as an alternative, rub the collar with a cloth dipped in ammonia.

A common thing which ruins the look of a pair of trousers is bagginess at the knees. This is caused, to a large extent, by sitting, and ordinary pressing will not remove it. It is possible to remedy it in the following simple manner.

Place the trousers flat on a table (in the same way as indicated in Fig. 2 of illustrations of how to fold a lounge suit) and damp the knees slightly with a moist cloth. Then place the left hand firmly just above the knee so as to hold it in position, and with the right hand take hold of the back of the trouser leg, about midway between the knee and the bottom of the leg, and pull hard towards the bottom. Transfer the right hand to a similar grip in the front of the leg, and again pull downward. It will be found that this entirely removes the bagginess from the knee. Each trouser leg should be treated separately. The trousers can then be pressed in the usual way, if desired.

Never use a light-coloured cloth in pressing dark

clothes, since the white lint invariably leaves an impression which is difficult to remove. Do not rub, as in ironing, but lay the iron on gently and move it slowly over the garment. When clothing has become mildewed, put the affected part in a bowl of buttermilk and it will come out like new. In the case of a fabric on which there are acid stains, it is best to apply ammonia. If this is done without delay the effect of the acid will be neutralised, the material prevented from rotting, and the colour saved.

Clothes which are made of light materials can be cleaned with a cloth ball (q-v.). Perspiration stains should be treated as early as possible by soaking the affected part in cold water for 15 min., then sprinkling it with lemon juice and leaving it for a few minutes before rinsing it in clean water. If the first treatment is not successful, repeat the process, taking care not to leave the lemon juice on too long, as this might affect the dye in coloured materials.

**CLOTHES BRUSH.** In the best sorts the fine, springy quality of the bristle is easily noticeable. In a common brush the bristle will either be soft or cut short to produce greater stiffness. If preferred, a brush can be obtained with the end portion of the back set with short, stiff knots of bristle which are useful in removing hard deposits of mud.

In a hat brush stiffness is not so essential. A clothes brush and a hat brush of the square-back shape, with screw eyes to hang on a polished board, make a hall set, and are less obtrusive than the more elaborate ones with bevelled mirror, besides the fact that fibre, which is extensively used with bristle in making common clothes brushes, is often found to be a component part of such hall sets. Fibre is detrimental to good cloth, and the knots of this mixture are usually punched into the holes; this can be detected by the absence of a separate glued and screwed veneer back. The fibre mixture will not last in wear; the bristle is poor, the fibre soon wears off, and the polish on the back quickly dulls, so that this brush is soon rendered almost useless.

A good brush should have stiff bristle of fair length, a well-filled stock and a separate back. The back should be secured by brass screws and finished by polishing. *See Brush.*

**CLOTHES HORSE.** A clothes horse is usually made with two folds of equal size, but sometimes with three or four, the latter being cumbersome to handle. A more compact form is to make it in three folds, the centre one wide and each of the wing folds half the width of the centre fold, so that the whole closes flat into two widths only. The uprights should finish  $1\frac{1}{2}$  in. by  $1\frac{1}{8}$  in. each, to be mortised right through for the spaced rails to enter. These can be tenoned to enter right through and be double wedged. When fitted up they can be well sandpapered and left with the natural surface, the rails being slightly rounded on top edges. The folds are hinged together with strong webbing, with two hinges above and two below to each pair of meeting uprights.

The dimensions may vary according to requirements. A size of 3 ft. 6 in. high may be 2 ft. 9 in. wide, each fold being, therefore,  $16\frac{1}{2}$  in. A 4 ft. size can be 3 ft. wide when closed, and a 4 ft. 6 in. size 3 ft. 4 in. wide, all with three rails to the fold. Larger sizes of the article may have four or more rails. *See. Airer.*

**CLOTHES LINE.** When clothes are hung up to dry they are suspended from lines which may be made of hemp, jute, or galvanised iron stranded wire. The hemp lines are generally put up in 18 to 20 yd. lengths with a ring at each end. Galvanised wire lines are made in two thicknesses, the No. 11 gauge and a much stouter line, known as No. 8 gauge, and generally in 50 or 100 ft. coils.

The lines are supported by wooden posts  $2\frac{1}{2}$  to 3 in. square and 8 ft. long. The upper end has wooden pegs for attaching the lines on all four faces; the lower end has a fillet A to support the post as it rests in the wooden socket B (Fig. 1.). The latter should be tarred and buried in the ground, preferably in a lump of concrete built round it as a foundation. With this arrangement the posts can readily be lifted out of the sockets and stored away when not in use.

*Clothes Line. Fig. 1. Post with four wooden pegs and fillet, A, for inserting into the socket shown at B. Fig. 2. Cast iron socket bedded in concrete. Fig. 3. Method of keeping post-rigid.*

The socket shown in Fig. 2 is made of cast iron: it is sunk into the ground and bedded in concrete. The posts used for this socket should have tapered ends to fit tightly into the hole in the socket. However carefully the sockets are fixed, the post is seldom rigid; it is a good plan to provide a hook low down on

an adjacent wall, or screwed into a wooden post driven into the ground, and to attach one end of the line to this hook, then twisting it around the post. The line thus acts as a guy or stay and keeps the post rigid. (*See Fig. 3.*)

When a wall or the side of the house is available it is best to fix a hook or an eye-bolt securely into the brickwork and to provide a pulley for the line. A clothes line should always be brought indoors when not in use. It is unsightly, and exposure to wet rots the rope. Frequently in towns, and occasionally even in the country, the line should be cleansed in hot soda and water, otherwise it will collect smuts and leave dirty marks on the clean linen. Fine, light clothes lines, which fold up very small and are easily set up in an ordinary room, with small pegs to suit, are sold for travellers and women who live in bachelor flats, and are a help in the laundering of light articles. *See Airer; Cord.*

**CLOTHES MOTH.** This tiny winged insect of the moth family is most injurious to clothes, particularly furs and woollens. Before dying in early autumn it lays its minute flat eggs in such materials, on which the larvae feed when they emerge in the spring. The chief times for the housewife's vigilance are August and September, when the eggs are laid, and the spring, when they hatch. The spring and autumn household cleanings, with their attendant turning out of every drawer and cupboard, protect against moth as well as clearing away dirt and lumber. There is little risk of moths attacking clothes which are in constant use. The things that need watching are woollen cloths, curtains, blankets, eiderdowns, and furs which, not being in use, are stored away during the summer months.

**Preventives and Remedies.** The contents of all drawers and wardrobes should be turned out periodically, and every item examined for moth marks. All should be well shaken in the open air, and if possible hung out of doors for a few hours. Furs should be hung over the line and well beaten with a light cane before being packed away.

Pockets in overcoats and winter wraps not in use should be turned inside out and brushed free from fluff, and then filled with small broken pieces of a cigar box or cedar chips; moths object to the smell of cedar. Clothing stored in newspapers, linen and other materials with a cold surface is seldom harmed, since moths avoid all substances of a chilly nature, because they are unfit for hatching. The only precaution needed is that the edges of the paper must be pasted together, and the linen sewn so that no moth can enter.

Apart from their dislike of cold substances, moths have a distinct aversion to certain odours, such as tobacco, Russian leather, and sandal-wood. Two other odours which keep away moths are those of naphtha and lavender, and both should be freely used among stored things. Naphtha balls can be bought by the pound and placed one or two in drawer corners and in the folds of blankets, etc. They are, however, not fully effective and a far more up-to-date and efficacious remedy is dichlorbenzene, obtainable in crystals from

any chemist at about 9d. per half-pound.

When it is suspected that moths are in an article of clothing that will lend itself to steam treatment, wrap it in a clean damp towel, put it in the oven with the gas turned low, and steam out the grubs. If the garment is too large for the oven, place it under a damp towel, and press it with a rather hot iron.

When moths have actually been detected in furs or clothes, brush the latter with a whisk broom saturated with formaldehyde solution. Trunks should also be treated with this solution, and afterwards left in the fresh air for a few hours. A good substitute for formaldehyde consists of 3 tablespoonfuls of turpentine added to 3 quarts of cold water. This may also be used for rubbing on floors under carpets and rugs which have been attacked by moths.

**CLOTHES PEG.** Probably the best is the American, turned from a piece of beech or other hardwood, and the V-shaped slot or jaws, formed by sawing away the material to the shape substantially as shown in the illustration. They are readily produced from dowel-rod, turned to shape with chisel and gouge. A two-part block, hollowed in the centre to receive the peg, is used to support it in a vice while sawing out the slot.

*Clothes Peg. Types in common use :  
top American;*

*centre, spring-grip;*

*bottom, gipsy*

Another type of clothes peg, known as the gipsy, is made from odd bits of wood whittled with a knife and the two pieces secured with a narrow band of tin-plate. The patent pegs furnished with spring grip are small in size but scarcely so durable as the American type; they are more suited for indoor use. Clothes pegs should hold tightly, and never get rusty, or otherwise they are liable to damage the clothes. On this score the American type is undoubtedly superior, as there is no metal to rust, no joints to give way, and the long tapering slot, together with the natural springiness of the material, gives it a secure and powerful grip.

**CLOTTED CREAM.** In the preparation of clotted cream it is desirable to use rich milk, but this is not essential. Whole milk, warm from the cow, is strained into setting pans. The pans most suitable for the purpose hold about 6 to 8 quarts of milk, and measure 15 in. across the top, 7 in. in depth, and 11 in. across the bottom, being somewhat deeper than the usual. The pans of milk are left undisturbed in a cool dairy for the cream to rise. In summer 12 hours or less

is the time allowed, but in winter 24 hours is usual.

Scalding is then carried out by placing the pans on a hot-water stove, and allowing steam to play under them until they have attained a temperature of 175° to 185° F. in not less than 20 min., when they are removed, and allowed to cool naturally in a cellar or other cold position. The scalding should not be done too quickly, or the cream is rendered greasy. The heating may be carried out by placing the pans on a kitchen range or hob, but the hot-water method is preferable.

When the scalded milk and cream are cold—in warm weather the cooling should be done quickly—the cream may be taken off in a thick clotted condition, and is ready for use. The cream is generally sold by the lb., and 1 lb of cream may be obtained from 1½ gal. or less of Jersey milk; nearly 2 gal. of Shorthorn milk may be required to produce the same quantity. *See Cream; Milk.*

**CLOUD GRASS.** The popular name of cloud grass is given to a hardy annual group of grasses called *Agrostis*, which are very useful, when dried, for the purpose of room decoration.

*Clout or Broad-headed Nail. Left to right, fine wrought; strong wrought; counter-sunk; blue-wire.*

**CLOUT NAIL.** Having a broad head, relatively large in diameter to the shank, the clout nail is useful for fixing such material as zinc sheets, roofing felt, or for any purpose where the material to be fastened is comparatively thin or fragile. Various patterns are illustrated. Blue-wire clout nails are made from ½ in. to 1½ in. long; wrought clout nails, fine (that is, thin) or strong (stout), are from ½ in. to 1½ in. in length. *See Nail.*

**CLOVE.** The dried buds of an Eastern plant are widely used both in medicine and in cookery under the name of cloves. Their most valuable constituent is oil of cloves, of which the dose given by doctors varies from ½ to 3 minims. Applied outwardly it has a stimulant effect on the skin, producing heat and redness. When applied to a cavity in a decayed tooth it often relieves the pain of toothache.

Taken internally, oil of cloves causes an increased flow of saliva in the mouth. In the stomach the normal movements are stimulated, and there is an increased flow of gastric juice. Oil of cloves increases the appetite and improves the digestion; it is often prescribed in cases of indigestion with flatulency.

For culinary purposes cloves form a valuable spice, sold whole or in powder form; they have a strong aromatic odour, and a hot, spice-like flavour. A clove should not float horizontally when placed in water: if it does it shows that the essential oil has been extracted.

Two or three cloves added to apple while it is stewing or put into an apple pie will improve the flavour. Tincture of cloves is used for flavouring mulled wine. It can be prepared at home by dissolving ½ oz. fresh oil of cloves in ½ pint rectified spirits of wine.

**CLOVE HITCH.** This is a simple method of attaching a rope to an object without the use of a knot. The illustration shows how the fastening is made, the two turns being brought close together after they are formed. The security of this hitch depends largely on the fact that the rope bends over itself.

*Clove Hitch. Diagram illustrating turns of rope round a beam.*

**CLOVER.** The name is applied to various grasses belonging to the genus *trifolium*, of which the red clover, cow grass, zig-zag clover, and woodland clover are the best sorts for pasturage. The different clover grasses are sometimes included in the mixture of seed for lawns, but not for turfy stretches for the purposes of tennis, croquet, or bowls. The shamrock is commonly said to be one of the clovers, *trifolium minus*.

**CLUB FOOT.** Paralysis and the contraction of scar tissue after an injury are the commonest causes of club foot, which is a permanent malformation of the foot or ankle. The deformity may be present at birth or it may be the result of accident or disease, and there are four varieties. In the first of these, *Talipes equinus*, the heel does not reach to the ground, the patient's weight falling on the ball of the foot. The opposite condition is found in the second kind, *Talipes calcaneus*, the heel alone touching the ground, while the toes and the front part of the foot are lifted up. In *Talipes valgus* and *Talipes varus* the outer and inner sides respectively of the foot are turned upwards so that the patient walks on the inner or outer side. *See Foot.*

**CLUB ROOT.** In cabbages and other greens this is a most troublesome disease. It causes great loss and infects the soil, attacks the roots and causes the plants to rot. It attacks other members of the same family (eruciferae), e.g. turnip, wallflower, charlock and the shepherd's purse weed. The best treatment is to lime the land heavily and not to grow susceptible crops on infested land for three years. Anbury and finger and toe are other names for this disease.

**CLUMBER SPANIEL.** Both in disposition and appearance the Clumber differs materially from the rest of the spaniel family. He is heavily built, weighing from 60 to 75 lb., slow but an excellent game-finder; not being headstrong, he is easily broken. His white coat is relieved with lemon markings, and his square, massive head and deep flews give him a dignified look. The stout legs are, of course, short, and his back is powerful. The breed originated at Clumber House, near Worksop, Nottinghamshire, the seat of the dukes of Newcastle. *See Dog.*

*Clumber Spaniel. "Sandringham Spark" owned by King George V.*

**CLUMPS.** For a large party of people clumps is a good game, but it should not be attempted with fewer than 10. The players divide into two parties, which occupy opposite ends of the room. Each camp chooses a representative from the other, and the two representatives go out of the room together and decide upon some object—no matter how obscure—which is to be guessed by the others. They might, for example, choose the largest diamond found in the Kimberley mines in a given year. On their return each representative goes to the hostile camp; the one chosen from camp A goes to camp B and vice versa.

It is then the business of the respective camps to find out by close questioning what object has been chosen. To these questions only "Yes" or "No" may be given as answers. The camp which first arrives at the correct solution wins the round and retains the representative, as well as its own member, who returns from the losing camp. *See Children's Party; Evening Party.*

## THE CLUTCH ON MOTOR VEHICLES Its Working Principles Described and Illustrated

This is one of the articles in this work that deal with the mechanism of motor vehicles, others including Brake and Gear. See also Motor Car; Motor Cycle

The clutch is employed as a friction-gripping device by which the engine is enabled gradually to take up the drive through the gear box to the back axle. It is necessary to disengage the engine from the transmission before making any change of gear; as well to enable a vehicle to come to rest without having to stop the engine; also to allow the engine to run before the vehicle gets under way.

The importance of the part played by the clutch and the need of keeping it in good order cannot be over-estimated. Should the clutch get dirty and stick up, it will be impossible to engage the low gear without considerable noise and consequent damage to the gear teeth when starting away from rest. The clutch may fail to engage properly, or it may suddenly take up the drive, thereby throwing severe strains upon the transmission. As a result, gear wheels may be stripped, or the differential gear seriously damaged.

*Clutch. Fig. 1. Principal parts of a single-plate disk clutch. The outer plate (6) is bolted to the flywheel (A) and carries the driving member (D) which is located on the splined shaft (E). Coil springs (H) press the plates and friction disk together and the pressure is relieved by the action of the thrust race (O) and lever arms (N).*

**Single-plate Clutch.** This clutch, which has taken the place of the cone type, is the one in most common use to-day. Less expensive in first cost, it causes little trouble in upkeep, and has the great advantage that its speed quickly falls when disconnected. The principal parts are shown extended in Fig. 1. The plate G, which is bolted to the flywheel rim A, carries all the clutch elements. The parts are thus enclosed in but do not touch the flywheel recess. The driving member is a plate D, having a number of radial saw cuts which afford flexibility; the splined centre engages the end of the clutch shaft, E, on which it may slide slightly endwise. The plate D is held between a fabric disk, J, riveted to the pressure plate, K, and a similar disk on the plate G (not shown).

Studs, L, screwed into the pressure plate project through holes in the fixed plate, G, and pressure is applied by means of springs, H, fitted on the studs outside plate G and held fast by the nuts M, which

permit of adjustment. The parts are normally held together by the springs. When the clutch pedal is depressed the inner ends of the three levers, N, are forced towards the flywheel by means of the ball thrust race, O, the rear end of which is engaged by the clutch fork. The adjustable screws T, in the outer ends of the levers N, engage the pins P, and thus force the pressure plate away from the fixed plate, leaving the driven member, D, free.

*Clutch. Fig. 2. Typical dry single-plate clutch shown in part section. The driven plate is fitted with a cushion hub and the thrust bearing comprises a solid graphite ring (Courtesy of Morris Motors, Ltd.)*

Another typical single-plate clutch is illustrated in Fig. 2. As in the pattern previously described, this clutch has a driven plate which is faced in each side with friction material, and it is held between the face of the flywheel and a pressure plate by a series of coil springs. These are located in bosses formed on an outer casing and are compressed by the action of lever arms and a lever plate which are moved forward when the clutch pedal is depressed. Special features of this clutch are the solid graphite block thrust bearing and the cushion hub. The former is located in the withdrawal fork anchored to the cross shaft, and since it requires no lubrication the difficulty frequently experienced with the ball bearing type of race in maintaining an adequate supply of grease or oil is overcome.

The cushion hub referred to is a device incorporated to provide smooth running at low speeds and to lessen snatch in the event of the clutch being roughly engaged. The damping effect is achieved by interposing coil springs between the boss of the hub and the driven

plate. As in other types of clutch the chief point of maintenance is the retention of the requisite amount of clearance between the thrust bearing and the lever plate.

*Clutch. Fig 3. Main components of cork-insert plate clutch in extended view. The friction plate with double row of cork disks is disposed between the flywheel face and the pressure plate. A series of helical springs press the various elements together. Withdrawal fork and ball race are also shown. (Courtesy of Morris Motors, Ltd.)*

In some types of plate clutch fitted to cars cork inserts take the place of the fabric linings. This form of clutch runs in oil and as a general rule the lubricant is fed to the mechanism by means of a duct connecting the bell housing of the flywheel with the crankcase. The component parts of a cork insert plate clutch are shown in Fig. 3. It will be noted that the driven plate has a double line of inserts and has a cushion hub. The driving surfaces consist of the forward face of the pressure plate, shown immediately to the right of the driven plate, and the rear face of the flywheel seen on the extreme left. Pressure is exerted by helical springs on the cover plate bearing against the pressure plate, and the withdrawal mechanism consists of a fork, and thrust race which moves the plate away from the flywheel when the pedal is depressed, so compressing the springs and relieving the pressure on the cork inserts.

*Fig. 4. Newton automatic clutch in which engagement and withdrawal are controlled by engine speed and effected by an arrangement of links and weights working on the centrifugal governor principle. (Courtesy of "The Autocar")*

**Automatic Clutch.** In order to simplify the control of the modern car various designs have been evolved whereby the clutch is withdrawn and engaged

automatically. The essential principle of the automatic clutch is that it works in sympathy with the engine throttle opening and is not directly actuated by the driver. The systems in general use employ either the partial vacuum in the induction system of the engine or centrifugal force. In the former design an arrangement of servo cylinder and piston is utilized with connexions with the inlet manifold, the accelerator and clutch pedal. When the engine is idling a partial vacuum occurs in the servo cylinder which moves the piston and withdraws the clutch. On the accelerator pedal being depressed, however, the partial vacuum is destroyed and the piston moves in the opposite direction so engaging the clutch. The centrifugal type of clutch is represented by the Newton clutch (Fig. 4). It works on the same principle as the centrifugal governor and consists of three main parts, the driving member, driven member and friction plates. The driving member is bolted to the flywheel and comprises an outer casing on the circumference of which are fitted links with weights attached at their central hinges. These links are connected to a movable plate which bears against a number of coil springs. When the engine is running at low speeds these springs hold the plate so that it does not press on the clutch plates and therefore no drive is transmitted. When the engine speed increases above 500 r.p.m., however, centrifugal force acts on the weights and throws them outwards. This draws the arms of the links towards each other and moves the plate inwards so that the friction plates are pressed together and the clutch is thus engaged.

Although this type of clutch is automatic a pedal control is incorporated so that it can be actuated at any engine speed for the purposes of a gear changing.

*Clutch. Two examples of clutches used on motor cycles. Fig. 5. Sturmey-Archer countershaft clutch. Fig. 6 (right). Type with cork inserts in the driving disks.*

### Motor Cycle Clutches.

The clutch on a motor cycle is usually combined with the chain sprocket wheel driven by a chain from the engine, and also with the sprocket pinion, which is connected to the road wheel. In the multiple disk Sturmey-Archer countershaft clutch (Fig. 5), the chain wheel, A, geared to the engine drives the first motion shaft, B, of the gear box through a pack of driving and driven disks with interposed fibre rings; the main driven member, C, which is keyed to the end of the shaft, B, carries the three driven disks, D; several coil springs supported on pins, E, clamp the disks between the driven member, C, and the outer driven disk, D.

Another type (Fig. 6) employs cork inserts (G) in the driving disks, which rotate with the chain wheel, A. The driven disks rotate with a driven member, H, having a splined connexion with the shaft, J. The coil spring, K, forces the disks into engagement.

**CLYDESDALE TERRIER.** Of the several breeds of Scottish terriers the smallest is the Clydesdale. Its coat is long, fine and silky, with a high gloss, and there is no undercoat. A parting runs along the middle of the back and head, and from this the coat falls in two perfectly straight and even curtains to the ground, hiding the short legs and the dark, sharp eyes. The small ears stand erect almost on the top of the head, their long fringes covering the sides of the head. The general colour is an unmixed bright steel blue; but head, legs, and paws are a clear golden tan, and the tail is dark blue or black. The weight is about 18 lb. This somewhat rare breed is now seldom exhibited. *See Dog; Terrier.*

*Clydesdale. Specimen of the small Scottish terrier.*

**COACHMAN.** A coachman is a man who drives horses for an employer, the word being usually restricted to one engaged by a private employer. Being a male servant, his employer must take out a licence for him; this costs in Great Britain 15s. a year. *See Chauffeur; Driving; Horse; Insurance.*

**COAGULATION.** The change from a fluid to a more or less solid state, as seen in the clotting of blood, the curdling of milk, and the hardening of white of egg by heat, is termed coagulation. Blood coagulates when it is shed, and when it is received in a vessel the following sequence of events is easily observed. The

process begins on the surface of the blood, which in about 2 or 3 minutes begins to stiffen and become jelly-like. This takes place throughout all the blood, and is complete in from 10 to 15 minutes. Then a pale straw-coloured fluid oozes out from the clot, until in an hour or two the clot, which has become smaller and harder, is floating in the fluid.

Clotting is due to the formation of a substance known as fibrin ferment by the injured cells and the leucocytes. In the presence of salts of lime this ferment throws the solid substance of the clot out of solution. If blood when it comes from an opened blood vessel did not undergo this change, which plugs the opening, we should be in danger of bleeding to death from the slightest wound, as is the case in haemophilia where the process is delayed beyond the normal time.

In addition to haemophilia the blood is long in clotting in haemorrhagic purpura, pernicious, anaemia and jaundice. In these conditions slight bruises may produce considerable bleeding under the skin, and bleeding occurs in alarming quantity from wounds or mucous membranes. *See* Clot; Milk.

**COAL.** Coal is made up of a combustible portion, which is chiefly carbon, and an incombustible portion, which is mineral matter and constitutes the ash. Of all kinds of coal the richest in carbon is anthracite, which contains 90 per cent. Harder and heavier than ordinary coal, it burns with practically no flame or smoke, giving out an intense heat and leaving little ash. It is not very suitable for ordinary grates and should be burnt in specially constructed stoves. An anthracite stove is very useful in a hall or library, and once it is started it needs practically no attention beyond being replenished every 12 hours or so.

Soft or bituminous coal is sold under such names as Wallsend, silkstone, selected, Derby or Nottingham brights, household and kitchen. A coal that gives excellent results in the kitchen range may not be good on the other hand for the drawing room, and on that account two varieties of coal may be used in larger homes.

Cobbles and nuts are intended mainly for kitchen use. The terms refer to size rather than to quality, cobbles representing pieces between 6 in. and 4 in. and nuts between 4 in. and 2 in. If a separate coal-fired boiler is used in connexion with a central heating installation, hard steam coal is to be preferred to a soft one.

Dross or coal dust is a bugbear to the householder, and every effort should be made to prevent its accumulation in the cellar. When a big lump of coal has to be broken it should be placed on the floor of the coal cellar and not allowed to rest upon the other coal; in this way a clean break can be made.

When a fresh supply is got in it should not be dumped on top of any small coal and dust remaining. This should be scraped to one side, and it should be a rule to use some of it every day along with the larger lumps. A good fire can often be kept burning for a long time without attention if banked up with small stuff.

The dust can also be formed into solid blocks or

briquettes with the aid of a little Portland cement and water, a vessel such as a flower-pot being used as a mould. The briquettes and ovoids (egg-shaped cakes) obtainable at the shops are made of small coal compressed with pitch as a binding material. *See* Anthracite; Cooker; Range.

**COAL BOX.** For a drawing room the helmet-shaped box in brass, or a circular box of pierced steel or brass—the selection of metal being dependent on the other accessories of the hearth—with an iron lining and supported on feet, is always suitable. The latter with a lid is often vase-shaped in the Adam style of decoration, but is also seen in rather a heavier type of box without a lid. The iron cauldron and the wooden tub, strengthened with bands of copper and a separate lining, both look well with a brick hearth. Wooden boxes of the old-fashioned type with hinged and sloping lids are best in plain designs. Square-topped coal cabinets with drop fronts and removable liners, which tilt forward when the front is opened, are sometimes liked, as the top forms a convenient small table surface.

For a dignified fireplace, or with an oak-panelled chimney piece, nothing could be more suitable than the metal box illustrated. *See* Chimney.

*Coal Box. An attractive and useful example which can be tilted forward when used. (Courtesy of Waring and Gillow, Ltd.)*

**COALBROOKDALE.** Old china bearing this name was produced at the Shropshire village of Coalport in Coalbrookdale. Those pieces which are marked CD, CBD, CDale, or the full word, are called Coalbrookdale, to distinguish them from those bearing the later Coalport marks. One of the characteristics of the dalesmen potters was to produce careful copies of Sèvres, Chelsea and other wares. These were either unstamped or bore copied marks; when such pieces are traced to their real makers, they rank as Coalbrookdale. *See* China; Coalport.

**COAL BUNKER.** In flats and small houses a coal bunker is frequently built into some odd corner. It must be made strong enough to withstand the frequent introduction and removal of the coal. For this purpose boards are fitted into grooves or a channel at the front of the bunker (A, B, Fig. 4). These are removed one by one as the coal is consumed.

*Coal Bunker. Figs. 1-4. Diagrams showing two methods of arranging a small bunker so that the coal shall be easily accessible.*

In modern flats where the coal cellar is often simply a cupboard beneath the stairs, it is the cause of much grit and dirt getting scattered about. This can be remedied to some extent by building a rough partition with stout boards about a foot away from the door, as in Fig. 1. In front of this place a wire grid or woven wire mat, so that when handling the coal most of the dust will fall on to this grid, pass through it, and be kept from littering the house.

Where circumstances permit, a good plan is to construct a hopper, as illustrated in Fig. 2, provided with an exterior door sliding in strong grooves, shown in section, Fig. 3.

The upper part of the front of the bunker may be provided with a hinged flap or with removable boards having runners similar to those at the bottom. This provides for the introduction of the coal, which can be withdrawn by opening the door at the bottom and allowing the coal to fall out directly into the coal scuttle. A stout poker will be found convenient for raking the coal should it show any tendency to jam in the hole.

**COAL CELLAR.** A coal cellar in small houses is often an excavation beneath the floor, approached by a flight of steps; the coal is delivered through a shoot covered by a circular iron plate, protected against intruders by a chain or bar. Such cellars are liable to be flooded during heavy rain or by the overflowing of a gully or drain. This can be dealt with by raising the height of the curb and providing more suitable channels for the overflow water to drain away.

*Coal Cellar. Method of converting a coal cellar into a useful room.*

A cellar that is not wanted as a store for coal can be converted into a useful room, provided that it is dry and there is sufficient height to move about. The walls may be covered with old or cheap linoleum, with the back of it facing the room, as it is damp-proof and durable. Nail this to the walls and decorate it by panelling with narrow wooden strips. The ceiling is covered with beaver boards, nailed to the joists, and panelled in any way desired. The lino can be painted.

The stairs are improved by fitting a newel post, handrail, and balusters, as shown in the illustration, and another handrail secured to the wall with brackets. The floor can be concreted, covered with flooring boards, or if in fairly good condition and already concreted, can be tarred, covered with ordinary tarred roofing felt, and finished with linoleum.

The coal plate can be converted into an air shaft for ventilation by boxing it in and fitting a grating at the top. It is often feasible to fit a skylight. *See Architecture; Coal; Cottage; House.*

**COALPORT:** The China. One of the historic potteries flourishes at Coalport in Shropshire, and turns out excellent modern fabrics. The old Coalport works produced the most careful reproductions of Sèvres and Chelsea made anywhere; the mock marks may be recognized by being over the glaze, often with a small x added. The rose Du Barri, turquoise and apple-green grounds were especially rich, and the landscape panels neatly done. The Chinese willow pattern, which was first imitated at Caughley, was continued at Coalport. Old Coalport was undated, and much of it unmarked. *See China.*

*Coalport China. Modern plate reproducing an old design. (Courtesy of Coalport China Co. Ltd.)*

Coal Scuttle. *See Cauldron; Coal Box.*

**COAL TAR.** Coal tar is a black viscous liquid which is obtained after coal has been heated in the production of illuminating gas. It contains valuable chemicals used in the manufacture of dyes, drugs, and disinfectants, and after these have been extracted it is used to protect wood, brickwork, stone and iron, for which purpose it is merely painted on and allowed to dry.

As a protective material it is widely employed in laying wood pavements and in preventing dust on roads. It would be of value in treating dusty spaces around the house, being sprayed or painted on the surface and then covered with sand or gravel, but it must be remembered that it has a poisonous effect on vegetation.

Coal tar soap consists of soap impregnated with a certain proportion of coal tar disinfectants, and is used for the same purposes as carbolic soap. Disinfectants made from coal tar are amongst the most effective that science has produced. *See Disinfectant; Soap.*

**COARSE STUFF.** A mixture of lime, sand, and hair is used in plastering under the name of coarse stuff, generally for the first and second coats on internal surfaces. The proportions are 1 part of lime to 3 parts clean, coarse, sharp sand, gauged by measure, not by weight. To this is added about 1 lb. by weight of long, clean ox hair to every 3 cubic ft. of the coarse stuff or, say, 3 pz. of hair to a pailful of mixture. *See Ceiling; Cement; Lime; Plaster.*

**COASTER HUB.** The design of this hub provides a free wheel, as well as a powerful brake having a very

sweet action; the brake is applied by back-peddalling, while the free wheel or coasting action is obtained by keeping the feet stationary.

To take the driving and free wheel action first, it will be seen from A that there is no part of the mechanism that can be said to have any resemblance to the free wheel as commonly understood. Its mode of operation is as follows: A and B are the driving members, and rotate as one with the chain ring; B is machined integral with the chain ring seating. On A is secured the friction spring C, which bears against the inside of the hub shell. It follows that if B is rotated in a forward direction faster than the hub shell is moving, then A, the rotation of which is being hampered by the frictional contact of the spring C, will be made to screw itself on to B through the medium of the quick pitch screw D. The drive to the hub is taken up by the teeth shown on the face of B meshing with the corresponding teeth on the inner face of the hub shell, marked X. The harder the pedalling, the firmer will become the grip of these teeth, so ensuring there being no possibility of slip.

*Coaster Hub. Diagram showing the principle on which the hub is constructed.*

The free wheel, or coaster action, is practically a reversal of the foregoing, and is obtained in this way. Stop pedalling and the hub, which is still being rotated by the momentum of the bicycle, will now be rotating faster than B. The result is that, through the medium of the spring C, the cone A will unscrew itself along B, thereby becoming disengaged from the hub. Thus the hub is left to rotate free, whilst the cone A is left stationary with B, ultimately making a very light contact with the brake operating cone clutch E.

**Operating the Brake.** To operate the brake it is only necessary to move the pedals in a backward direction. This will further unscrew A off B. Therefore, A will be forced tightly into the brake clutch cone E, and a further backward direction of the pedals will cause the pin F to operate the cam lever G by means of the slot H, into which it fits, thus expanding the brake band K against the brake drum that is a part of the hub shell. The pin F is machined integral with the cone E, and is held in a stationary position by the slot H.

The brake band with operating cam lever G is held in position by the cover plate M, the arm of which is secured to the bottom chain stay of the bicycle by the clip N. The brake shoe is returned to rest by the

natural spring of the brake band itself. This band is formed of two metals; the outer band, which takes the wear, is of phosphor bronze, and the inner band, which acts as the brake release spring, is of spring steel. The brake is immediately released by a forward movement of the pedals, which action by means of the quick pitch screw D immediately draws the cone A from the brake cone E. The spindle which passes through the centre of the unit carries the cone R, for the ball race P, which is provided to take the thrust of the cone A during brake application, and is adjusted in the usual way. When fitting the hub to the machine it should be noted that this adjustment also controls the main bearings.

The proper functioning of the hub depends almost solely upon freedom of movement between the quick pitch screw on A and B. Therefore, wash out with paraffin occasionally and lubricate at regular intervals, as specified by the makers. A point to remember with practically all forms of coaster hubs is that the brake will be gradually wearing away its frictional faces during the whole of its life; which means that the day will come when the hub as a brake will fail to operate. To forestall this contingency, make a point of noting how far the pedals have to be reversed before the brake operates. When this distance becomes excessive it is time to renew worn parts.

Other types of coaster show a certain amount of similarity in their design to the hub already described, i.e. the brake is applied through the medium of friction plates or by an expanding split sleeve operated by backpedalling. The coaster hub is frequently combined with a change-speed gear, and a diagram of a typical hub is given in the article on three-speed gears. *See* Bicycle; Brake; Gear.

**COATING:** For Clothing. The wool cloths used in men's suits are called in general coatings, and their variety is great. Coatings are ordinarily about 54 in. wide, and thus more economical to cut up into suits and costumes than the narrower and lighter dress stuffs. Their weights run from about 8 to 22 oz. per yard. Wool cloths materially heavier than 22 oz. are over-coatings or mantlings. In single (i.e. 27 in.) width the goods are called trouserings or vestings.

Coating serges, most often plain black or blue, are the chief type of plain coating; fancy coatings have check, stripe, or other patterns, usually in coloured threads. Coating is best for classical tailored suits for women. Warmer in wear than wool stuffs, coatings are also more expensive. Botany coatings are smoothest to the touch, and cost more than Cheviot or crossbred cloths. In buying coating serges it is advisable to see that they are warranted fast dye and fully shrunk. *See* Cloth; Serge.

**COBAEA.** A quick-growing climbing plant popularly known as cups and saucers, owing to the shape of the flower. It is raised from seeds under glass in spring and is usually grown in the greenhouse. Pron. Co-bē'-a.

**COBLER:** The Drink. This long drink is made

with almost any kind of wine or with brandy, whisky or gin. One of the best is sherry cobbler, which can be made from about  $\frac{1}{4}$  pint sherry and a teaspoonful each of sugar syrup and pineapple syrup or curaçao. Ice well, and stir up. Strain into a tumbler which has been filled with broken ice and serve with straws. Champagne or moselle cobbler is made with one glass of champagne or moselle in a large tumbler, a spot of old brandy, a slice of lemon, and sugar if desired. Finally fill up the tumbler with crushed ice.

**COBBLE STONE.** Round cobble stones are used for paths and roadways, especially in the Midlands and the north of England and in Scotland. Walls of buildings are sometimes constructed with them in districts where this material abounds. They make cheap and durable garden paths, as they present a dry surface under most conditions.

Cobbles are laid by first excavating the top soil and ramming until a firm base is obtained. The stones are then set in sand or fine earth and beaten down to a uniform surface with a beetle or mallet. Considerable skill is needed in choosing and setting the stones and to secure a bond or stable condition by properly placing them one with the other, so that no stone lies unsupported. They can further be secured with a grouting of cement mortar.

**COB LOAF.** A white loaf of bread, shaped into a roundish form, and baked on the bottom of the oven and not in a tin, is in certain localities called a cob loaf. *See* Bread.

**COB NUT.** A variety of the hazel-nut, cob nuts are frequently cultivated. Kentish cobs are considered specially good, being large and well-flavoured. They should be gathered when fully ripe, but before the lightest touch causes them to drop from the bushes, and dried well in the sun. After that, in order to keep them, put them in a cool, dry place, or pack them in layers with salt in dry jars. The cob is a good dessert nut, the kernel being sweet and firm. It is larger than the hazel or Barcelona, and is rounder than the filbert. *See* Filbert; Hazel Nut; Nut.

**COBURG CAKE.** To make these little cakes, cream together 3 oz. sugar and 4 oz. butter, and add two beaten eggs and 1 teaspoonful golden syrup. Beat well, and then mix in 6 oz. flour, 1 small teaspoonful baking-powder, 1 teaspoonful ginger, the same quantity of cinnamon,  $\frac{1}{4}$  teaspoonful mixed spice, and a little milk to bind. Half fill some greased patty tins with the mixture; bake for about 20 min. in a moderate oven.

**COCAINE:** Its Uses. An alkaloid that is obtained from coca leaves, cocaine is used in medicine chiefly as a local anaesthetic. Thus it is useful in eye work and in operations on the nose and throat and elsewhere; it is

of great service in dentistry. For most of these purposes it is combined with suprarenal extract. It is also used sometimes in cases of pruritus. Among other conditions which may be benefited are sea-sickness and the vomiting of pregnancy and asthma.

But its employment should be limited as far as possible to single occasions, as a craving for the drug is very easily established, and the moral and physical degradation thus produced is a price which no person can afford or should be allowed to pay for the relief of any pain or discomfort whatsoever. Cocaine can only be procured by a patient on a doctor's prescription, and a fresh prescription must be procured for each occasion.

In poisoning, among other symptoms there may be difficulty in breathing and convulsions. Pending the arrival of the doctor sal volatile may be given or strong coffee by the mouth, or, if necessary, by an enema.

**COCCIDIOSIS:** The Disease. This is a disease of various animals caused by the multiplication of a very small protozoan parasite in the tissues of the intestine and liver. Animals most frequently affected are rabbits, poultry, feathered game, sheep, goats and cattle.

In the rabbit, coccidiosis may affect either the liver or the intestinal wall. The disease may take an acute or a chronic course. As a rule the acute type is seen only in young animals, which appear sleepy and dull. In the early stages of the disease they may eat and drink ravenously when roused. Later they refuse food and rapidly become emaciated. Not infrequently there is a profuse discharge of saliva from the mouth. Diarrhoea sets in and the animals die within a short time of the onset of the first symptoms. Where young rabbits are dying in large numbers and the deaths are usually preceded by diarrhoea, the owner should always suspect coccidiosis as the cause and send material for microscopical examination to the Ministry of Agriculture, from whose Bulletin No. 6 these particulars are taken. In older animals the disease takes a more chronic course, and the mortality is not nearly so high.

Amongst poultry the symptoms of the disease are similar and the acute type is essentially a disease of young birds. It is commonly classed by poultry breeders as white diarrhoea, or white scour of young chickens, but not all these are due to coccidia. It must be understood that coccidiosis is only one of several diseases, the most prominent symptom of which is diarrhoea.

Certain workers have reported satisfactory results from the use of crude catechu. The catechu is powdered and mixed with water in the proportions of from 10 to 15 grains to one gallon of water, and this is given to a badly infected flock in place of drinking water. In the chronic type, where catarrh is a prominent symptom, washing of the nostrils and eyes with antiseptic solutions may be of some value.

Cardinal rules to be observed if prevention of outbreaks amongst young animals is desired may be stated: (a) Use high, well-drained land for young stock and take care that the land chosen is clean, that is, that it has not been soiled during the last twelve months by

the faeces of animals suffering from the disease or even by any adult animals. (b) Avoid overcrowding. (c) Keep the young separate from the older stock until they are past the age of two months, (d) Keep the foster-mothers, pens, or hutches clean. Where these are of the floorless type move them frequently, (e) See that a good supply of fresh drinking water is available, and use a type of drinking trough not likely to be soiled by faeces.

Once diagnosis has been made by means of microscopical examination, all sick animals should be segregated and their droppings burnt. Carcasses of any animals that die must also be burnt. The pens or hutches containing the healthy animals should be disinfected thoroughly with hot water and strong cresol, or 3 per cent, sulphuric acid, every other day. Lime washing of the pens will serve as well. Where pens of the removable type without floors are used, they should be moved to fresh ground and cleaned out every other day. The object of fixing this 48 hour interval is to ensure that any parasites passed out with the faeces shall not have sufficient time to enable them to reach the infective stage before the animals are again moved or the pens thoroughly disinfected. Infected pastures may be given a top dressing of quicklime, say, 6 cwt. to the acre. *See Poultry; Rabbit. Pron. Coc-cid'-i-osis.*

**COCHINEAL.** The red colouring matter obtained from the cochineal insect is most valuable in the kitchen, being perfectly harmless and devoid of taste, while by its use the appearance of many foods, such as blancmanges, stewed pears, etc., can be greatly improved.

**COCHIN FOWL.** This is one of the breeds of poultry that has come much to the fore from an exhibition standpoint but in so doing has suffered from a utility standpoint. It is a massive bird with heavy feathering. There are several varieties, buff, partridge, black and white being the most popular. The cochin is considered by some a good winter layer, but its merits as a table fowl are small. *See Poultry.*

*Cochin Fowl.  
Cock and hen  
of the  
partridge  
variety.*

**Cochlioda.** The name of a family of orchids with showy flowers. They need the same treatment as does the odontoglossum (q.v.).

**COCK - A - LEEKIE.** This highly nutritious soup has its foundation in chicken stock and leeks. A cheap way of making the stock is by simmering the neck, gizzard, feet, and bones of a fowl for one or two hours in salted water. To one quart of stock, which should be skimmed of all fat and strained, four leeks should be allowed. These are cleaned, trimmed, and cut into inch-long strips, and put into the stock, with a small onion, carrot and turnip, grated finely. Then bring the whole to the boil and simmer for about half an hour. Salt and pepper should be added, and if the soup is not considered thick enough, a white roux may be added. The roux is made by melting a tablespoonful of margarine in a saucepan and stirring in the same quantity of flour until a smooth paste results. A little of the soup should be poured into the roux in the pan and stirred round until it is liquid, and the liquid then added to the soup—which should be brought to the boil again.

**COCKATOO.** A member of the parrot family, the cockatoo is distinguished by its crest of feathers. Compared with the parrot, though equally docile and affectionate, it is an indifferent talker. The two species most commonly kept as pets are the great white-crested and the lesser, or sulphur-crested. Like the parrot, the cockatoo may be kept in a large bell cage, or it may be chained to a stand. *See Parrot.*

*Cockatoo. Specimen of the sulphur-crested species, with crest erect.*

**COCKCHAFER GRUB.** The grub of the great brown "Maybug" is the cockchafer grub, which is quite capable of eating through thick roots, but fortunately is rarely seen in large numbers. It is not uncommon to turn one up when forking among trees, shrubs, and herbaceous plants.

When the grub is present in such numbers as are likely to become a danger or nuisance, it is well to dose the roots of suspected trees or shrubs with a strong solution of salt. As the grubs take three years to come to maturity, and can do quite a lot of damage during that period, it is well to destroy them while they are young.

**COCKER SPANIEL.** The smallest and merriest of all spaniels, this dog weighs from 25 to 28 lb. His cheery nature and bustling ways make him a universal favourite, either for work or as a companion. Fairly short in back, and moderately high on the legs, he is as active as could be wished. His head is cleanly chiselled, of moderate size, ears lobular, long, and set on low, clothed with long, silky hair; the eyes are hazel or brown in colour, harmonising with the coat, which may be all black, black and white, or roan, brown, liver and tan, black white and tan, etc. The tail, which is said to be indicative of blue blood, although set on low, should be carried in a line with the back, and when the dog is in action it will be waved incessantly to and fro. The coat of the cocker spaniel should be flat and silky, never waved or harsh. *See Dog.*

*Cocker Spaniel. A popular animal noted for its lively nature, and used as a sporting dog.*

**COCKLE.** The small shellfish known as cockles are found in great abundance on many parts of the British coasts. The double shells are rounded and deeply ribbed, more like scallop than oyster shells; the fish when cooked and removed from the shells are marked yellow and red. All cockles need to be thoroughly cleaned, otherwise they are exceedingly gritty. The best way is to wash well the shells till they are free from sand; then lay the fish in cold water to cover them, and a handful of salt and oatmeal, and leave them till the next day to rid themselves of any sand they may contain.

To open cockles, put them in a basin and pour on to them fast-boiling water to which a little salt has been added. Repeat this if the shells do not open easily with the point of a knife. When open take out the fish and cook them as desired. Cockles can be used in most recipes suitable for oysters. They make excellent patties or sauce. *See Oyster.*

**COCKROACH.** Known as the black beetle, although its colour is really brown, the cockroach cannot claim

any close affinity to the hard-shelled beetle tribe.

Cockroaches are members of the straight-winged (Orthoptera) order of insects. They are much flattened from above and below, which enables them to hide in crevices during the day, and the upper pair of wings are merely leathery, instead of being horny, as in beetles. In the female of the common cockroach the wings do not develop, and are represented by mere scales, and those of the male cover only half of the body. The front part of the fore-body is developed into a broad shield under which the insect hides its head. The mouth is furnished with powerful jaws. There is a pair of very long, flexible antennae, and the long legs are covered with strong bristles.

A nocturnal insect, a house that swarms with cockroaches might appear in the daytime to be free from them but for the unpleasant odour characteristic of them. The eggs are contained in little horny purses, which are deposited in crannies; each receptacle contains 16 eggs. The common cockroach is an alien which came from the East. There are three native species, quite small creatures which never come into houses, but the alien, used to warmer conditions, only ventures out of doors in the hottest weather for the purpose of establishing itself in neighbouring houses. There is a smaller and paler species, known as the Croton bug (*Blatella germanica*), which emanates from Central Europe, and in some places is exceedingly abundant.

A good remedy against the cockroach is to strew its nocturnal haunts with fresh slices of cucumber, which, being consumed, renders them helpless. Beetle traps which entice them to fall into beer and get drowned may also be used with success in reducing numbers; but a more deadly device is the spreading of phosphor paste on thin bread or mixing it with honey and laying it in their way. Arsenic added to potato boiled and mashed, or mixed with the pulp of a roasted apple, is a certain remedy. Great caution must be observed in the use of these poisons, or food may get polluted with them. See Beetle Destruction.

*Cockscomb. The curious head of the cockscomb, Celosia cristata.*

#### COCKSCOMB.

This is the popular name of *Celosia cristata*, a half-hardy annual which bears cockscomb-like heads of bloom in crimson, yellow, and

other colours. It is usually grown for the summer decoration of the greenhouse, but may be used to fill summer flower beds. Seeds are sown in February-March in a temperature of 50-55 degrees, and the plants are potted finally in 5-in. or 6-in. pots in a rich compost. *Celosia plumosa*, which bears feathery heads

of bloom in red and yellow, needs similar treatment.

## COCKTAILS AND COCKTAIL PARTIES

### How to Mix Cocktails and What to Serve with Them

This is one of various articles containing suggestions for the hostess. Other entries of related interest are Bridge Party; Dinner; Luncheon. See also Hors d'Oeuvre; Sandwich

A cocktail party may be an informal gathering before dinner, usually from 6 p.m. to 7 or 7.30 p.m., or sometimes such a party is given later in the evening, when varieties of refreshments accompany the cocktail tray. These may take the form of hot toast sandwiches, containing a mixture of grilled kipper and bloaters (freed from bones and skin and sharpened with a squeeze of lemon juice and a little cayenne), or a slice of grilled bacon. Tiny squares of hot buttered toast may have a spoonful of caviare or a curled anchovy placed on them; dishes of crisp potatoes are also liked, and may be eaten with the fingers at a cocktail party. Other refreshments suitable to be served on any such occasion are finger-strip sandwiches with appetising fillings such as smoked salmon or bloaters cream, stuffed olives, plain biscuits buttered and spread with Gentleman's Relish, salted almonds and cheese straws. A big dish of fruit is decorative, and useful with dainty cakes, fruit punch and pineappleade to offer any guests who do not take alcoholic drinks.

**Cocktail Appetisers.** Although a cocktail is usually a mixed drink there are certain appetisers known under that name which may be served either at a cocktail party, or may replace hors d'oeuvre at a dinner or luncheon. An oyster cocktail, which may be put into stemmed glasses and accompanied by biscuits, is made with shelled oysters, and a tablespoonful of the following sauce to each glass: Mix one tablespoonful lemon juice, two tablespoonfuls tomato ketchup, a dash of tabasco sauce, a teaspoonful of vinegar and salt and pepper to taste. Clam cocktail can be made in a similar way, using six of the smallest clams and their liquor.

Tomato cocktails are made by placing the pulp of fresh tomatoes in a glass, flavouring with tomato sauce and garnishing with chopped olives. These appetisers should be placed on ice before serving.

A pick-me-up cocktail is the prairie oyster. For this two teaspoonfuls each of Worcester sauce and brandy, one teaspoonful of vinegar, and one of tomato ketchup are mixed together, the yolk of a fresh egg is dropped in, and a dash of red pepper added.

Many cocktails can be made easily at home. A shaker, a pair of nickel receptacles is required to mix the ingredients properly and ensure the cocktail being cold. Crushed ice is required for most cocktails. For an almost complete outfit the mixer needs a bottle each of dry gin, whisky, brandy, pale sherry, French and Italian vermouth, Angostura bitters, orange bitters, plain sugar syrup, orange syrup, grenadine or

raspberry syrup and such ingredients as oranges, lemons, eggs, tinned pineapples and soda-water. When serving a dry cocktail put an olive in the glass, with a sweeter one a cherry. nut, dried or desiccated, keeps for years in a dry place, and is used for cakes, puddings, and confectionery.

**COCONUT BISCUIT.** Prepare these by mixing 4 oz. desiccated coconut, 2 oz. flour, 3 oz. granulated or castor sugar, and 1 oz. cornflour. Beat up an egg, mix it with these ingredients, and then pour in sufficient milk to form the whole into a dry paste. Turn the mixture on to a slightly floured board, roll it out till it is about  $\frac{1}{4}$  in. thick, dust it with sugar, and then cut it into rounds the size of ordinary biscuits. Place these on a greased baking-sheet and bake them in a hot oven for 10 or 15 min. These biscuits are better if baked the day after they are prepared.

*Coconut Biscuit. Small, round biscuits, very attractive for afternoon tea.*

**COCONUT CAKE.** From the recipe here given a light coconut cake may be made, provided always that the ingredients are thoroughly beaten. Sieve  $\frac{3}{4}$  lb. flour with 2 level teaspoonfuls baking-powder. Put 6 oz. each butter and castor sugar into a warmed basin, beat with a wooden spoon to a soft white cream, and work in 3 or 4 eggs, whisked to a froth. Now add the flour lightly, folding rather than stirring it in. Now mix in a teacupful of desiccated coconut and 6 tablespoonfuls of milk. Pour the mixture into a paper-lined tin and bake the cake in a moderately hot oven for about  $1\frac{1}{2}$  hours. A pretty finish is given by coating the top of the cake when cold with a little glaze icing and sprinkling coconut and chopped pistachio nuts on the top.

Small coconut cakes are made by creaming together 3 oz. margarine and  $\frac{1}{4}$  lb. granulated sugar and beating in an egg. In a separate basin sieve  $\frac{1}{2}$  lb. flour and 1 teaspoonful baking-powder, add  $\frac{1}{4}$  lb. desiccated coconut, and then stir these into the sugar, etc., together with  $\frac{1}{2}$  gill or more of milk and a few drops of vanilla flavouring. Put the mixture into small greased cake-tins and bake them in a hot oven for about 20 min.

**COCONUT CREAM.** To prepare mix 3 oz. ground rice to a smooth paste with  $\frac{1}{2}$  gill milk. Put what remains from 2 pints of milk into a saucepan,

together with  $1\frac{1}{2}$  oz. margarine or butter and 2 oz. white sugar, and when these are boiling pour them on to the rice paste. Return it to the saucepan and bring it again to the boil, keeping it well stirred. Then add 2 oz. desiccated coconut, cook the whole slowly for 8 or 10 min., and draw it away from the fire before adding a little almond or vanilla flavouring,  $\frac{1}{2}$  gill cream, and 1 oz. quartered glacé cherries. Mix all these ingredients together, then pour them into a glass dish and leave them to cool. Before serving decorate the top with some more glacé cherries.

*Coconut Cream. Party sweet flavoured with coconut and ornamented with glacé cherries.*

**COCONUT DROP.** These cakes are prepared from  $\frac{1}{2}$  lb desiccated coconut, 6 oz. castor sugar, 3 eggs, and a little almond flavouring. Whisk the sugar and eggs together for about 12 min., or until the mixture becomes thick and free from streaks, then sprinkle in the coconut and beat the whole thoroughly for a few minutes before adding the flavouring. Grease a baking-tin, take a dessertspoonful of the mixture at a time and drop it on to the tin. Cook the drops in a moderately hot oven for about 10 to 15 min., cool them on a sieve, and sprinkle with castor sugar.

**COCONUT FIBRE.** Made from the coarse fibrous covering of the nut or fruit of the coco palm, coconut fibre has many uses in the home. It is employed in horticulture, and occasionally as a packing material, sometimes as the fibrous constituent of plaster ornaments. Its principal domestic applications are in the form of matting, rugs and carpets. The material is made in different widths and obtainable in many colours, patterned and plain.

For hard wear on rough or uneven surfaces it has many advantages. It conforms readily to unequal surfaces, and is not seriously affected by damp. A tendency to roll up at the corners is checked by a drugget pin if on a wooden floor, or by a screw driven into a rawlplug in a solid floor. A countersunk brass screw and washer to suit is the best arrangement under these conditions.

Periodical shaking and beating are essential, but in addition the matting can be washed and scrubbed to remove dirt and stains.

The fibre of the coconut is a useful medium in which to grow such bulbs as hyacinths, tulips, narcissus, snowdrops and crocuses in bowls. When making up a fibre bowl, a layer of charcoal should always be placed at the bottom of the receptacle, and the fibre must not be knotted or lumpy. *See* Begonia; Bulb; Hyacinth; Mat.

**COCONUT OIL.** The oil obtained from coconut, which in appearance resembles a white solidified fat, melts at a comparatively low temperature. Coconut oil is used in the manufacture of margarine, for which purpose it undergoes a process that deprives it of its taste. Large quantities are used in the manufacture of soap, a variety known as marine soap giving a lather with sea water; the soap is the basis of a shampoo for the hair. *See* Hair; Shampoo.

**COCONUT PUDDING.** Pieces of stale bread may be used in the making of a good baked coconut pudding. Prepare it by cooking 3 gills milk and  $\frac{1}{4}$  lb. desiccated coconut in a saucepan over the fire for a few minutes. When the milk boils sprinkle into it 2 oz. breadcrumbs, and add also  $1\frac{1}{2}$  oz. margarine and 3 oz. white sugar. Mix all together thoroughly, then draw the pan to the side of the grate. Separate the yolk from the white of an egg and stir the former into the milk, etc.; add a few drops of ratafia flavouring and then fold in the white of egg, previously whisked to a stiff froth. Turn the whole into a greased pie-dish and bake in a moderately hot oven for about 35 min., or until the pudding is golden brown. It should be served in the dish in which it is cooked.

**COCONUT PYRAMID.** When possible, these cakes should be mixed the day before they are baked. Prepare them by mixing  $\frac{1}{2}$  lb desiccated coconut with  $\frac{1}{4}$  lb granulated sugar, adding a beaten egg, a little vanilla flavouring, and enough water to make the coconut and sugar adhere when pressed together. Form tablespoonfuls of this mixture into pyramids, place them on rice paper in a baking-tin, and bake them in a cool oven until they are firm and lightly browned. A few drops of cochineal may be added to the mixture.

*Coconut Pyramid. Cone-shaped cakes made with desiccated coconut, very popular with children.*

**C.O.D.** Recognized abbreviation for cash on

delivery, a method by which the Post Office collects money for goods sent through the post. The amount collected must not exceed £40. The charge is 4d. for parcels worth 10s. and under, then it rises to 6d. for those up to £1, to 8d. for those up to £2, and to 10d. for those up to £5. Beyond this there is an additional 2d. for each £5 or less. If the parcel is sent by rail the charge is 3d. more.

An incoming cash on delivery parcel is delivered by the postman in the ordinary way (except that, if the trade charge exceeds £5, the parcel is kept at the Post Office to be called for, notice of its arrival being sent to the addressee). The postman is strictly forbidden to give up a cash on delivery parcel, or to open it at the request of the addressee, or to allow the addressee to open it until the trade charge and any other charges due have been paid. A delivery fee of 4d., in addition to the amount of the trade charge, is collected from the addressee of a cash on delivery parcel received from a place abroad. The amount of the trade charge collected is remitted to the sender of the parcel without deduction. No receipt is given for a trade charge. When the trade charge has been collected, the Post Office undertakes the responsibility for the due remittance of the amount to the sender of the parcel; and a trade charge, once collected, is in no circumstances refunded to the addressee.

This service does not apply to the Irish Free State. There is, however, a reciprocal service between Great Britain and various parts of the British Empire and certain foreign countries.

**COD: How to Cook.** A highly nutritious fish, cod is at its best from November to March. The liver contains valuable products, and can be cooked separately from the fish; from it is obtained the well-known oil. Cod's roe is also made into a separate dish. The head and shoulder of cod are the parts most in demand, but from the thin tail end suitably sized steaks for frying are obtained.

To boil cod, the fish is washed and placed in a deep fish kettle containing warm salted water, with a tablespoonful of vinegar added. It is then brought to the boil and allowed to simmer gently for about 30 min. The fish is served with parsley, egg, anchovy or caper sauce, or melted butter, and garnished with slices of lemon.

A method of baking a cod steak is the following: Wash and dry the fish, trim off the fins, and tie the steak in shape. Dip it in flour, brush it over with beaten egg, cover it with breadcrumbs, and then put it in a greased fireproof dish. Mix together 2 tablespoonfuls breadcrumbs, 2 oz. chopped suet, 1 dessertspoonful chopped parsley, and a teaspoonful chopped herbs. Season this mixture, heap it on the steak, lay a piece of greased paper over the top, and bake it from 15 to 20 min. Serve it in the hot dish with anchovy or other fish sauce poured round.

To fry cod steaks, wash and dry the fish, coat it on both sides with flour that has been seasoned with salt

and pepper. Fry it in hot fat until it is light brown in colour, then turn and fry it on the other side. Cod may be banded in June with old frayed sacking, folded paper or ropes of hay. If possible, two bands 4-6 in. wide should be used on each tree, one just below the junction of the branches with the trunk and the other a few inches from the surface of the ground. The larvae on leaving the fruit are likely to make their cocoons in the folds of the sacking or in the hay, and the bands must therefore be burnt in the autumn.

*Codling Moth.* 1. Perfect insect, magnified to show markings. 2. Caterpillar and two pupa skins, magnified.

All fallen fruit should be picked up and disposed of in such a way as to kill any larvae inside. All rubbish near the trees should be cleared away and burnt. *See Apple; Pear.*

**COD LIVER OIL.** Whether in its natural purified state or in the form of an emulsion, the oil extracted from the liver of the codfish provides a valuable nutritive tonic for invalids and particularly for consumptives and rickety children. It is a useful addition to the diet when one is working at high pressure; and persons suffering from chronic bronchitis will derive benefit from it. It is rich in the fat soluble vitamin A, which is so important in nutritional efficiency, its absence from a diet leading to the development of rickets and other conditions.

Cod liver oil is often prescribed with iron, as in the following tonic mixture, for a rundown thin child and for children developing tubercular glands in the neck. The dose is 1 to 2 teaspoonfuls three times a day after meals.

Cod liver oil

2 oz.

Syrup of ferrous phosphate	1 oz.
Oil of cassia	10 minims
Mucilage of gum acacia	4 oz.

Mixtures of cod liver oil, malt, and iron such as the following are also useful tonics to be taken during the convalescence after any severe and lowering illness: The dose for a child of 6 to 10 years is  $\frac{1}{4}$  to 1 teaspoonful three times a day after meals.

Cod liver oil	1 oz.
Extract of malt	1 oz.
Compound syrup of iron phosphate	1 oz.

**COELOGYNE.** This has been described as the amateur's orchid, for it is one of the easiest to grow. The imported plants should be placed in a warm bed of moss and sprinkled with tepid water in the greenhouse, until the pseudo-bulbs have swollen to their normal size. They should then be placed in well-drained pans containing a mixture of loam and peat, with a little crushed charcoal, and treated as ordinary heated greenhouse subjects for winter flowering. *C. cristata* and its varieties propagate readily by division of roots. The flowers of *C. cristata* are white with yellow crest on the lip. Those of *C. pandurata* are green and black, a striking combination. There are other species and varieties. *See Orchid. Pron. Coe-log'y-ne.*

**COFFEE.** Coffee is a general stimulant and promotes the activity of the brain and the heart. It is refreshing when one is fatigued, and, like tea, its beneficial effects are more lasting than those of alcohol. In cases of heart disease and in prolonged depressing febrile diseases, e.g. pneumonia and enteric, coffee, either black or with milk, is a useful addition to the dietary.

**How to Roast.** In making coffee, if the best results are to be obtained, the berries should be freshly roasted and ground. If a coffee roaster is not available use an ordinary enamelled frying-pan. Melt just enough butter in the pan to moisten the berries, and turn them frequently over a smokeless fire or moderate gas stove until they become rich brown in colour. It is a good plan to roast them in relays, passing them to the coffee-mill at once, and making the coffee as soon afterwards as possible. If any of the berries turn black during the roasting process, take them out of the pan without delay. One of the strongest and most serviceable kinds of coffee mill is made of cast iron, and fitted with a funnel-shaped top, into which the beans are poured. The grinding action is controlled by means of an iron handle, which, when turned, causes the ground coffee to fall into a tin or basin placed immediately beneath the mill.

When using a coffee mill, make certain that the coffee is being finely ground, otherwise its full strength will not be extracted. If the coffee appears coarse, it is generally a sign that the mill requires readjusting.

A French method of coffee-making consists of allowing 1 tablespoonful of coffee to  $\frac{1}{2}$  pint of water, pressing the coffee down in the percolator or cafetière; pouring on 1 pint of boiling water and slowly adding as many coffee-cups of water as are required. Should the coffee-pot be made of silver, scald it out twice before pouring in the coffee, and if the latter has to stand for some little time before being used, keep the pot in a bowl of boiling water.

*Coffee-making Machine.*  
*Right. 1. Cona coffee-making machine.*

*Above 2. Cafetière in fireproof ware.*

*Below. 3. Coffee-making machine component parts (Courtesy Cona Coffee Machine Co., Ltd.)*

Flavour can be improved if the amount to be used is put in a cup, covered by a saucer, and placed in the

oven for a few moments to warm; also by adding a pinch of salt to the made coffee. Reheated coffee loses its flavour. To make the grounds settle in the pot a little coffee should be poured into a cup and then poured back in the pot. This should be done several times.

Coffee is drunk either white or black—that is, with or without milk. Black coffee should be strong and may be served only with sugar after dinner. Never use cold milk for white coffee.

**Iced Coffee.** A method of making iced coffee consists of putting 4 heaped tablespoonfuls coffee into a quart of boiling water, boiling them in a pan over the fire, then removing the pan for a few seconds, replacing it again and re-boiling the whole. Repeat this process 2 or 3 times, then let the coffee stand for 5 or 10 min. before straining it. Put 4 oz. castor sugar and  $\frac{1}{2}$  pint milk into a pan over the fire, stir these until the sugar has dissolved, and then bring them almost to the boil. Add these to the coffee, and leave the mixture to cool. When it is quite cold, add  $\frac{1}{2}$  pint cream and a few drops of vanilla essence, putting the jug in an ice cave or in a vessel which is well packed round with ice.

**Coffee-making Machines.** There are many varieties of coffee-making machines in most of which the same principle is employed of straining the freshly ground coffee through boiling water. In a cafetière the necessary quantity of coffee is placed in an upper part which forms a strainer. Boiling water is then poured in, which passes through and is impregnated by the coffee, and percolates through the strainer into the lower part.

In some of these coffee-making machines there are two vessels, an upper and a lower, on the same principle. In others the upper vessel is of glass and the container is made of brass with a small spout; when the coffee has passed into the container the latter can be removed for use as a coffee-pot.

In another class of machine a glass globe is used, and in this the filtered coffee is heated by means of a small spirit lamp. The coffee is placed in an upper glass vessel and percolates into a boiler or lower glass vessel, circulation being effected by a central connecting pipe. These machines are generally arranged so that when the coffee is ready for service the upper vessel is removed, and the lower glass globe, complete with the stand and handle, acts as a coffee-pot.

Figs. 2 and 3 show a cafetière with its component parts. As the material of which these are made is fireproof, they can be left to simmer over a gentle heat and thus extract the best of the flavour from the coffee.

**Coffee Service.** In silver or plate the 18th century designs for the three-piece coffee services have not been improved upon. Beautiful among these are the octagonal style with ebony, fine wicker, or stained green ivory handles to coffee pot and jug, and moulded bases; the pear-shaped, plain-bodied pattern with ornamentation round the edge of lid and foot with round sugar basin; and the vase-shapes copied from old Sheffield plate examples in Adam styles.

For after-dinner use coffee cups in one of the many old English designs look best with this description of service, while the conventional patterns, the plain coloured china rimmed with black, the all-black except for gold or coloured insides, or the harlequin sets are most effective with coffee pot, jug, and sugar bowl to match.

For Turkish coffee, the correct beaten brass or copper pots can be bought with spirit stove and cups in metal containers to match, but these services are somewhat expensive. With a percolator any cups that are liked can be used. In earthenware, coffee pots and milk jugs are sold to match most of the good stock patterns, and are made in various sizes suitable for breakfast use. *See Breakfast.*

**COFFEE CREAM SANDWICH.** Make this in a round, shallow, greased cake-tin lined with greased paper. Whisk the yolks of 3 eggs with  $\frac{1}{4}$  lb. castor sugar for 15 min. Mix together  $\frac{1}{4}$  lb. flour and 1 level teaspoonful of baking-powder then sieve and add them to the yolks and sugar. Whisk the whites to a stiff froth,

fold them lightly into the other ingredients and add milk if required. Put the mixture into the prepared tin and bake it in a hot oven for about 20 min. When cold split the cake in half, and prepare some icing with  $\frac{1}{4}$  lb. butter, 1 oz. chopped walnuts, 9 oz. icing sugar, and 2 dessertspoonfuls coffee essence (obtainable at any grocery store). Beat the butter and sugar to a cream, add the flavouring; and then put  $\frac{1}{4}$  of the icing aside. To the remaining  $\frac{3}{4}$  add the chopped walnuts, then spread this on top of the lower half of the cake, replace the top half, and leave it to get firm. Spread the outside of the cake with 3 tablespoonfuls of apricot jam, and sprinkle over this 3 oz. of chopped walnuts. Decorate the top with the remainder of the icing, forced through an icing tube into a decorative pattern.

*Coffee Cream Sandwich, a dainty and delicious cake for afternoon tea.*

**COFFEE ÉCLAIR.** These finger-shaped cakes are made in the same way as chocolate éclairs, except that they are coated with coffee icing. *See* Chocolate Éclair.

**COFFEE ICING.** To prepare coffee icing, put 2 oz. fresh butter into a basin and beat it to a soft cream with a wooden spoon. Then add  $\frac{1}{4}$  lb. sieved icing sugar and beat the two ingredients together until the mixture looks like whipped cream. Gradually add about 1 dessertspoonful of coffee essence. A forcing-bag and pipe should be employed to apply the icing on cakes.

An excellent coffee glacé icing which must, however, be used immediately after making, can be prepared from  $\frac{3}{4}$  lb. icing sugar,  $1\frac{1}{2}$  tablespoonfuls strong coffee and the same quantity of hot water. Mix all these ingredients well together, and warm the whole.

**COFFEE MÉLANGE.** Cut a pint packet of vanilla jelly into small pieces and pour over them a pint of hot—not boiling—milk. Stir the mixture occasionally until the jelly is thoroughly dissolved. Let it become almost cold, then add 2 large tablespoonfuls of coffee essence. If the jelly is not sufficiently sweetened, add extra sugar dissolved in a little hot milk. Pour the whole into a wetted mould, and when it begins to thicken stir in a thinly sliced banana and a few slices of tinned apricots, peaches, or pears. When the mould is set, turn it out on to a glass dish, and serve it with whipped cream.

**Cognac.** The French brandy known as cognac is distilled from the vines of the Charentes. It is acknowledged to be one of the finest of all liqueur brandies. *See* Brandy.

## COINS: THEIR COLLECTION AND ARRANGEMENT

### With Instructions on Making a Display Cabinet for the Specimens

Other collecting hobbies described in this Encyclopedia include Birds' Eggs; Butterfly; China; Stamps. *See* also Brass; Pewter; and Amateur Carpentry

The earliest known coins are those of Greece, with only an obverse design, the reverse showing the impress of the punch or vice which held the ingot steady for the coiner's hammer. These date back 700 years B.C., and are supposed to have been struck in the Greek colonies in Asia Minor, which were more or less under tribute to Lydia. No earlier coins are extant of ancient Egypt, Babylon, or Assyria, and the original Jewish shekel was only a weight. So the Greek coinages, from the period stated to about the 3rd century A.D., form the first division in numismatics.

The next important division is that of the Roman coinages, starting nearly 400 years B.C., with large coins cast in bronze, and ending with the fall of Rome in the 5th century A.D., although the Latin language on Byzantine coins was continued until the 11th century, when it was finally displaced by Greek. A third division of numismatics is concerned with Oriental coinages distinguished by Eastern languages on the specimens and comprehending Persian, Arabian, Afghan, Indian, Chinese, and Japanese coins.

The later coinages of the Western world, can be divided into two periods: (1) from the Carolingian coinage in the 8th century, when the Roman denarius became a denier or penny, to the rise of the U.S.A.; (2) the ultra-modern coinages of the democratic era down to the present day.

Among foreign coins of the former period is the silver thaler, daler, or dollar, coined in Germany about the time when Spain was under German domination. This coin was subsequently introduced by the Spaniards into the Indies and America as a piece-of-eight, the Spanish sixpence, or royal, or real, being then equal to one-eighth of a Spanish dollar. The modern American silver dollar is thus the lineal descendant of the piece-of-eight.

**British Coins.** As regards British coins, the custom has been adopted of placing the head of each sovereign in a direction opposite to that of the previous one. Thus the head of George V faces the reverse way from that of Edward VII, as can be seen from a glance at any of the coins issued during their reigns.

British coins may be divided into three sections: (a) coins issued in Great Britain by regal authority, (b) tokens issued in Great Britain by private authority, (c) coins and tokens of Britain Overseas. In these three sections is a magnificently varied range for specimens. A complete series of types of English pennies, in bronze and copper, is quite a fascinating start for a small

*(Continued in page 493)*

## COINS

*Coins: pieces typical of those found in the collector's cabinet. 1. Greek, silver coin, Corinth, 350-250 B.C. 2. Roman, brass coin, Vespasian, A.D. 70-79. 3. Isle of Man, copper penny, 1758. 4. Spanish, silver piastre or piece-of-eight, 1762. 5. English, copper penny, 1797. 6. English, copper penny, 1841. 7. Bengal, copper half anna, 1835. In each case the obverse of the coin is shown either above or to the left of the reverse.*

collection before developing a larger one. Begin with the bronze penny of King George V, already described. The penny of Edward VII has DE S. for the designer's initials, meaning de Saulles, and the legend on the obverse shows, for the first time, the monarchical title BRITT: OMN: REX—King of All the Britains.

There are two types of Queen Victoria's pennies in bronze and one in copper. The later bronze, which was coined from 1895 to the end of the reign, depicts the crowned queen in her widowhood, with IND: IMP: (Empress of India), added to the royal title. The earlier bronze type, 1860 to 1894, pictures a younger queen, and the crown is not expressed, while on the reverse a lighthouse and a ship are in the device.

**Penny Coinage.** Preceding the bronze coinage was the larger Victorian penny in copper, from 1839 to 1860, with the date on the obverse, under the head of the queen as she appeared in her girlhood, and the exergue on the reverse bears the rose, shamrock, and thistle. The 1860 penny is very rare.

The copper pennies of William IV and George IV differ very little in style from those of the queen's first issue. Prior to them was the George III penny of 1806 and 1807. And when the George III penny of 1797, with its raised rims for the legends and with the date on the reverse, is reached, one has got to the first copper penny issued by royal authority in England. The copper pennies circulated in England during the token period were mostly those issued by private authority, and a collector needs great judgement in selecting specimens. Between the years 1811 and 1815 these pennies were coined in at least 70 different types all over England and Wales. Each of the genuine specimens usually indicates clearly the name and locality of the issuer.

The beautiful Anglesey pennies were issued by the Parys Mines Company in 1787-91; but most of the other so-called pennies dated in the latter part of the 18th century are either private medals made by collectors, or imitation tokens made by dealers for sale to collectors. The rare book of plates by Pye, of Birmingham, published in 1801, is a good guide to the genuine tokens of the time.

There are copper pennies issued earlier still, in the 17th century—such as Prockter's Lancaster penny of 1671, with the Stanley crest of an eagle and a child; Sytton's Blackfriars penny of the same year, with the figure of a friar; and Taylor's penny, issued at Settle in Yorkshire in 1668. When one has included all these with the other types sketched a fairly complete collection of English copper and bronze pennies will have been obtained. Then the halfpennies in copper and bronze can be tackled and the farthings, and the silver pennies that reach from Charles II right away back to the time of Offa of Mercia. The rest can follow later.

Clean dirty coins with oil of turpentine and a badger-hair brush, but do not rub them so as to take off the tarnish of age.

*Coin Collecting. Obverse and reverse of the Anglesey Penny, one of the best designed copper tokens issued in place of coins during the 18th century.*

**Making a Coin Cabinet.** The simple cabinet shown in Figs. 1-5 is quite easy to construct, and the home worker will find many helpful hints in the article on Birds' Egg Cabinet.

First make the coin trays themselves. This can be done by obtaining from any master-carpenter or wood-dealer or other worker in timber, half a dozen planed unpolished pieces of mahogany board, about  $\frac{3}{8}$  in. thick, and of convenient size, say, 11 in. by 8 in., according to price and to the sort of case into which they are ultimately to be fitted. A carpenter's brace will be needed, with several centre bits of the respective sizes required for sinking circular partitions in the wood to hold the coins (Fig. 3). Some kind of press to steady the tray while it is bored should be improvised (Fig. 2).

A piece of deal planking under the mahogany is useful while boring, as it eases the strain on the tray. The pivot of the bit must go right through the tray, but when the circle has been sunk about  $\frac{1}{8}$  in., it is best to finish off with a chisel, so as to get a flat surface on which to rest the coin. The boring of a tray and its chiselling would be two operations. When all the circles in a tray have been sunk and chiselled and the tray sandpapered, the coin-spaces can be lined with stiff white paper on which to enter references to the catalogue or other particulars. A rebate is formed at each end of the tray, thus leaving projection which runs in a groove formed in the end wall of the cabinet (Fig. 5). The completed tray is shown in Fig. 4.

The cabinet itself may be made to the dimensions required, the number of trays being suited to the collector's present or future needs. The cabinet illustrated accommodates fourteen trays; a larger one might have the trays arranged in two tiers on the lines of the Birds' Egg Cabinet. The Methods of construction may be gleaned from the last named article, and from the one on Cabinet Making.

**COIN TRICKS.** One of the simplest of coin tricks is to offer to spin a penny on a smooth table, from which the cloth has been removed, and to tell, when

## COIN COLLECTING

A useful cabinet and diagrams illustrating how the trays should be adapted for displaying the specimens.

blindfolded, whether it has come down head or tail. The secret is a very simple one. On the extreme edge of the penny a small notch is made with a penknife, so that a tiny piece of the metal projects. This projection is so small as not to be noticed. When the coin is spun it will settle on the unnotched side with the usual long, steady, even whirr.

If it settles on the notched side, however, the time of settling is only about half the other, and the sound, instead of gradually becoming fainter until it ceases, ends suddenly. The difference in the two sounds is rarely detected by those who do not know the trick.

The simpler the principle of a trick the more difficult often is its detection. The following depends upon a simple arithmetical principle. Announce to the audience that any member can take a handful of coins and that you will say whether the number is odd or even.

Ask him to place his coins in a hat, and announce that you will, even when blindfolded, add a handful of coins from your own pocket so that the total will be odd if the number of his coins is even, and even if the number of coins is odd. When you have dropped in your coins ask him whether the number he chose was odd or even, and it will be found that the total in the hat is always the reverse. The trick depends simply upon the performer dropping into the hat an odd number of coins. The principle involved in this coin trick is the simple one that the sum of an even and an odd number is odd and of two odd numbers even.

*Coin Trick. Fig. 1. Diagram showing how to place five pennies so that each touches four others.*

The following trick is one which will keep an audience guessing for a very long time before they solve it. The trick is to place five pennies so that each penny touches four others. Fig. 1 shows how the pennies should be arranged in order to perform the trick.

*Coin Tricks. Fig. 2. How to take a halfpenny from the table without touching the coin.*

A simple vanishing puzzle is performed with a threepenny-piece or a sixpence and an ordinary matchbox.

The coin is spun on the table, and the performer, while it is spinning, brings the matchbox sharply down on it, and asks a member of the audience to call out whether it is head or tail. The matchbox is lifted to verify his

guess and the coin is found to have disappeared. The coin is actually forced into the box, which should be empty when the performer brings the box on to it.

Another puzzling trick is to take a halfpenny from the table without touching the coin. The halfpenny is placed on the table at a short distance from the edge, and the half-open hand a little behind it. The performer blows sharply upon the table in front of coin, which will jump into the hand. *See Conjuring.*

**COKE:** For Household Fires. Of the coal heated in gasworks for the production of gas, about  $\frac{5}{8}$  by weight remains as a carbonaceous residue known as coke. This coke contains about as much heat, weight for weight, as coal, burns without smoke and usually costs less than the better sorts of coal. For domestic purposes it can be burned in slow combustion stoves and in many anthracite stoves instead of anthracite, though a larger quantity of fuel will then be required. It is also employed in heating boilers.

For open fires coke is best mixed with coal, especially for kitchen ranges. The semi-cokes or smokeless fuels, such as coalite, are made at a much lower temperature than gasworks coke, and therefore contain a larger percentage of the volatile matter of the original coal. The result is that they ignite more easily than ordinary coke and produce a more cheerful fire, while giving off little or no smoke. *See Breeze Block; Coal.*

**COLANDER.** One of the most useful articles in the kitchen equipment, the colander is a perforated bowl through which vegetables are drained so that they will be free of moisture when dished up. *See Baking.*

*Colander made of aluminium, with perforated presser. (Staines Kitchen Equipment Co., Ltd.)*

**COLCANNON.** This consists of potatoes and cabbage boiled together and mashed. Cold remains of potatoes and cabbages fried together are in some places called by the same name.

**COLCHICUM,** Another name for meadow saffron or autumn crocus. *See Meadow Saffron.*

In medicine colchicum, a drug obtained from its seeds and crowns, is used to relieve the pains of gout. The wine of colchicum is the preparation commonly chosen, and is combined as a rule with an alkali and with Epsom salts. The dose is 10-30 minims. The active

principle colchicine is sometimes used instead. Colchicum should only be used by the orders of a doctor.

**COLD: Prevention and Cure.** This is an acute infection producing sore throat, a "stuffed" head, and later a free discharge from the nose, headache, signs of feverishness, and possibly bronchitis. Close contact with a person suffering from a cold, as in a room, a railway compartment or the inside of a bus, is almost certain to produce infection. In addition, sources of irritation may be present in the nose, or a chronic irritated condition of the throat and the back of the nasal passages may be kept up by constipation, dyspepsia, pyrrhoea, the abuse of alcohol or tobacco. If the colds are frequent and there is no evident cause of irritation, advice should be taken about vaccine treatment.

The tendency to cold may be lessened by hardening oneself against the chilling effects of changes of temperature. This can be done by exercise in the open air and by keeping rooms thoroughly ventilated. The windows of the bedroom should be widely open at night. The morning tub is very useful, but if it is not taken a good substitute is to douche thoroughly the neck and shoulders with cold water and a sponge. The underclothing should be of wool or, for those who can afford it, silk.

**Treatment.** In treatment of the condition it is wise to consider whether the cold is not the beginning of such a condition as measles or influenza, as in such a case the patient should keep to bed, as also he should do if he is particularly feverish even from a common cold. In any case a hot mustard foot bath at night is a good thing, with some hot whisky and lemon, and perhaps 5 grains of Dover's powder. Headache may be relieved by 10 grains of aspirin. If the patient perspires freely he should be careful about exposure on the following day, should he go out.

Ammoniated tincture of quinine is often taken at this time in tablets or a mixture, such as this: ammoniated tincture of quinine, 6 drams; tincture of orange, 3 drams; glycerin, 4 drams; chloroform water to 6 oz. Take a tablespoonful in water four times daily. Cinnamon essence and spirit of camphor are also used, about 15 drops of either on sugar. Carbolised smelling salts may be inhaled, or pinol, eucalyptus, or menthol. The oils may be inhaled from the bottle, dropped on a handkerchief, or from steaming water. If the throat is sore a gargle of steel drops, 20 minims to 1 oz. water, or a weak antiseptic solution, e.g. permanganate of potash, should be used.

The diet should be light and easily digested. If the bowels are constipated give 2 grains of calomel, followed by 2 drams of Epsom salts in the morning. When the cold has passed off, Easton's syrup in ½ dram doses, or the compound syrup of hypophosphites in dram doses, could be taken for a week or two. See Catarrh; Cod Liver Oil; Cough; Friar's Balsam, etc.

**COLD CHISEL.** The name cold chisel is applied to all kinds of metal cutting and chipping chisels, which

are used for cutting cold metal, but have other applications in the house. The cheapest and commonest type is a round steel bar flattened and sharpened at one end. Such a tool is only fit for use as a case opener, or for breaking down old brickwork.

Those which are of real use to the home worker are the flat chipping chisels, in three sizes, 6 in. long by ⅜ in. wide, 8 in. long by ¾ in. wide, and 18 in. long by 1 in. wide. The first are for small work in brass, copper, or thin sheet-iron. The intermediate size is for such jobs as cutting sheet-iron and chipping off the projecting ends of bolts. The large size is for cutting brickwork and all kinds of demolition work. A 6 in. cross cut, a 5 in. diamond point, and a 4 in. half-round will all be found worth their trifling cost.

The chisels must be kept sharp by grinding the cutting edges. For very fine work they can be sharpened on an oilstone in the same way as carpenters' chisels. Bricklayers' chisels are ground rather finer and thinner than those for metal cutting. A round-ended chisel is handy for cutting corrugated iron. The diamond-point chisels are useful for chipping lines on metal and squaring up corners, and the half-round for chipping out screws or bolts that have broken off in their holes, and for shaping curved surfaces. A wise precaution is to grind off the ragged ends that form on the head of the chisel after use. See Chisel.

*Cold Chisel.*

1. Round-ended chisel for cutting corrugated iron.
2. Ordinary type of cold chisel; and,
3. how it should be held for cutting brickwork.

**COLD CREAM.** As a toilet requisite cold cream is used for softening and cooling the skin after sunburn, as a cleansing cream, to relieve harshness of the skin, etc. It may be obtained by asking a chemist for the official ointment of rose water. The usual foundations for cold cream are either white vaseline, benzoated lard or white wax. *See* Beauty Culture; Skin.

**COLD FRAME.** Frames as used by gardeners for the growth and protection of certain plants and fruits are known as hot or cold, according to whether they are heated or not. *See* Cucumber; Frame.

**COLD MEAT: Useful Hints.** The remains of different kinds of meat can sometimes advantageously be made up together. For instance, veal is improved if combined for a made-up dish with a little cold ham or bacon; mutton and rabbit combine well, and poultry combines with ham or veal. An underdone joint can be reheated and served in the same way as a freshly baked joint if it is covered with mashed potatoes and placed for half an hour in a quick oven. Beef stands being recooked better than any other meat, and veal can be made into good entrée dishes. Boiled rice is served with mince and curries, and sippets of toast are arranged round dishes of hashed meat.

A joint of meat can be used down to the last. The bones should be scraped of all the meat that remains, and this should be minced. Soak some slices of bread in cold milk and let them stand for an hour. Whisk the bread and add the mince and season well. This mixture can be used to stuff tomatoes, to fill scooped-out baked potatoes, to add to omelettes and scrambled eggs. The bones should then be put in the stock-pot and used for soup. The bones of poultry or game can be devilled.

**Savoury Puddings.** Cold beef or mutton can be utilised for savoury meat puddings. A batter is made from potatoes, boiled, then rubbed through a colander, and beaten well with two eggs, a dessertspoonful of butter, and sufficient milk to make them into a batter consistency. This potato batter should be spread on a baking-dish and slices of meat placed over. These are covered with a layer of batter and the dish is baked for about an hour.

A steamed pudding is made in the following way. Soak pieces of stale bread in milk and strain from the liquid. Beat up the bread with an egg and a dessertspoonful of butter and stir over gentle heat until the mixture stiffens. Allow it to cool. Add seasoning, a sprinkling of mixed herbs, and a spoonful each of tomato ketchup and mushroom ketchup. Add the meat, minced finely, and mix well. Turn into a buttered basin and steam for about two hours. Serve with thick, brown gravy.

A pie is made from cold meat, macaroni, and pastry. A pie-dish should be lined with pastry and filled with a mixture of minced meat, ooked macaroni, and seasoning. Pour over a little white sauce and cover with pastry. Bake in a moderate oven for 45 min.

Another form of savoury pie is made by mincing the meat, seasoning it well, and placing it in a pie-dish with

gravy or stock. Fry one or two onions and about four tomatoes, and cover the mince with alternate layers of onions and tomatoes. Cover the dish with mashed potatoes roughed up with a fork. Bake until the potatoes are nicely browned. *See* Casserole; Cornish Pasty; Rissole; Stew.

**COLD PACK.** Cover the bed with a waterproof sheet and over this lay one or two blankets. Wring a sheet out of cold water and spread it on the bed. Lay the patient stripped on this, and wrap it round him, quickly folding it around each leg separately and leaving the arms free. Then cover the patient with a couple of blankets and tuck them in about him. The pack may last 15 min. to an hour, and may be repeated several times a day. It is used in cases where the temperature remains obstinately high.

**Cold Storage.** *See* Refrigerator.

**COLE.** The local name of cole is applied to several members of the brassica or cabbage family, including kale, cottager's-kale, curly kale, borecole, kohl-rabi, and other greenstuffs. *See* Cabbage; Curly Kale, etc.

**COLEUS.** This greenhouse plant is grown for the sake of its brightly coloured leaves in the greenhouse in summer. It is usually treated as a half-hardy annual and raised fresh each year from seeds sown in warmth in February. Coleus can also be increased by cuttings taken from the old plants in spring or summer. Coleus thyrsoideus, which bears blue flowers in winter, is increased by cuttings inserted in a propagating case in early spring.

*Coleus. Brightly coloured foliage of one of the varieties of the handsome greenhouse plant.*

**COLEWORT.** This useful little autumn cabbage is raised from seeds sown out of doors in May; the seedlings should be thinned to 10 in. apart, not transplanted. The rosette colewort and hardy green varieties are grown: the former is the favourite.

*Colewort. Specimen of the rosette colewort, an excellent little autumn cabbage.*

**COLIC: Its Causes and Cure.** The prominent symptoms of colic are severe griping pains over the centre of the abdomen, with flatulence, distension of the abdomen, and either constipation or diarrhoea. Eating overripe or unripe fruit, a chill, or neglect to keep the bowels regular, are the chief causes of the ailment. Acute indigestion from any source may be accompanied by the pains.

Where indigestible food is known to have been taken, from one to two tablespoonfuls of castor oil should be given to clear out the intestine. To check the pain, 10 to 15 drops of tincture of opium may be mixed with the oil. Locally, a hot-water bottle applied to the abdomen while the patient lies on his side in bed is helpful in getting rid of the flatulence and relieves the pain. The diet should be entirely milky until the attack has subsided, and afterwards for a time the total amount of food taken should be reduced, and all indigestible articles as well as coarse vegetables should be forbidden. When flatulence is a prominent symptom, this mixture is useful, taking the 1/6 part three times a day:

Tincture of ginger	1 dram
Aromatic spirits of ammonia	2 drams
Spirit of chloroform	2 drams
Cinnamon-water	6 oz.

When the cause of the colic is not clear, or if there is vomiting or the patient looks ill, opening medicine should not be given without medical advice. An enema will be safer.

With infants and children severe colic may be brought on by such widely differing causes as improper feeding, want of cleanliness in the feeding bottles, sudden changes in the temperature, or exposure to chill. The patient should be kept thoroughly warm by being wrapped in blankets with a protected hot-water bag at the feet. A turpentine stupe, made by sprinkling a cloth wrung out in very hot water with a few drops of

turpentine and placed over the abdomen, usually eases the pain. Teaspoonfuls of hot water may be given.

Colic in an infant may be taken as a sure sign that something is wrong with its feeding mixtures. The milk may be too rich, and when diluted with whey or barley water all tendency to colic may pass off.

**COLITIS: Its Treatment.** Inflammation of the colon, the large intestine, is termed colitis, and is of three chief types, namely, simple, mucous, and ulcerative.

The first of these comes on suddenly with severe pain in the abdomen, diarrhoea, perhaps vomiting, cramp in the calves, sometimes slight fever, and considerable mental and physical depression. Generally the attack is comparatively mild, but occasionally the diarrhoea is severe and exhausting. The treatment is to put the patient to bed between hot blankets and apply hot-water bottles or hot poultices to the abdomen. The patient should be kept on a milk diet chiefly while the attack lasts. The milk is best taken cold and should be sipped. Whey, milk, and isinglass, or white of egg beaten up, may also be given. To check the diarrhoea, give three minim doses of strong spirit of camphor every 10 min. for an hour.

In mucous or membranous colitis, large shreds or pieces of membrane may be passed by the bowel, and there may be much pain, with symptoms of indigestion and constipation with flatulence. The disease is a very chronic one, and associated with hysteria or neurasthenia, but there may be a tumour or other condition obstructing the bowel. It is therefore desirable that the patient should be overhauled by a physician at the start.

Ulcerative colitis is inflammation of the bowel combined with the presence of ulcers, some of these cases being really dysentery. The symptoms are first colicky pains in the abdomen, with attacks of severe diarrhoea often alternating with periods of constipation. Blood and some mucus are commonly passed. Vomiting is often very severe. Keep the patient in bed, apply cloths wrung out of hot water to the abdomen, and send immediately for the doctor. *See Dysentery.*

**COLLAR: How to Stitch.** Collars, unless of lace or net, are mostly cut in double material, and if made in heavy material for outdoor garments should be interlined with canvas.

In the case of a roll-over collar, the outer or under section is slightly smaller than the inner section, and in any collar the canvas interlining should be slightly smaller than the material outer section.

To make a collar of this heavier type, tack the canvas to the wrong side of the outer section and catch the material edges over to the canvas; then hem the collar over the neck of the coat, unless it is one of the long roll shape. In this case the neck edge of the collar is left unneaten, and the neck edge of the coat hemmed over it. Finally the linen is covered with the inner

section of material, or with satin, velvet, etc.

*Collar. Diagram showing how the collar is stitched to the neck and revers of a coat.*

Soft collars are more simply made. They may be strengthened by an interlining, if necessary. To make one, join the edges on the wrong side, leaving the neck edge, turn over, and, if the collar is detachable, sew a narrow binding along the side left open. *See Crochet; Linen, etc.*

**COLLARBONE** or **Clavicle**. The collarbone runs from the shoulder to the top of the breastbone. It is frequently fractured, in children as well as adults, and this is usually due to a fall on the shoulder or the out-stretched hand. It may also be dislocated at either extremity, more commonly at the shoulder. In fracture the whole shoulder appears flattened, the arm is held close to the side, and the patient usually supports the elbow of the injured arm in the palm of his other hand. In order to relieve the tension the sufferer frequently bends his head towards the injured side.

*Collarbone. Diagram showing a fracture of the clavicle.*

First aid

consists in placing a considerable pad in the armpit on the injured side, and then supporting the limb with a greater arm sling, except that here the lower end, instead of being laid over the injured shoulder, is passed through the armpit below the pad, and the two ends are knotted behind. The elbow is drawn well forward, and is held there by the point of the bandage, which is brought round it and pinned off. A narrow fold bandage is then tied round the body and the affected arm just above the elbow, with the object of levering the shoulder outward. Apart from apparatus, the patient may be kept flat on his back on a hard mattress without a pillow, till seen by the doctor. Some deformity usually remains after most fractures of the collarbone. *See Bandage; First Aid.*

**COLLAR BOX.** Collar boxes, which may be obtained or made in, a variety of shapes, rectangular, square or circular, are made of leather, or some kind of wood. A suitable size for a rectangular box is 1ft. 6 in. by 10 ½ in. by 4 ½ in., but these measurements may be varied.

For a really nice article hardwood should be selected. Mahogany, if chosen, will look well all plain with a full polish, or may be inlaid with satinwood banding, box, holly, and ebony lines, or a little coloured inlay in centre only. Walnut takes a waxed finish well, and may have inlaid ebony lines, or a little grey-wood with ebony lines may be introduced in tablet form. Oak may be either fumigated or full-polished after staining to a nut-brown colour, if to be kept plain. Rosewood may carry mahogany, satinwood, and ebony inlay.

Making a start with the box frame, this will take two pieces 1 ft. 4 in. by 3 ¾ in., and two pieces 9½ in. by 3 ¾ in., the material used finishing ¾ in. thick. In best style they can be secret-dovetailed together, or may be lap-dovetailed together. In a simpler way the sides may be housed into front and back (Fig 3), or, again, they may be mitre-halved together and stiffened by the neatest possible rounded and glued slip in the angle. The bottom may be ¼ in. thickness, cut to a size to project ¼ in. all round, this portion being rounded and the bottom screwed up to under edge of sides with small brass screws. For the moulded effects shown at Fig. 2, a ¾ in. section can be mitred round a flush-finished bottom. If the moulded front of box is preferred, a ¾ in. section kept as flat as possible can be mitred round, glued, and panel-pinned on. The lower length of mould beading upon the bottom will be cut sufficiently wide to finish flush.

The lid, if to be jointed up, may be tongued together to finish 1 ft. 6 in. by 10½ in. by ¾ in. thick. As shown at Fig. 1, it is in two parts, opening out left and right, the projection being a little more over sides than at front or back. The edges may be kept square, but will be improved by thumb moulding, or to an ovolo or ogee section. The lids are hinged on with brass butts (Fig. 2). The face treatment of lid in Fig. 1 may be

*(Continued in page 501)*

## COLLAR BOX

*Collar Box. Fig. 1. Useful wooden collar box, instructions for making which are given in the accompanying text.*

*Figs. 2-7. Diagrams showing how the box can be made, with alternative designs for the lid. (By arrangement with Evans Bros. Ltd., London)*

either an inlaid line or banding; but if something better is preferred, Fig. 5 may serve as a suggestion, showing an inlaid line round, with broken key corners, and a central wreath inlaid equally each side of the meeting edges of lids. Such a wreath could have the stem in brown and leaves in green, with berries in red, and the knotted ribbon in blue.

The inlaid front (Fig. 1) might also be made in colours to match the wreath. An alternative treatment for the front is seen at Fig. 2, and on a birch or satinwood ground such detail could be painted in oil colour, mixed with gold size, which is quick drying in its action and useful to those who are clever with the brush. The ulterior fitting of Fig. 2, with three long and three square divisions, will be handy for gloves, ties, handkerchiefs, mufflers, etc., but does not provide for collars, and is for a smaller-sized box, which might then be made 6 in. deep and fitted with a lift-out tray.

The arrangement indicated at Fig. 4 works out very usefully, and is comprehensive. The lining can be of  $\frac{1}{8}$  in. thickness, cleaned up and V-grooved together and polished. The circular portion can be of knife-cut veneer, steamed or soaked in hot water and carefully bent and glued round a core of at least 6 in. diameter, such as a straight-sided flower-pot, or even the domestic cake tin. This part could also be made of stout bendable cardboard (two layers of  $\frac{1}{16}$  in. thick will do), glued together and covered with thin silk, the remainder of the interior being finished to match.

In a smaller box a single lid only may be desired, and, in an endeavour to make it look as well as possible, treatment may follow the method suggested at Fig. 6. This shows quadrant corners to a cross-banded surround, and the panel quartered up in oak, walnut, mahogany, or satinwood. The central device, neatly lined in, also affords a chance for careful quartered filling. All four sides can be finished as at Fig. 7. The small brass ball feet can be screwed into blocks glued under the bottom, and will add lightness to the general effect.

**COLLECTING.** The collecting of articles which are rare or noteworthy for their age or beauty, or both, is a hobby which is greatly increasing in popularity. Many make collections of china or furniture, while other articles collected include books, brass ware, coins, etchings, glass, miniatures, and silver. Another class of collectors go to nature and make collections of beetles or birds' eggs or butterflies. Some of the collections, e.g. china and birds' eggs, are often kept in special cabinets. *See Antiques; Birds' Eggs; Brass; Butterfly; Cabinet; Chair; Coins; Glass, etc.*

**COLLEGE CREAM.** Make some cheese pastry, a few hours before it is required, using 2 oz. each of flour and butter, 1 oz. cheese, the yolk of an egg, and a little salt and cayenne. Mix the cheese and flour, then lightly rub in the butter; season the mixture well, and add the beaten yolk of egg and enough water to make a stiff paste. Roll it out  $\frac{1}{4}$  in. thick and stamp it into rounds with a sherry glass. Bake these carefully for

about 8 to 10 min. in a moderate oven, and let them cool. Whip one gill of cream till it just hangs on the whisk, add 2 table spoonfuls grated Parmesan cheese, and season the mixture with salt and cayenne. Then heap it up on the cold cheese biscuits.

**COLLEGE PUDDING.** Mix  $\frac{1}{2}$  lb. fresh white breadcrumbs with 3 oz sugar, 3 oz. chopped suet, 3 oz. sultanas, or currants and sultanas mixed,  $\frac{1}{2}$  oz. chopped peel, a good dust of powdered spice, and a small saltspoonful of salt. Beat an egg to a froth, add it to 1 gill of milk, and stir it well into all the other ingredients. Turn the mixture into a thickly greased pudding basin, twist a piece of greased paper over the top, and steam the pudding for  $3\frac{1}{2}$  hours. Then turn it out and serve it with sweet melted butter sauce. If liked, chopped raisins, dates or figs can be used instead of the fruit named.

**COLLES FRACTURE.** This is a fracture of the lower end of the radius just above the wrist. It is one of the commonest fractures, especially among elderly women, and is usually caused by falling on the hand with the arm outstretched. Unless properly treated it may cause permanent deformity of the wrist and some loss of movement in the joint.

First aid consists in taking two splints reaching from the elbow to the finger-tips and padding them. The forearm is bent to a right angle at the elbow with the thumb pointing upwards, and the splints are applied on the back and front of the forearm. A narrow-fold triangular bandage or a handkerchief is used to fix the splints just in front of the elbow and another to fix them at the wrist. In applying the latter the middle is placed over the outer splint just above the thumb, the ends are crossed over the inner splint, brought forward below the thumb, and tied over the outer splint. The forearm is then supported by a greater arm sling. Probably some degree of shock will be present, and should be treated. *See Bandage; Fracture.*

*Colles Fracture. Diagram showing the displacement of the broken portion of the radius immediately above the wrist.*

**COLLIE.** Though the collie belongs chiefly to the farm, he is not infrequently compelled to put up with a more domestic existence; sometimes too, in establishments that are too small to set off his fine proportions.

The collie is 22 in. to 24 in. high at the shoulders, with a weight between 45 lb. and 65 lb. The head is flat, wide between the small, semi-erect ears, tapering to the eyes and thence to the always black nose. The long, dense coat is harsh to the touch, but beneath it is a soft, furry undercoat. The conspicuous feature of the collie is the heavy mane, continued as a frill over the shoulders. The muscular legs are all well feathered, as is the long tail, usually carried low. *See Dog.*

*Collie. Champion rough collie, a splendid example of the breed.*

### **COLLINSIA.**

This is a pretty, easily grown hardy annual, 10 inches high. Seeds are sown out of doors in March-April, where the plants are to bloom in summer. Favourite sorts are bicolor, lilac rose and white, and candidissima, white.

*Collinsia. Lilac and white flowers of Collinsia bicolor, a hardy annual.*

**COLLODION.** When it is wished to spread a protective film over an injured skin surface collodion is often used by doctors. When it is applied

the contained ether rapidly evaporates, leaving a smooth, glistening, hard, transparent surface, which prevents germs and other substances from reaching the wound. Collodion should not be used to cover a dirty or a discharging wound. New skin can be used in the same way as collodion. Collodium callosum is a preparation which may be used for dissolving warts or corns, and salicylic collodion can be used for the same purpose.

**COLLOMIA.** This showy hardy annual, about 10 inches high, is grown from seeds sown out of doors in spring where the plants will bloom in summer. Collomia coccinea is chiefly grown: it bears red flowers.

**COLLOPS: How to Cook.** Take 1 lb. raw lean topside of beef, or good steak, and mince it finely by hand, as a mincing-machine cuts it too small. Remove any fat or skin, replacing some of the former after chopping it finely. Melt about 1½ oz. good beef dripping or butter in a saucepan, and fry in it 3 teaspoonfuls of very finely-chopped onion. Stir in ½ oz. flour and then the beef.

Stir it over a moderately sharp heat till the beef changes from red to a brownish tint, then pour in ½ pint stock.

Stir over a gentle heat until the gravy thickens, then

add a dust of seasoning and simmer it all till the meat is tender—probably for about 30 min. If it boils the meat will be leathery and tasteless. Add 2 oz. breadcrumbs a few minutes before serving, to absorb the grease. Serve the collops with a border of sippets of toast, or croûtons.

Mutton collops may be made with about 1 lb. cooked mutton. Cut it into rounds, about ½ in. thick and 2 in. in diameter. Chop one small onion and mix with it ½ teaspoonful powdered herbs, a pinch of powdered mace and salt and pepper. Spread this mixture on one side of each collop and let them stand for about an hour, in order to flavour them. After that time fry them quickly in a saucepan in about 2 oz. of clean dripping, turning them with the savoury mixture downward.

Then take them out of the saucepan and into it stir 2 teaspoonfuls of flour, browning this carefully. Any fat not absorbed by the flour should be poured off. Stir in ½ pint of good stock and allow it to boil. Simmer the sauce for 10 min., attending to the skimming and seasoning, and strain it round the collops after arranging them neatly on a hot dish. This is sufficient for three or four persons.

**COLLYRIUM.** An eye lotion which is termed a collyrium may consist of solutions of boracic acid, zinc sulphate, permanganate of potash, and other antiseptics. The solution should be warm and may be applied by a swab of cotton wool or an eye-bath; or a few drops may be put into the eye. The following would serve if mixed with an equal quantity of warm water: Boracic acid, 20 grains, and distilled water, 1 oz.; or boracic acid, 15 grains, zinc sulphate, 1 grain, distilled water 1 oz.

**COLOCYNTH.** Colocynth is a fruit also known as bitter apple. It is a drastic cathartic, but in small doses it is frequently given in aperient pills. It may be used as colocynth pill or the colocynth and hyoscyamus pill, the dose of each being 4 to 8 grains. Hamilton's pill resembles the latter in its medicinal action.

### **COLOUR SCHEMES FOR THE HOME**

#### **How to Achieve Pleasing Effects in the Various Rooms**

Other articles in this Encyclopedia dealing with the subject include Decoration; Drawing Room; Nursery; etc. See also Carpet; Curtain; Cushion

The primary colours are red, yellow, and blue, which in combination give black, if they are exactly balanced. The secondary colours consist of a mixture of two primary colours, varying according to the proportion of each. A mixture of red and yellow gives orange. Yellow and blue give green; blue and red purple.

There are innumerable tones in these colours,

according to the proportion in which the two primary colours are mixed. The purples will vary from the red purple of the Orleans plum, through amethyst to the mauve of wistaria. Similarly with orange and with green. Tertiary colours are compounded of two secondary colours.

Complementary colours are those which complete one another, i.e. the pigments when mixed with one another make black. Thus red is the complement of green, yellow is the complement of purple, and blue the complement of orange. The various shades of grey are, if the grey is pure, broken down from black by the addition of white. Mixtures of the secondary colours give a range of greys.

**Harmonious Effects.** Where rooms open out of the same hall it is well to remember that the hall should form a kind of bridge between them. A grey hall, with rooms opening out of it, in which a range of colours from pinks (pink is only insipid when badly selected), reddish purples, and blues are well blended and contrasted, makes a charming interior for those who have old china and Persian rugs for purposes of decoration and relief. A hall with black and white tiled floor, black paint and grey walls, will allow of vivid touches of colour in curtains, etc., which notes of colour are repeated in the rooms opening off it. Another device is to choose the same colour for the carpets or flooring throughout, and to build up harmonious colour schemes on that.

Each room will then have a dominant colour. The dominant colour is the one which draws immediate attention, and not necessarily that which covers the largest surface. In a lounge, for instance, whose general colouring is fairly soft—browns, fawns, pale yellows—the dominant note might be struck by a vivid red-and-gold book table, the same note being picked up in appliqué (q.v.) on curtains, also on the mirror-frame and one cushion. In a small room the dominant colour note may be provided by a painting or the tiles of the fireplace. Nevertheless, colour schemes to-day are on the whole very gentle, suggesting a return to Georgian or Victorian modes.

### Psychological Effect of Colours

In selecting harmonious schemes it should also be borne in mind that blues, purples, and greys are soothing, orange and red stimulating, light warm pinks and also yellows give an effect of sunshine in dark rooms. Green should only be employed in sunny rooms, as it absorbs instead of reflects the light. These remarks apply to large surfaces treated with these colours, as practically any colour can be utilised merely as colour accents in right relation to various schemes; a cool scheme requiring certain warmer notes to prevent it from being depressing, a warm scheme requiring to be toned down by a neutral shade to prevent it from being either garish or irritating. It may also be noted that no colour is successfully used unless the right materials are selected for its expression. Thus certain shades are beautiful in glossy surfaced fabric, which are oppressive or dull in a matt surfaced one; while in

every colour the range of shades makes it possible for certain combinations—say green and purple—to be either harmonious or crude and unpleasant.

**Colour Details.** Blue is an instance of a colour the use of which is sometimes misunderstood. Wedgwood is a beautiful shade to combine with purples and also with pinks which have a tinge of mauve in their composition. In pale shades Wedgwood blue can be used in a sunny room for the walls and also for the ceiling. It is charming with ivory paint or with grey woodwork picked out with lines of metallic silver paint. The tulip colourings (except red) are exquisite against this shade of blue as a background. Greenish blues are useful as sharply decorative notes. Turquoise tiles or kingfisher blue cushions are points of interest in a neutral scheme.

Grey is a dignified colour for walls, but is depressing if carried over the ceiling. For a bedroom, grey, black and coral pinks are a good choice. In a sunny room the walls could be grey, paint black, and the furnishing fabrics could introduce the pinks with discretion, avoiding too much warmth; or for a room with a north aspect, walls and ceiling could be distempered a yellowish pink, which gives a beautiful sunny effect, and the grey introduced into the furnishing details with a patterned cretonne in grey, deeper pink, yellow and black. For this scheme the woodwork could be painted grey with skirting board, window frame and architrave of the door in black or a deeper shade of grey.

### Backgrounds for Oak and Walnut

Yellowish-pink is also excellent with browns, and may be most successfully used for a ceiling in a scheme in which brown panelling and oak parquet flooring are employed. Rose pink is good with dainty furniture, especially with panel mouldings and woodwork in ivory paint. Pinks are successful in distempers, and their gradations of colourings are excellent.

Light apple green is right for walls in a room with walnut furniture in the style of Queen Anne, the woodwork and mouldings picked out in gold and the ceiling enriched with a dull gold paper. Pinky-mauve and plum colour are the notes to emphasise in colour accessories with such a green. Malachite green is a good choice for woodwork with apricot tinted walls, and mauve shades introduced into loose covers or curtains.

Red definitely needs most careful treatment. In a sunny room indiscreet use would be most irritating: even in a room with a cold aspect bright red is only right for a colour note. A claret shade may be beautiful in rich materials for upholstery, especially for winter use in a room with stone coloured walls.

Orange and brown are a good combination with cream or golden yellows. Such a scheme will probably require cooling with the judicious use of green or blue. A yellowish orange is best with lighter browns, and a reddish orange with very dark browns. Mahogany has so much red in it that it is better with a yellowish orange—suggesting the colour seen in Sheraton inlaid

furniture. Black is too violent a contrast to be used in a mass with orange, but is valuable as a colour accent, as in a cretonne or other patterned fabric into which yellowish-pink, soft blues and mauve may be introduced.

**Uses of Colour.** Defects in the shapes of rooms can be to some extent corrected by the proper use of colour. The ceiling may be washed in a paler shade toning into the walls if the room is a low one. Pale grey on walls and a cloudy blue for a ceiling also give height. A box-like room, too high for its breadth, can be made to appear lower by having the ceiling painted with a design in colours or by being treated with a colour darker in tone than the walls or carpet of the room. With ivory panelled walls cobalt blue is a fine ceiling colour, either plain, slatted with ivory lincrusta or wood, or painted with clouds or stars.

Glowing sunshine can be simulated in a dark room by a wallpaper which graduates upwards from deep orange-yellow to palest primrose, with paintwork in umber scumbled over a gold undercoat and then varnished. Happy schemes—particularly for bedrooms—may be evolved by taking a flower as a pattern for each room.

**Aids to Selection.** Before deciding on colours for a decorative scheme a good idea is to lay out on a table a number of small samples of shades of paints, distempers, etc., and also of colours approximating the ideas for furnishing fabrics. Bearing in mind the exigencies of existing carpets and furniture, place the colours fancied next to each other, altering the various shades until the harmonious effect required is obtained. Then paste those decided upon for each room, grouped together on a piece of white paper, and a workable guide is evolved. Such a method is exemplified in the following colour schemes suggested by Waring and Gillow. Taste and ingenuity are more necessary now that the violent contrasts popular a few years ago have been toned down.

**The Dining Room.** The foundation of the scheme is a modern flecked carpet: the fleck might be repeated, according to taste, in a cushion or lampshade. While the traditional advice, that green should be used chiefly for sunny rooms, still holds good, there is a growing fashion for green in almost any room, if the shade is discreetly chosen. So, for walls, green is recommended. A slight contrast is advisable for the woodwork; a somewhat softer green would be preferable. Green occurs again in the damask curtains, varied, perhaps, with gold patterning and a striped, or even braided, pelmet. For ceiling and frieze a simple wash of fairly deep cream colour could scarcely be bettered. Since green predominates in this scheme, excessively dark furniture should be avoided. Limed oak is popular nowadays for simply-made chairs and tables, but walnut is equally harmonious.

**Lounge or Lounge Hall.** This room, large or small, should be coloured in such a way as to give it some connecting link with the adjacent rooms. A gold or

metallic motif would thus link a lounge hall with the above dining room; or possibly a continuation of the carpet fleck in the lounge curtains. More typical of present tendencies, however, is a floral damask for lounge curtains, supported by a smaller-flowered repp for chair covers with a set design for settees. The heavy floral effect is set off with a light copper-coloured carpet. Wallpaper is white, illuminated by a fairly elaborate silvery pattern.

**The Sitting Room.** Colour schemes for sitting rooms are, of course, much the same as for the lounge above, there being no essential difference between a sitting-room and a lounge other than in implications of size and atmosphere. The general scheme for a fairly large sitting-room would, however be less rich than the lounge scheme, with rather more "streamlining" in the furniture, and more unstained or uncovered wood. Ideas might well be borrowed from such a scheme as the dining room outlined above. Light woods rule modern sitting-room colour schemes to some extent; but a jet black grand piano is never out of place, while a walnut one harmonizes admirably with limed oak tables, etc., and with pale-stained plywood or "units." Fawns, biscuit, copper and flecks predominate in carpet colours.

**The Bedroom.** The latest colour schemes for bedrooms aim at various depths of the same dominant colour rather than at contrasts. Grey for the woodwork of walls and furniture has been popular for some years now, and seems to have come to stay. Bluish-grey wallpaper with a faint pattern; a soft rose carpet; a paler shade of silk or damask for curtains and chair, relieved by a small interesting motif; a mouse-coloured bedspread, quilted in pink; and paintwork a shade lighter than the paper—these combine to give a "restful" effect which used to be considered the monopoly of green.

Colour schemes for the nursery will be found under that heading, where various methods of suitable treatment are discussed both for day and night nurseries.

**COLOUR BLINDNESS.** The commonest variety of colour blindness is that in which the person is unable to distinguish red and green. He confuses these colours with grey, yellow and blue. This form of colour blindness is very important, as it disqualifies a man from service on the sea or on a railway, when duties involve the recognition of these colours. People who are blind to violet confuse purple, red, and orange. The test may be performed by placing skeins of wool of varying shades of different colours before the person being examined, and asking him to match samples, usually light green, pink, and red.

Acquired colour blindness may be due to poisoning by alcohol or tobacco, or both, or to atrophy of the optic nerve. There is no cure for the congenital complaint, but something may be done for the acquired

form.

Colour blindness may vary from a slight difficulty about one colour combination up to inability to see anything but shades of black and white, but this latter condition is rare. The abnormality is commonest among men.

## COLOUR PHOTOGRAPHY FOR THE AMATEUR

### How to Obtain Naturalistic Results by Transparencies

Other articles in this work for the amateur photographer include Camera; Dark Room; Developing; Exposure, as well as the main article on Photography.

Considerable progress has been made recently in processes for producing photographs (prints on paper) in natural colours, but these methods are still much too complicated for the average amateur, since they involve the preparation of three separate prints (red, yellow, and blue) and the combination of these three in exact register. There are, however, several processes which are almost as easy as ordinary photography. The results differ from those of the latter in being transparencies on glass or film viewed by holding them up to the light, or shown on a screen by means of an optical lantern.

With some colour films it is just as simple to load the camera and make an exposure as it is with monochrome, no external filters or modifications to the camera being required, and in some cases the purchase price of the film includes the charge for processing.

**The Two Principles.** Colour transparencies can be made by either of two methods, one of which is known as the "additive," and the other the "subtractive" process.

If the visible spectrum is divided into three approximately equal parts and the radiation in each portion is grouped together, red, green and blue lights are obtained. Obviously if the three resultant coloured lights are added together we can re-form white light, and this principle forms the basis of the additive process. To take a colour photograph by this method a special kind of plate is used, viz. one having a coating of extremely small transparent dots, or a fine mechanically printed colour pattern, red, blue and green in colour, made so that the mixture does not show any colour at all. These dots are really colour filters of microscopic size mingled in close juxtaposition, and are known as a mosaic screen. On this coating is a sensitive emulsion similar to that used for ordinary photography, and when the photograph is taken on this latter (through the coating of coloured dots) the result of special treatment is a picture in all the colours of the subject photographed.

The chief additive processes in colour photography are Dufaycolor, Finlaycolor and Lumière Filmcolor.

Whereas in additive colour photography we start with a dark screen and build up the picture by adding to it coloured light, in the subtractive process we start off with white light and remove from this light all the

colours not actually required. Therefore the three negatives required must be exposed (either simultaneously or in rapid succession) through filters which will absorb from white light the unwanted rays and transmit the rest. These filters are yellow (which absorbs blue), blue-green (which absorbs red), and magenta (which absorbs green).

In modern subtractive processes such as Kodachrome and the new Agfacolor, three colour-sensitized emulsions are coated on one support with the filter components sandwiched between, the combined thickness of the various layers being no more than that of ordinary roll-film, so that the rear image shall not be appreciably diffused by light scatter. This makes it possible to take colour photographs with one exposure in the same manner as for black and white.

**Colour Films.** There are now a few films available which can be used in almost any camera and do not require special filters. Of these Dufaycolor is supplied in sizes to fit all popular makes of cameras, Lumière Ultra-Rapid Filmcolor and Lumicolor are made in cut film and roll-film respectively. Kodachrome and Agfacolor have proved successful in 35-mm. film for miniature cameras, and neither requires external filters in daylight.

**Exposures.** Much greater accuracy of exposure is necessary in colour photography than in black and white, and the maker's instructions should be carefully observed and some form of exposure meter employed, the best results being obtained with the photo-electric type. As a rough guide to possible exposures, on a bright summer's day in direct sunshine, with a light-coloured subject, one can obtain sufficient exposure with a shutter speed of 1/50 sec. at f8.

The type of subject suitable for colour photographs is not always one containing brilliant colours of every shade. Just as the beauty of many black-and-white photographs lies in the contrast of the main subject against a subdued background, so a colour photograph, where the brilliance of the colour is confined to the principal theme, will present a colour contrast which is often more pleasing than an intricate mass of bright colour all over the picture.

The contrast in a colour photograph is not confined to lighting conditions, but includes change of colour, and where two entirely different colours of nearly the same depth of tone would present a flat subject in black and white, the difference in shade may produce great contrast in colour. However excellent colour films may be, they cannot yet cope with excessive lighting contrast. Note this when choosing a subject.

The amateur who is not excessively critical will find any of the well-known makes of colour-film excellent under most lighting conditions, but the discriminating worker will have to select subject matter with much greater care. Amongst the most common troubles experienced with colour films is a tendency for any

predominating colour covering a large portion of the picture to be present in small light portions of the subject. For instance, if a white cottage is photographed against a deep blue sky, the colour of the cottage may be shown as pale blue instead of white, light clothing on a figure against a bright background may disclose a pale shade similar to the background, while deep shadows are blue, as often in nature, although the film may exaggerate them.

In many subjects a flat front lighting that would be uninteresting in monochrome work is quite satisfactory in colour, but in order to obtain good roundness or third-dimensional tones the sun should be to one side of the camera and excessive shadow should be avoided. Pictures against the light are by no means impossible in colour, but they should not be attempted in very brilliant sunshine, the ideal time being when the sun is partially overcast with thin cloud.

Although colour filters are not necessary as a general rule in daylight exposures, special filters are sold for specific purposes and must be used with discretion. On no account should filters marketed for one colour film be employed on another.

**Indoor Colour Work.** Kodachrome film is supplied in two types: one for use in daylight, and another (Type A) balanced for artificial light. A filter can be used which will allow the latter to be employed in daylight.

Agfacolor provide a pale blue filter (No. 28) for use on special occasions when red and yellow light predominates, and a special filter (29B) for high altitudes. There is also a series of filters available for Dufaycolor, which embrace various forms of artificial light, but the amateur is recommended to become familiar with straightforward exposures before extending the work into special fields.

Indoor good colour results may be obtained with most forms of artificial light, including flash-bulbs. Kodachrome (Type A) in particular is exceedingly fast and may be exposed almost as a medium speed ordinary film. Lighting arrangements are slightly different from those usually employed for monochrome. Good flat lighting is advisable. Back lighting may be added to increase subject interest.

The best results, both in daylight and artificial light, are those where accuracy of exposure combined with suitable lighting brings colour values well within the latitude of the film, and a good exposure meter, preferably photo-electric cell type, is essential.

**COLUMBINE.** This is the popular name of *aquilegia*, one of the loveliest of hardy garden flowers. The new long-spurred varieties in many charming colours are far superior to the old short-spurred ones. Columbines thrive in ordinary soil, in sunshine or partial shade; they are grown from seeds sown in a box of soil in a frame in March-April, the seedlings being planted out of doors in summer, preferably where they are to remain. The final planting may, however, be done in October. After two, or possibly three, years the plants generally lose vigour and a fresh lot should be raised from seed. Several columbines are suitable for well

drained loamy soil in the rock garden, e.g. *alpina*, blue, *coerulea*, blue and white, and *glandulosa*, blue and white.

*Columbine. Flowers of the long-spurred columbine, a beautiful hardy garden flower. (Photo, Sutton & Sons)*

**COLZA OIL.** Colza, or rapeseed, oil is the commercial name for oil obtained from brassica seeds. Its chief use is for illumination.

There are many qualities of colza oil and colour is the best indication of value, the more highly refined oils being of a very pale golden shade, as distinct from the dark brown colour of the crude product. The illuminating power of colza is not so great as that of paraffin or petroleum, but in practice it is found more economical, being slower in burning.

Care should be taken to keep the oil in a clean vessel, as even small particles of foreign matter will cause the wick of the lamp to become clogged, and when this occurs the wick should be removed and cleansed, and a small lump of common salt put into the reservoir of the lamp. This will attract and hold foreign particles and prevent them reaching the wick. Should water become mixed with the oil it is removed by placing strips of gelatine to absorb it. The gelatine is not solvent in oil, and may be taken out, dried, and used again for a similar purpose.

**COMA.** Deep unconsciousness from which the patient cannot be aroused occurs in cases of severe head injuries, in apoplexy and heat stroke, in uraemia and diabetes, from poisons circulating in the blood, in narcotic poisoning, as from opium, alcohol, coal-gas, etc. after epileptic fits, and in many other conditions. Coma vigil is the name given to a condition which sometimes occurs in typhoid and typhus fevers, and in the typhoid state when the patient lies with his eyes half open and keeps on muttering to himself but is unconscious.

First-aid for persons found comatose is to send for

the doctor, loosen tight clothing, place the patient's head in the position in which his breathing appears to be easiest, take careful charge of any bottle or other receptacle which may have contained poison, and keep the patient warm. In heat stroke he should be moved to a cool, shady spot and doused with cold water. *See Delirium; Sunstroke.*

**COMB:** For the Hair. Dressing combs should not be too cheap, or the teeth will break readily: also roughness in finish irritates the scalp. The teeth should be of two different sizes, coarse at one end and fine at the other, and the comb should be discarded as soon as it becomes damaged. Many people who wash their brushes regularly are careless about their combs, which need periodical attention just as much. Special comb cleansers, consisting of an arrangement of threads which enter between the teeth and clear out the dirt collected at the roots of them, can be bought.

Real tortoiseshell combs, though most pleasant to use on account of their superior finish and smoothness, are expensive and need careful handling as they are easily broken. Tooth combs, which have very fine teeth set close together, are useful for cleansing the scalps of children, and must be kept scrupulously clean.

**COMFORTER:** For the Baby. The chief danger of the comforter is that it is liable to be soiled, and so infected with microbes, which produce indigestion and sometimes diarrhoea, inflammation of the mouth, and other diseases. Also, the comforter tends to spoil the shape of the mouth, and very often deforms the palate, with the result that the air passages of the nose are narrowed and the child becomes a mouth breather. A mother who gives a comforter to her baby (q.v.) may quiet the child for the time being, but the baby too often has to pay heavy penalties.

*Commode. Semicircular example in satinwood, c. 1785.*

**COMMODOE.** This word is used for a small sideboard. In another sense it means a box used for holding a chamber utensil and also a seating arrangement of that kind suitable for invalids. Of the sideboard known as the commode there exist very beautiful examples, some being associated with the name and work of Buhl. The finest were made towards

the end of the 17th century in mahogany and in pine, often with marquetry of brass, ebony, mother-of-pearl, etc. In England commodes were made by the Adam brothers and their successors. Some of them are of satinwood, semicircular in shape, and are beautifully ornamented with medallions painted by Italian artists. *See Buhl; Sideboard.*

**COMMUTATOR.** The device known as a commutator forms part of an electric generator or motor, and is designed to convert an alternating into a continuous current. Commutators are found on any continuous current or direct current generator, or on any motor intended for use on a continuous current. *See Dynamo; Motor.*

**COMPASSES.** These are mathematical instruments used for drawing circles, or arcs of circles. Variations of this instrument are the chalk compasses used by teachers in schools and by scene painters and others, also the wing compasses employed in carpentry and for metal work. The Lancashire wing compasses, shown in Fig. 1, are provided with a quadrant or wing, and a thumb-screw which is tightened up to hold the legs rigid.

*Compasses. Fig. 1. Lancashire wing compasses in use. Fig. 2. Six-in. compasses with pencil point. Fig. 3. Spring bow compasses with pen point; below, divider point. Fig. 4. How compasses should be held, with needle-point and pencil both upright. Fig. 5. Beam compass, used for circle; of large radius.*

The compasses used in mechanical drawing are made in numerous patterns, priced from a few pence upwards. The amateur draughtsman will be wise to purchase a good quality instrument of moderate cost. Compasses with solid points should be rejected in favour of those with needle points. These have needles held in a clamp, and make only a very small hole in the drawing paper; if damaged the needles are easily replaced.

Essential features are rigidity, freedom of action at the joint, and all detachable parts secured with a clamping screw acting between two jaws and holding the removable part as in a vice. Other requirements

are a knee joint above the pen or pencil point, Fig. 4, and some means of adjusting the needle, as in all good drawing work the needle and the pen or pencil point must be vertical when drawing the lines. These characteristics are shown in the 6 in. compass illustrated in Fig. 2, with pen and pencil and divider points. Spring bow compasses, as shown in Fig. 3, are excellent for small work and to be preferred for circles up to  $1\frac{1}{4}$  in. diameter.

Beam compasses are used for drawing large radius circles, such as occur in surveyors work or in laying out a garden plan. A typical set, pictured in Fig. 5, consists of a jointed metal beam 24 in. long in four sections, with pen and pencil points, two steel points, and a shouldered needle point. *See Dividers; Drawing.*

**COMPASS SAW.** For curved shapes the compass saw is invaluable. It is stronger than the keyhole saw, but can often be used when lock fitting or on any internal sawing where the curves are not too sharp.

When sawing a curved shape always take care to keep the saw blade at right angles to the face of the work, unless a bevelled edge is the objective. Work with a steady sawing stroke, avoiding heavy pressure on the teeth, or the saw will wander away from the line.

Compass Saw, a tool used for cutting curved shapes, and on internal sawing.

**COMPENSATION:** In Law. This term is sometimes used by laymen as synonymous with damages, but in fact the two are generally different. The word compensation is rightly applied to the money payable by an employer to a servant who has been injured by an accident arising out of and in the course of the employment. It is also used in its proper sense to describe the amount that must be paid to anyone whose land or building is compulsorily acquired by a public authority, with powers conferred by Act of Parliament to take property. *See Accidents; Employer's Liability.*

**COMPLEXION:** Its Care. This depends primarily on the state of the health. Some women naturally have a white, clear skin of a soft and delicate texture. Those who have not should pay attention first to digestion, for a sallow skin is often due to dyspepsia. An unnatural pallor may be due to anaemia or a poor circulation.

Those whose complexions are muddy or of too high a colour should carefully consider their diet, avoiding rich and highly seasoned dishes. Over-feeding is one of the commonest causes of skin blemishes and greasiness. Women with greasy skins have need of a good cleansing cream and a lotion which will stimulate the circulation, remove the grease from the surface of the sebaceous glands and leave the pores free.

Women with sensitive skins often find their complexions affected by sudden changes of temperature. Such skins are usually of the dry type,

and require very pure emollients, and only mild astringents. The use of ice or a strong astringent to close the pores after washing is dangerous for this type of complexion, as such drastic treatment often results in small broken veins.

When washing the face, soft, warm water is necessary. If soap is used it must be of a pure superfatted variety and should be thoroughly sponged off before drying. The final sponge should be with cold water. Soap should only be used once a day, at bedtime; after drying, the complexion will be improved by the use of a good massage cream, in order to maintain the skin in a healthy condition and keep its transparent look. *See Beauty Culture: Face; Powder; Skin; Soap.*

**COMPO:** For Building. This is a mortar composed of Portland cement and sand, or a mortar containing a proportion of Portland cement in addition to the usual mixture of lime and sand. A sound compo mortar for general house-building purposes should contain: one part by measure, of grey lime (measured before being slaked) and one part by measure of Portland cement to seven parts by measure of clean sharp sand.

Owing to the extreme difference in the time taken by lime and cement in setting, special precautions have to be used in the mixing and using of compo. The lime and sand should be mixed and made up as mortar in advance in order to ensure that no hot, i.e. unslaked, particles of lime remain to expand in the finished work.

The proportion of cement is only added just before the compo mortar is required for use. Three pailfuls of lime mortar are taken from the heap, and to them one pailful of cement is added and well worked into the mass with a shovel. If necessary a little water is added. The compo mortar must be used immediately after mixing.

A wall laid in compo mortar hardens and dries quickly and attains a great proportion of its final strength very much sooner than a wall built with lime mortar. The shrinkage of the joints is not so great as with lime mortar alone. *See Brick; Cement; Mortar; Plaster.*

**COMPOST:** For Plants. This is the term applied to mixtures of soils used in the garden, or for potting purposes in frames or hot-houses. Compost may consist of two, three, or more of various ingredients necessary for the successful culture of the plants which are to derive their nourishment from it. Loam (pieces of old turf) forms the basis of nearly all potting composts. Other ingredients, such as leaf-mould, peat, and sand are added in proportions varying according to the needs of the plants.

**COMPÔTE:** In Cookery. This word is usually understood to mean a carefully prepared dish of fruits

stewed with syrup, but in a few instances it is applied to a rich variety of stew, such as a compote of pigeons or of plovers.

The secret of making good compôtes lies in stewing such fruits as gooseberries, cherries, and currants in a casserole in the oven before using them. Dried fruits can be used if, after washing, they are soaked overnight and then stewed in the water in which they were soaked.

An excellent compote syrup is made with  $\frac{1}{2}$  pint water and  $\frac{1}{2}$  lb. good white sugar. Put these in a saucepan, let the sugar dissolve by the side of the fire, then boil it without a lid for about 10 min., skimming it well, or until it forms a good thread when a little of it is taken between the thumb and first finger. To this syrup add any flavouring wished, such as lemon-juice or grated lemon-rind,  $\frac{1}{2}$  a glass of some liqueur—kirsch, maraschino, etc., or vanilla or almond essence. Pour the syrup over the fruit, and allow it to cool.

**COMPRESS.** Folded lint or other material applied firmly as a pad to prevent bleeding or inflammation is termed a compress, and may be applied either wet or dry. For open wounds boracic lint should be used or the lint should be wrung out of anti-septic solutions.

For a black eye the compress may be cold, preferably iced. A spirit compress is made by lightly wringing the lint out of a lotion consisting of methylated spirit 3 parts and water 2 parts, and may be applied to a bruise. It should be covered completely by gutta-percha tissue and oiled silk. *See Bandage.*

**CONCERTINA.** The English 48-keyed concertina consists of two hexagonal keyboards, connected by bellows, and with keys arranged on the following plan:

This plan must be memorised. As a help towards this, it should be noted that the two centre rows —

here shown white—are all natural notes, written on lines for the left hand and on spaces for the right. The notes on each of the outer rows are in the same position on the stave as the natural row next to them, but are varied by a sharp or a flat. It will also be seen that the keys are arranged in sequence of 5ths. Sometimes the keys giving C natural are coloured red, the other naturals being white, and the flat or sharp keys black; but an expert player does not need this help. There is some duplication, three D sharps corresponding to three E flats, three G sharps to three A flats, and a B sharp to C.

On each keyboard is an adjustable strap in which the thumb is placed, while in a line with this is a rest for the little finger. The points of both these fingers must press firmly on the keyboard. The concertina is best played in a sitting position, when the left hand rests upon the left knee, the other knee being kept low and out of the way, and the bellows are then worked by the right hand. They can only be inflated or deflated when a key is depressed, as there is no other air-channel.

The first and second fingers are mainly used to depress the keys, their normal position being above the centre rows, to which they immediately return after playing on an outer row; but in certain passages the third finger is also used. The chief rule is not to use the same finger twice consecutively.

Chords are possible on the concertina, and music written for the violin, flute, or oboe can be played on it. It might well meet with more general cultivation, for the sake of its sweet tone, its easy manipulation, and its portability; but unfortunately its reputation suffers by reason of the cheap German variety, which is a much inferior instrument, both in tone and range, playing only in the key in which it is set, and possessing a very simple modulation. In this concertina the keys produce different sounds, according as the bellows are pressed in or drawn out. *See Accordion.*

*Concertina. Left, interior view of keyboard. Below, three principal parts of the instrument; left to right, reeds; bellows; keyboard.*

## CONCRETE AND ITS PREPARATION

How it is Applied to Structural and Ornamental Work

Other articles which describe building materials and processes include Brick; Bungalow; Cement; Cottage; House; Lime; Monar; Wall.

The material called concrete is a mixture of lime or Portland cement, called the matrix, with small pieces of stone, broken brick, gravel, or other hard substances, known as the aggregate, together with sufficient clean sand to fill in the interstices between the aggregate, the whole moistened and consolidated with water. It can readily be prepared by an amateur, and used for foundations, floors, walls and other parts of buildings.

When cast to shape in a wooden mould it makes admirable ornamental figures, garden seats, steps, imitation crazy or stone pavings, and numerous other items. The difference between lime concrete and cement concrete is that lime forms the matrix in the former case, and Portland cement in the latter. The amateur will generally find it best to use Portland cement, and the following hints are based on that assumption.

Good concrete must be homogeneous, dense, fire-resisting and strong, qualities attained by using suitable aggregates. For density, the cement must entirely surround every particle of aggregate and sand, and fill the spaces between them to form a solid mass. This can be ensured by proper mixing, and by ramming and tamping the mixture when it has been placed in position. This ramming consolidates the concrete, and should on no account be omitted for foundation work or where greatest strength is needed.

Suitable proportions of aggregate and cement for building uses are as follows:

### FOUNDATIONS

Cement	1
Clean sharp sand	3
River ballast or gravel	5

### FLOORS

Cement	1
Sand	2½
Broken brick	5

### WALLS

Cement	1
Sand	2
Broken brick, furnace clinker or broken stone	3

This is for walls when cast between shuttering or boards so erected as to form a cavity, which is then filled with concrete.

### PARTITION SLABS

Cement	1
Coke breeze	5

### OR

Cement	1
Sand	1½
Broken clinker or granite	3

This is for partition slabs made in wooden moulds. All proportions are by bulk, or measured with a pail and not by weight.

These materials will be mixed as follows. Place a large board or boards on the ground to form a solid platform. At one end of this place the aggregate, then add the sand, and put the cement on the top, making the heap conical in shape. Turn it over with a shovel to the other end, making another conical heap, and then back again. Then add water from a watercan with a rose head, and turn the material over again twice, in a moist condition. Remove it in a wheelbarrow to the place where it is wanted, and gently tip the mass into the trench or mould, doing this carefully to avoid separating the large from the small pieces. Then ram and consolidate the concrete and work it to as level a surface as possible. This causes a considerable shrinkage in the bulk, and sufficient extra material must be mixed in the dry state to compensate for this, at least 30 per cent. more dry material being needed to fill a given space with well consolidated wet concrete.

The size of the pieces composing the aggregate varies according to the work; for foundations, the aggregate may pass through a 2 in. mesh sieve; for floors, the largest pieces should pass a ¾ in. mesh. For fine castings the aggregate should pass a ½ in. mesh. Coke breeze and fine clinker used for partition slabs should pass a ⅜ in. mesh. Granolithic concrete for the surface of floors and hearths, etc., should be composed of 2 parts cement, with 5 parts of fine granite chippings or fine limestone chippings. The amateur will find that coke breeze, gravel (generally called "ballast"), or broken brick are the best aggregates to use, but on no account must garden mould or any other soft material be employed.

Concrete blocks for building walls and partitions are often made in machines built for the purpose, and when any considerable number of blocks are needed it is an economy to purchase or hire such a machine; but an efficient substitute consists simply of four stout pieces of board of correct height, supported by pegs driven into the ground. These sides should rest upon a wooden base (Fig. 1). The concrete is shovelled in, rammed, and levelled off with a trowel, and left to set for a quarter of an hour. By using four such moulds the work of block-making may proceed uninterruptedly. The wooden sides are removed and the block lifted by the bottom board and set on one side to dry off. Stack the blocks so that the air can circulate between them, and to avoid their adhering to one another place pieces of newspaper between them. This class of block should be allowed to dry off thoroughly before it is used, and will be improved by storing for a month or so. The concrete should only be made sufficiently wet to hold together; too much water is detrimental, as it brings the cement to the surface. A better mould for making a breeze block is shown in Figs. 2 and 3.

Concrete lintels, door posts, window-sills, fencing posts, and similar details are generally cast in a wooden

## CONCRETE

Concrete. Fig. 1. Simple mould for breeze block. Fig. 2. Breeze in a mould. Fig. 3. Mould knocked apart, showing block. Fig. 4. Casting a hollow breeze block, the core removed and shown on right. Fig. 5. Casting a quoin block. Fig. 6. Partition wall of breeze blocks; quoin block used for bonding.

Fig. 7. Diagrams showing mould and core used for casting a hollow concrete block.

Right, construction of core for a concrete quoin block.

box or mould, and should have a stout iron bar embedded in the centre. The sides of the box are screwed or bolted to the ends to facilitate their removal. The same principles are applied to the construction of plinths and cornices, the strength of concrete being greatly increased by embedding iron rods, expanded metal, or even stout chicken-run wire, an elementary type of ferro-concrete construction.

The construction of a simple building, such as a garage or storehouse, is well within the capacity of an amateur. The procedure will be governed by local conditions and personal requirements, but any one of the following methods can be applied. The ground is marked out, excavated, and the trenches filled with concrete as if for a brick building, as detailed under bricklaying. The walls can then be erected, with coke breeze or ballast as the aggregate used for making the concrete blocks, the work being carried out as if using bricks, except that cross bonding is effected with galvanised iron wall-ties built in as the work proceeds.

Another method is to use hollow blocks cast in a mould made for the purpose, as in Fig. 4. The construction of those moulds is quite simple, and all dimensions can be taken from the diagram, Fig. 7. With this class of block wall-ties are not needed. Partition walls can be built in by using quoin blocks cast for that purpose, as shown at A in Fig. 5, using the same mould box, C, with the core, B. The former or core is shown in Fig. 7. These blocks can also be used in conjunction with the flat coke breeze blocks and the quoin blocks. The method of bonding a wall made of coke breeze blocks is shown in Fig. 6, which also indicates the use of quoin blocks in making a return wall.

Still another method is to erect shuttering composed of stout wood boards with battens nailed to the back. These are held upright by simple struts. The gap left between the two sets of shuttering determines the thickness of the wall, and is filled in by shovelling in the moist concrete and ramming it down hard and solid. When the concrete has set the shuttering is removed and re-erected farther along for the wall. Frequent use of the plumb rule and the line will ensure the wall being straight.

Several types of shuttering have been developed for such work, one of which is shown in Fig. 8. Metal strips are placed across the wall at intervals of, say, 5 ft. Through holes in the strips tee irons are threaded and secured by wedging. Planks are inserted and concrete is poured between.

The following are essentials to any satisfactory concrete building work. Use only the best cement; see that clean sand is used—it must be free from clay or earthly material; if it is not it must be washed by putting the sand in a trough and, while gently stirring the material, letting water run through it. This will overflow at one end and carry away the particles of dirt. The sand used must be coarse and graded—that is, some coarse and some fine. The aggregate must be clean and graded, some to be larger and some smaller, generally ranging from  $\frac{3}{4}$  in. downwards for small work, walls, and floors. Concrete must not be applied to existing dry work, as in the form of dry foundations.

The latter must always be saturated with water before the concrete is laid.

Concussion. See Brain.

**CONDENSED MILK.** Sold in tins, either sweetened or unsweetened, condensed milk will keep for any length of time, and can be used, diluted with water, for all purposes for which milk is required. It is made by fresh milk being boiled and evaporated until almost all the water has been drawn out. Sugar is added as a preservative, and, in the best makes, no chemical preservatives are used. When required for use as fresh milk it should be diluted with water in the proportion of 4 or 5 parts of water to one part of condensed milk.

Condensed milk that is free from chemicals is considered to be a valuable food for infants and a good substitute for mother's milk, being used in proportions that vary with the constitution and age of the child. As little as  $\frac{1}{4}$  teaspoonful to 1 tablespoonful of water is recommended for a newly-born infant. The proportion is increased as the child grows older. For infants' food the water must be boiled and allowed to cool before the condensed milk is added. The diluted milk must be allowed to cool to blood heat (98° F.) before being given to the child. See Milk.

**CONDENSER.** This is an apparatus for storing up electrical energy. It consists of two or more conductors separated by a nonconductor or dielectric. The actual capacity of the condenser may be fixed, or variable. In a wireless receiver the conductors or plates may consist of aluminium, brass, copper, etc., and the dielectric may be air, mica, waxed paper, ebonite or bakelite. *See Capacity.*

**CONDIMENT.** Condiments are the seasonings and spices used in cooking, which not only enhance the flavour and give zest to a dish, but are of value as aids to digestion. The quantities used are determined by individual taste, and care must be exercised in their usage. Condiments should always be cooked with the dish, and not added to it afterwards. The condiments in most common use are salt, pepper, mustard, and vinegar. Other much-used condiments are allspice, cinnamon, cloves, mace, nutmeg, ginger, and cayenne. All of these can be obtained ground to powder. *See Allspice; Curry; Ginger; Mustard; Pepper; Salt, etc.*

**CONDUIT: For Electricity.** An electrical conduit is an outer casing or covering in which the insulated conductor or wire is inserted in order to protect it from injury, and also to add to the electrical efficiency.

Steel conduit is made from welded steel pipe of various sizes, enamelled inside and out. Connexions are made by screwing the pipe on to sockets or other fittings in much the same way as gas piping. In other systems the pipes push into sockets formed in the fittings, and are sometimes scoured by means of a clip. Standard fittings for use with this material include bends and angles, for turning corners, junction boxes for connexions and branches, inspection boxes with removable lids for access to interior. The system is the only one that can safely be embedded in plaster or out-of-the-way locations.

When installing such a conduit system the whole of the pipes, complete with junction boxes, bends, and so forth, are fixed up in place, and then the electric conductors or wires are drawn into the tubes, using a thin steel wire pushed through the tubes from a junction box or inspection box, and attached to the wires to be pulled in. All wires that have to go through a particular section of conduit must be pulled through together. The conduit must be electrically continuous, and properly earthed to a large copper plate buried in the ground, or by a wire connecting the conduit to the water-supply pipes, but never to gas pipes. *See Electricity.*

**CONEFLOWER.** This is the popular name of *rudbeckia*, a vigorous hardy perennial which bears yellow flowers in late summer and autumn. It thrives in ordinary soil, may be planted in autumn or spring, and is easily increased by division of the clumps in March. The best are: *californica*, 6 ft., *Golden Glow*, double, 6-7 ft., and *speciosa* (Newmanni), 2 ft. *Rudbeckia* (*echinacea*) *purpurea*, grows 3 ft. high and bears reddish flowers.

**CONFECTIONERY.** This word is used for sweetmeats, and for cakes, rolls, tarts, and fancy pastry generally. *See Cake; Chocolate; Pastry; Sweets, etc.*

**CONFETTI.** These are tiny circles of coloured paper. They are used at fancy dress balls and carnivals; and at weddings, being thrown in handfuls at the bride and bridegroom as they emerge from church or set out for the honeymoon. For this purpose it is more suitable than rice.

Confetti can be purchased so cheaply that not many people will trouble to make it for themselves, though it can be done simply enough by folding sheets of thin coloured paper across several times, and cutting half-circles out of the folded edges.

**CONFIRMATION.** In the Church of England and the Roman Catholic Church confirmation is the ceremony by which a person becomes a full member of the Church and is allowed to partake of communion. The person then for himself or herself confirms the promises made by the godparents when he or she was baptized. The Church of Rome regards confirmation as a sacrament, but the Church of England does not. It can only be administered by a bishop, and candidates are usually between 14 and 18 years of age.

Those wishing to be confirmed should apply to a clergyman or priest. Confirmations usually take place early in the year, in order that the confirmed can partake of the sacrament for the first time on Easter Day. In most parishes classes for young men and classes for young women are arranged, and therein instruction is given by the clergy in the principles of the Church. Special arrangements are made for older people, the main point being that the person presented to the bishop must have satisfied a clergyman that he or she is fit to receive the rite. The public schools usually make their own arrangements for confirmation, boys being confirmed in the school chapel.

Confirmation services are held at stated times. A centre is chosen by the bishop, and at that church the candidates from the neighbouring parishes are required to present themselves. It is usual for girls to be dressed in white. At the service the bishop places his hand upon the head of each candidate as he or she kneels before him, and says over each a short prayer.

**The Confirmation Cap.** To make a confirmation cap,  $\frac{3}{4}$  of a yard of material 27 or more inches wide is required, and the edges should be hemstitched. Three narrow tucks are placed at one end, and two short ends of ribbon fastened to the ends of the tucks on the wrong side of the cap. These tie in the nape of the neck, holding the cap tightly over the brows.

**CONGER EEL: How to Cook.** This fish is at its best for eating in September and November. The flesh, being coarse, requires thorough cooking, but is highly

nutritious. When small, it may be cooked in the same way as a fresh-water eel, but if large it is best cooked like cod. Conger eel can be boiled in a fish bottle in enough hot water to cover it and a teaspoonful of vinegar. After being brought to the boil it is allowed to simmer until the flesh falls away from the bone. It is served with parsley sauce. To fry conger eel, it should be dried, cut in slices, and sprinkled with flour. It is then dipped in beaten egg rolled in breadcrumbs, and fried in hot fat. It can be served with any fish sauce.

Another way of preparing conger eel is to let it stand for over an hour in a dish containing 3 tablespoonful of vinegar,  $\frac{1}{2}$  tablespoonful of chopped onion and a sprinkling of popper and salt. Then stuff it with veal forcemeat, bind it up with a piece of tape, and bake it for about 1 hour on a well-greased tin, basting it frequently. When it is ready, remove the tape, and serve the fish on a hot dish, with anchovy or other sauce strained round. *See Eel.*

**CONGESTION:** How to Avoid. This means an abnormal filling of the bloodvessels with blood. Active, congestion occurs when such filling is a result of the dilatation of the arteries. This form of congestion is the first stage of inflammation, but it can be deliberately produced in the superficial parts in order to draw off the excess of blood from a congested, deeper organ.

Acute congestion of the lungs may arise from breathing irritating vapours, e.g. poison gas, or from bathing when overheated or drinking large quantities of cold liquid. (*See Lung.*)

Passive congestion occurs when the blood lingers overlong in the vessels. The blood in this case is dark or venous in character. Inefficient pumping by a diseased or exhausted heart is a common cause. It may also be due to obstruction of veins, e.g. in pregnancy or from wearing tight garters or to the veins becoming varicose. Dropsy occurs and the legs swell. Relief is afforded by reclining at intervals with the legs somewhat elevated; in pregnancy a properly fitted abdominal belt, and in varicose veins elastic bandages, will reduce the tendency to passive congestion when one has to be up and about.

**CONJUGAL RIGHTS.** By English law when one spouse has left the other and refuses to return to matrimonial life without lawful excuse, the other may bring a suit in the divorce court for restitution of conjugal rights. The one who sues must be ready and willing to resume cohabitation, and thus it is usual for him or her (generally it is the wife) to write a letter inviting the other to return.

There are very few excuses that are lawful excises for not returning: but a wife may refuse to return to a husband who has treated her cruelly; and a husband may refuse to return to a wife who has made unfounded charges of horrible conduct against him. A good excuse would be that the other spouse was suffering from a certain disease, or that it was otherwise dangerous to cohabit with him (or her). Matrimonial infidelity is a good excuse. If the respondent disobeys the order, he (or she) cannot after the time allowed is up come along

and say "I am now willing to come back." Disobedience to the order is equivalent to legal desertion, and the petitioner is entitled to alimony. *See Desertion; Husband; Separation.*

**CONJUNCTIVITIS.** This complaint is an inflammation of the delicate membrane which covers the white of the eye and lines the eyelids. It may result from a blow, a speck of dust, or the action of microbes. As most cases of conjunctivitis are very catching, the greatest care should be taken that the patient's sponges, towels or bed-linen are not used by anyone else.

In the acute catarrhal form of conjunctivitis the whole eye is bloodshot. There may be swelling with burning, itching, and a sensation of sand or grit in the eye. There is a sticky discharge, and the patient generally complains that his eyelids are stuck together in the morning. Pain and inability to look at a bright light may become marked and the discharge may become mattery. The eye should be bathed every half-hour with a 10 grain to the ounce solution of warm boracic lotion.

There is also the chronic catarrhal form. Here the white of the eye is constantly more or less bloodshot, and there may be inflammation of the edges of the lids and a slight amount of discharge collecting in crusts in the inner corner of the eye. It ought to be determined at once whether or not the patient requires glasses. If he does, and his vision is corrected, a long step may be taken towards curing the condition. A lotion that often gives excellent results consists of boracic acid 5 gr., zinc sulphate 1 gr., distilled water 1 oz.

Infection with the micro-organism of gonorrhoea results in a form of conjunctivitis known in infants as ophthalmia neonatorum, and said to be responsible for 30 per cent of the cases of blindness in Great Britain. A contagious form is trachoma or granular lids chiefly affecting the lining of the upper eyelid. Membranous conjunctivitis is frequently a symptom of diphtheria. Medical advice should be obtained at once.

Spring catarrh is a condition which affects chiefly boys and young men, giving them a pale, sleepy look. Reddish grey elevations form on either side of the cornea or clear part of the eye, and granulations on the under surfaces of the lids which have a pavement appearance. Signs of irritation, itching, intolerance of light and glueing of the lids in the morning are the result. Recourse may be had to radium therapy. *See Eye.*

### CONJURING: SOME SIMPLE TRICKS

Useful Information for the Amateur Entertainer  
See also Card Tricks; Children's Party; and the many entries on indoor and outdoor games that form the recreation section of this work

The conjurer should never tell an audience what is going to be done. For example, if a coin is to disappear

magically, call attention to it by holding it up, and after the disappearance has been accomplished, it can be safely stated that a touch of the magic wand on the hand which apparently holds the coin will cause it to disappear.

A great many of the most puzzling effects are produced by simple means. If a trick has been well received, resist all requests to repeat it before the same audience, unless the performer has the knowledge which will enable him to bring about the same result by a different method. Never perform any trick in public until it has been thoroughly rehearsed. In practising sleights do so before a mirror, and endeavour to deceive yourself.

One of the most difficult branches of conjuring to acquire is the patter, or description of the problem to be presented. If a humorous style suits the personality of the performer, adopt it, but be careful that the jokes are really witty and appropriate. A story is sometimes useful to illustrate the trick. Others may find a mysterious style more suitable. Whatever is chosen, it must be rehearsed continually until the performer is capable of exhibiting the trick without hesitating in his patter. It is not easy to do one thing while talking about something else.

**The Magic Wand.** The conjurer should provide himself with a magic wand. This is essential, as it is quite possible to have a small ball, a coin, or other article concealed in the hand if a magic wand is also held in the same hand. A small table is also a very useful accessory, especially if a servante is included. This latter is a shelf hidden behind the table which will receive any small article dropped on it.

**Palming a Coin.** In order to palm a coin, take a half-crown, or, if the hand is small, a two-shilling piece, and place it on the tips of the second and third fingers of the right hand. Hold the left hand open, palm upwards, and pretend to place the coin into the left hand. As the right hand approaches the left, bend the fingers, pressing the coin into the palm of the right hand, slightly contract the hand, and if the coin has been placed in the correct position the fleshy portion of the palm will hold it firmly. A few experiments will readily show the best position suited to the individual performer.

As the right hand reaches the left, close the latter as if it contained the coin. During these moves the eyes of the performer must follow the supposed position of the coin, and on no account must a glance be directed towards the right hand. If the wand is used, it can now be picked up in the right hand, which will help to conceal the fact that the coin is there.

As the disappearance of the coin is now an accomplished fact, state openly that by the aid of the magic wand it is possible to make the coin disappear. Suiting the action to the word, touch the back of the left hand with the wand, or wave the wand round the hand, and demonstrate that the coin has magically flown by slowly opening the hand. When palming a coin, endeavour to hold the hand naturally, so that it looks to

the audience as if it concealed nothing. Practise this sleight in front of a mirror, and before attempting to palm the coin actually place it in the left hand and study carefully the movements, especially the position of the empty right hand, then endeavour to imitate these movements when palming the coin.

**Tricks with Cards.** Card tricks may be described as a special branch of conjuring. The essential sleights which must be learnt are the force, the top and bottom change, and the pass, and until these are mastered no really effective card tricks are possible.

The sleight called the force only becomes successful by experience and practice. It is used when it is desired that a certain card shall be selected. Have the card at the bottom of the pack. Insert the little finger half way down the pack so that the pass may be made. As the performer approaches the one on whom he wishes to force the card, the pass is made which brings the lower half of the pack to the top, with the selected card at the bottom of this position. Fan out the cards as they are offered and keep them moving towards the right, and just as the person puts out his hand to take a card, the fingers of the performer's right hand push forward the desired card.

*The Pass. 1. Little finger of left hand is inserted between halves of pack, remaining fingers resting on top. 2. Bottom half of pack, in right hand, is then pressed into fork of left thumb, top half being lifted by left little finger. Right. Conjuring. Forcing a card. The card to be forced, A, is pushed slightly out of the fanned-out pack.*

There are two chief changes, one where a card held in the right hand takes the place of the top card of the pack, which is held in the left hand. This is known as the top change. The second, designated the bottom change, is effected by changing a card held in the right hand for one on the top of the pack, but instead of the card taking its place on the top of the pack it is put at the bottom. To make the first change, hold the pack in the left hand with the thumb across the pack and the fingers underneath.

The card which is to be changed is held between the thumb and first finger of the right hand. While attention is drawn to this card the thumb of the left hand pushes the top card forward to the right about  $\frac{1}{2}$  in. Making a smart half-turn to the left, the right hand meets the left, which is advanced, and the top card is secured with the first and second fingers of the right hand, and at the same time the thumb of the right hand pushes the card that is to be changed on to the top of the pack.

In the second method, the card in the right hand is held by the first and second fingers only. As the hands reach each other, the fingers of the left hand are opened to receive the card and at the same time the top card is pushed forward and secured by the first finger and thumb of the right.

The pass is one of the most important moves in card conjuring, and consists of a sleight which transposes the top and bottom halves of a pack. Making the pass can be accomplished with one hand only but for all practical purposes the double-handed pass is preferable.

The pack is held in the left hand in the position usual for dealing, the thumb being on top and the four fingers at the opposite side. Lift half the pack, and insert the little finger of the left hand at the break so made. The other three fingers should now rest on the top of the pack so that if the little finger is straightened out the upper half of the pack will be lifted to a vertical position.

The right hand now grasps the lower half of the pack by the edges of the cards, the thumb being at the lower end of the pack and the first three fingers at the top end. Pressing the lower half pack into the fork of the left thumb, it is pivoted upwards, and at the same time the little finger of the left hand raises the top half. As soon as the lower half can pass the top half, the pack is closed up and the pass is completed. When making the pass it is best to make a backward move of the hand, which will cover to a certain extent the various moves.

**Handkerchief Tricks.** There are many pretty illusions with silk handkerchiefs which are always popular. A simple production and disappearance of a handkerchief can be brought about as follows. A small hollow rubber ball about 1½ in. in diameter is necessary, which is prepared in the following manner: A hole about ½ in. in diameter is cut in the ball and the piece removed. Opposite the hole two small holes are bored, through which a piece of thin catgut or flesh-colour silk is tied. The loop formed should be long enough to allow the ball to rest on the back of the hand when suspended from the thumb. To produce a handkerchief with this simple apparatus, it is only necessary to push a thin silk handkerchief into the rubber ball, suspending the ball on the back of the right hand, the palm being towards the audience.

*Handkerchief Production. Hands are first shown empty and a handkerchief is produced magically from the finger-tips. The trick is performed by producing the handkerchief from a hollow wooden ball palmed in the right hand.*

*(The photographs illustrating this article are by courtesy of L. Davenport & Co.)*

Showing the left hand also empty, make a half-turn to the right and bring both hands together, and under

cover of the fingers of the left hand get the ball between the palms. A turn to the left is now taken, and with an up-and-down motion of the hands the handkerchief is slowly produced at the tips of the fingers. The handkerchief is now held in the left hand and the ball, which up to the present has been suspended from the thumb, is disposed of on the servante. To make the handkerchief disappear the several actions mentioned above are reversed.

**CONSEQUENCES: An Indoor Game.** This can be played indoors by any number of people. Each is given a slip of paper and a pencil, and is asked to write down an adjective applicable to a man. This done, each slip of paper is folded over, concealing the writing, and is handed to the player on the left. Next comes a man's names and the slips are once more passed on. These are followed by another adjective, this time applicable to a woman, and a woman's name: the name of some place or public building; a remark made by the man; and a remark made by the woman; what the consequence was, and what the world said.

As most players will follow out their own train of thought in writing these answers, and as each answer will come on a different slip of paper, the results when read out at the end are often both amusing and surprising.

## THE CONSERVATORY AND ITS CONTENTS The Gardener's Duties Simply Explained

Throughout this work articles on the flowers cultivated in the conservatory will be found, e.g. Begonia; Geranium; Orchid. See also Greenhouse and the constructional articles, e.g. Brick

For the house of small proportions there is no more delightful adjunct than a well-planned conservatory, opening, perhaps, from the drawing room by glass doors. Position is a matter of importance, and a conservatory with a southern or south-western aspect is more favourably placed than one built to the north or east side of the house; but whatever the position, many advantages will be obtained by artificial heating during winter.

A conservatory may be described as a glasshouse in which plants in flower, previously grown in a greenhouse, are arranged for effect. Most of the plants used in conservatory decoration are grown in flower pots, but if there is room for a border of soil certain kinds, e.g. camellia, acacia, abutilon, fuchsia and heliotrope may be planted there.

By cultivating a suitable selection of plants, in pots and planted out in the borders, it is possible to keep the conservatory attractive the whole year round, providing it is heated sufficiently to maintain a minimum winter temperature of 50-55 degrees.

Usually there is a bed of soil in the centre where the vigorous plants and shrubs are grown, and staging for pot plants at each side. It is an advantage to have the

paths paved or tiled, for they can be kept clean with the minimum of labour. Certain plants may be grown even beneath the staging: the most popular for this purpose are the green-leaved and variegated-leaved *tradescantia*, a creeping plant, and *Begonia rex*.

An attractive edging to the staging for pot plants adds considerably to the charm of the conservatory. Two favourite plants for this purpose are *isolepis gracilis*, which is of drooping grasslike growth, and *panicum variegatum*, with narrow green-and-white leaves. These may either be grown in pots or planted in a narrow border of soil contained in a zinc trough alongside the edge of the staging. *Herniaria glabra*, a creeping plant, with tiny green leaves, also makes a neat edging.

Climbing plants improve the appearance of a conservatory, and a careful selection will provide flowers throughout many months of the year. It is a mistake to train vigorous sorts on a trellis fixed beneath the glass roof, for they cast too much shade on the plants on the staging beneath. The less vigorous kinds are to be preferred for this purpose, for instance, roses in variety, *abutilon*, *fuchsia*, and the blue *plumbago capensis*, all of which lose their leaves in autumn. The conservatory pillars ought to be covered with climbing plants; a choice may be made from *hibbertia dentata*, yellow, *cestrum elegans*, rose, *asparagus plumosus*, *smilax*, *heliotrope*, ivy-leaved *geranium*, the yellow *acacia baileyana*, the yellow *jasminum primulinum*, the scarlet honeysuckle (*Lonicera sempervirens*), the blue and white passion flowers, and the gorgeous orange and red *streptosolen Jamesoni*.

Vigorous climbing plants suitable only for training beneath the roof-glass of a large conservatory are the white *clematis indivisa*, *cobaea scandens*, *solanum jasminoides* (which has white flowers), the rosy mauve *bougainvillea glabra*, and the yellow *cassia corymbosa*.

The *lapageria*, with rose or white blooms, is a charming climbing plant for the shady side of a greenhouse, and the night-flowering cactus (*cereus triangularis*) is worth growing, but it must have a sunny place.

Plants grown for the sake of their ornamental leaves are invaluable in the conservatory. Chief among them are:

*Coleus*, *dracaena*, green-leaved and variegated *india rubber plant*, (*ficus elastica*), *grevillea robusta*, palms (*coccoloba weddelliana*, *geonoma gracilis*, *kentia belmoreana*), *araucaria excelsa*, ferns, *asparagus Sprengeri* and *plumosus*, *smilax*, *aspidistra*, *cyperus alternifolius*, *eucalyptus* and *ophiopogon variegatum*, with green and yellow leaves.

Certain plants grown in baskets suspended from the roof are most decorative, and add to the attractiveness of the display. Some of the chief sorts are:

Drooping varieties of tuberous *begonia*, *asparagus sprengeri*, *begonia gloire de Lorraine*, *campanula isophylla*, blue and its white variety *alba*, the rat's tail cactus (*cereus flagelliformis*), cape cowslip (*lachenalia*), *fuchsia*, *lobelia tenuior*, *oxalis floribunda*, ivy leaved

*pelargonium*, *tradescantia*, the variegated stonecrop (*sedum sarmentosum variegatum*) and some of the ferns—*nephrolepis*, *davallia* and *asplenium bulbiferum*.

**The Management.** With regard to the management of a conservatory, the following suggestions will be found useful. When the temperature by day, as a general rule, exceeds 65 deg., ventilation must be given. During cold or frosty periods of weather the temperature should be kept at about 55 deg., this being done by the aid of artificial heat. During the winter months the ventilators should be closed about 2 p.m. during the summer they should remain open till about 5 p.m.

Shading from hot sunshine is most essential, and this may be accomplished by one of the summer-cloud preparations sold by seedsmen, or preferably by movable roller blinds. Watering is another important item, and each morning sufficient should be given to moisten the soil, using water of the same temperature as the air inside the house. In addition, it may be noted that cleanliness and method are as essential in the conservatory as in the greenhouse.

During hot summer days it may be found necessary to give water both morning and evening, but in the event of a plant drooping by reason of dry roots, do not water in the usual way, but stand the pot in a vessel for 10 min. to ensure equal moisture of the whole of the soil. During winter sponge foliage plants with milk and water. Keep all dead blooms and foliage removed, and fumigate occasionally to destroy pests. If stimulants are necessary, use one of the excellent chemical manures on the market, strictly according to the maker's instructions.

When properly conducted, a conservatory should be a source of interest and charm all the year round, and its possibilities, in conjunction with garden and greenhouse will be apparent from the following hints, which describe the plants which are most suitable for the conservatory in the various months of the year.

For January, early tulips, Dutch and Roman hyacinths, daffodils, freesias, winter flowering begonias, cyclamens and azaleas are suitable, as also are cinerarias and Chinese primulas. The same flowers are suitable for February. For March a succession of most of those mentioned for January will be found best, together with spiraeas, primulas, heaths, clivias and carnations. The same remarks apply to the succeeding month, April.

In May the showy herbaceous calceolarias are in full beauty together with amaryllis, Dutch and Spanish irises and annuals raised from seeds sown in September. Throughout the summer months there will be bloom from tuberous *begonia*, *gloxinia*, *achimenes*, *geranium*, *heliotrope*, *fuchsia* and many others. In autumn reliance must be placed chiefly on *chrysanthemum*, *Scarborough lily*, *nerine*, *lilium auratum* and other lilies. These will be followed by early bulbs, Chinese primulas and cyclamen, winter

cherry, winter begonias and carnations.

**Building a Conservatory.** Whatever the dimensions of a conservatory, it should be free from any suggestion of heaviness. It generally has means for heating, for regulating temperature, and controlling the amount of light. A water supply is desirable, and for the benefit of the plants a conservatory should be built facing the south.

*Conservatory porch outside a French window (Courtesy of Boulton & Paul, Ltd.)*

*Below. Conservatory with semi-octagonal end exposing a large surface to the sun.*

The usual construction comprises a brick or tiled floor, set in cement mortar, with a fall to one corner where a trapped gully communicating with an adjacent drain enables any surface water to be disposed of. The surrounding walls are made of brickwork to a height of about 18 in. The walls and roof are composed chiefly of glass, carried in wood or metal framing. The latter is more durable, but requires frequent painting owing to the dampness of the atmosphere in the conservatory. The roof should be constructed with throated or channelled bars to act as gutters. This to a large extent overcomes the objectionable effect of a dripping roof. Fig. 5 shows a standard form of machine-moulded wood bar made for conservatory and greenhouse purposes.

Elaborate conservatories are frequently made with large panes of glass, cut to ornamental shapes and framed accordingly. The amateur would do well to obtain horticultural glass, which is sold by the 100 sq. ft., in widths and lengths such as 10 in. by 8 in., 100 sq. ft. being quite sufficient glass for the purpose of covering an area equal to 10 ft. long by 10 ft. high.

The framing is readily constructed by using greenhouse bars for the windows. A section is shown in Fig. 4, and this wood can be obtained in various widths and thicknesses. Windows to open will be framed up and provided with a strong framework to which they may be hung, generally from the top. A top and bottom framing should then be constructed, supported by upright corner posts about 3 in. square. The most convenient method is to make up the sides and ends in sections and bolt them together, then erect a ridge board and fix the glazing bars to it. A proper wooden ridging is made for this purpose, and a section of it is given in Fig. 1; other figures illustrate the regulation sills and end plates, all of which are obtainable from any timber yard.

Fig. 1

Fig. 2

Fig. 3

Fig. 5

*Conservatory. Figs. 1-5.*

*Diagrams showing sections of moulded and prepared timbers used in building a conservatory.*

A water supply is generally obtainable either by means of a rubber hose pipe that can be connected when required to the nearest water tap, or preferably by running a  $\frac{3}{4}$  in. iron pipe to the water main or other adjacent water supply pipe. In some districts the water company may charge an extra rate if this is done.

Means for heating may be a simple oil lamp and some hot-air pipes. A similar arrangement with hot-water pipes, or a regular hot-water circulating system, can be installed with a separate greenhouse type of boiler. A gas heater circulator with electric or thermostatic controls is a boon in changeable weather. It can be left burning all night, and any sudden drop in temperature will cause the controls to operate and so turn up the gas supply, and keep it up until the desired temperature has been attained.

**Console.** A console is a projection resembling a bracket (q.v.) used to support a cornice, or to hold busts, vases or figures.

**CONSOLE TABLE.** A console table is a table supported by brackets, or upon legs not unlike brackets in form, and made to stand against a wall. Some of these tables, which were chiefly made in France in the 17th and 18th centuries, have the

supports elaborately carved, and are beautifully adorned with representations of fruits, flowers, scrolls, etc. Some were gilded and covered with a marble slab. The chief woods used for them were rosewood and mahogany.

**Consommé.** This clear soup is made from meat, vegetable, or bone stock. *See Soup.*

**CONSTANTIA.** This district of Cape Colony is noted for the excellent quality of its red wine, the best produced in S. Africa. Constantia as applied to wine is a territorial description like Beaune. Most of the South African wines, with the exception of the one called Constantia, are named after their European prototypes. *See Wine.*

**CONSTIPATION.** This may be due to disease, general or local, but apart from disease the condition is more often induced by individual habits and customs. The movements of the bowels are induced by the presence of a certain amount of indigestible material and of fluid. Modern methods of preparing and cooking food tend to eliminate indigestible constituents, the result being that the bowel is deprived of a normal stimulus. Then, some people take too little liquid, and what they drink may be tea sufficiently strong to have an astringent effect. An active out-of-doors life has a stimulating effect on the muscles of the bowel and on the muscles of the abdominal wall, which contribute powerfully to the emptying of the bowel. This stimulus is reduced in those of sedentary occupations and habits.

The taking of food has the effect of producing movement along the alimentary tract, and with the majority of people this, coming on after breakfast, leads to a habit of relieving the bowels then. Many men find that a pipe of tobacco is a further help. But the particular time does not matter so much as the habit of soliciting an action of the bowels at the same time every day, as they can be trained to act regularly. The bowels may not move for two or three days without apparent ill-effect, but generally there is discomfort in the abdomen and a heaviness in the head, or even headache. If the condition is not relieved, the local discomfort becomes greater, perhaps accompanied by colicky pains, the appetite falls, the tongue is furred, and the spirits are depressed and the temper is irritable. If the constipation is chronic, the absorption of poison from the bowels may lead to a large number of bodily and mental infirmities.

In addition to the importance of regular habits stock should be taken of the diet, and this can be made more effective by the addition of fruit and vegetables, either cooked or raw, and by the use of wholemeal bread and oatmeal porridge. Syrup and molasses will be found helpful, and amongst fruits marmalade and stewed prunes are especially useful. Many find that a glass of water first thing in the morning and at bedtime keeps them right. Eating plenty of greens keeps the intestines clean. Milk, especially boiled, is often constipating, and the same, it is sometimes found, applies to red wines.

### Value of Exercise and Massage

Exercises, especially those which bring the abdominal muscles into play, are useful, and should include as much open-air activity as possible. Massage of the abdominal muscles may be resorted to. This may be done by hand, but a heavy ball, say about 5 lb. weight, rolled round the abdomen from the right groin up and across and then down to the left groin is found effective by many. A useful ball may be made by filling a chamois leather bag with swan shot.

Should there be any difficulty in getting the bowels to move, a small enema,  $\frac{1}{2}$  pint of cold or warm water or 2 drains of glycerin injected into the bowel, or a glycerin or soap suppository, should be employed. It may be necessary, however, to resort to drugs. Under the heading *Aperient* a list is given of a number of common preparations, with the dose prescribed.

During the first year of life the bowels usually move two or three times a day; in the next year twice, and thereafter once. Infants at the breast should be restricted to their regular times of feeding, and should not be put to the breast, merely to pacify them, outside these times. Constipation may be due to a lack of fat or sugar in the diet, however the infant is fed, and an increase of these should be tried, fat in the form of fresh cream, a teaspoonful once or twice a day, being given. If the constipation is urgent an injection into the rectum of a few ounces of warm water to which a little soap has been added, or a teaspoonful of glycerin, will be the quickest way to give relief.

To train the bowels into normal regularity when once constipation has become the habit, nothing gives better results in infants and young children than cascara. To a half-teaspoonful of sugar and water add 5 to 10 drops of the liquid extract of cascara, and give it to the child last thing at night; or twice this dose of the aromatic syrup of cascara may be given. The dose may be decreased or increased if necessary. When the requisite amount has been determined by experience, let the child have this dose nightly for two or three weeks, and then gradually reduce the amount, finally withholding it altogether. *See Aperient; Cascara.*

**CONSUMPTION.** This is the common name for tubercular disease of the lungs (pulmonary phthisis) or of the bowels. The word denotes the wasting of the body in tuberculosis. The cause of the disease is always the tubercle bacillus that was discovered by Koch. This minute organism may enter the system and settle in the lungs through a person partaking of meat that is tuberculous, or milk, or even through a wound in the skin. The commonest source of infection is from breathing germs floating in the air. The expectoration of a consumptive may be laden with millions of such germs, and when it dries on the ground or the floor the germs may live for months. Clinging to dust particles, they are carried about the atmosphere, and can infect other people. Sunlight, however, possesses a powerful effect in destroying their activities.

Tuberculosis is still one of our commonest and most deadly diseases. Since 1913 it has been notifiable. It is estimated that about one-seventh of the human race dies from tuberculosis in one form or another. It is possible that the infection takes place chiefly in childhood, when unhealthy tonsils and adenoids are rife, and when the resistance to the passage of bacilli in milk through the intestines is relatively low. Some children are born with a low resistance to tuberculosis; but a large number of cases in which the disease appears to be inherited are really instances of direct infection from an affected parent.

When the tubercle bacillus invades and develops in the lung there is a new growth of cells which solidifies the part of the lung affected. These masses of cells, known as tubercles, may be sufficiently numerous thus to solidify a considerable area and destroy the lung tissue there. The cells commonly become converted into cheesy matter, which softens and is coughed up. A cavity is left with ulcerated walls, and blood vessels are opened up or burst, causing haemorrhages, which may be large. These cavities are liable to become infected with the microbes of putrefaction, and this adds greatly to the poisoning which is already being caused by the tubercular microbes and is the cause of the foul sputum brought up. The disease tends to spread and destroy the adjoining healthy lung. In some cases, however, repair processes come into operation, new fibrous tissue forms, the disease is walled off, and a cure results, with a scar in the lung.

Tuberculosis of the lungs may show many variations of form. It may occur as a part of a general blood poisoning by tubercle bacilli, in which symptoms indicative of the involvement of other organs besides the lungs are present, e.g. meningitis. This occurs most frequently in children, and is usually rapidly fatal. There is also the acute infection of the lungs, known as galloping consumption, in which the condition may resemble pneumonia (q.v.) or broncho-pneumonia. The latter is common in infancy, and may follow measles, whooping cough or simple bronchitis. These forms may prove fatal in a few weeks or may pass into chronic tuberculosis of the lungs. This is the commonest form of the disease, and usually comes on insidiously.

#### Significance of a Persistent Cough

Persistent slight cough with no expectoration at all at the start may be the earliest sign. Later there may be streaks of blood in the expectoration. A doctor should then be consulted. Ready fatigue, a tendency to sweat at night in bed, and a slight afternoon rise, in temperature are other early symptoms.

The spread of consumption is favoured by herding people together in small houses and in workshops, and by insufficient or improper food. But even if accommodation is restricted the danger can be minimised by flooding the premises with air and light. With regard to food, it has been pointed out that the decline in consumption during the last 50 years coincides with the importation of foreign meat into this country, with an increase and cheapening of protein food. It is of great importance that patients, and

especially children, recovering from acute diseases, particularly measles, whooping cough, and broncho-pneumonia, should be closely watched throughout their convalescence, as the seeds of consumption are often sown then. It is obvious that grave danger lies in allowing people to spit on the streets, in public places or vehicles, or elsewhere, at large.

*Every time an advanced consumptive speaks, coughs, or sneezes, he exposes those about him to the possibility of infection.*

Persons who suffer from tuberculosis should carry a sputum flask or cup, which can be obtained from any chemist or hospital that treats lung diseases. A few drops of some disinfectant are carried in these flasks, and in using them care should be taken that all the sputum goes inside. If any is left on the orifice it dries and is scattered as dust, and this is the danger that lies in using a handkerchief.

To protect the rest of his household the consumptive should have his own table cutlery, plates, serviettes, etc., and no one else ought ever to use his towels or sleep in the same room with him. The habit of washing the hands before touching food should be inculcated and practised. The consumptive's handkerchiefs, pillow slips, etc., should be soaked for some hours in a solution of carbolic acid (1 part of carbolic to 20 parts of water) or some other disinfectant before being sent to the wash. The person who has to look after the rooms of a consumptive should always wear a light muffler covering the nose and mouth when sweeping, and utilise wet tea leaves to prevent dust. Instead of sweeping or dusting, cleaning should be done when possible with a damp cloth, which can be wrung out from time to time in a disinfecting solution.

**Treatment.** The treatment depends on the stage of the disease. Broadly speaking, if the patient has an evening temperature above 100°, he should be kept in bed. On the other hand, he may be put to exercises or graduated work, particularly when the disease tends to become quiescent. The treatment must be closely supervised by the doctor at all stages, but the intelligent cooperation of the patient and his friends is necessary. Essential constituents of the diet are raw meat and eggs. Smoking is likely to be harmful. Alcohol, with the exception of beer or light red wine, should not be taken except under a doctor's orders.

The maximum of fresh air, both day and night, is required at all stages. If a shelter with a well-boarded damp-proof floor can be arranged in the garden, the patient should begin by sleeping out of doors on fine nights. After a few nights he will find that he is perfectly comfortable, even when the weather gets colder. The effects of fresh air are often very noticeable. The hectic flush, the pallor, the irritating cough, and the tendency to night sweats often immediately pass off. If the patient cannot sleep in the open, his bedroom should be as simple and bare as

possible. The bed should be placed near the open window. Draughts will be avoided by having the window widely open night and day.

The most useful of all medicines in consumption is cod liver oil (q.v.). Other drugs frequently used are creosote, guaiacol carbonate, and arsenic. Treatment by injections of preparations of gold have given good results. Preventive measures include the administration of Calmette's tuberculin during the first week of life.

**Intestinal Consumption.** Consumption of the bowels is common in young children, and the tubercle bacillus may cause ulceration of the bowels, and may settle in the glands running along the spinal column at the back of the abdomen. This abdominal tuberculosis is very frequently associated with the disease on the lungs or elsewhere. In the great majority of cases it is due to the infection by the type of tubercle bacillus found in cattle and conveyed in unboiled cow's milk. Fresh air and sunlight are essential. If possible the child should be taken to the country or the seaside. Complete rest is necessary, but when the child's condition warrants it, this should be on a bed out of doors, or in a long perambulator or invalid carriage. With regard to diet, here also raw meat and eggs are indispensable. Cod liver oil will be useful. One way to give it is to rub it gently into the abdominal wall, or apply it there and cover over with a flannel binder, when the movements of the child will rub it in.

**CONTAGION: How to Avoid.** Infectious diseases may be acquired by direct contact with a person suffering from such a disease, from handling clothing or other articles which have been in contact with him, from infected air, water or milk, or other food, or in some cases the disease may be through the agency of insects.

In public places of refreshment, during a rush of business, the glasses, cups and other dishes would appear often to be washed in a perfunctory manner, and it may be wiser to go thirsty than drink out of a glass which has possibly just been used by one whose mouth is in an infectious state. The use of a hairbrush which is at the disposal of all and sundry involves a risk, at the least, of dandruff, and possibly of ringworm. The same applies to laying one's head on the cushions of a public conveyance. Anthrax has been acquired from shaving brushes imported from abroad, and when a new one is purchased it should be soaked in a disinfecting solution. Various disorders are propagated by air; for example, a common cold, influenza, measles, tuberculosis, etc. In such diseases as consumption where there is much expectoration a sputum flask should be rigorously employed.

There is always a risk of infection through unprotected cuts or sores on the hands. When one has come into contact with a possibly infected person in any way a free use of soap and water, and preferably also of an antiseptic solution, such as permanganate of potash, should never be neglected. A measure of protection more or less effectual is afforded by vaccination against smallpox, by inoculation against enteric fever, etc., and

by vaccines against colds, influenza, and other diseases. *See* Disinfection; Fever; Fly, etc.

**CONTAGIOUS DISEASE.** Disease that is passed from one person to another by contact is termed contagious disease. The person passing the disease may be one actually suffering from it or he may be a carrier: that is to say, that although he may be quite well in himself he carries disease-producing microbes about his body. This may be because he has at one time had the disease, but not necessarily, as people are found with the microbes of such diseases as diphtheria and cerebro-spinal fever in an active form, although they might not have shown the symptoms of the disease or, at any rate, have attracted any attention.

The contact may be of an intimate character, as in ringworm and other diseases; but, on the other hand, clothing which has been worn by infected persons, e.g. smallpox or scarlet fever, may be conveyed hundreds of miles away and infect other people.

In Great Britain the law requires the notification of certain of these diseases, smallpox, scarlet fever, diphtheria, enteric fever, etc., to the medical officer of health, and, if necessity arises, other diseases, such as measles and whooping cough, may be added to the list.

Anyone who knows he is suffering from a notifiable disease must not expose others to infection in any street, place of entertainment, club, hotel or shop; he must not take books from any circulating library; he must not use any public vehicle such as a train, tram or bus; and before he hires a taxi he must tell the driver of his illness. Infected articles must not be sent to a laundry until they have been disinfected.

Any child which has suffered from or been exposed to infection of a notifiable illness may be prevented from going to school. Anyone who ceases to occupy a house within six weeks after some person in the house has been suffering from some notifiable disease must have the house disinfected and give notice, to the owner. A hotelkeeper must, not allow any room in which there has been anyone with a notifiable disease to be used until the room and its contents have been disinfected.

The advantage of notification is that means can be taken at once to isolate patients and those who have been in contact with them. *See* Disinfectant; Fly; Notification; Quarantine; Vaccine, etc.

**CONTRACT: The Legal Sense.** A contract is an agreement enforceable at law. It requires an offer and acceptance of that offer; valuable consideration; and an intention that the agreement shall be a legal one; thus, if one offers to receive a man to dinner in a friendly way, and he agrees to come, it is not a contract. Offer and acceptance may be by word or conduct. An acceptance of an offer is not an acceptance unless it is unconditional. Thus, if one man offers to sell another something for £20, and the other replies that he will take it subject to 5 per cent, discount for cash,

he has not accepted the offer and there is no contract. A contract by post is complete and binding on both parties the moment a letter accepting the offer is posted.

An offer can be cancelled at any time before it is accepted, unless something has been paid for it to be kept open. Thus, if a man asks a tradesman to keep open till Monday at 12 noon an offer to sell him a dress at a certain price, and the tradesman agrees, he can nevertheless cancel his offer before 12 on Monday. But if even a penny has been paid to keep the offer open till that time the tradesman must keep it open. An offer is open for a reasonable time, unless a definite time is specified; and after a reasonable time has elapsed it is automatically cancelled without further notice.

Acceptance must be expressed whether in words or by an act. Thus, a letter says, "You can have the sealskin coat you saw for £50, and if I do not hear from you I shall send it to you." The person to whom such an offer is made is not bound to answer: and if he does not, and the coat is sent, he is not bound to take it. Of course, if he keeps it, he must pay the £50.

A few contracts require to be evidenced by writing. The writing may be signed at the time, or may be contained in subsequent correspondence so long as all the terms of the contract are shown. The following are contracts that must be in writing:

Contracts for the sale of land or any interest therein.

Contracts which cannot be completely performed within a year from the; day they are made, e.g. a contract to engage a governess for a year, the service to begin two days hence.

Contracts in consideration of marriage—not a promise to marry; but such a contract as this: "If you will marry me (or my son or my daughter), I will give you: £100."

Contracts of guarantee.

Contracts for the sale of goods at a price of £10 or over. But if anything has been paid for or on account of the price, or to bind the bargain, or the goods or part of them have been delivered to and accepted by the buyer, there is no need for writing.

Although in either cases writing is not necessary, it is always better to have the terms of a contract of any importance in writing. One should sit down and write a letter, "Confirming our conversation of to-day's date," and set out all the terms agreed on as clearly as one can.

The consideration for a contract required by English (but not Scots) law may be a payment or a promise in pay; doing something or promising to do something. And the payment or the act done need not be for the benefit of the person who makes the contract. Thus, if A chooses to say to B, "If you will give Jones a job as your gardener, I will give you a ton of coal," and B gives Jones the job, A must give B the coal or pay him the value thereof. If one party to a contract fails to carry out its terms, the other may sue him for any damages caused by the breach of contract. Usually this is the only remedy available, but in cases in which damages would not adequately compensate the other party, the party at fault may be compelled to carry out the

contract as he promised. Thus, if I buy from you 1,000 lb. of tea for 1/- a lb. and you fail to deliver, I cannot compel you to do so, because I can probably buy 1,000 lb. of tea elsewhere, and if I have to pay more for it you must pay me the excess as damages. If, however, I buy from you a snuff-box which is supposed to have been used by Prince Charlie and you refuse to let me have it, I can compel you to do so, for however much you may pay me as damages I would probably not be able to buy another snuff-box with the same associations.

In some cases contracts which are otherwise valid may be held to be void on the ground that they are against public policy. Obviously a contract to commit a crime is void on these grounds. Further, any contracts which restrict more than is reasonably necessary the right of a man to carry on his trade or profession are also void. Thus a doctor in a country town, on taking an assistant, could agree that the assistant should not set up in competition in the same district for a certain time. If however the district set out in the contract is wider or the time is longer than the court thinks was necessary to give the doctor reasonable protection the clause will be void. *See Agreements.*

**CONTRACT BRIDGE.** This form of the game of bridge differs in one or two important ways from auction bridge, which it has now almost entirely superseded. It is fully explained under Bridge (q.v.).

**CONTUSION.** Any injury inflicted on the tissues by a blow from a blunt body or instrument which does not break the skin is termed a contusion. The soft tissue below the skin is torn, and bleeding takes place from its vessels. The part is swollen, hot, and painful, and discoloration usually follows. The treatment consists of rest and the application of cold cloths. *See Bruise.*

**CONVALESCENCE.** The period following recovery from a disease, but before the restoration of normal health, is known as convalescence. In acute febrile disorders this usually dates from the final drop in the temperature, but the patient is left with debilitated tissues and organs. This condition is the effect of the fever and the poisons in the blood which were responsible for its production. In the case of diseases, the brunt of which falls on particular organs, there are gross lesions to be recovered from, e.g., ulcers in the bowel in enteric fever, and more or less consolidated lung in pneumonia. The patient's digestive powers and his capacity for exertion are therefore reduced, perhaps very much reduced. He may himself be conscious of this and amenable to necessary restrictions imposed by the doctor, but sometimes he may be impatient, thinking that he is better than he really is. The doctor's instructions must nevertheless be carried out, and on the part of the nurse firmness and tact will be called for.

In changing from slops to ordinary diet there should be a progressive introduction of articles of food which make greater demands on the digestion. Variety should be aimed at, and the cooking and serving should be as attractive as possible. The nurse and not the patient should decide, what food is suitable.

**Food for Convalescents.** To facilitate the composition of the daily menu the following suitable foods may be named, it being understood that those first mentioned are intended to be the sole diet in the first days of convalescence, though they may be continued throughout; but those in the latter part of the list are not selected until after four or five days of uninterrupted progress. All pastries should be avoided.

Milk, alone or with soda or potash water, Benger's Food, Allenby's Diet No. 3, beef tea, strong hock soup, egg flip, thin arrowroot made with milk, tea and coffee.

Calf's-foot jelly, chicken jelly, mutton broth, chicken soup, thin bread and butter, toast, plain biscuits, plain sponge cakes, milk jelly, junket.

Oat flour porridge, revalenta, good milk puddings and custards, eggs poached or soft boiled, steamed fish (whiting, sole, plaice or haddock) with milk sauce.

Cauliflower with white sauce, spinach, tripe or sweetbreads, chicken or rabbit, baked apple with cream, a little fresh fruit.

Roast, mutton or the eye of a tender mutton chop, a boiled mealy potato.

In convalescence from enteric fever the craving for solid food may be very strong, but should be resisted until the doctor gives his permission, as rupture of the bowel through a partially healed ulcer has been a not infrequent sequel to an evasion of his orders. At the same time it must be ever present in the minds of patient, nurse, and friends that while the pace must be regulated, steady progress towards recovery is expected.

In general, convalescence is that period during which a patient either regains or fails to attain a full measure of health; and it has been well said that more lives are ruined by faulty nursing or insufficient care during convalescence than by disease itself. In the home there is no excuse for failing to carry out the simple requirements of convalescence.

Above all things, a cheerful outlook must be maintained, for convalescent patients are very apt to feel depressed. Nevertheless, noise must be avoided, as it exhausts the patient's energy more than he realizes.

Convalescents have been known to shed uncontrollable tears because the voice of the person speaking to them was too loud.

**CONVOLVULUS.** Alternative name for bindweed. There are perennial and annual bindweeds: two of them, *Convolvulus arvensis* and *sepium*, are most troublesome weeds. *Cneorum* is a charming rock garden plant with grey leaves and pink flowers; it needs well-drained soil and a sunny place, and is hardy only in mild districts. Among the annual forms of *convolvulus* are several showy half-hardy plants. They are raised from seeds sown under glass in March, the

seedlings being planted out of doors in May. Seeds may also be sown out of doors in April. *Convolvulus major*, a climbing plant, and minor, of low growth, have flowers in many showy colours—pale blue, crimson, purple and rose. Other flowers often called *convolvulus* are known botanically as *ipomoea*. The loveliest of these is *Ipomoea rubro-coerulea* which bears large blue flowers and is best grown in the greenhouse from seeds sown in spring. *Coccinea* has bright red flowers.

*Convolvulus.* The climbing annual *convolvulus*, a showy summer flower.

## CONVULSIONS:

**Cause and Cure.** In infants and young children convulsions are most often due to teething, indigestion, worms, rickets, or the onset of acute fevers. In grown people the commonest causes are epilepsy, hysteria, uraemia, poisoning, chronic alcoholism, pregnancy, and brain tumour or injury. The rolling of the eyes, jerky movements of the limbs and head, with twitching of the muscles and grinding of the teeth cannot be mistaken. Consciousness is lost, except in strychnine poisoning, where the mind remains clear, and in hysteria unconsciousness is more apparent than real.

If an infant is attacked the doctor should at once be sent for. The infant must be placed in a warm bath, and a succession of cold cloths applied to the head. The duration of the bath will be 5 to 10 min. In adults the convulsion will probably come on suddenly, and the patient falls down if he is on his feet at the time. No attempt should be made forcibly to prevent the movements, but these may be controlled sufficiently to prevent the patient from injuring himself, and if necessary he should be moved out of the way of danger. A pillow or a folded coat should be placed below the head and shoulders, and any tight clothing about the neck or waist should be loosened. To protect the tongue, which is often bitten, cork or a piece of wood, or the handle of a pocket knife, well guarded by a handkerchief, should be thrust between the back teeth.

**CONY.** The old name of the rabbit is now used chiefly for its fur when employed for wearing purposes. Ordinary cony skins come in vast numbers from Australia, and white rabbit pelts either from Normandy and other parts of France: or from China.

Cony is usually treated to imitate one of the more costly furs. Thus white rabbit figures as ermine and, when dyed, as chinchilla, beaver or electric sealskin. White rabbit furs, if first stripped of their linings and wadding, will wash beautifully in a lather of warm soapy water. They should be shaken out well and hung in the open air to dry. *See Fur.*

**COOK.** Except where there is a housekeeper the cook is the head woman servant. She is responsible for the cleanliness of the kitchen premises, though in larger households she takes no actual share in the work of cleaning. The dining room meals are her chief concern. She is often expected to arrange as well as cook them, and probably has a kitchen maid to do the rough work and help with the preparation of the food.

In smaller households where there is neither kitchenmaid nor scullerymaid she is usually expected to do a certain amount of cleaning and housework as well; she is then responsible for the kitchen premises herself, and may occasionally be expected to look after the hall and dining room in the early morning. If this is to be included in her work it should be mentioned when she is engaged. A cook can command higher wages than any other maidservant. *See Chef; Servant.*

### COOKERS: GAS, ELECTRIC, OIL, AND FUEL The Best Examples of Various Types Described and Illustrated

For further information see Boiler; Kitchen; Oven; Range. The entries Electricity; Gas may also be consulted with advantage.

Apart from the ordinary kitchen range, which may be made to burn coal, coke, wood or household rubbish, cookers are constructed to consume three main types of fuel: gas, electricity and oil. For this reason they are dealt with here under these main headings. It should be remembered, however, that the kitchen range usually performs four separate and distinct functions. The first of these is cooking, toasting, heating flat-irons. It heats the kitchen and heats water, usually by means of a boiler at the back of the fire-box, or use in the scullery, lavatory or bathroom, or for warming the house by hot water or steam radiators. It also consumes household rubbish.

When the three types of fuel are used, these functions are performed separately, and it may be necessary when replacing a kitchener to divide up these four functions among the various fuels available. For instance, if gas, coke and electricity are available, a good method is to cook by means of gas or electricity, and to central-heat with coke.

Where electricity is already installed, gas is generally available. Most gas or electricity companies will, if desired, hire out a cooker, and some companies supply cookers on hire-purchase terms, payments for these being made over one or three years.

In considering cost, it may be taken that where the cost per unit of electricity is not more than one-tenth that of the gas therm (e.g. 1d. per unit and 10d. per therm), electric cooking is as cheap as gas cooking. An advantage in the use of electricity is that the heat can be produced in the exact spot where it is required. In a saucepan or kettle the heating coil can be placed in the middle of the liquid. A cheaper rate is allowed for electricity for cooking and heating than for lighting, and for the former purpose a separate meter is installed.

**Types of Gas Cooker.** It is always advisable to examine the latest improvements in cookers within the purchaser's scope.

In some cases it is possible to place a cooker in a recess, either formed by the removal of a kitchen range or in the original plan of the room; this arrangement has the advantage of screening the heat from draughts. The recess should be lined with sheets of enamelled iron, oxidised metal or by tiles to ensure cleanliness. In the small type of kitchenette found in many flats an enamelled cooker, with racks for dishes, etc., is admirably suitable. The latest designs embody such features within the main cabinet of the design, so that the old form of a gas cooker as a machine bristling with "gadgets" has become a compact and simple whole. In the small model, Fig. 1, hotplate burners are self-lighting, and the Regulo control (described below) and taps are built into a single control-panel.

*Cooker. Fig. 1: "New World" gas cooker with Regulo-control. Top: close-up view of oven heat control, adjusted from thumb-wheel at left. Below it, the hot-plate (Radiation, Ltd.)*

#### Oven Heat Control. In

Fig. 2 is shown a type of cooker suitable for the culinary purposes of a larger household. It serves the functions of a complete kitchen range, and may be obtained in various mottled-porcelain designs to taste. The oven is, as in all up-to-date cookers, Regulo-controlled; and the warming-chamber also included can be used for low-temperature cooking as well as for its normal purposes of keeping things freshly hot until dishing-up time and re-heating cooled dishes. The usual plate and saucepan racks are provided, and thermo-static control maintains the desired temperature exactly.

*Cooker. Fig. 2. "New World" range, consisting of a Regulo-controlled oven and (on left-hand side) a warming-chamber for food ready for serving, plates, dishes, etc., which can also be used for low-temperature cooking.*

Other smaller types of cookers also are obtainable with ovens fitted with thermo-static control. If the oven becomes too hot, the gas automatically goes down; should the heat begin to cool off below the desired temperature, the gas goes up again to keep the heat just right. A chart is supplied with the cooker, by which the oven is regulated. The

bottom of the oven is closed in by a baseplate upon which low-temperature cooking — milk puddings, casseroles, etc. — may be carried on while the other items of the meal are cooking above. Gas is economised by having only one burner in the oven instead of two, and by the fact that the flue outlet is at the bottom instead of at the top of the oven, so that the heat is retained for a longer time.

In some makes of cookers the boiling burners are so designed that they do not become clogged, neither will flames be extinguished by liquids boiling over. Each burner is fitted with regulators to ensure an even heat spreading over the bottom of the cooking utensil. Metal disks provide a rest for small saucepans on the hot-plate.

A pre-determined temperature can be maintained without any practical variation, by means of the Regulo oven-heat control (see Fig. 1, top illustration), which operates on the principle of the bi-metallic coupling. Its use has given a considerable impetus to home cooking, owing to the ease with which really good results are obtainable.

**Hints on Cleaning.** Little and often should be the motto for cleaning all gas cookers. The oven, plate-rack, stand, trays, etc., should be all washed every day if possible, but at least once a week. The burners, in particular, cannot be expected to give their highest efficiency and economy unless they are kept scrupulously clean. For this reason, all burners and grids should be easily removable by hand. If very dirty they may be boiled in water and soda. A wire brush is useful for cleaning these (see illustration) and also for removing the dirt from corners and ledges in the oven. Grease should be washed from the cooker with hot water with a little soda in it after the cooker has been used. Grease is easy to remove while the stove is still hot. A preparation is obtainable from most oilmen which can be used with a special brush to remove stale grease. The preparation is left on all night and washed off with boiling water.

*Cooker: how to keep a gas cooker clean. Grids and burners being scoured with hot water and soda. Below. Fig. 4. Removing grease with a special preparation.*

Unless of rustless steel, the bright steel parts should be cleaned every day with fine emery cloth, and the hot-plate grids with a rag moistened with turpentine and then wiped with a dry

cloth.

Unless the unpolished parts of the outside of the cooker are enamelled, they should be cleaned with blacklead daily. If the stove is not going to be used for some time, these parts should be thoroughly washed and dried, then covered with grease. Before using the cooker the grease must be washed off again with hot water and soda. When using a gas cooker always turn out the gas immediately it is no longer needed, and never allow flames to flare-up the sides of pots.

**Hints on Using.** The proper way to heat up a gas oven is to turn the gas half on, light it, and leave the door closed for two or three minutes. Then turn the gas full on for about 10 min., after which the oven will have attained its full heat, and the door should be left open for a minute or two to allow all the steam formed to escape. The oven will then be ready to give out the steady, dry heat required for baking, roasting, etc. It is best to get the oven up to the required temperature to start with, and then lower the gas to maintain this. Never turn on the oven gas without first opening the oven door. Always have a lighted match ready before turning on the gas, especially for the oven burner. Don't heat the oven up specially for one or two small dishes; make good use of it on baking days. As soon as cooking is completed, the oven should be wiped out with a damp cloth. A bowl full of water placed in the oven immediately after cooking is finished and the gas has been turned out will provide hot water for washing-up without extra cost.

Never use a solid shelf in the oven, excepting as a deflector to throw down the heat on to the top of the food being cooked (for browning purposes), as a solid shelf effectively prevents the heat from rising to the food on the shelf above. With all ordinary gas cookers the hottest portion of the oven is at the bottom. Steamers with several compartments over one burner, instead of several pans, each on a different burner, should be employed for this work.

**Fuel Stoves.** On this page is also shown the "Aga" Cooker. It burns coke or anthracite. For cheapness and general convenience coke is preferred. It is remarkably efficient for a household of no fewer than eight people. For smaller families there are smaller cookers working on similar principles.

*Cooker. Fig. 5. "Aga" kitchen unit, designed on the "heat-accumulation" principle, and insulated so that only the heat necessary to warm the kitchen can escape (Aga Heat, Ltd)*

"Heat accumulation" is the idea of this kind of cooker. Food can be well cooked over a small fire, provided that the heat is taken by

conduction and radiation to the various parts of the cooker in the exact proportions required. Large heat-resisting alloy castings inside the cooker are kept, by means of an automatic draught control, at a specific and very high temperature day and night. From these castings the heat is taken to the other parts of the cooker. But the entire cooker itself is insulated so that only the amount of heat necessary to heat the kitchen can escape. Hence kitchens can be cool in summer and warm in winter, with remarkable fuel economy.

**Electric Cookers.** It may be as well to state that with a properly installed electric cooker there is no danger whatever of shock. Electricity, properly used, is such a convenient form of providing heat, without fumes, smoke or smell that it means cooking under ideal conditions. The heat is always constant and there is saving in weight and value of foods cooked by this method.

Generally speaking there is a cheap rate available of about 1d. per unit for cooking purposes, plus a small standing charge based on the rates of the house or whatever the system of the town may happen to be. In the country, however, electricity is often much more expensive. Most supply companies will instal a cooker on simple hire terms, the hire including cost of wiring and fixing.

*Cooker. Fig. 6. Shown at 1938 British Industries Fair, this electric cabinet includes 2-bar fire unit for warming kitchen. (Jackson Electric Stove Co.)*

The heat can be perfectly regulated and controlled in a satisfactory electric cooker. Each part, oven, grill, or boiling plate, is in the larger models independently switched. Temperature indicators ensure scientifically accurate results. Somewhat similar oven control as the thermostat for gas cookers is obtainable in the more expensive electric models, by means of an automatically operating time switch. Electric cookers are easily movable, so that they can be placed where required, and are made in various sizes to suit the requirements of the household.

For the very small kitchen or the bachelor flat, a convenient cooker, illustrated on this page, is the small "Magnet." A useful adjunct to this is a fast-boiling kettle, which boils at the rate of 3 pints in 3 minutes. Such a cooker can, and should, be placed in a good light, within easy reach of pantry and table. Cleaning it is a simple matter; to some extent, it cleans itself, as the current quickly burns away any fat splashed upon it. What fat remains is wiped off with a damp cloth while the oven is warm.

A luxury model, of up-to-the-minute design, is the white-enamelled Cabinet Cooker also shown on this page. The rectangular enclosed rapid boiling plates will

each take four utensils which can be kept boiling or simmering simultaneously. The spacious hot-cupboard has a spring-loaded door with concealed hinges.

*Cooker. Fig. 7. Small thermostatically-controlled "Magnet" electric cooker for general household purposes, comprising oven, grill and boiling plate (British Electrical Development Assn.)*

**Oil Cookers.** For the country cottage, bungalow, camping out, and as an aid to save using a

kitchen range daily for light cookery, one of the various kinds of oil-cookers is invaluable. Oil burners may be divided into two classes: Wick burners and wickless (or pressure) burners. The wick burner works on the principle of the ordinary oil lamp used for lighting purposes, having from one to four burners. Fig. 8 shows an efficient type of cooker for family use with three burners, one being a giant burner for rapid boiling. There is a wick-adjusting apparatus, and a glass door to the oven which obviates the necessity of opening the door to see how baking progresses. The cabinet top possesses a plate rack. The double walled chimneys concentrate the heat where it is required. The wicks should be thoroughly cleaned at least once a week by raising them even with the top of wick tubes and scraping the carbon from the top of the wick with a cleaning tool provided with the stove. The wick is then turned down and the screw top removed and any dirt cleansed from the inner wick tube, the screw top then being replaced. It requires from three to five minutes for the flame to reach full height after lighting. The flame should be a clear blue colour and extend above the top of the grate.

*Cooker. Fig. 8. Oil cooker with three burners and having a glass door to the oven. (Courtesy of Anglo-American Oil Co., Ltd.)*

The pressure type of oil stove (Fig. 9) burns paraffin without a wick. This type of burner first vaporises the oil by ejecting it under pressure through a small heated nozzle, then mixes it with air, and finally burns it in a rose, not unlike a modern high efficiency gas burner. This type of stove is suitable for camping or for use where baking is not required. It can be furnished with accessories for toasting, etc. A similar stove may be obtained with only one burner. A small oven on legs might be added.

A comparison of the working costs can be made by assuming that each burner, when full on, will use from a quarter to half a pint of paraffin per hour. The pressure type of burner is undoubtedly very

economical, but has two main disadvantages. One is the necessity of heating up the burner with methylated spirits for a few minutes before lighting the stove, and the other is that of having to pump up the pressure from time to time while the stove is working.

*Cooker. Fig. 9. Pressure type of oil cooking stove, which burns paraffin without a wick. (Courtesy of Optimus (London), Ltd.)*

The chief cause of all working troubles with oil cookers is dirt. Dirt causes smell, smoke, clogging, and many other ills which accompany such slight details as allowing carbon deposits to form on nozzles, etc.

A good wrinkle with a pressure cooker is from time to time to open the valve after the pressure has been pumped up, but before the burner has been heated. This will force a thin stream of oil through the nozzle and air injector, and carry away any small particles of dirt or carbon deposit.

**COOKIE.** These cakes are prepared by creaming 5 oz. of butter and 6 oz. of sugar. Into these beat an egg, then stir in  $\frac{3}{4}$  gill milk, finally sieving in  $\frac{3}{4}$  lb. flour and 1 teaspoonful baking-powder. Roll out the mixture thinly, adding more flour if necessary, and then form it into rounds. Bake the cookies in a fairly hot oven until they are golden brown.

**COOKING BOX.** When long and gentle cooking is required a cooking box will be found useful, the food being brought to the boil before being placed in the box. To make a cooking box, line a packing-case or sugar box with two or three thicknesses of newspaper, covering the latter with flannel or the type of felting used under stair carpets. Nail this on neatly, and line the lid in the same manner. Make some balls of newspaper, pack them tightly into the bottom of the box to a depth of 3 in., and place the saucepan or casserole on top of them, packing it round with more newspaper balls so that, when it is lifted out, a nest is formed. Should there be room for two saucepans, stand both on the layer of paper, but put a thick padding of paper balls between the two. The cushion or cushions placed over the top can be made of flannel or felting stuffed with paper torn into small shreds. *See Haybox.*

**COOLING: Of Rooms.** In temperate climates a few simple precautions suffice to keep a room cool on the hottest day. Most important of all is the outside blind, which need not necessarily be a sunblind on an iron frame, though that is the most convenient. Any dark blind which comes outside the window pane answers the purpose by preventing the radiation of the

sun on the glass.

Windows should be shut during the heat of the day and the outside blind pulled down. They may be opened again when the heat of the sun has abated, the blinds being then pulled up, provided that the sun no longer shines on that particular window. Where a window may safely be left open all night this should be done, particularly passage and landing windows, which ensure a current of air through the entire house.

Electric fans are of assistance in circulating air and so keeping rooms and passages cool. In rooms with tiled or stone floors, such as sculleries, dairies, and old-fashioned kitchens, a little water may be sprinkled on the floor with a watering-can to cool the air by evaporation. Hyposulphite of soda has a cooling effect when it is dissolving, and some crystals moistened in a dish may be placed on the window ledge and the window pushed up a few inches. *See Ventilation.*

*Coop. Useful and effective type of hen coop, instructions for making which are given in the text.*

**COOP.** A coop is a wooden structure, with bars in front, and is used to house a hen and her brood until the latter are weaned. The bars are so arranged that the chickens can have free ingress and egress to an attached run without the hen. The main essentials in a good coop are durability, security against inclement weather and rats, etc., together with ample ventilation without draughts. When rats are troublesome, a floor is necessary; but, when ever possible, a coop should be located on short grass and moved to fresh ground from time to time.

A coop is quite easily made at home, and the design here given has proved satisfactory either as a sitting coop or as the first home for the hen and chicks; it has been devised for use in conjunction with a small portable chicken run.

Made in sections to bolt together, it can be dismantled and packed away during the winter months. The dimensions are given in the accompanying drawings.

The first thing to do is to make up the front (Fig. 1) and back (Fig. 2) frames from deal  $1\frac{1}{2}$  in. square, the corners being mortised and tenoned and well screwed. Five  $\frac{3}{8}$  in. diameter holes are drilled through the front frame and the iron bars driven through the four outer holes. The central hole is used for a movable rod, which prevents the hen escaping, but gives complete freedom for the young chicks.

The door or cover (Fig. 3) is made from  $\frac{5}{8}$  in. tongued and grooved matchboard, has a batten across the centre, and three 1 in. diameter holes at the top for

## COOP

Diagrams showing how to make the portable coop illustrated. Fig. 1. Front frame. Fig. 2. Back frame. Fig. 3. Door, with three ventilating holes. Fig. 4. Roof. Fig. 5. Side

ventilation. This fits into the front framework, and is kept in place by two turn buttons. The back frame is covered on the outside with  $\frac{5}{8}$  in. T. and G. matchboard. The two sides (Fig. 5) are made up from similar material nailed to battens 2 in. wide and  $\frac{3}{4}$  in. thick at top and bottom. These must be made up in pairs so that the battens are on the outside. The roof (Fig. 4) consists of four lengths of weather-board, preferably moulded and rebated as shown. It is nailed to the  $1\frac{1}{4}$  in. by 1 in. battens, which are at such a distance apart as will just clasp the sides.

The coop is assembled by drilling  $\frac{1}{4}$  in. diameter holes in the two side pieces, near the front and back at  $\frac{3}{4}$  in. from the edges, corresponding holes being made through the framework of the front and back. The front and back are then bolted in place, and the roof put on top and secured to the sides with two stout brass screws on each side, passing through the roof battens and those on the side pieces. A hole is drilled through the roof to permit the passage of the movable rod. The resulting coop is shown in the photograph. The best finish is a coating of creosote inside and out; this is a good preservative and an efficient insecticide. *See Chicken; Poultry.*

**COPAIBA.** An oily resin obtained from the bark of a S. American tree contains a medicinal oil which has been extensively employed in the treatment of gonorrhoea. It has also been found helpful in chronic bronchitis. The dose of copaiba is  $\frac{1}{2}$  to 1 fluid dram, and that of the oil is 5 to 20 minims. The oil may be taken in capsules or in mucilage of acacia, prescription consisting of copaiba 2 drams, mucilage of acacia 2 oz., peppermint-water 8 oz. The dose is 2 tablespoonfuls 3 times daily after food. Pron. Co-pā 'ba.

**COPAL VARNISH.** This hard clear varnish is usually employed in finishing carriage bodies, and because of its durability and brilliance is suitable for all outdoor work, or for indoor work subject to hard wear. Varnish made from the darker tinted copal is in no way inferior to the lighter grades, but it fetches a lower price because its usefulness is more restricted. Colourless varnish can be used for covering very delicate colours, but the deeper coloured variety is only suitable for such purposes as varnishing wall-paper or for dark woodwork where the yellow tinge will not mar the body colour.

Oil should on no account be added to varnish, or it will be found almost impossible to get it to dry. Thinning should be accomplished with turpentine. The varnish should be stored in dry airtight vessels. *See Varnish.*

**COPENHAGEN WARE.** The hard porcelain produced at the Royal Copenhagen factory stands in the front rank of technical precision and decorative excellence. Employing a high percentage of pure Swedish crystallised felspar, combined with fine china clay which is obtained from Cornwall and elsewhere, it

yields a singularly limpid white ware.

*Copenhagen Ware. Vase with characteristic pattern. (Courtesy of Danish Art Galleries, London)*

Copenhagen ware dates back to 1772. Its most characteristic designs, in cool, under-glaze blues, greys and greens, are sometimes based upon the virile motives of Scandinavian art, sometimes suffused with Japanese feeling, and these are imitated by Japanese potters themselves. Besides dinner and tea services, there are charming figures of birds, fishes, and the like, both in white biscuit and in subdued tints, together with reproductions of Thorwaldsen figures and reliefs. The mark is a triple wavy line in under-glaze blue. *See China.*

**COPPER:** The Metal. Although displaced to a great extent by aluminium for cooking utensils, copper is still used for preserving pans, kettles and moulds, while for other household purposes, such as accessories for the fireplace, and for appliances such as geysers, boilers and electric fittings, it is a satisfactory metal. Extremely ductile, malleable and tenacious, it is the best known conductor of heat and electricity. It possesses a beautiful colour, and if suitably chosen for decorative objects may enhance a room.

For culinary purposes the drawback to its use, besides the initial expense of copper articles, is that acids on its surface form poisonous salts. To obviate this, cooking vessels should be tinned on the inside, as tin does not form salts, nor is it acted upon by weak acids or other substances met with in articles of food. Utensils such as kettles and coffee percolators are satisfactory in copper; they rarely need returning, as there is nothing in their ordinary use to wear the lining. It is an economy to have a tinned iron kettle with a copper bottom.

If kept scrupulously clean and well dried after washing there is no danger in using un-lined copper

preserving pans and moulds. If allowed to remain dirty or moist the two chief poisonous salts which might form are verdigris and copper carbonate. The first is formed by the action of vinegar on this metal, the second on wet copper by the action of carbon dioxide, always present to some extent in the air.

**Cleaning Methods.** Decorative articles or those partly decorative and partly utilitarian, like fireirons, knockers, coal scuttles, etc., are usually covered with a lacquer when new, chiefly composed of shellac, coloured, and dissolved in alcohol. This solution is painted on to the article and prevents tarnishing and oxidation. As long as the lacquer remains, no cleaning is necessary. Any good metal polish that does not corrode can be used for articles not employed for culinary purposes, e.g. hot pipes and geysers.

Cooking utensils require special care in cleaning. Scouring with silver sand and soap is an excellent method. When the copper has been well rinsed and dried, a brilliant polish can be obtained by rubbing over a little paste made of whitening and water. Bath brick moistened with water and soap or any other gritty cleaning powder can also be used for cleaning.

**The Manipulation of Copper.** One or two practical hints may be serviceable to the amateur craftsman who desires to undertake work in copper, for it has peculiarities that render it easy to work in some ways and more difficult in others. It is easily bent, curved, or beaten to any desired shape or bent to acute angles without fear of cracking. For ornamental purposes it is embossed and worked up into plaques and decorative panels. When a plain lathe is available sheet copper can be spun into circular forms, such as flower-bowls. But the metal is difficult to machine, as it is liable to tear; drilling and sawing are more troublesome than with brass. Copper adheres to and clogs the cutting edges of tools, and it is therefore necessary to use a lubricant, either milk or tallow or a mixture of lard, oil, and turpentine. To file copper without tearing the surface French chalk should be employed as a lubricant.

Do not use copper for bearings or on working surfaces, as it is difficult to keep it from seizing, and it would speedily wear away. Copper wire is useful for binding metal fittings to hose pipes, for the fastening of rods and canes, and any purpose where a secure joint is needed more durable than one made with string. A difficulty sometimes is the selection of a suitable gauge of metal for a particular job. In general copper pipes are satisfactory in Nos. 18 or 16 gauge; sheet copper for spinning in No. 22 gauge; for beaten metal work about No. 24 to No. 20 gauges will be found to answer very well.

Copper nails and rooves are used for making joints between the planks of small boats, and can be used for other purposes where an iron or steel nail would be objectionable on account of rusting, as for lead flushings or gutters. Small copper rivets and washers, or burrs, are invaluable for making riveted joints in sheet metal, and are available in convenient sizes at

most ironmongers. Thin sheets of copper can be pierced by sawing with a fine metal-cutting fret-saw, by punching, or by cutting with very keen cold chisels.

Sometimes the amateur is confronted with a damaged piece of copper, such as a cracked pipe. In general the best method of repair is by silver soldering or brazing. To solder copper with ordinary soft solder, it is first necessary to tin the surfaces to be united. When hard or silver solder is used the borax is generally applied to the joint, and the silver solder melted by means of a blow pipe (q.v.), heat being applied until the solder has flowed properly into the joint. The brazing of copper requires care, as the melting-points of the copper and the spelter are very nearly alike. For all ordinary small pipe joints, such as those found in motor vehicles or in hot-water installations, silver soldering is preferable to brazing.

### How to Bend Copper Pipes

The bending of small copper pipes can often be satisfactorily carried out with the hands alone, especially if the copper be soft or well annealed. If the bends are very sharp it will be desirable to grasp the pipe between two pieces of wood held in the vice, and tight enough to hold the pipe, but not so tight as to crush it. The object is to prevent the tube from buckling or flattening. The pipe can then be pulled into shape by slipping a larger-size pipe over the outside where it is desired to keep it straight. This localises the pressure and whereabouts of the bend. Pipes about  $\frac{1}{2}$  in. diameter and upwards are generally bent in a pipe-bending machine, or are filled with sand, which must be rammed hard and the ends securely plugged.

The annealing of copper for amateur use is a very simple matter; merely heat the copper to a uniform dull red heat and immediately plunge it into cold water, and leave it to cool. If any hollow work has to be annealed, take special care to avoid the escaping steam.

**COPPER: The Boiler.** A washhouse boiler, generally made of galvanised iron, is known as the copper, and the best sorts are in fact made of copper. There are two types: one is built into a brickwork furnace, and is found generally in older houses: the other, the portable type, consists of a metal exterior that supports the inner pan or copper. The bottom part is adapted to receive a gas burner, a high-pressure oil burner, or an ordinary coal or wood fire. Some patterns have removable pans, a draw-off tap, and a steam escape pipe connected to the flue pipe.

To instal a portable copper the only fitting necessary is to provide a good, solid, fireproof base, and to see that no part of the copper is near any woodwork or inflammable material. The smoke box terminates in a socket, into which is fitted the cast-iron or sheet-iron stove pipe, which is preferably taken directly out to the air by breaking through the brickwork of the wall, and then fitting a canister elbow with an inspection door in it, and carrying the stove pipe upwards to a point some 3 ft. above the level of the roof and terminating in a

cone cowl.

The inside of a copper should be thoroughly washed and dried, and any signs of rust carefully guarded against. If greasy, it can be cleaned with paraffin and soft soap, then scoured, and afterwards rinsed with hot water. Coppers should be filled before the fire is lighted, and emptied after the latter has been put out. Coke and cinders, being cheaper than coal, are frequently used as substitutes for the latter in copper fires. *See Laundry.*

*Copper or boiler for washing clothes, heated by a gas burner.*

**COPPER NUCLEINATE.** The organic preparation of copper known as copper nucleinate is made by combining its oxide with nucleol, a substance obtained from yeast. It is a fine powder and 5 to 10 per cent solutions have been found useful in various forms of conjunctivitis (q.v.), for example, trachoma or granular ophthalmia. This preparation is known also as cuprol.

**COPPER SULPHATE.** In medicine copper sulphate is sometimes used externally as a caustic or internally as an astringent or as an emetic. As an astringent the dose is  $\frac{1}{4}$  to 2 gr. and 5 to 10 gr. as an

emetic. It is a useful emetic in narcotic poisoning and in acute phosphorus poisoning. As blue stone it is used in reducing "proud flesh." In styes, after pulling out the affected eyelashes the parts may be bathed with a 1 per cent solution every hour or oftener. The lashes will grow again in the course of time.

Poisoning by copper sulphate produces vomiting, abdominal pain and more or less shock. The doctor should be sent for. The vomiting should be encouraged by copious draughts of tepid water. White of egg or rich milk should be given after the stomach has been thoroughly emptied. Rest in bed, with warmth to the feet, and stimulation by tablespoonfuls of hot strong coffee comprise the rest.

**COPYING: In Photography.** In copying pictures, photographs, engravings, and printed matter, it is necessary to use a  $\frac{1}{2}$ -plate or larger camera with a good lens and a ground glass focussing screen. If a smaller camera is used it will generally be necessary to make enlargements from the negative, which will not always give results as good as direct prints from larger negatives. Roll film cameras cannot be used, and the best results will be obtained with backed plates.

Very short focus lenses are unsatisfactory for this work; but the longer the focus of the lens the greater must be the extension of the camera bellows.

The print to be copied must be fixed in an absolutely vertical position and the camera pointed squarely at it, otherwise some portion of it will not be sharply in focus. The original may be pinned to a door or wall. A good working arrangement is illustrated in Fig. 1.

The best arrangement for regular work is to have the camera in a fixed position, square to the easel, the easel itself being supported on runners so that it may be moved backward and forward in line with the camera, according to the size of the original to be copied. The final focussing is then done with the camera.

The lighting is of the greatest importance. Light must be evenly distributed over the whole subject. Perhaps the best is obtained out of doors on a north wall (not in the sunlight). Indoors, a room with a good north window will serve if care be taken that the camera itself cuts no light from the object.

Artificial light is satisfactory if properly arranged and controlled. Two lights of equal strength, placed on either side of the copying board and shielded from the camera lens (Fig. 2, A and B), or one strong light immediately above the centre of the camera (Fig. 2, C) may be used. Electric light is easily arranged with sufficient flex. Magnesium ribbon is one of the best artificial illuminants. Two pieces can be burnt simultaneously, as at D and E (Fig. 2), or one, centrally, as at F (Fig. 2).

An excellent way of using magnesium is to erect a screen of tissue paper, with the camera lens projecting through, and burn about a foot of ribbon behind it, moving it about during the exposure.

## COPYING

Copying. Fig. 1. How to arrange camera and copying board.

Fig. 2. Method of arranging artificial lights to secure even illumination of the object being copied.

To test evenness of illumination when two lights are used, place a pencil in front of each light. The shadows ought to be of equal depth. If on looking at the original through the focussing screen or over the top of the camera any reflection of the light from the surface of the original is seen, the light must be diffused by means of tissue paper, or a thin handkerchief held in front of each light. Altering the position of the lights will also reduce the trouble.

**Panchromatic Plates.** If the picture to be copied contains much colour (especially reds, browns, yellows, or greens), colour sensitive or panchromatic plates must be used in conjunction with a light filter in front of the lens. Similarly, if an old print has brown stains (foxing), or an old photograph is yellow and faded, much the best results will be obtained by using panchromatic plates and a light filter. An old photograph should first be cleaned by rubbing with cotton-wool, part of the aged appearance being due to dirt. Exposure in copying is largely a matter of trial and error, but, in general, there is little risk of over-exposure. Out of doors an exposure meter can be used. Indoors, near a good north-lighted window, at mid-day in bright weather, using a stop of f 16, ordinary medium speed plates, from  $\frac{1}{2}$  to 1 min. would probably be sufficient.

With artificial light from 2 min. to 2 hours may be required. It is best to waste a plate at first on a trial exposure. Drawing out the slide about  $\frac{1}{4}$ , a minimum estimated exposure of, say, 5 min. with a strong light may be given. Exposing each successive  $\frac{1}{4}$  of the plate for double time, i.e. starting with 5 min. and then giving 10, 20 and 40, the correct exposure can be judged after the plate is developed and printed. Thereafter, if the same lights and the same plates are used and the same distance kept between camera and copying board, no difficulty will arise. If it is necessary to make copies in different sizes, reference should be made to tables of relative exposures in a photographic text-book. It is particularly desirable to keep to the use of one kind of plate in copying work to obtain uniform results. *See* Blue Print; Panchromatic; Photography.

**COPYING INK.** A special ink is used to copy letters by pressing them upon damp tissue paper. This copying ink is best made by evaporating 10 volumes of ink until reduced to 6, and adding 4 volumes of glycerin. Sugar candy dissolved in the ink may be used in place of glycerin. Ink for copying pads or hectographs is made by dissolving methyl-violet aniline dye 1 oz., in a mixture of water 7 oz., and methylated spirit 1 oz. *See* Ink.

**CORAL:** For Wearing. The value of coral, which is fashioned into many pretty articles of jewelry, depends upon its colour and upon the high polish which its close, hard texture permits it to take. It varies from a deep red to a delicate rose or flesh tint, and sometimes a milk-white variety is obtainable. Coral is essentially suited for children's ornaments. A string of pink coral beads is a favourite christening gift from godparents to

a baby girl.

**CORAL SPOT.** No fungus is more plentiful on dead twigs and dead branches and more familiar to every gardener than the coral spot. It is abundant and conspicuous in damp weather on dead branches of elm, lime, poplar, sycamore and many other trees, and is always to be noted plentifully on old pea-sticks, particularly hazel, in autumn and winter. The coral spot fungus may be recognized by the small pink or flesh-coloured warts which are thickly scattered over the surface of the dead and dying branches. The warts are spore-pustules, which consist of fungus filaments bearing masses of spores.

On fruit trees coral spot is particularly common on red and black currant and gooseberry, but it also attacks apples and pears. The fungus gains entrance in two ways, viz., through dead branches and through wounds. All dead shoots and branches should therefore be removed during pruning and care taken that no snags which will die back are left. Injury to bushes should also be avoided, whether in pruning or in cultivation with the hoe. Wounded surfaces should be protected by tar. Diseased branches should be cut clean out, taking care to cut back to healthy wood and to protect the wound.

Accumulations of dead wood and sticks should never be allowed in an orchard. On such debris fungi of all sorts flourish, and millions of spores are liberated and blown amongst the trees. The better the sanitary condition of the orchard, the less the chances of infection by fungus parasites. This information is taken from Leaflet 115, issued by the Ministry of Agriculture. *See* Apple; Black Currant; Gooseberry; Peas; Red Currant, etc.

**CORBEL:** In Architecture. This term is now used of any masonry built in tiers outwards from the plane. Even the upper storey of a house that overhangs a lower storey may be said to be corbelled. In modern building, however, the term is chiefly employed in connexion with purely ornamental features, generally stonework, but sometimes timber, on the exterior of a house, and is rarely seen except on structures of some pretensions. In the latter a corbel support for an oriel window sometimes affords effective relief to the façade of a house.

In brickwork corbelling is a method of laying bricks where one or more courses project above the others. Corbelling reduces the stability of the wall, unless compensated by a beam or floor joist, spanning the space between two walls. *See* Brick.

**CORD:** How to Purchase. Wholesale, the cheapest way to buy cord is in a 50 yd. hank. The poorer quality cord is used for clothes lines, which should be well washed before use, to prevent the clothes from getting soiled. The better quality cords are used as sash cords, blind cords, for hanging pictures

and binding cushions. Thick cord is necessary for window sashes, and for this purpose a special kind is sold. Linen blind cord has two qualities. It can be purchased in white, green, crimson and brown. Upholstery and cushion cord is sold by the yard in any colour. Fancy cords of twisted silk and silk mixtures are used in fancywork and upholstery. Piping cord is used in gauging cushions and to cover seams in dresses, etc. *See Airer; Blinds; Clothes Line; Picture; String.*

*Cordon: method of training fruit trees. A treble vertical apple is here shown. (Courtesy of Laxton Bros.)*

**CORDON: For Fruit Trees.** These are invaluable for small gardens, for they take up little room and produce first-class fruits. There are both upright and horizontal cordons. The single-stemmed upright cordon is chiefly grown, though each tree may be trained with two or three stems. The horizontal cordon, which is very useful for planting alongside a garden path, has a stem about 12 in. high and one long branch, trained horizontally, on each side. Single-stemmed upright cordons may be planted at 18 in. apart, those with two or three branches must obviously be placed farther from each other. Instead of being perpendicular, the branches are often trained at an angle of 50 degrees to

prevent the growth becoming vigorous at the top and weak at the base.

Apples and pears are chiefly grown as cordons. Plums do not flourish in this form. Gooseberries and red and white currants do well as cordons. The trees may be trained against a trellis in the open border or on a wall. Cordons must be hard pruned or they will soon cease to be cordons. The side shoots which grow in summer are pruned to within about six leaves of the base in late July, and these shoots are again shortened in winter, leaving only two or three buds. As the trees age the fruit spurs will become large, and a few of them ought to be cut back every year. Summer growth at the top of the cordon is pruned by about two-thirds every winter until the tree has reached the desired height. It must then be treated in the same way as the side shoots. Vigorous varieties of apple and pear are not so suitable to grow as cordons as those of moderate vigour. *See Apple.*

**COREOPSIS.** The annual and perennial coreopsis are very free-flowering hardy plants; they yield a wealth of long-stemmed flowers in summer. The best of the perennials are *grandiflora* and *auriculata superba*, both having yellow flowers; they are, however, not long-lived,, and it is usual to treat them as biennials and raise a fresh lot of plants each year. Seeds are sown out of doors in June to provide plants that will flower the following year. The seedlings are set in their final position in October. The annual forms of coreopsis are sown out of doors in March—April, where they will bloom from July onwards; *tinctoria*, yellow, *atrosanguinea*, dark red, and *Drummondii*, yellow, are some of the best.

*Coreopsis. Golden-yellow flowers of Coreopsis grandiflora.*

**Corer.** *See* Apple Corer.

**CORIANDER.** Flourishing in light, warm, sandy soil, coriander is a hardy annual which produces white flowers on stems 1½ to 2 ft. high in June. As it soon runs to seed, those who want a continuous supply should sow at intervals from March onwards, and thin to about 9 in. apart. Coriander is almost exclusively grown for the seeds, which are used in the manufacture of liqueurs such as kummel.

It is also used in medicine, the dried ripe fruit being an aromatic and carminative. It yields an oil, of which the dose is ½ to 3 minims. This is used in some of the preparations of rhubarb and senna to prevent griping.

Coriander is also used for flavouring confectionery, and forms one of the chief ingredients in the making of curry powder. The leaves may be used in salads.

**CORK:** For the Home. The light, porous bark of the cork-oak has numerous applications in industry, and is chiefly found in the domestic sphere in the form of stoppers for bottles, floats for fishing-lines, and cork mats. For the latter purpose it is prepared as a composition. Cork linoleum is an instance of its use in industry. The amateur can repair cracks and bad places in cork linoleum by using a paste composed of finely powdered cork and shellac varnish or hot beeswax. This is pressed into the cracks and smoothed off with an iron bar, warmed to prevent the shellac chilling too quickly. Colouring pigments may be added.

A cork that is a little too large for the bottle may be made to fit by rolling the cork on the floor and pressing upon it with the sole of the boot. When a cork becomes lodged in the neck of a bottle an effective way of loosening it is to hold the neck before a fire, or to wrap it up tightly in a thick piece of cloth which has been previously heated. This will have the effect of expanding the glass slightly, and the cork will then come out readily.

**Cleaning Hints.** Instead of throwing away old corks it is worth while to collect them in a box, because of their practical value as cleaning agents. A cork dipped in paraffin is effective in removing rust from metal and stains from lamp-glasses and hearth-tiles, while disfiguring marks on polished wood and also on wall paper and window-panes will often yield to treatment with a dry cork. Stains on aluminium and enamelled saucepans can be removed by means of a cork dipped in salt, and kitchen knives, together with any cutlery not made of stainless steel, are best treated with a moistened cork rubbed along a bar of household soap. Burnt marks on plates can be removed by means of a cork dipped in a little damp salt; spots on linoleum disappear when rubbed with a cork repeatedly dipped in benzine or petrol. *See* Bottle; Bung; Cramp; Linoleum; Mat.

**CORKSCREW.** The ordinary corkscrew made with a wooden handle and a twisted wire worm or screw does not always get a sufficiently powerful grip

on the cork, and sometimes pulls out, leaving the cork in the bottle. Another type of all-metal corkscrew has a cast metal handle with ears at the side to provide a powerful hold.

Many kinds of self-extracting corkscrews have been evolved. In one characteristic type the worm is driven into the cork by turning the handle at the top. This drives the cage down until it engages with the top of the bottle. Further rotation of the handle draws the cork out of the bottle, this being accomplished by the screwed shank of the worm itself, which winds its way up the cage, bringing the cork with it.

In the absence of a proper corkscrew a cork can often be drawn by screwing a stout wood screw into it and grasping the head with a pair of pincers. Another method is to insert two knife blades between the cork and the neck of the bottle and on opposite sides of the cork. By grasping both knife handles with a cloth the cork may be removed with a screwing motion. *See* Bottle.

**CORK SOLE.** These inner soles are usually made of compressed granulated cork, covered with felt, and are used either to secure increased warmth for the feet in cold weather or to fill footwear which is slightly larger than required. The comfort attendant upon wearing cork soles can be increased by fixing them to the soles of the boots with dextrine paste.

Cork soles can be manipulated to afford some relief from the tortures of an enlarged toe joint or a callus on the sole of the foot. Remove the stocking and moisten the affected joint or the hardened skin so that when placed upon the cork sole their exact position will be clearly indicated. With a sharp pocket-knife cut away the part of the sock marked, slanting the knife so that the edge of the cut will slope outwards. Sockets will thus be formed that will relieve all pressure upon the affected parts.

A common fault in walking, namely, treading over the heel, can be cured by a cork half sole cut as follows. Procure a piece of cork ¾ to ½ in. thick, as long as from the heel to the ball of the foot and half as wide as the tread. With a sharp knife cut this on one edge to the shape of the foot. This should be pasted into the boot with dextrine on the side which is usually trodden down. *See* Boot.

**CORN:** How to Remove. Pressure or prolonged rubbing on the toes or soles of the feet causes thickening of the skin into painful circular swellings with a core or eye in the centre. These are hard corns, but where the feet perspire freely soft corns may develop. Tight boots are a common cause of trouble, and before anything can be done they must be exchanged for boots that fit easily and so relieve the pressure. Ridges, creases, or lumps inside boots may be responsible for corns, and in such cases the boots should be sent to the shoemaker for attention. Often a pair of cork soles is of assistance.

Corns are removed either by cutting or by applying a plaster or solvent of which salicylic acid is generally the base. It may be used in the form of salicylic collodion, collodium callosum, or salicylic plaster 10-40 per cent. The collodions are painted on and allowed to dry. If the plaster is used, a piece sufficient to cover the corn is applied and kept in position by a strip of adhesive plaster. These preparations may be left on for 4 or 5 days, when the softened skin is peeled off, and another application made if required. If necessary, the foot may be soaked in hot water to get the dressing off.

The removal of corns with a razor or knife requires some skill and care. If bleeding occurs an antiseptic dressing should be applied to prevent poisoning of the wound. For soft corns socks with separate compartments for each toe, similar to gloves, may be worn or pads of cotton-wool may be placed between the toes during the day. The thickened skin should be removed by applying a salicylic plaster, or a little piece of felt with a central hole to fit over the corn may be used to separate the toes, the hole in the centre being filled with powdered salicylic acid. The skin between the toes should be frequently washed and carefully dried and painted once a day with spirit of camphor. A zinc powder may then be dusted on. *See Bunion; Chiropody; Foot.*

**CORNCAKE.** These cakes are of American origin and are made of the best yellow maize meal. Mix together 1 breakfastcupful each of maize meal and milk, quarter of a cupful sugar, half a teaspoonful salt, 3 level teaspoonfuls baking powder, 1 well-beaten egg, and 1 tablespoonful warmed butter. Blend all these very thoroughly and spread the mixture in greased tins until they are half full, baking them in a hot oven.

**CORN COB.** These green cobs should be cooked quickly after they are cut, as they soon deteriorate. Remove the husks and strip off every thread of the silky fibre. Take some of the cleanest of the husks, wrap these round the cobs, and tie them in place. Lay the cobs in boiling, slightly salted water to cover them, and cook them quickly for about 10 min. after the water reboils. When nearly cooked, try one of the kernels to see if the raw taste is destroyed; if so, drain them at once from the water, or the kernels harden and lose flavour. Then remove all the outer husks and serve the cobs on a hot dish with oiled butter, seasoned with cayenne and salt. When eating the corn, score each row of kernels through with the point of a sharp knife, pressing out the centre of the grains with the teeth or the knife, and leaving only the indigestible hulls on the cob.

Another way to prepare the green cob is to make it into fritters or rissoles. Grate or chop the grain finely, allowing to every breakfastcupful 2 eggs, 1 dessertspoonful of melted butter, twice that amount of milk, and about a tablespoonful of flour. Beat the eggs well, and while still beating them slowly drop in the grated corn. Season the mixture, then add the melted butter and the milk, and bind the whole with the flour. Form it into round flat cakes, and fry them in hot fat. This dish should be served very hot. The unripe grains

of the corn cob are roasted to make pop-corn, while hominy, maize meal and cornflour are all products of the ripened ear. *See Cornflour; Hominy; Maize.*

**CORNEB BEEF.** A round of beef is required, and this must be pickled and then slowly simmered. To pickle the beef, 2 quarts water to  $\frac{1}{2}$  lb. common salt, 3 oz. brown sugar, and  $\frac{1}{2}$  oz. saltpetre must be used. These ingredients should be boiled together for 10 min. and then skimmed and strained. When the liquor is cold the meat should be immersed in it and allowed to remain for about 10 days. The use of an earthenware vessel is advisable for this process. After the 10 days' immersion, the beef should be boiled up with sufficient warm water to cover it, simmered gently for 2-3 hours, and lifted out when cooked. *See Beef.*

**CORNER CUPBOARD.** (*For diagrams see pg. 537*). The corner cupboard is a cupboard made to fit in the corner of a room. It originated in the 18th century, and soon became a decorative piece of furniture. It was made of oak and mahogany, and some had a glass and some a solid front. Many were inlaid with ebony, box and satinwood. Instructions for making a hanging corner cupboard in the Chippendale style are given in the article Cupboard (q.v.).

A corner cupboard as shown in Fig. 1 is of service in utilising space that would otherwise be lost and often furnishes an awkward blank. It can be tastefully handled without elaborate construction, and whether finished with a straight or bow front, should not set up undue difficulties. The height from ground to table top is 3 ft. and depth on angle back to front is put at 1 ft. 6 in., which will give a width over front of 2 ft. 1 in. These sizes can, of course, be altered slightly to meet individual requirements.

The style of the cupboard would agree with Chippendale furniture of the earlier period, and either walnut or mahogany would be a suitable wood to use. Oak, stained to a nut-brown colour and with panels bevelled, would achieve a good result. The cupboard can also be made of birch, American whitewood or pine, painted green, grey, fawn or pink, to suit the colour scheme of the room in which it is used. The cupboard can, of course, be constructed to size in several slightly varying ways, and it is rather with the lighter and cheaper method that these details and notes are offered, the enlarged sketch of cabinet front (Fig. 2) giving an alternative finish to Fig. 1.

The top (A, Fig. 3) can be of  $\frac{3}{8}$  in. thickness (or even  $\frac{1}{4}$  in. hardwood if of picked wood, sound and dry) glued up of narrow boards with the grain reversed, to cut 1 ft.  $7\frac{1}{2}$  in. by 1 ft.  $7\frac{1}{2}$  in. on the angle. The frame front (B) is finished hollow mould, as indicated, to a curved line showing 3 in. to 4 in. projection in centre, and the top (A) will follow this line with  $\frac{1}{4}$  in. projection beyond it. (*Continued in page 538*)

## CORNER CUPBOARD

Left. Fig. 1. Bow-fronted cupboard.  
Below. Fig. 2. Alternative design for the bow-fronted cupboard.

Figs 3-12. Diagrams showing how to make the corner cupboard illustrated.

## CORNER DRESSER WITH WORKING DIAGRAMS SHOWN BELOW.

The piece will be finished  $\frac{7}{8}$  in. thick, making (with the top)  $1\frac{1}{8}$  in. thick. It has a mortise cut in each end. A length of material 2 ft. 3 in. by  $\frac{3}{4}$  in. net will allow for paring to shape. The angle battens (C) are rebated into each other in the corner at back and halved into B at front, the mortise being cut through both. Pieces 1 ft. 6 in. by 3 in. by  $\frac{7}{8}$  in. net will answer for these; they are set in  $\frac{1}{4}$  in. from angle edges of top (A). The inner lining of top (D) can be of  $\frac{3}{8}$  or  $\frac{1}{4}$  in. thickness, cut to finish flush with angle edges of C, but set in sufficiently under B to serve as a stop for the doors to close against when hinged. The bottom frame (E) can be put together in a similar manner of material about  $1\frac{1}{2}$  in. thick, the bottom (F) being glued and panel pinned down to serve as a stop for doors in line with D above. The upright (G) finishes  $2\frac{3}{4}$  in. by  $\frac{7}{8}$  in., or in pine had best be made up to  $1\frac{1}{8}$  in. thickness, with  $\frac{1}{4}$  in. hardwood facing. A length of 3 ft. will include joints and paring.

The angle sides (H) of  $\frac{3}{8}$  in. or  $\frac{1}{4}$  in. thickness, tongued or butted together, can be nailed into rebate top and bottom or can be grooved in. The part plan (Fig. 5) refers to the above and indicates, in the wall angle, an upright (J) tenoned top and bottom in similar fashion to G, of material  $1\frac{1}{2}$  in. by  $1\frac{1}{2}$  in. or so.

The doors, as Fig. 2, with flush fronts to finish in line with uprights (G), are made up on a framing in the manner indicated by Fig. 11. Two uprights  $1\frac{1}{8}$  in. wide, and three rails, say 2 in. wide, are halved and screwed together. The rails can be cut to shape from the solid, or laminated on a template to finish  $\frac{5}{8}$  in. thick in oak or other hardwood, and  $\frac{7}{8}$  in. in pine. They are then faced with stout three-ply or  $\frac{1}{4}$  in. hardwood boards, which require to have the meeting edges slightly bevelled to obtain a good joint.

#### Details of Door Construction

The material used should be thoroughly well seasoned, and the surface of door can be veneered. The angle of bevelling is easily ascertained from the working drawing by a pencilled line connecting the set-out of meeting edges with the centre from which the front curve is struck. The doors are hung on uprights with fancy plate hinges of the Queen Anne type, or a form of strap hinge could be adopted. In the design illustrated at Fig. 1, a three-beaded fillet, to finish with  $\frac{1}{8}$  in. projection beyond face of doors, is fitted to the meeting edges in centre, size being  $\frac{3}{8}$  in. by  $\frac{3}{8}$  in. thick. (See detail in Fig. 12.)

A more substantial method of construction is indicated by the part plan (Fig. 4). In this way the angle sides are framed up by mortise and tenon and grooved for panels to finish flush inside, the whole being tongued into the uprights (G) and rebated together in the wall angle. Both bottom and top are then rebated and dovetailed flush into the frames and pilasters and afterwards screwed. A little relief, in a simple way, can

be given to the uprights (G) by mounting a length of moulded flat after the manner indicated at M, Fig. 9. This also indicates the cabinet as finished with a straight, instead of a shaped front, the doors being of the usual mortise and tenon type, with panels rebated in and beaded from the back. In this case a  $\frac{1}{4}$  in. ovolo mould worked round the panel opening has a neat effect. Stiles can be  $1\frac{1}{2}$  in. wide and rails 5 in. wide by  $\frac{7}{8}$  in. thick. Ball feet of the bun pattern can be fitted, cut and shaped from blocks 3 in. by 3 in. by  $1\frac{3}{4}$  in., and screwed on.

The interior fittings consist of three shelves supported on  $1\frac{1}{2}$  in. by  $\frac{3}{4}$  in. fillets, screwed and glued to the angle sides, or toothed into the uprights. The front edges of the shelves may be made to heighten the effect of the cupboard when opened by shaping them to either of the alternative lines indicated at Fig. 6. A section of upright (G) entering top is seen at Fig. 7, and a section for built-up top with door closed at Fig. 8. Fig. 10 is an alternative mould for the front of the cupboard. See Cupboard; Lacquer.

**CORNER DRESSER.** (For diagrams see page 537) The corner dresser shown in Fig. 1 is made in oak, and embodies in its detail many Jacobean features. Nearly all the joints of the under part are of the mortise and tenon type, the only awkward part being the juncture of the sides into the front legs (Fig. 4), for since the legs are turned it will be obvious that the square portion at the top must not be cut away at a greater depth than the top member of the turning.

This difficulty can be obviated by setting the job out full size, as in Fig. 3. Fig 4 shows just how much to cut away and how the side of the leg is cut in to take the side rail. The back and the front legs are from 2 in. squares, and the two side legs 2 in. by 1 in. These should be first prepared to shape (the front legs being turned) and mortised and all rails cut out. The tenons of the side rails should be run right through the side legs and be wedged from the back. When glueing together, it is advisable to glue the front first and allow it to set; then glue the two back framings and finally the sides. It is necessary slightly to strain the rails outwards when doing this.

When dry, the drawer runners are fixed. It is impossible to allow the drawer to take up the full width of the front, as this would mean that the drawer would have little or no depth. The difficulty is surmounted by recessing the drawer sides from the ends, as in Fig. 3, and fixing the runners accordingly. These are dovetailed into the front rails and sunk into the back rails and nailed or screwed. The drawer sides are dovetailed into the back in the usual way, and a dovetail is cut right across the drawer front for the front joint. After this is made, it should be put into position and guides fixed to the lower runners at each side. The top overhangs at the back 1 in., that it may come flush with the wall (the skirting prevents the legs from reaching the wall) and is pocket screwed from underneath. The mitred mouldings on the drawer

front and those round the framework complete the under part. Note that the moulding under the top is glued to the carcass only, so that the screws hold the top.

The upper portion measures 4 ft. 6 in. in height. No back is shown in the illustration, though this may be added if desired. In that case the ends would be rebated and the shelves recessed in a line with the rebate to take the back. The ends and the corner pieces are made from 1 in. stuff and are grooved to take the shelves, the tops being rebated for the top. Next cut out the top and upon this mark out the shelves to ensure their fitting accurately with the top. These shelves are tongued and grooved together at the angle (Fig. 2), and are grooved into the corner pieces in a similar way to the ends. They also have a bevelled groove run along the top near the back, in which the plates stand.

A rail 2 in. wide is tenoned at each side at the bottom into the ends and corner pieces. When glueing together, fasten all the shelves into one end first; next into the other end, the top being put on last. The cornice moulding is glued and pinned round the top and the shaped heading fixed, as in Fig. 5. by cutting away the ends and nailing, and by screwing to the back of the moulding. The complete upper portion is not permanently fixed to the lower, but rests upon the top, secured by dowels. *See Dresser.*

**CORNER SEAT.** As a rule, a corner seat will look best with the woodwork finished to match the woodwork of the room. Thus, in some rooms it will be painted or enamelled in ivory or any colour used for the skirting and door, etc., in others it will be stained a dark brown colour and finished by wax polishing. An impression of the finished job is given in Fig. 1. and details of construction in other diagrams. The size may be modified to suit requirements, the dimensions given being appropriate to rooms measuring about 15 by 20 ft.

The simplest way in which the amateur can make such a corner seat is by using the ordinary commercial building deal, selecting pieces that are as dry and as free from knots as possible. For the corner posts use ordinary 2 in. by 2 in. and plane it up nicely to  $1\frac{3}{4}$  in. square, cut to length (4 ft.), and shape the tops by careful paring with a paring chisel. Mark out and cut the mortises for the back rail. This can be made from  $1\frac{1}{2}$  in. T. and G. prepared flooring 6 in. wide. When planed up it will measure about  $1\frac{1}{8}$  in. thick, and be about  $5\frac{3}{4}$  in. wide. The tongue must be planed off, and the edge rounded; the groove can be widened with a plough plane or chisel to accommodate the  $\frac{5}{8}$  in. seat back, as shown in the detail, Fig. 4.

When the two back rails have been fitted to the mortises in all the corner posts, they may be put aside and the two sides prepared from  $1\frac{1}{4}$  in. T. and G. flooring. Five pieces of 6 in. flooring will be needed to form the end, and should be glued together, well cramped up and allowed to set. Then glue and screw on the  $1\frac{3}{4}$  in. square battens (Fig. 4).

Afterwards cut the boards to the shape required and

finish off the edges by rounding them with a spokeshave. Take care to have the projecting tongue on the wall side, as this has now to be fitted to the two outside corner posts by ploughing a groove along the face to take the tongue, as shown in Fig. 3. Glue the tongue and secure to the corner post by long, thin screws put in from the back.

Prepare two brackets from  $1\frac{1}{4}$  in. wood, to the sizes in Figs. 2 and 5, and a similar one but 15 in. long for the angle corner. Next fit a 3 in. by 1 in. bearer, by notching into the angle corner post as in Fig. 6. Mortise the bracket into it, and cut a flat on the angle face of the post to allow the bracket to seat home upon it. Take care also to set this bearer and bracket at the same angle as the battens on the end pieces. Glue and screw the bearer and bracket in place, and fix the top rails to the corner posts, standing the whole structure on a level surface and securing the bottom with a temporary strut. Test the corners and sides to see that all is square, and then cut the pieces for the seat, mitreing them carefully at the angle-corner. Glue and screw the first boards in place, then cut and fit the remainder, cramping them tightly together, after glueing the joints, and making them secure.

The seat is best made from  $1\frac{1}{4}$  in. T. and G. flooring, arranging the tongues to the front. If a circular corner is wanted cut and fit the pieces to make up, glue them in place and finish off by the spokeshave while in their proper place, also shave off the tongue and round the edge of the seat. The seat can be secured with  $2\frac{1}{2}$  in. oval brads punched well below the surface.

Drill the dowel holes and glue the brackets in place. Then cut the back pieces from  $\frac{5}{8}$  in. boards or from  $\frac{3}{4}$  in. T. and G. matchboard, and prepare the top so that it fits snugly into the groove cut in the back rails. Glue and screw the  $1\frac{1}{4}$  in. square fillet to the seat and glue and pin the back boards with 1 in. oval brads.

A channel must be cut across the corner posts at the outer ends where the seat back slants across. This can best be done by marking the exact position from one of the seat back boards and then sawing and chiselling away the unwanted parts. A little detail fitting is called for at the angle corner, as the two end boards will have to be cut tapering somewhat, and the edges mitred.

In order to make the corner firm they can be blocked up with wooden blocks glued in place from the back and inserted between the post and the seat back.

*(See next page for diagrams)*

**CORNER WARDROBE.** *(See next page for diagrams)* The corner wardrobe as shown at Fig. 1 is enclosed with curtains and is suitable for fitting in the hall, on a landing or in a bedroom.

The fitting is shown complete at Fig. 2, and a plan with a suggested dimension at Fig. 3. The boards forming the top could be  $\frac{3}{4}$  in. thick, with grooved and tongued edges, cut to fit the corner. The top is nailed to the sides, which are 3 in. deep by  $\frac{3}{4}$  in. thick

*(Continued in page 541)*

## 540 CORNER SEAT

## CORNER WARDROBE.

Left. Fig. 1. Useful fitment consisting of a wooden top and curtains.

Figs. 2-6. Diagrams showing how curtains are hung and method of fixing hooks.

section, rebated and nailed together at the back as at Fig. 4. The front corners of the sides are rounded, and finish about  $\frac{1}{4}$  in. in from the edge of the top. The pediment is 4 in. high by  $\frac{3}{4}$  in. section, glued and nailed above the top. A piece of 1 in. moulding should be fitted along the edge, and a few glue blocks fitted between the pediment and top, as indicated in Fig. 5.

Three or four coat hooks should be fitted at each side, and a swivel hook in the middle of the top, as illustrated at Fig. 2. The fitting may be fixed to the wall with hanging plates, or nails may be driven through the sides into the wall, a suitable height being about 6 ft. from the ground. A pair of curtains is generally more convenient than one, and they may be easily suspended from a wood or metal rod fitted to the edge of the top with a screw eye at one end and a hook at the other, as shown in Fig. 6. Brass rings sewn to the curtains a little from the top should be used. *See Bedroom; Wardrobe.*

**CORNET:** How to Play. The player holds the instrument with his left hand, fingers around the valves, while his right thumb is placed under the main tube between the first and second valves, so that he can easily press the pistons with the first, second, and third fingers. The finger action from the knuckle-joint must be firm yet agile, and care must be taken to allow the piston to return to its normal position, by raising the finger very slightly above its surface. Put the mouthpiece to the centre of the mouth, the lower lip occupying two-thirds of the cup. The sound is produced by forcing breath between the tense lips, the air in the tube being thus made to vibrate. Increased pressure results in higher pitch. Breathe through the nostrils or the sides of the mouth, but not through the instrument.

It is advisable to use a plated cornet for the reason that it looks nicer, while so far as the cup is concerned, plating may obviate any trouble arising from sore lips coming into contact with brass. Should the valves work stiffly, the remedy is to unscrew the cap, take out the piston, wash it, dry it with a soft silk handkerchief, slightly moisten it, and replace. It should never be oiled. Should grease get upon it, the best plan is to wash it in hot water, dust it with French chalk, replace it, and work it until it moves freely. It should then be washed again in order to get rid of the chalk. A little water is the best lubricant for this purpose.

**CORNFLOUR.** Cornflour, which is obtained from finely ground Indian corn, is used much in the same way as ordinary flour, but is better adapted for thickening sauces, gravies, and soups, as its flavour is more delicate. It is specially valuable in making blancmanges, puddings, and cakes. It should always be moistened with a little cold milk or water before being used for thickening. *See Arrowroot; Blancmange.*

**CORNFLOUR CAKE.** To make these take 8 oz. cornflour, 2 oz. flour, 4 oz. sugar, 3 oz. margarine, 3 eggs, and a teaspoonful of baking powder. Beat the margarine and sugar to a creamy consistency. Then add the eggs, one at a time, beating each in well. Mix the

flour, cornflour, baking powder, and a pinch of salt together before stirring them lightly into the margarine, eggs, and sugar. Beat the whole lightly but well, turn it into patty tins, and bake the cakes in a moderate oven until they are done.

**CORNFLOUR MOULD.** A fancy mould is used for this sweet. To prepare it, mix 1 oz. cornflour to a smooth paste with a little milk, putting what remains from a pint into a saucepan containing 1 oz. butter. Heat it over the fire, then pour it on to the cornflour; return the whole to the saucepan and bring it to the boil. Let it simmer for 6 min, keeping it well stirred, add 2 dessertspoonfuls castor sugar, and draw the pan from the fire to cool the mixture slightly.

Beat up the yolks of 2 eggs and stir them quickly into the cornflour. Cook the whole slowly at the side of the fire for a few minutes, but do not let it boil. Cool it again slightly, then add the stiffly whisked whites of eggs and a few drops of vanilla. Finally, stir in  $\frac{1}{4}$  oz. leaf gelatine dissolved in  $\frac{1}{2}$  gill of hot water, and pour the whole into a wet mould. Turn it out when set.

**CORNFLOUR PUDDING.** Blend 2 oz. cornflour, 1 tablespoonful custard powder, and a pinch of salt, with a little cold milk. Put what remains from a quart of milk into a saucepan with a thin strip of lemon peel and bring it to the boil. Pour this on to the cornflour mixture, stirring the whole well; return all to the saucepan, and boil it for 8 min., stirring all the time. If the mixture is too thick, add a little more milk or water. Then put in 1 oz. sugar and a few drops of any flavouring essence, and pour the whole into two soup plates previously rinsed in cold water. When the mixture is cold and set, warm a little jam, put the contents of one soup plate on to a glass dish, spread the jam over, and then put the other portion of the pudding on top. Sprinkle chopped nuts over it when dished.

**CORNFLOWER** (*Centaurea cyanus*). This favourite hardy annual bears blue, white or rose-coloured flowers. The best results are obtained by sowing seeds out of doors in early September. The final thinning of the seedlings should be done in spring; the plants left to bloom ought to be 10—12 in. apart. Seeds may also be sown out of doors in spring to provide flowers from July onwards. *Centaurea montana*, sometimes called the perennial cornflower, grows 2 feet high and bears summer flowers of various colours. It lives on from year to year and is increased by division in autumn or spring.

*Cornflower. Flowers of Centaurea montana, popularly called the perennial cornflower.*

**CORNICE: Of the House.** A cornice is an ornamental moulding applied to the upper parts of the walls. Modern cornices are frequently used as decoration without practical significance, and may be made in several different materials, such as stone, brick, stucco, Portland and other artificial cements. In cabinet and other work, the moulded top, as of a wardrobe, is also known as a cornice.

Cornices for the ceilings of rooms are composed of plaster and cement. They are sometimes produced by casting in moulds and screwed to wood grounds fixed in the building. Plaster cornices are, however, usually run on the work itself. The backing for the cornice is first built in brick or stone roughly hacked to the shape of the moulding, or is constructed in wood with rough brackets, lathed as if for a ceiling.

In fire-resisting construction, steel lathing is used, and is secured to bars bent to the required shape. The pricking-up or rendering coat is trowelled on as in ordinary plastering. The second coat is applied thickly, and the mouldings are formed by dragging a template cut out of zinc on wooden guides already nailed in position. The final coat in internal work is generally made of gauged stuff, composed of one part of fine stuff, lime putty, and washed sand in equal proportions, to one part of plaster of Paris. This is a quick setting mixture, and the plasterer only applies as much as he can finish at one operation.

The guide rails of the template ensure a good joint at the commencement of the next length of run. Plaster of Paris is soluble in excess of water, and where used in external work must be protected by several good coats of oil paint. Where backings of cornices are built of brick, the greatest care must be taken to ensure that their connexion with the wall is thoroughly sound in every way.

Where two walls meet at either an external or internal angle the cornice on these walls meets in a mitre line. A mitre mould is sometimes employed, but the angles are, as a rule, made by hand, and are mainly worked with the joint rule, the smaller members and those at the top and bottom being first worked, and the larger members ruled in afterwards. *See Adam Style; Cappings; Ceiling; Moulding; Picture; Plastering.*

**CORNISH HEATH.** This is a beautiful species of English heather, found wild in Cornwall. Its botanical name is *Erica vagans*. The small pinkish mauve flowers come out in August and September. The plant forms very neat close clumps, from 6-12 in. highland is extremely useful for edgings to flower gardens. *See Heather.*

**CORNISH PASTY.** A plain short-pastry is needed, and the meat is best when uncooked; but cold cooked meats can also be used up in this way. To two small potatoes and half an onion 8 oz. meat are allowed, all cut small, mixed together with seasoning, a sprinkling of mixed herbs, and a tablespoonful of gravy. When the paste is made, it should be rolled out and cut into rounds. A portion of meat and vegetables is laid in the centre of one half of the round of pastry, and

the other half is folded over, the edges being moistened and pressed together. The top of the scallop must be pricked twice with a fork to let the steam escape. The pasties are then baked in a moderate oven for about half hour.

A sweet Cornish pasty can be made by placing a large spoonful of jam on the pastry instead of meat. Slit the top covering once or twice with the blade of a knife. In this way the jam escapes when it boils up in the baking, without spoiling the appearance of the pasty. In Cornwall the custom is to pour the cream through the slits in the pastry cover as soon as the pasties are cold.

*Cornish Pasty. Dish of light pastry turnovers which can be made with meat or jam.*

### **CORNISH SPLITS.**

Sieve  $\frac{1}{2}$  lb. flour, and rub well into it  $1\frac{1}{2}$  oz. lard. Then add a teaspoonful cream of tartar, a level dessertspoonful sugar, a pinch of salt, and mix well together. Dissolve half a teaspoonful bicarbonate of soda in  $\frac{1}{4}$  pt. milk, or sour milk if it is available. Pour this over the other ingredients and mix quickly to a dough. Turn it on to a floured board and roll it very lightly and quickly to a thickness of about 1 in. Cut it into rounds with a pastry cutter about the size of the top of a tumbler, put them on a floured baking sheet, and bake in a moderate oven until browned. When these little scones are cold, split them in halves. Spread each half thickly with jam, and put on the top of each a large dab of clotted cream.

**CORONILLA.** These herbaceous perennials and shrubs, which bear pea-shaped flowers in summer, need well drained soil and a place in the sunshine. The chief favourite is *Coronilla glauca*, which has yellow flowers; it is commonly grown as a pot plant in the greenhouse but is hardy in mild districts. *Cappadocica*, which is of trailing growth and bears yellow blooms in late summer, is grown in the rock garden. *Emerus* is a leaf-losing shrub, 4 feet high, with yellow flowers in spring; *varia* has pinkish blooms in summer and grows 2 feet high. The shrubby coronillas are increased by cuttings placed in sandy soil in a frame in August, the others by seeds sown under glass in spring.

*Coronilla. The pink-flowered Coronilla varia.*

**Corpulence.** *See Obesity.*

**Corridor.** *See Hall; Landing.*

**CORROSIVE.** A poison which destroys tissues with which it comes into contact is a corrosive. Included in this class are the following: Strong mineral acids, such as sulphuric acid (oil of

vitriol), nitric acid (aqua fortis), hydrochloric acid (spirit of salt); strong alkalies, such as caustic soda; carbolic acid and creosote; strong solutions of oxalic, citric and tartaric acids; chlorides of zinc, tin, antimony, and mercury (corrosive sublimate).

When swallowed the substance will have a strong acid, alkaline, metallic, or sweetish, pungent taste, according to its nature, the last being suggestive of carbolic acid and creosote. There is also an intense burning pain in the mouth, gullet and stomach, and shortly over the whole abdomen. The patient vomits, and there is also purging. Difficulty of breathing may occur from damage to the larynx. The patient may quickly show signs of collapse. There will be signs of burning on the lips and adjoining skin, and in the mouth in the shape of white, yellow, or black patches, and signs may also be found on the clothing.

Treatment consists in giving an appropriate antidote moderately diluted with water, warm fomentations to the abdomen for the pain and to the throat for the difficulty in breathing, and warmth for the collapse. A doctor should be summoned. *See* Antidote; Poisoning.

**CORROSIVE SUBLIMATE.** This is another name for bichloride of mercury. It is used, dissolved in water, to form antiseptic lotions: 1 in 1,000 to sterilise the hands before operating or dressing a wound, 1 in 4,000-8,000 for washing out wounds, 1 in 10,000 for an eye or ear lotion. Coloured tablets are sold which tint the water and prevent its being mistaken for and drunk as plain water; and they also make it easy to prepare lotions of any desired strength. Metal instruments should not be put into these lotions, otherwise they are blackened and destroyed. Solutions 1 in 10,000 to 1 in 1,000 may be used for disinfecting linen.

The drug is very poisonous, and if taken has a strong metallic taste, and produces a burning sensation in the throat and gullet, severe vomiting and purging, perhaps difficulty of breathing, and pain, though this may be absent. The lips and tongue are white and shrivelled. In the end there may be coma or convulsions. Pending the arrival of a doctor, whites of eggs and milk may be given. The patient should be kept warm in bed, in which are placed hot-water bottles, and if breathing is difficult hot fomentations should be applied to the throat.

**CORRUGATED IRON.** This useful material is made from sheets of iron, by a machine which bends it into a series of parallel ridges or corrugations, thus greatly increasing the effective strength of the material. As generally used for domestic work, the iron is galvanised to render it rust-proof; but there are many qualities on the market. When comparing prices be certain of the gauge or thickness of the sheets; a few pence more expended at the outset will often save pounds in the long run.

A medium gauge is known as No. 24, a light or thin sheet as No. 26, and a heavy as No. 22 gauge. The sheets measure 2 ft. 3 in. wide, and are generally stocked from 4 ft. to 8 ft. in length; 9 ft. and 10 ft. lengths are obtainable on order, although for long spans of over 8 ft.

it is generally preferable to use two shorter sheets and to overlap them at the joint.

The approximate weight of a No. 26 gauge sheet is 2 lb. per foot run, a 6 ft. length thus weighing 12 lb. The 24 gauge sheets go a little under 3 lb. per foot run, a 6 ft. sheet weighing 17 lb., an 8 ft. sheet 23 lb. In conjunction with corrugated iron, it is well to use a few sundries made for the purpose. These comprise galvanised ridge capping, to finish a span roof at the top or ridge; galvanised nails and washers for fastening the iron sheets to the rafters; and, when required, galvanised shuting to collect the rain water, together with the needful stop ends, angles, brackets, and outlet pieces for use with the shuting.

Corrugated iron is admirable for outbuildings, stables, and other erections. The objections to its use for dwelling-houses include lack of durability as compared with tiles or slates, the noise it makes in a heavy rain, and a peculiarity known as sweating. It is also cold in winter and hot in summer, unless special precautions be taken when designing and building the roof. Against these objections are the advantages of cheapness, lightness, and ease of erection. Durability can be gained by repeated and regular coating with preservative paints. When the iron is laid over a boarded and felted roof, with an air gap, the objections of noise and sweating are largely eliminated. This material is satisfactory, when properly applied, as a roof covering for bungalows, etc.

When laying corrugated iron always reckon that a sheet only covers a width of 2 ft., as the odd 3 in. has to be lapped over the top and edge of the next sheet. Always endeavour to use the iron in its stock length, as it is difficult to cut. The best way to do this is to cut it lengthways with stout tinman's shears or snips. To cut across the corrugations, use the proper kind of chisel, and cut the iron by laying it flat on a solid support, with a hollowed block of lead immediately beneath the chisel. An alternative method is to saw it across with an old hand saw, exactly as if cutting a piece of wood, using plenty of oil as lubricant.

When covering a roof, if the length of the sheet is sufficient to reach from ridge to eaves in one piece, work from the ridge downwards. If two or more sheets are needed, begin by planning out the best arrangement by placing one sheet at the eaves, with its proper projection, temporarily fix another sheet from the ridge, and fill in the gaps by overlapping equally on each sheet above and below. Then fix the sheet next above the eaves course, follow this with the next above, and so on, finishing at the ridge.

It is generally more convenient to lay the sheets from eaves to ridge and then the next set from ridge to eaves. When three such sets have been laid, fix those on the other side of the roof, if a span roof, then fix the ridge capping. Then do the next sets, and so on to the other end of the roof. By these means it is easier to get at the sheets than by laying the whole eaves course first. Use a line stretched taut to keep the courses level,

especially at the eaves, unless the roof has been boarded, when the line is not needed. The proper way of fixing corrugated iron is to drive the nails or screws through the ridge and not in the trough of the material, the object being to keep the nail as far as possible out of the water, which naturally runs down in the troughs or hollows. The scantlings needed to carry the iron, as well as questions of the arrangement of the roof, if it is to be boarded or felted, must be decided according to the nature of the building and the purpose for which it is required. See Galvanised Iron; Roof.

Fig. 1  
Corrugated Iron. Fig. 1. Diagram showing how sheets are fastened to joists and bolted together.

Fig. 2. The end of a building with roofing in progress.

**CORUNDUM:** An Abrasive. This is a natural aluminium oxide. The finely coloured transparent varieties include such stones as rubies and sapphires, while the impure and coarse forms are known as emery. Corundum is used as an abrasive; it is extremely hard, and fractures in such a way as to ensure sharp, cutting points, hence its value and extensive use. It is chiefly found in the home in the form of emery powder or knife powder.

India oil stones are made of pure corundum in three grades—fine, medium, and coarse. They are excellent for sharpening tools and the grades are often found in combination on the same stone. See Emery Powder; Grindstone.

**CORYDALIS** (Fumitory). These hardy perennial

plants, 10-12 inches high, with graceful, somewhat fern-like leaves are suitable for the rock or wall garden. Most of them will flourish in the shade. They like well drained light soil. The commonest is *lutea*, which has a long flowering season and will thrive in any odd corner. *Cheilanthes* *folia*, *nobilis*, *thalictroides* and *Wilsoni* are other attractive sorts: all bear yellow flowers in summer. A distinct group of *corydalis* has tuberous roots: two of the best are *Scouleri*, with rose purple blooms in May, and *tuberosa* with purplish flowers in March and April: these may be propagated by detaching small tubers in autumn or by seeds sown in spring in a frame. The fibrous rooted kinds mentioned above are increased by dividing the old plants in autumn or by sowing seeds in spring.

*Corydalis*. Fern-like leaves and yellow flowers of this hardy perennial plant. See below.

**CORYLOPSIS.** These Chinese and Japanese spring-flowering shrubs are nearly related to the witch hazels. They need peaty or leafy soil. One of the best is

*Corylopsis pauciflora*, which bears fragrant yellow flowers in spring. These shrubs are not very hardy and the young shoots and flowers are liable to be damaged by frost unless in a sheltered spot.

**COSMETIC.** A cosmetic is a preparation used for beautifying the skin and the hair. Among them are face creams, hair oils and similar compounds. See Beauty Culture; Beeswax; Face; Hand; Skin; Soap.

**COSMOS** (*Cosmea*). This beautiful half-hardy annual is raised from seeds sown in a heated glasshouse in February-March. The seedlings are planted out of doors in May. The plants grow 4 feet or so high and bear single or double long-stemmed flowers in rose, white and crimson. The early-flowering strain ought to be sown or the plants may not be in full bloom until autumn.

## COTS AND HOW THEY ARE MADE

### Considerations Affecting the Health and Comfort of the Child

The reader may consult the articles Baby; Child; while Nursery; Perambulator; Ventilation are other related subjects. See also Bedstead; Coverlet.

The average cot for a child measures 4 ft. by 2 ft. 6 in., but if space is no object, it is a great advantage to select one measuring 4 ft. 6 in. by 3 ft. The child can sleep in it comfortably up to the age of 5 or 6 years. The cot made of hardwood is to be recommended

rather than the iron cot. If the child falls against wooden bars, the injury is slight compared to a similar fall against iron; also wooden cots can always be obtained in a folding pattern, and can be conveniently carried from room to room, and if they have to be travelled, the charge for freight is comparatively light.

The bars should be perpendicular, and too close together to allow the child to push its head through. The height of the sides should be sufficiently great to prevent the energetic two-year-old practising his fondness for climbing. It should be possible to let down at least one side of the cot to within 2 in. of the mattress level.

A good hair mattress is strongly advised. It is twice the price of a wool one the same size, but it never goes into lumps and hollows, and is far more sanitary, and can always be re-made and cleaned. Hair pillows are also procurable, and have the advantage of being less heating for the head; but they are not necessities, and a well-stuffed feather pillow in a strong case of white drill can be safely used. Sheets should be avoided in a young child's cot. A mackintosh, an old blanket, or a thick cotton blanket are best for it to lie upon. One or two light but warm upper blankets and an eiderdown complete the bedding and can be adapted to temperature.

Many of the better-made cots are raised upon legs from the floor, so that there is no back-breaking work for the mother or nurse when baby has to be lifted in and out of his bed. These cots are also procurable in a folding form, so that they have a double advantage, especially for families who are accustomed to travel. In the case of a child who sleeps out of doors throughout the summer, the cot can be mounted on rubber-tired wheel castors and fitted with an all-enveloping curtain, arranged by means of a canopy pole and support. Mosquito nets on supports can also be fitted as extra attachments.

Fig. 1 shows an easily-made child's cot. As indicated the cot is made up of frames, three of which are fixed and one made to lower, and thus give convenient access to the bedding. A set of castors can be fitted to facilitate change of position: but, as the whole thing is light, it can easily be lifted from place to place. The size for a small, ordinary size cot is 4 ft. by 2 ft., and the height 3 ft. 6 in. For an older child the next size would be 4 ft. 6 in. by 2 ft. 3 in., after which it would probably prove more economical to construct a form of cot bedstead. Beech, birch, satin walnut, American whitewood, yellow pine, spruce, and red deal are all suitable woods that can be pressed into service. Finish can then be by staining, or in white enamel.

A commencement may be made with the two ends. The posts are of material  $1\frac{1}{2}$  in. by  $1\frac{1}{2}$  in. square, planed and cleaned up to  $1\frac{3}{8}$  by  $1\frac{3}{8}$ , and should be mortised for the rails as they occur. The tops of the posts can in the simplest manner be finished by rounding over as at Fig. 3, or, if a lathe is at hand, the upper 2 in. can be turned to a ball finish as at Figs. 1 and 2. Some working turners keep in stock a supply of such turned finials, and a set—with dowels—can be purchased for a small sum. An alternative method of

finish, which is also serviceable for the fixing of a cot-net, is that at Fig. 4, whilst a neat finish is afforded by the fitting of  $2\frac{3}{4}$  in. by  $2\frac{3}{4}$  in. by  $\frac{3}{4}$  in. caps with the upper edges nicely rounded as at Fig. 6. These are best fixed by a short tenon on posts, although they can be dowelled and panel-pinned to prevent twisting out of the square if preferred.

Cot. Fig. 1. Child's wooden cot.

Figs. 2 and 3. Alternative ends.

Fig. 4. Loose side. Fig. 5. Fretted panel. Fig. 6. Post with cap.

Figs. 7 and 8. Suggestions for lowering side.

The mortises for the upper rail should start 3 in. from the upper end of post, and the lower end rail can be 1 ft. 4 in. up from bottom. The cot may be framed together on all four sides at the seat, but being intended to have one side pivoted to let down, it is mortised on one side only to the posts above the seat rail. The position for pivot holes in posts is about 1 ft. 6 in. above ground.

**Panels and Bars.** The top end rails, which are shaped as at Fig. 2, can be finished from pieces 2 ft. by  $3\frac{1}{4}$  in. by 1 in. They can be tenoned or dowelled to posts, and should also be shallow-mortised on under edges to receive the bars and centre panels. The panels (Fig. 2) are  $3\frac{1}{2}$  in. wide, with a small fret-cut opening in the upper part by way of relief. A scratch bead may also be cut  $\frac{1}{2}$  in. from length edges with neat effect. The bars can finish  $\frac{7}{8}$  in. by  $\frac{5}{8}$  in. thick, and,

including joints, are 2 ft. 1 in. long. It is possible to use  $\frac{3}{4}$  in. dowel sticks for the bars instead of the square section, provided they are nicely cleaned up. The lower end rails finish  $2\frac{1}{2}$  in. wide, and are dowelled or tenoned to posts and mortised for housing the bars and panels.

The top side rails finish  $1\frac{1}{2}$  in. by 1 in. net thick (two lengths of 4 ft., allowing a trifle for fitting and joints, are required), and each rail is mortised on under edge to receive 10 bars. Instead of the mortises, a groove may be ploughed the length of the rail, and slips of equal length be packed between each bar in the groove. The ends of the top rail intended to lower should be banded or ferruled with sheet brass a full 1 in. wide as a provision against splitting. As this rail, when up, is kept in position by a brass screw-eye and chain attachment, no tenons are required. The attachment consists of a nut sunk in the rail and kept there by a brass plate screwed on, the eye being tapped to fit the nut, and a length of brass chain fastened thereto to hook on to a clip.

The lower rails are also  $1\frac{1}{2}$  in. by 1 in. net, and are mortised for bars in the same way, and, on the fixed side, have tenons cut to enter posts. The loose end, as indicated at Fig. 4, is banded and pivoted into posts, a brass screw with the head filed off answering well for the purpose. The bars can be entered into the rails to their full thickness; or, again, hardwood dowels can be employed closer together. These latter may be spaced with fretcut panels between, a suggestion for the latter being given at Fig. 5.

The seat rails can finish  $2\frac{1}{2}$  in. wide by 1 in. or  $\frac{7}{8}$  in. thick if tenoned to posts and pinned; or, as is sometimes done, dowelled and stiffened with brass or iron angle brackets to be screwed to angles formed by under side of rails and posts. Wire spring mattresses on iron frames are made specially for cots, and if one of these is used the whole structure will be rigid and comfortable for the child.

**Sliding Side to Cot.** As an alternative the side may be fitted to slide up and down a steel or nickelled rod, or a length of hardwood dowel could be substituted at a pinch. Figs. 7 and 8 will make the arrangement clear. The rod (B) can either be brazed or riveted into the cup, or may simply rest in it. The rod is capped at top and held by eyes (C) attached to posts as indicated, both rails of side being bored for the rod to pass easily through. When up, the sides can be kept secure by the device indicated at A. It consists of a rod with a clubbed end, and a bolt handle in centre normally pointing towards the ground, the whole being attached to under edge of lower (seat) rail of cot side by means of eyes. The clubbed end rests upon a metal box, as at Fig. 8, and this bearing keeps the cot side up in position. To lower the cot side the handle is grasped and raised outwardly, which disengages the club from the box and allows the side to slide down the rod, stopping upon the screw-eye.

In another type of fitting two catches screwed to the posts are made to engage with the lower rail of the cot

side. A set of nickelled fittings for this may be purchased for a few shillings from a furnishing ironmonger.

A support for a mosquito netting or a canopy is often added to a child's cot. It may be made from two pieces of  $1\frac{1}{4}$  in. by  $\frac{1}{4}$  in. hardwood (A) fastened by screws to the end of the cot, and secured at the apex by the screwed end of the short horizontal rod (B) which supports the canopy. The construction is explained by Fig. 9 below.

*Cot. Fig. 9. Support for canopy or mosquito netting.*

**Cotillon.** See Dance.

**COTONEASTER.** Also called rockspray, this is a hardy leaf-losing and evergreen shrub valued for its bright red fruits in autumn and early winter. They thrive in ordinary soil and are increased by cuttings set in a frame in August or by seeds sown out of doors in spring. One of the most striking is cotoneaster horizontalis which is an ideal shrub for a sunny wall; its branches spread in fish-bone fashion and become laden with red fruits in autumn. Microphylla is a trailing shrub suitable for the rock garden or border edging; against a wall it grows tall. Simonsii, rugosa Henryi, rotundifolia and frigida form large bushes and all bear showy fruits. Of those named, microphylla and rugosa Henryi are evergreens. Pron. Cō-tō-ne-ās'-ter.

*Cotoneaster. The bright red fruits of Cotoneaster frigida.*

## COTTAGES: ALTERING AND FURNISHING Advice on the Improvement of a Small Country Property

Other useful information will be found in the articles Architecture and House. See also the entries on Casement; Damp; Floor; Plumbing; Sanitation; and those on Chair; Curtain; Dresser and other furnishings

When buying a cottage with a piece of land attached, inquiry should be made into such matters as sanitation, water supply, and rights of way. An otherwise desirable plot may be rendered unsuitable by the existence of a footpath or right of way across it, while the proximity of a cowshed, with its manure heap, is likely to be an obstacle to many.

If there is a well on the property the water should be analysed to be sure it is fit to drink, or if it can be made so by not too expensive filtration methods. Sanitary

arrangements in most cases will probably be of a rather primitive character, which will have to be altered or replaced by the new owner either at the instance of the local authorities or for hygienic reasons. A good earth closet should not be condemned as, under approved conditions, it may be more efficient than a water-borne system. Where water supply is inadequate chemical closets are also worth considering. They are approved by the medical authorities and very efficient if carefully used.

The possibilities of renovation must be kept in mind, as very often a dwelling with communicating rooms can be converted with little expense into a convenient home, especially when the owner is able to undertake much of the work with his own hands. Economical methods are essential, but the very nature of the building demands plain work, with simple furnishings. The essentials of satisfactory restoration or the addition of new work calls for an adherence to the local traditions of building.

**Altering an Old Cottage.** The first thing is to decide upon the scope of the alterations, the location of additional windows or the enlargement of those existing. The whole of the exterior should then be gone over, replacing any missing tiles, repairing a stone roof, or renewing the thatch, as the case may be. Get up into the roof, inspect the rafters, and if any of them show distinct signs of failure these should be relieved by fixing a fitch plate or an extra rafter, laid alongside.

Then give attention to the walls. Brick work may need re-pointing, but do this carefully. A struck joint will probably look best, and it is not necessary to remove all vestiges of moss and lichen, as they add to the charm of the exterior. Oak timbering should be treated with boiled linseed oil well brushed into the surface; two or three applications may be needed to restore the dark colour associated with old work. Any damaged parts can be cut away and new wood fitted, taking care to model the surface to conform with the contours and characteristics of the old work. Never cut through old timbering unless fully satisfied that no damage will be done to the structure. Shoring may be needed to relieve the timber of all strains during renovation.

Old plaster panelling may look in bad condition, but if the lathing is sound renovation may consist in brushing off all loose material from the face, making good with lime or cement mortar, and applying a liberal coating of waterproofing paint or a good cement wash. Footings, foundations, and damp-proof courses will probably be very rudimentary, but if the building is dry it is best to leave it alone and be content with filling in any gaps with cement mortar. New or larger windows often improve the interior in a surprising way, and there is nothing more convenient for this than a metal-framed casement which can be built direct into the wall.

The staircase may call for renewal and some new arrangement, as many old cottages have dangerous winders if the stairway is at all cramped. The plans given will suggest typical treatment, but care must be taken to provide sufficient head-room, a clear height of

6 ft. being the absolute minimum. Attention should be paid to tie beams or other structural features that cannot be altered, and may be in the way of a contemplated position for the new staircase.

*Cottage. Plans showing how a terrace cottage can be improved at a minimum of expense. The above plan shows the ground floor before conversion.*

*Above plan, after the improvements have been made.*

Communicating bedrooms may have advantages when the second is used for young children, but this feature, frequently met with in old cottages, is generally objectionable. Much can be done by changing the position of the staircase, or by the provision of a partition wall, thus forming a passage-way between the rooms. Fireplaces or their absence offer another problem; a practical solution may be the use of a slow combustion or anthracite stove, which can have a stovepipe fitted into an existing chimney-stack, or to an outside flue-pipe placed in some inconspicuous position. In any case, care must be taken to keep clear of existing timber which might be set alight by the heat from the flue-pipe. Any room not provided with a fireplace should have a ventilating air brick or other

device arranged in the upper part of one wall, or a small grating over the door.

Old doors will often be found deficient at the bottom or ill-fitting in the framework. Effective remedies are to cut away the badly damaged parts, work a feather on the end, and fit a new piece. New door stoppings make a marked difference to the comfort of a room if they are fitted closely to an old door that has warped and does, not shut tightly. Worn thresholds are easily restored by cutting away the worn parts and making a new oak tread, which can be secured with well countersunk brass screws. Floors may need patching or renewal. A worn brick or the floor can be greatly improved by taking up the old bricks or tiles, re-levelling the soil, and re-setting the bricks or tiles in cement mortar, but with the worn sides downwards; the original under-sides of the tiles will probably be found to be in perfect condition.

**The Water Supply.** The provision of a bathroom, larder, and improved facilities for water supply depend almost entirely upon individual requirements, but one point must be mentioned in connexion with the erection of a water-tank or cistern in the roof. This must be very carefully considered and before commencing work it is necessary to make sure that the pipe lines can be laid correctly, and that the cistern is not placed in the middle of the ceiling rafters. A small tank of 50 gallons capacity may easily weigh  $\frac{1}{4}$  ton when filled, and the ceiling rafters will not support such a weight. The cistern had best be placed over a wall, or in some place where adequate support is obtainable. The great object in modernising a small dwelling should be to retain the charm of the country cottage while providing all the essential modern conveniences.

**How to Furnish.** The necessary repairs and renovations completed, the charm of the cottage can be added to by suitable interior decoration and furnishing. The keynote should be simplicity.

The type of cottage that one may wish to furnish may vary from an old half-timbered one with thatched roof, inglenook, etc., to a plain brick building with sash windows and Victorian fireplace. The furnishing of the former type is comparatively easy. Every possible use is made of the special features, and care taken that the furniture should go with its surroundings.

For example, the charm of a room with oak beams would be enhanced with old dark wood cottage furniture. If this is not available, inexpensive reproductions can be obtained in oak, walnut or birch colour; or wood may be left unstained and wax polished where there are no dark oak beams to set the decorative scheme.

The rooms of most cottages are small, the doors narrow, and the ceilings low-pitched, so pieces of heavy furniture that would suit a house of moderate size would look too large and take up too much of the limited space available.

Unless two cottages have been knocked into one, thus providing more accommodation, the arrangement of

the rooms must be well thought out. Sometimes the living room has a dining recess, the room having been enlarged by taking in the old kitchen and converting the scullery into a more modern kitchenette. Thus a dining room and sitting room are obtained, the former sometimes combining with the hall as the front door opens directly into it and the staircase may lead out of it to the first floor. Such a plan has an informal and at the same time decorative effect if the woodwork is of oak and an old lantern is hung from a wall bracket to light the staircase angle. The sitting room may contain two or three useful pieces of furniture, a few comfortable chairs, a good table, shelves for books, window seat, and an upholstered settee or divan.

If the window curtains, valances, and chair covers are made of some figured fabric like chintz or cretonne, the wall should be rough surface plaster, distempered with some self-colour or papered with plain paper. An unpatterned wall surface gives a greater idea of space, so is eminently suited to small rooms. Even more important, the gay colours and design of furnishing fabrics show to perfection against a plain background.

*Cottage. Typical English thatched cottage. (Photo, courtesy of Our Homes & Gardens)*

Occasionally cottages used for short holidays and week-ends only are furnished with unwanted pieces from another house. A cottage can be made attractive under such conditions if attention is paid to colour and details. To supplement oddments, the amateur or village carpenter can make such things as angle-nooks, window seats and other useful pieces. In small, low pitched rooms wall ornaments should be used with discretion. An antique warming pan, a few pieces of pottery, an arrangement of flowers on a shelf to break the wall line are more restful than odd pictures or crowded effects.

*L-shaped living-room. The dining recess is in the smaller portion beyond the fireplace; it holds a refectory table and six chairs and has a serving hatch. The armchair is covered in a printed linen and the curtains are of gaily checked gingham.*

Attention must be paid to floor coverings. Even a brick floor that could not be classed as damp allows a certain amount of moisture to percolate through it. For this reason avoid the use of tight-fitting linoleum or other covering which excludes access of fresh air. Uneven surfaces, such as worn brick or flagged stone floors, soon cause holes and cracks to appear in the linoleum, and any dampness on the under surface would tend to rot the cork. Coconut matting is excellent on such floors. Strips can be used for passages, and mats and small carpets in coloured fibre can be bought very cheaply. The advantage of fibre is that air can readily pass through it to the bricks, and any moisture that is absorbed by the matting helps to lengthen its life.

The living-room with dark beams lends itself to stone-coloured, or cream distempered, or painted walls. In north rooms warmer tones could be used with advantage; buff, apricot or primrose yellow are suitable. The woodwork would probably be finished to match the timbering, though lighter colours are effective for window woodwork, unless the windows are latticed. A suggestion for a sunny room is cream-coloured plastered walls, oak-coloured paint, short curtains with the valance fixed to a pelmet board. A window seat with upholstered cushions could be covered, and all other hangings made from a cretonne in which blues, yellows, greys and soft reds mingle.

A predominant note of blue harmonises well with brick tiling on the floor or a brick fireplace. Striped woven rugs or a small oriental carpet may be used. Oak or other hardwood stairs merely require to be stripped and wax polished. Those made of white wood and having painted sides can be made attractive by having plain or bordered hair stair-carpeting laid. Light coloured walls are essential if the staircase should be dark or narrow.

The furnishing of the bedrooms should be simple; cheap painted furniture is suitable, in the absence of better pieces. If space is limited, make a dressing table from a triangular shelf placed across one corner. If a bathroom has been introduced during alterations it is rarely necessary to have washstands.

A cupboard with fitted drawers at the bottom answers as a wardrobe. This should be placed against a dry inside wall. Corner fitments with curtains are useful for hanging clothes. If the floor boards are in good condition, linoleum or cork carpet can be used with rugs, or square of fibre or hair carpet. In order that the exterior of the cottage may be as charming as the inside, the curtains of all windows that can be viewed at the same time should be of, or lined with, the same colour.

**Cottage Pie.** This is made from cold minced meat and potatoes, and is also known as shepherd's pie (q.v.)

**COTTER:** A Wedge. A wedge-shaped piece of metal, known as a cotter, is adapted to draw up the joint between a shaft and a crank, or other part of a machine. A familiar application is the cotter pin in the crank of a bicycle (q.v.). Essential requirements in

fitting such cotter pins are, that the pin shall fit accurately in the hole drilled in the crank, and that the flat surface on the cotter is correctly shaped to bear on the flat formed on the shaft. Both surfaces should be in contact over as large an area as possible. It is tightened up by a nut and washer.

**COTTON.** Not only are clothes, furnishing fabrics, and sewing materials obtained from cotton, but the seed on which the cotton fibre is found is rich in oil, and this is pressed out and used to make soap, margarine, and so on. The lint adhering to the seed after the main part of the fibre has been removed forms a base for making guncotton, collodion, and artificial silk, and is frequently made into cheap cotton wadding. The residue of seed remaining after expressing the oil forms a cake which is widely used and highly valued as cattle food.

The superior cotton fibres are silky and soft, whereas some are harsh and wiry. The longer and silkier are naturally the most expensive, and from them the finest threads and most delicate cloths are made. The very best cotton spun into the finest yarn fetches a far higher price than silk.

**Cotton Fabrics.** Tent and sailcloths are generally cottons, and so are nainsooks and cambrics. The lawns, sheetings, and shirtings once universally made of linen are now generally cotton, which also replaces wool in flannelettes and even in blankets. It takes the place of silk in mercerised linings and embroideries, in velvets and umbrella cloths. Cotton reps, damasks, tapestries, and cretonnes cover furniture, and cotton rugs and mats are used on floors. Lisle or hard-twisted, superior cotton thread makes stockings; and cotton fabric, with a suède finish, is used to make gloves. Raincoats are often cotton, as are curtains, tape, lace, imitation leathers, bandages. Much twine and cord, containers like flour bags, and most of the webs for braces and belts are cotton. Motor tires are made upon a foundation of the very best cotton; electrical wires are insulated with cotton, and nearly all clothes are sewn together with it.

**Uses and Defects.** Cotton is blended with woollen materials that would otherwise be too poor for use, in order to lend strength to the whole and not necessarily for cheapness. Fairly expensive cloths used in place of flannel are rendered practically unshrinkable and better wearing for being made of a blend of fine cotton and fine wool. It is now possible to dye cotton with more fastness than any material. Cotton can be lent the appearance of silk, as seen in the mercerised cottons employed for so many purposes. By being woven in open cellular texture, or bushed like flannelette, or made with a loop surface like Turkish towelling, or with a smooth pile like velvet, it is made an efficient non-conductor of heat and thus warm to wear.

The defects of cotton vary, and in general it does not

*(Continued in page 554)*

## COTTAGE: BUILDING AND REBUILDING

### Schemes for Rural Homesteads Old and New

*Above, section of reconstructed cottage on line B—B, shown in the plans below. Note interior improvements: oak external framing, Columbian pine floors, and a new Claygate fireplace set in the entrance-hall.*

*Left, the front elevation of a Tudor cottage after reconstruction. A new wing has been added on foundations where a third cottage formerly stood. The whole building was underpinned and concrete foundations laid.*

*The word "cottage" is applied to a wide range of domestic buildings; but it really implies a small dwelling for people of limited means. A parlour and three bedrooms is the minimum standard of accommodation, and this type, with Mansard roof, is here shown. Below, elevation of a design which avoids a stereotyped square plan by means of a projecting face. Left, same design shown in section. The living-room should not, if it can be avoided, face north.*

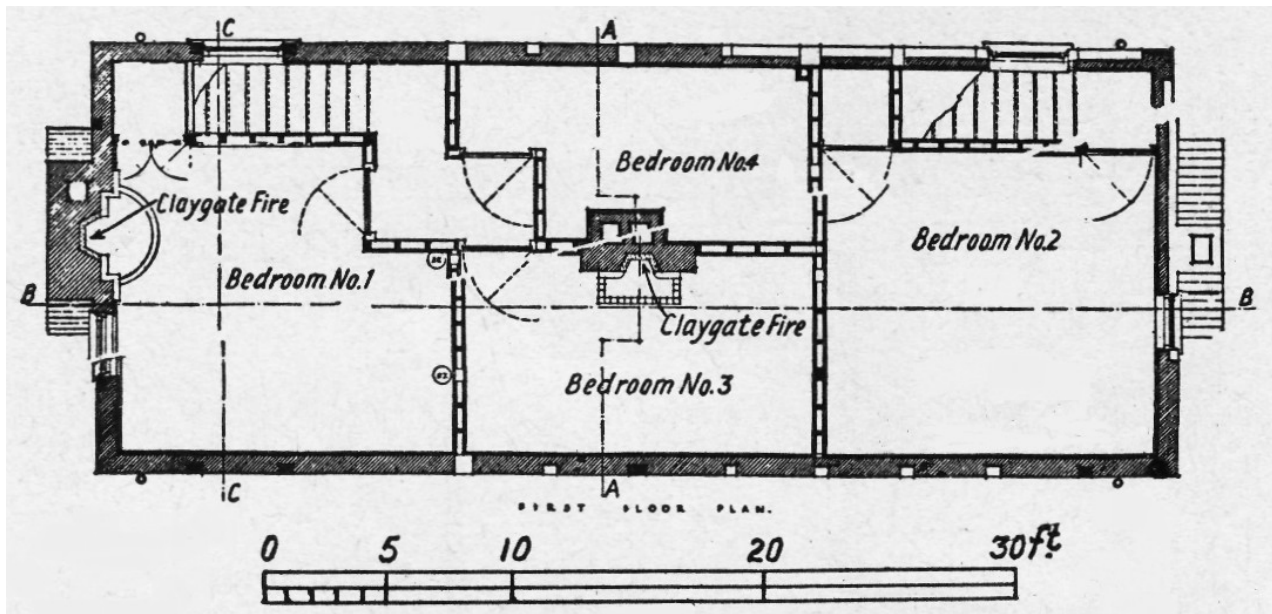

Above, photo shows the ruined skeleton used as basis of work on two tumble-down cottages. Much has to be done. The aim should be to use the old form as far as possible. The roof should be felted, boarded and counter-battened. Chimneys are usually very substantial, and should retain their characteristics. In half-timbering, trace the original timbering lines; mend with old oak members, without disturbing their weatherproof surface. Fill gaps with slate-lined brickwork; not with wattle and daub, which is generally forbidden by Local Authorities (Architect, Eric Hayman)

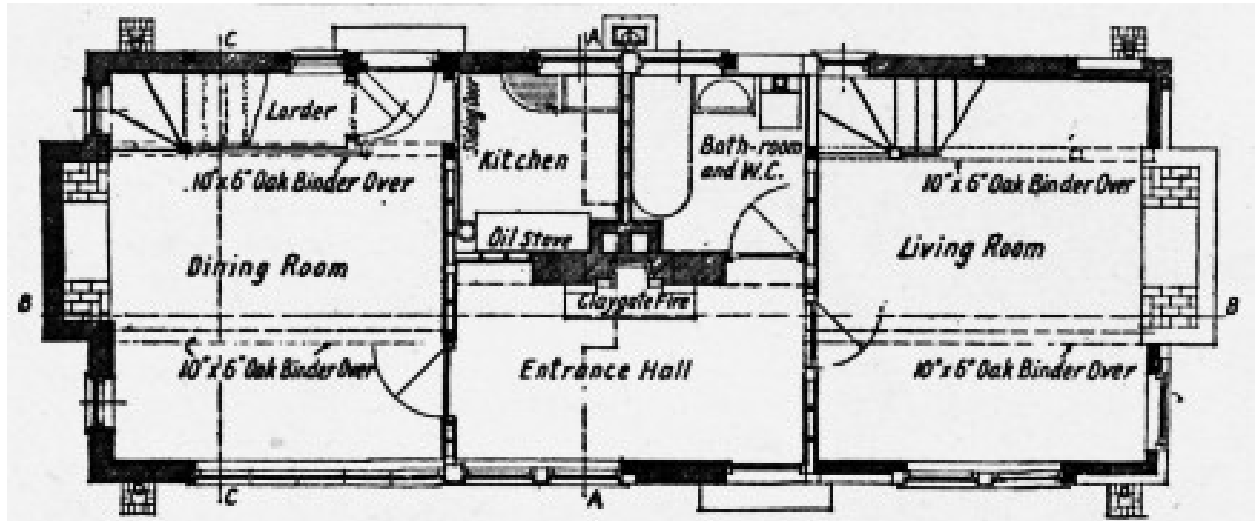

Below, note how the common defects in old cottages are remedied: a new damp course; thicker walls; larger and better-positioned windows; and new roof tiles.

Above, first floor and next page ground-floor plans of the rebuilt cottage seen on the previous page. The outline of the three former cottages is retained; so the bathroom had to be placed on the ground floor. The common fault of trying to make everything look rough and "quaint" should be avoided.

### COTTAGE: A RUIN TRANSFORMED BY OUR EDITOR

*Left, North view during rebuilding; unroofed portion on right later converted into walled garden with rain water cistern under.*

*Below, West Front from garden showing verandah and entrance.*

*Above, East view of the ruin before conversion; unroofed portion on left later converted into commodious garage and pump house.*

*Left, general view of cottage from North East after completion. Compare with view, top left.*

bear washing as often as linen. Cotton damask tablecloths and napkins are more fluffy and less firm than linen. The short fibre comes away as lint, as is seen in using cotton dusters or glasscloths. Used as dress material, cotton shows creases more than wool or silk, for it lacks resiliency.

A simple and moderately effective process to reduce the inflammability of cotton is to steep the article in  $\frac{1}{2}$  lb. alum,  $\frac{1}{2}$  lb. phosphate of ammonia, dissolved in one gallon of water. As the deposit of these salts left upon the fabric produces the flame-proofing effect, the articles must not be wrung too heavily and should be hung to dry. Cotton goods are easily scorched in ironing or in drying too close to a fire, and such heat enfeebles the fibre and shortens the life of the cloth.

**Sewing Cotton.** A fine quality of raw cotton is required, and a uniformity of thickness for the yarn from which sewing cotton is made. It is important for neat and strong needlework to use sewing-cotton of the proper thickness. No. 50 is a good average for general sewing, with 60 or even 70 for fine work such as babies' garments, 40 for strong calicoes and 30 for such jobs as securing buttons on which there is considerable pull.

A convenient way of storing reels of cotton, which take up too much room in the workbox, is to string them on a long loop of string, and hang them from a hook or nail. The loop can easily be taken down and laid on the work-table when sewing is in progress, and every colour and thickness will then be handy. Mercerised sewing-cotton is dipped in a solution which gives it a silky appearance. It is useful for stitching mercerized and mixed cotton and silk fabrics. *See* Laundry; Mending; Sewing Machine.

**COTTON THISTLE** (*Onopordon*). A very fine and vigorous growing biennial plant, the cotton thistle is suitable for shrubberies. The stems are covered with whitish hairs, and the heads of flowers are thistle-like in form and purple in colour. The best sorts are *acanthium* (known as the Scotch thistle) and *bracteatum*, which grow 6 feet or more high.

**COTTON WOOL.** Cotton wool is used for affording protection from cold and injury and for absorbing discharges. It can be obtained medicated with boric acid, salicylic acid, iodoform, etc. For dressings the absorbent variety should be used.

Cotton wool is sometimes used to plug the ears, e.g. in bathing and after syringing. Care should be taken to prevent the plug from slipping into the ear by making it sufficiently large and not pushing it in too far. When the ear is discharging, a plug may be dangerous, as it may imprison the discharge; so if this is at all free it is safer to place a pad of cotton wool over the ear hole and keep it in position by a bandage or sticking-plaster.

A piece of absorbent cotton wool is a good thing to use as a sponge in dressing wounds, etc. It is soft and comfortable, and can be burnt afterwards.

Thick pads of cotton wool may be used in conjunction with camphorated oil to cure colds on the

chest. The oil should be rubbed on the chest just before the patient retires for the night, and a pad of cotton wool placed over it. The pad may be held in position by means of a bandage, but the latter must not be too tight, otherwise it will interfere with the patient's breathing. The most useful form of cotton wool for this purpose is gamgee tissue, which may be shaped to form a jacket.

**COUCH.** Originally meaning any article or spot used for resting or sleeping on, a couch is now usually a synonym for a sofa. *See* Chesterfield; Settee; Sofa.

**COUCH GRASS.** One of the worst of garden weeds, its botanical name is *Agropyrum repens*. It spreads alarmingly by means of its creeping rootstock and can be exterminated only by digging out the roots.

**COUGH.** A cough is nature's method of clearing the air passages of material which should be got rid of, whether it has been introduced from without or been formed in the lungs or air passages themselves. If anything we are swallowing goes the wrong way we at once cough and prevent its entrance into the trachea. What happens is that in response to the irritation produced by the substance on the lining of the entrance to the larynx, we take a deep breath and the vocal cords are closed. We then make to breathe out strongly, the vocal cords fly apart, and the air is expelled with force and suddenness, sweeping the offending material in front of it. The irritation has stimulated a centre in the medulla oblongata, the part of the brain which is continuous below with the spinal cord, and this sets the expiratory muscles in motion.

Frequently the centre is stimulated by irritation, occurring at various parts, when there is nothing to be brought away, and the cough serves no useful purpose. This is spoken of as a dry cough, and it may be due to irritation from adenoids, or a long uvula, to inflammatory mischief in the air passages or elsewhere in the organs of respiration, to tumours of the larynx, and other causes. It is the cough of dry-catarrh which is often so troublesome in elderly people. Irritation of the larynx produces a croupy, hoarse, or brassy cough. This occurs in laryngitis, diphtheria, aneurism of the chest, and other conditions.

A paroxysm of coughing may occur from persistent or severe irritation, but when it terminates in a crowing sound produced by a long-drawn intake of the breath it usually means whooping-cough. Winter cough is that due to a chronic bronchitis, which improves in fine weather and grows worse or only appears when the weather becomes cold and damp. A stomach cough may occur, but it is much more uncommon than is supposed, and a persistent cough should not be accepted as merely a stomach cough without consulting a doctor, as it may be due to early consumption. Cough is merely a symptom, and its treatment should be directed to its cause. *See* Bronchitis; Cold Consumption, Whooping Cough, etc.

**COUCH GRASS.** One of the worst of garden weeds, its botanical name is *Agropyrum repens*. It spreads alarmingly by means of its creeping rootstock and can be exterminated only by digging out the roots.

**COUGH.** A cough is nature's method of clearing the air passages of material which should be got rid of, whether it has been introduced from without or been formed in the lungs or air passages themselves. If anything we are swallowing goes the wrong way we at once cough and prevent its entrance into the trachea. What happens is that in response to the irritation produced by the substance on the lining of the entrance to the larynx, we take a deep breath and the vocal cords are closed. We then make to breathe out strongly, the vocal cords fly apart, and the air is expelled with force and suddenness, sweeping the offending material in front of it. The irritation has stimulated a centre in the medulla oblongata, the part of the brain which is continuous below with the spinal cord, and this sets the expiratory muscles in motion.

Frequently the centre is stimulated by irritation, occurring at various parts, when there is nothing to be brought away, and the cough serves no useful purpose. This is spoken of as a dry cough, and it may be due to irritation from adenoids, or a long uvula, to inflammatory mischief in the air passages or elsewhere in the organs of respiration, to tumours of the larynx, and other causes. It is the cough of dry-catarrh which is often so troublesome in elderly people. Irritation of the larynx produces a croupy, hoarse, or brassy cough. This occurs in laryngitis, diphtheria, aneurism of the chest, and other conditions.

A paroxysm of coughing may occur from persistent or severe irritation, but when it terminates in a crowing sound produced by a long-drawn intake of the breath it usually means whooping-cough. Winter cough is that due to a chronic bronchitis, which improves in fine weather and grows worse or only appears when the weather becomes cold and damp. A stomach cough may occur, but it is much more uncommon than is supposed, and a persistent cough should not be accepted as merely a stomach cough without consulting a doctor, as it may be due to early consumption. Cough is merely a symptom, and its treatment should be directed to its cause. *See* Bronchitis; Cold

Consumption, Whooping Cough, etc.

**Cough Lozenge.** Numerous lozenges for relieving coughs can be obtained from chemists, but for a simple and slight cough a lozenge can be made at home, if desired, from syrup of horehound. The syrup can be made from the stems and leaves of the horehound plant steeped for several hours in cold water. Allow  $\frac{1}{2}$  oz. of horehound to a cupful of water. The syrup can also be obtained from a chemist.

Boil up the liquid with 2 lb. of demerara sugar and 2 tablespoonfuls of vinegar until the syrup sets when dropped into a cup of cold water. Add  $\frac{1}{2}$  a teaspoonful of carbonate of soda, and boil up again until, when a little is dropped into water, it sets and is brittle. Pour it out on to a buttered tin to set, mark it out in squares with a knife, and, when cold, snap off as marked and wrap each piece in waxed paper. Store them in an airtight tin. Ordinary treacle toffee has a soothing effect.

**Cough Mixture.** Cough is merely a symptom of a large number of different complaints, and in the case of any particular complaint a drug which is useful at one stage may be harmful at another. It is unwise, therefore, to take medicine for a cough without knowing what the cough is due to, and to persist with a cough mixture because it has benefited somebody else's cough. In the case of a cough which comes on each year in cold, damp weather, the winter cough, the following may prove useful: Chloride of ammonium, 2 drams; compound tincture of camphor, 4 drams; liquid extract of liquorice, 2 drams; spirit of chloroform, 2 drams; infusion of senega, to 6oz. The dose is a tablespoonful thrice daily, in a little water, after food. *See*, Bronchitis.

**COUNTERBORE.** This tool consists of a central peg, or pilot, and a larger diameter cutting part, rotated in a lathe or drill press. The tool is fed into the work until the desired depth has been attained. A good counterbore should be capable of turning out a neatly finished hole or recess having square corners, such as are required for the reception of a screw head that has to be sunk below the surface of the surrounding metal, as illustrated. The same result is obtained in woodwork by using an auger bit, drilling out the larger diameter hole first and following with the smaller one, otherwise there would be no material to guide the auger, unless the small hole be temporarily plugged for the purpose.

*Counterbore. The tool used in metal work, and diagram showing counter-bored recess for a bolt head.*

**COUNTER IRRITANT.** A counter-irritant is an agent which produces redness and irritation of the skin. The idea is to bring an abundance of blood to the skin vessels, with a view to relieving congestion of

deeper structures or organs. Counter-irritants include rubefacients which redden, e.g. acetic acid, solution of ammonia, liniment of camphor and ammonia, liniment of capsicum, mustard, iodine; vesicants which blister, e.g. cantharides or Spanish fly; and pustulants which produce pustules (blisters containing matter), e.g. lunar caustic and croton oil.

It should be remembered that substances of the first class, if used too strong or too long, may blister, while those in the other class may be used sufficiently diluted to produce redness only. In applying counter irritation for the relief of an underlying condition, better results may be achieved if it is applied rather at a little distance than just over the seat of the pain. *See* Plaster.

Counterpoise. *See* Earth.

**COUNTERSHAFT.** A countershaft is used in connexion with belt-driven machinery. It is a short shaft mounted in suitable bearings and equipped with pulleys.

*Countershaft for use with belt-driven machinery.*

The counter-shaft is driven by a belt from the main or line shaft, and another belt transmits the drive from the countershaft to the machine. As usually arranged, a striking gear is provided to move the belt from the driving pulley on to one of equal size, situated next to it, called the loose pulley, as it is free to revolve on the countershaft itself. A typical countershaft that is suitable for an amateur's turning lathe is illustrated above. *See* Amateur Carpentry Gear; Lathe.

**COUNTERSINK:** A Brace Bit. The name of countersink is applied to a type of brace bit used to form a conical-shaped recess in wood or metal, etc., whereby the head of a screw or rivet can be let in flush with the surface. *See* Bit.

**COUNTESS PUDDING.** A good steamed pudding is made by greasing a mould with butter, and arranging 2 oz. quartered glacé cherries and the same quantity of quartered stoned raisins in the bottom of it. Now line the sides with some thin strips of plain madeira or almond cake. About  $\frac{1}{2}$  lb. cake should suffice. Mix any left over with 4 oz. crushed macaroons, 2 lightly beaten eggs, and  $\frac{1}{2}$  pint milk. Fill the mould with the mixture, tie a buttered paper over it, and steam it for about  $\frac{3}{4}$  hour. Turn it out to serve.

**COURSE: At Meals.** For the ordinary luncheon two courses, either an egg dish, fish or meat and a sweet, are the rule, but the menu may be supplemented by a soup, or cheese course. For dinner it is usual to plan a meal of four courses, stretching to five or six for special occasions. In small households, soup or fish, entrée or joint, sweets and savoury, are generally enough, serving melon, grape fruit or hors d'oeuvre instead of soup for a change, or including fish and omitting the savoury.

When entertaining, a poultry or game course can be introduced after the entrée, or this can be varied by a vegetable, such as asparagus, salsify or seakale, served as a separate course. It is not usual now to serve an ice as well as sweets, but the former frequently takes the place of the latter at either a luncheon or dinner party. At a small dinner dessert may be omitted, especially when some kind of fruit ice or salad forms the sweet course.

For a more ceremonious dinner party the full list of courses would be—melon or hors d'oeuvre, soup, fish, entrée, joint, poultry or game, sweets or ice, savoury, dessert. The entrée should be complete with any necessary vegetable in one dish, but potatoes and one or two vegetables are served with the joint and salad with game or poultry. On rare occasions a sorbet—a punch ice—is served between joint and game, and small Russian cigarettes may be handed round with this course. For a supper hot soup may be served, but otherwise the term usually signifies a cold meal with meats, sweets and savouries either on the table or sideboard, and no formal courses. *See* Dinner; Luncheon.

**COURT PLASTER.** This is a mixture of isinglass, glycerin and alcohol spread on silk. It is used to bring the edges of a cut together and to protect it.

**COVER: For Furniture.** Loose covers of chintz, cretonne, etc., afford protection for furniture, and are also useful for bringing odd chairs into a harmonious colour scheme or for placing over worn chairs or settees. These should be cleansed thoroughly before the new covers are put on. An armchair should be rubbed with stale bread, and if this fails to remove the marks, benzoline will probably be successful. This is best applied out of doors benzoline being highly inflammable.

A plain rep fabric or one with a small pattern can be chosen for a cover because it is easily fitted, but if a distinct pattern is selected for decorative value care must be taken to see that it is correctly placed. Hang the fabric wrong side out over the chair, so that any pins used in fitting can remain until the cover is sewn. Allow at least 1 in. all round for the hem at the bottom, and, when fitting, tuck the material well in at the back of the seat. Since the covers are not to be tight fitting, a certain amount of fullness should be allowed at the back and front, and plenty of material used for tucking in at the sides, where if possible, all joins should be arranged.

If necessary pieces should be let in at the front of the

arms. Having fitted the chair, cut the materials to the required shape, remove the fabric, and the cover is ready to be sewn up. In doing this leave the necessary opening at the back, make a false hem for the buttons, and an inside flap for the buttonhole. The seams and lining edges of the furniture should be piped. Use strong cotton for the sewing, and oversew each corner firmly. Turn up the hem and thread a tape through it from end to end. The tape will draw the cover neatly round the frame and can be hidden by a flounce reaching to the floor. For a chesterfield or large settee double width material about 50 in. wide is best. *See* Cretonne; Decoration.

**COVERLET.** This is another word for bedspread or cot cover. A waterproof or a fabric cover of an ornamental nature for the perambulator is also called a coverlet.

A cosy cot cover is worked with blue and cream double knitting wool, and besides being very warm will outwear any of the woven variety. The necessary materials are 1 lb. of double-knitting wool in blue for the centre, 6 oz. of cream for the border, and a bone crochet hook, No. 8. These produce a cover measuring 49 in. long by 39 in. wide, but the size can be varied.

Begin by making 134 chain, and work the first row thus: Treble in the 5th chain from the hook, then treble in each chain to the end of the line. Make 2 chain, turn, and in the second row miss the first stitch over which the 2 chain stands, as this will represent one double crochet. Then double-crochet in each treble to the end of the row, taking up the back loop only. Make 3 chain, turn, and commence the third row by missing the first double chain.

Do one treble in each stitch to the end of the line, taking up the back loop only; the last treble will be worked in the top of the 2 chain. Make 2 chain, turn, and then repeat the second and third rows alternately 53 more times.

For the border, use the cream wool, and work all round thus: Do 2 treble under the side of the trebles on the left side of the cover, and 1 treble in the double crochet; then across the ends there will be 1 treble in each stitch. At the corners put 2 treble, 2 chain, and 2 treble right in the cornermost stitch. In following rows there will be 1 treble on each stitch, and 2 treble, 2 chain, 2 treble under the 2 chain for the corner. There are 11 border rows in the model illustrated, the order being 5 cream, 3 blue, and 3 cream.

*Coverlet for a baby's cot, made after the pattern given in this article.*

Cot or perambulator covers may be made in linen or wool blanket cloth. The former may be embroidered and hemstitched in a contrasting colour, the latter bound with satin ribbon and either worked in coloured wools or suitable designs appliqué. *See* Appliqué; Bedspread; Quilt.

**COVERT COATING.** This is a tailor's cloth in neutral shades, heavier than the similar-looking gabardine cloth, and the front edges of coats and raincoats made from it are less inclined to roll at the flap. Made both in worsted and woollen cloth, it shows a steep and pronounced screw twill, and the colouring is usually raised light and dark in the same thread.

Good covert coating wears well, but has been imitated in light and cheap makes, although these are more usually called gabardines.

**COWHEEL.** Boiled cowheel is a nutritious dish. To prepare it, wash the heel thoroughly, and boil it for 1-3 hours in sufficient milk and water to cover it. The milk and water may be mixed in any proportions. Add one large sliced onion and a little salt, and when the meat is cooked take it out and keep it hot. Thicken the liquor with flour, using 1 oz. to every pint of liquid, and mixing the flour thinly with cold milk before adding it. Stir the sauce till it boils, then add 1 teaspoonful chopped parsley and seasoning, which should include a few drops lemon juice and a light dust grated nutmeg. Arrange the pieces of the heel on a hot dish, pour over the sauce, and border with toast sippets.

An excellent family broth is made by dividing one boiled cowheel into quarters and putting it in a saucepan with 3 pints cold water and a small teaspoonful salt. Bring to boiling point, skim it well, and add 1 oz. each of carrot, turnip, onion and celery cut into dice. Let the soup boil for about 1 hour, or until the meat slips off the bones. Then take out the meat and bones, cut some of the best pieces into dice and put them back into the soup with 1 oz. rice. Boil the broth again until the rice is thick, then season the whole carefully, adding a tablespoonful of chopped parsley and a dash of lemon juice. Serve the soup with toast cut into dice. If a cowheel which has not had the preliminary boiling is used, it will require 3 or 4 hours' cooking before the meat leaves the bones.

**COWPOX** or *Vaccinia*. This is a mild, contagious disease of the cow in which vesicles or blisters appear on the udders and teats. The lymph obtained from these vesicles, calves being used for the purpose, is the material used for vaccination against smallpox. It does this by producing vaccinia in the human subject. There are strong grounds for believing that human smallpox and cowpox are the same disease, or, at any rate, that both diseases have had the same origin, that is, from one type of micro-organism whose progeny show differences according as their transmission has been through man or cattle. *See* Smallpox; Vaccination.

**COWSLIP.** The popular name of *Primula veris*. This is a well-known wild flower, common in meadows and open woodland. It is the parent of the auriculas and other spring-flowering favourites and will flourish in moist places in the garden.

**COX'S ORANGE PIPPIN.** This apple is the finest flavoured in cultivation. The fruits are at their

best in November and December. It is self-sterile and does not fruit well unless it is planted among other free-blossoming varieties, e.g. Worcester Pearmain. *See* Apple.

*Cox's Orange Pippin, a good dessert apple.*

**CRAB: How to Prepare.** It is of the greatest importance that a crab should be perfectly fresh and in good condition. It should be heavy in comparison to its size, with large claws, and the shell free from white incrustations, these denoting that the fish is aged and probably stringy. Crabs are at their best from May to August, but, like other shellfish, with the exception of oysters, are far from being digestible, and should be eaten sparingly and never given to invalids. A crab when bought at a shop is already boiled.

To dress a crab break off the large and small claws, remove the underneath portion and all the flesh from the shell, also the little bag near the head, usually full of sand, and throw away all bone and the long greyish pieces termed dead man's fingers. The flesh is of two kinds, some firm and white, the rest soft and dark. Separate the former into shreds with a fork, also the meat from the claws after cracking them. Mix the dark soft meat with about 2 tablespoonfuls each of fresh breadcrumbs and oil and vinegar, and seasoning to taste. Season the shredded white meat, but keep separate from the remainder.

Wash and dry the empty shell, chipping off the under portion up to the faint line which serves as a guide. Fill the shell with the two mixtures, arranging them alternately, so that they appear in dark and light stripes, heaping them higher in the middle than at the sides. Decorate with lines of finely chopped parsley, and force a little butter round the edge with a forcing bag and pipe. Place the crab on a fancy paper or on a bed of fresh salad.

For a quickly made savoury dish, prepare some rounds of crisp, neatly trimmed buttered toast, and keep them hot. Melt 3 teaspoonfuls of butter in a chafing dish, stir into it 1 tablespoonful of flour and then  $\frac{1}{2}$  pt of milk. Stir these until they thicken, then add the meat from a medium-sized crab, seasoning it with cayenne, salt, chopped parsley, 2 teaspoonfuls of Worcester sauce and 1 oz of grated Parmesan cheese. Heap this mixture on the toast and serve hot.

Potted crab is a good fish paste. Remove all meat from the shell and pound it, adding salt, cayenne, mustard, and vinegar to taste. With a wooden spoon rub it through a hair sieve, and press it into small pots, which must be clean and dry. Bake slowly for 30 min. and then leave them until cold. Pour on the top of each pot melted mutton fat, to the depth of about  $\frac{1}{8}$  in., taking care not to move the pots until the fat has set and hardened.

**Crab Croquettes.** An excellent fish course is made by pounding the flesh of a crab to a smooth paste, and adding half the quantity of fine breadcrumbs, with enough melted butter to bind the mixture. Season it with lemon juice, pepper and salt, and make it into small rissoles. Coat them with beaten egg, roll them in breadcrumbs, and then fry them to a light brown.

**Crab Pie.** Crab pie or partan pie, as it is called in Scotland, can be made as follows: Pick all the meat out of a freshly boiled crab, mixing dark and white meat together with a seasoning of salt, cayenne, oil, and vinegar. If the mixture is too soft, work in a few breadcrumbs, put the whole back into the shell, strew it over with crumbs and grated cheese, mixed in equal parts, and bake it in a quick oven until lightly browned. Serve the pie hot, with thin slices of brown bread-and-butter, cayenne, and sprigs of prepared watercress.

**CRAB APPLE.** The common wild crab (*Pyrus malus*) is used as a stock on which to graft standard apple trees, and thus serves a very useful purpose in gardens. There are many ornamental crabs valued for their blossoms or fruits or both. The Siberian crab (*Pyrus baccata*) makes a large tree which is beautiful when in bloom in spring and its fruits make excellent jelly. The crabs named John Downie, Dartmouth and

Transparent bear handsome fruits of decorative value. *Pyrus spectabilis*, *floribunda*, *Schiedeckeri* and *Eleyi* are grown for the sake of their exquisite spring blossoms. All four are hardy, and thrive in ordinary soil.

*Crab Apple. Cluster of fruit.*

**Crab Apple Jelly.** After being washed and stalked, but not pared or cored or flavoured will be lost, the fruit should be cut in halves with a plated knife. Put 3 lb. thus prepared in a pan with sufficient cold water to float them—probably about 3 pints. The thinly pared rind of 1 lemon is added and the fruit boiled gently until soft, but not in a mash. The juice is strained through a jelly bag or tammy-cloth, the fruit being pressed gently but not squeezed or the jelly will be cloudy.

After rinsing out the pan the juice is put back into it, with  $\frac{3}{4}$  pint of good white sugar to each pint of juice, and the jelly boiled quickly with the lid off the pan. It must be well skimmed all the time, and a few of the pips may be peeled and stirred in. When a small portion of the jelly sets firmly on a plate, it is ready to be poured off into clean, dry pots. These should be securely covered and stored in a cool, dry place.

**CRACKER:** For Christmas. This harmless indoor firework may be a tiny bonbon of ordinary shape in a brightly coloured paper covering, or one of the giant variety, either bolster or fancy shaped, to be suspended from the ceiling at a Christmas party and containing all sorts of toys and trinkets. Fancy crackers are quickly trimmed with small dolls, holly or flower

sprays, etc. Centre pieces can be easily made by using a gilded or silvered basket decorated with coloured berries and tinsel ribbon and filling it with pretty crackers, or the crackers may be suspended in a toy aeroplane. By the addition of some little ornament or flower the simplest crackers can be transformed into decorative ones. The tiny bonbons may be used to surround a Christmas cake, placed upright and held in position with a ribbon until the cake is cut and the crackers distributed among the guests. *See Christmas.*

**CRACKLE WARE.** This term is applied to Chinese and Japanese pottery whose surface is covered, partly or wholly, with a network of fine cracks. They vary in size from tiny meshes like fish-roe and pigskin up to ostrich-egg effects, and the still wider fissures called ice-cracks. One form resembles trout scales.

Crackle is produced intentionally by the unequal contraction of the body, and should not be confused with the accidental crazing of the glaze seen in some European ware, both old and new. Black inks or red ochres, sometimes both, are rubbed in to make the lines prominent. The oldest pieces, which are Sung ware, go back nearly 1,000 years, and a good apple-green, turquoise or celadon crackle is highly prized.

**CRADLE.** The cradle is a very old piece of furniture, but the oldest existing examples probably date from the 16th century. In the 18th century, following the French example, some were made in very elaborate styles, being panelled or carved and inlaid, but the ordinary type were of plain oak or other wood. In the 19th century iron cradles were introduced, but these soon gave way to wicker ones. Cane is also sometimes used, but the cradle itself has disappeared in favour of the cot in many nurseries.

It is never wise to put much lace on a cradle. Narrow Valenciennes eased on to the muslin covering is permissible, but the better trimming is to frill the material itself.

A usual type of cradle is about 2 ft. long, 14 in. broad, 6 in. to 12 in. high. The cradle may have a hood over one end as in the bassinet type, or a canopy formed from some light and porous fabric, preferably muslin, and lined with a darker piece of the same material; the object being to provide the requisite shade and yet allow free ventilation. When in use the cradle must be kept scrupulously clean, and free from any rough edges or projections which are likely to disturb the rest of the infant. *See Baby; Cot.*

In surgery the term is given to an appliance which protects an injured limb in bed. *See Bed Cradle.*

**CRAMBO: How to Play.** Crambo is a good game for adults, and is suitable for any games party. Each player is given two slips of paper, distinguished from each other in some way. On one of these he writes any noun that occurs to him, and on the other a question.

He then folds each paper over and hands it to the person in charge. The nouns are put into one bowl and the questions are put into another. When they have been well shaken up they are handed round once more, each person taking a noun and a question. His task then is to write a verse answering the question and including the noun.

A time limit should be set, and when it has expired the papers on which the verses have been written should be collected and the results read aloud. Dumb Crambo (q.v.) is an entirely different game.

**CRAMP.** The commonest form of cramp, which is a local painful spasm of a muscle, occurs in the calf at night, when one wakes suddenly with an excruciating knife-like pain, and finds the calf like a hard ball. The pain may pass off after a moment or two as suddenly as it appeared. Gouty or rheumatic tendencies, exposure to cold or damp, and over-fatigue are the commonest causes.

Cramp is not uncommon in pregnancy from pressure on the nerves supplying the legs. It is also a symptom of the neuritis produced by chronic alcoholism. There is a form of cramp which is caused amongst other things by excessive tobacco smoking. After walking a short distance cramp occurs in the calves; this passes off in a short time, but recurs when a short distance has again been covered; so that in taking a walk it is necessary to make frequent halts.

In treating cramp, rub the part vigorously with the open hand, alternating this with massage with the fingers. When the acute spasm has passed off rub in well any household liniment, wrapping the part immediately afterwards in cotton-wool to prevent chilling. People subject to muscular cramp will find the following liniment of the greatest service:

Chloral hydrate	1 oz.
Menthol	1 „
Camphor	1 „

The liniment should be mixed well in a mortar until of a syrupy consistence, and used externally, rubbing in well. Where the tendency to cramp at night is associated with flatulent indigestion, it will be found helpful if a teaspoonful of sal volatile in a little water is taken at bedtime.

Stomach cramp is a common symptom in indigestion. The pain may be the result of sudden distension of the bowel with gases caused by abnormal fermentation of the contained food, or the spasm may be due to irritation of the nerves supplying the stomach and intestines. Apply a hot-water bottle and give bicarbonate of soda and carminatives. *See* Colic; Muscle.

**Cramp in Poultry.** Cramp is a complaint to which both chickens and ducklings are subject. It generally affects the legs, causing the bird to squat down helplessly, and is usually brought on by damp surroundings. The condition is sometimes liable to be confused with leg weakness.

The only cures for cramp are warmth and friction to

restore the circulation. Rubbing the legs freely with embrocation, provided the bird is kept in a warm place while under treatment, will generally effect a cure. *See* Poultry.

**CRAMP: The Tool.** The tool named a cramp is used for tightening the joint between two pieces of wood or other material, and it frequently forms an integral part of a small machine such as a mincing machine, which can thus be readily attached to a table. It is sometimes called a clamp.

Ordinary woodworkers' cramps are made in a very light pattern, comprising a light steel bar bent to shape, and one leg screwed and fitted with a clamping screw. A superior pattern called the G-cramp is made of solid cast metal, and will last for years, especially if fitted with a clamping screw having a square-sectioned thread. Such cramps are made to hold from 2 in. to 12 in. in width. Parallel cramps are made with two hard steel jaws, which are drawn together by two hand screws. They are very useful for small metal work of all kinds, and will hold work up to 1¾ in. in thickness. Corner cramps are used to hold the two parts of a picture-frame or other mitred work while the joint is being fastened. Sometimes four of these cramps are used with a tensioning bar between them, and adapted especially for picture-framing. With all types it is desirable to interpose wood between the work and the jaws, to avoid bruising the surface.

*Cramp: various types used for special purposes. 1. G-cramp, with square thread screw. 2. Toolmakers' parallel cramp. 3. Corner cramp. 4. Bench-cramp. 5. Sash cramp.*

Sash cramps or bar cramps consist of a long steel bar about 1¼ in. deep and ¼ in. thick, from 24 to 48 in. long. At one end is a strong upright with a square-thread cramp screw which pushes a sliding jaw along the bar. A movable jaw is arranged to be fixed by means of a steel pin to any desired position on the bar, and by this means all classes of work can

readily be held, up to the capacity of the cramp. It is of great use to the amateur who undertakes the construction of doors, cabinets, and other large work.

A bench cramp is useful to carvers and other woodworkers, as by its aid the work is held down on the bench. The tool comprises a circular bar that is inserted into a hole bored in the bench top. The cramp screw presses the long bar tightly on to the work, which is thus securely held in position. *See Glue; Picture.*

**CRANBERRY.** Those who have a moist site with peaty soil may grow cranberries, but they are very rarely cultivated in gardens.

The plant is a slender, wiry, trailing shrub, with small red acid berries. It grows wild in England and Wales and in Scotland. Its botanical name is *Vaccinium oxycoccus*. The whortleberry and bilberry are closely related to the cranberry. *See Bilberry.*

**How to Cook.** To stew cranberries, put in a stewpan 1 lb well-picked fruit, just enough water to cover it, and at least  $\frac{3}{4}$  lb. sugar. Let it simmer slowly until soft. Stewed cranberries are best served cold with custard or junket. To relieve the acidity apples are often stewed with them in the proportion of  $\frac{1}{2}$  lb apples to 1 lb. cranberries.

Cranberries make appetising condiments for meat and poultry dishes. A good chutney is prepared by putting 2 quarts of the pickled berries into a pan with  $3\frac{1}{2}$  lb. white sugar, 1 lb stoned, coarsely chopped raisins, the thinly pared and finely chopped rinds of 2 oranges, and  $\frac{1}{2}$  lb. chopped onions. Add  $\frac{1}{2}$  pint good vinegar, the strained juice of the oranges,  $\frac{1}{2}$  oz. mustard seed, and a level teaspoonful each of ground ginger, powdered cloves, and cinnamon, and a little salt and pepper. This is boiled until it is thick, and is then bottled.

**Cranberry Jelly.** Cranberries are excellent as a jelly to vary red currant jelly with venison, roast mutton or jugged hare. Taking 3 lb. of the fruit, pick over and wash the berries, put them into the preserving pan with 3 pints cold water, and let them boil until soft and broken.

Strain off the juice through a fine hair sieve, or through a jelly bag, pressing, but not rubbing down the fruit, or the sparkling clearness of the jelly will be spoilt. Add 1 lb. loaf sugar to each pint of juice, and boil it without the lid until it jellies on being tested on a plate. It can then be poured into jars and stored. It keeps some months without deteriorating.

**Cranberry Sauce.** A sauce which is specially good with turkey, though it may well be used with other poultry, is simply made by simmering a pint of cranberries in a gill of water until they are soft, and adding 3 oz. of white sugar and a glass of port wine. The liquid is then re-boiled, seasoned, and strained ready to use.

**CRANE FLY.** The larvae or grubs of the large, awkward, long-legged fly known familiarly as Daddy

Long Legs are very destructive of all kinds of garden crops. These pests are, however, chiefly found in gardens which have been recently converted from grass or waste land, or where the grass and weeds have been abundant the previous summer. Sods of turf buried in the ground will attract them. Where the grubs are numerous an application of semi-refined naphthalene at the rate of 2 to  $2\frac{1}{2}$  oz. per sq. yd. is worth a trial. The naphthalene should be worked into the soil, after which a thorough watering is advisable. This should not be used on seed beds just about to be sown. *See illus. below.*

*Crane Fly or Daddy Long Legs. A. Male. B. Female. C. Larva. D. Pupa case.*

*(By permission of H.M. Stationery Office and the Ministry of Agriculture))*

**CRANE'S BILL.** This is a popular name given to the hardy geranium. This is quite a distinct plant from the geranium (really pelargonium) used in summer flower beds. *See Geranium; Pelargonium.*

**CRANK.** This is a bent axis in any form of machinery, and is used as a driving or driven means of transmitting power by radial motion. To name but a few common forms, there is the pedal crank of the bicycle, the starting handle of a car, the crankshaft of any engine. In fact, any form of leverage working through a radial motion by means of an off-set arm becomes a crank.

**CRANKCASE.** In its widest sense this term relates to the cavity in which works the crankshaft, and very often the camshaft, the timing gears and the oil pump of an internal combustion engine such as that employed in the motor car. This cavity is included between the sump at the lower part and the casting forming the upper part of the crankcase.

In nearly all motor car engines this casting is integral with the cylinders and the flywheel housing, as well as with the upper part of the crankshaft bearings. The upper part of the crankcase and the parts with which it is associated form one of the largest and most complicated components on a car. In some cases the crankcase is made of aluminium and the cylinders form an independent casting bolted thereto. This method of construction does not, however, produce such a rigid engine.

The crankcase or cavity contains, in addition to the parts mentioned above, the following: magneto or

distributor driving shaft, dynamo shaft, oil pipes, oil filter, and in certain cases the troughs for the dippers on the big-end bearings.

The crankcase casting is provided with seatings for the electrical units, timing gear cover, fan bracket, water circulating pump, and other minor parts. It is also formed with bearer arms by means of which it may be bolted to the car frame, or with seatings to which such arms may be secured.

In most engines the gear box is bolted up to the flywheel housing or to an intermediate casting or clutch casing, and the flywheel housing carries bearings or attachments for the clutch, brake, and accelerator pedal bearings.

When the crankcase is of aluminium, studs are always firmly screwed into the metal for the attachment of other parts. Set bolts are never used, as the screwing in and out would damage the soft aluminium. Studs must never be allowed to work loose, as the thread in the hole would soon be destroyed.

All oil-retaining joints should be made with thick brown paper coated on both sides with gold size, or with a suitable jointing compound. When the co-acting faces are roughly finished, or one of them, such as the sump, is made of flexible sheet metal, a cork washer or gasket may be used.

In motor cycle practice a crankcase is usually divided through the centre, i.e. vertically instead of longitudinally. In all other respects the principle is virtually the same, except that the one-piece casting, meaning the cylinder and top half of crankcase in one, is not employed. *See* Gasket; Lubrication.

**CRANKSHAFT.** The crankshaft is one of the oldest methods employed for mechanically converting power developed by a reciprocating motion into a rotary force, and as used in internal combustion engine practice differs only in accordance with the needs of the design of the engine. As commonly employed, there are the throws or cranks, according to the number of connecting rods and the main journals.

The crankshafts of modern internal combustion engines show considerable variety both in the number of cranks combined in one shaft and in the arrangements of the cranks and main bearing journals.

In nearly all cases the crankshaft is designed to run in anti-friction bearings, which are of the split type formed of brass or phosphor bronze shells, lined with white metal; in fact, practically identical to the big-end bearing. The perfect rotary balance of a crankshaft always receives careful attention, because with this lies to a great extent the perfectly smooth running of the engine. *See* Big-End; Internal Combustion Engine; Motor Car.

**CRAPE: A Dress Material.** Crispness and a crinkled surface characterise all crapes and form the justification for the name. In the manufacture of such fabrics the threads are twisted so much beforehand that when they are woven they do not naturally lie straight, and this feature is seen alike in wool, cotton and silk crapes.

Black silk crapes used for mourning are made more crisp by being treated with shellac, and as this is not a gum soluble in water it tends to remain. The stiffness of such crapes returns if the fabric after wetting is dried before the fire. Waterproof crape should be asked for. In wool or cotton crêpes, as used for summer and indoor dress, the original character returns after washing, although cotton crapes should not be ironed. *See* Crêpe-de-chine; Mourning.

**CRASH: A Linen.** Originally a rough linen imported from Russia and used for kitchen towelling, crash has now a wider range of meaning. Coarse fabrics of various compositions sell under the name, including rough linen towelling, dress and household linens, unbleached or in fancy colours. *See* Linen.

**CRASSULA.** Plants of the genus *crassula*, popularly known as thick leaf, require greenhouse treatment. All the species may be successfully grown in a compost of two parts loam, one part leaf-mould, and a sprinkling of sand, with some broken brick or mortar rubble. Propagation is by cuttings of the tops dibbled into sandy soil, under glass, which strike more readily if laid out to dry before being inserted. They need a sunny, airy greenhouse and little water in winter. It is usual to shorten the shoots which have flowered in late summer, and to re-pot in spring. The best species are: *coccinea*, scarlet, 18 in., a summer bloomer; *jasminea*, white, 1 ft., spring bloomer; and *actea*, 1 ft., white, at its best in September.

*Crassula. Flower heads of the scarlet coccinea.*

**CRATE.** Crates are made both of wicker and of wood, and their main use is for holding goods that are sent away by rail or road. China, crockery, glass and similar wares are usually packed in crates for transportation. Crates made of slats of wood are largely used for conveying poultry, rabbits and other domestic animals by rail, as they are for bicycles, perambulators and certain articles of furniture.

**CRAWFISH.** This crustacean is a species of rock lobster common round the British coast. It is larger than the lobster and is cooked in much the same way. The flesh, however, is coarser and the flavour inferior, though it is often substituted for lobster in salads. It is totally different from the crayfish.

**CRAYFISH.** The small freshwater crayfish found in the rivers of Great Britain is of a delicate flavour and is highly esteemed as an article of food. Quantities of crayfish are imported into Great Britain from the Continent, the home supply being limited. They are

usually boiled before being put on the market; where this has not been done they should be plunged in boiling fish stock for about 10 minutes.

*Crayfish, the delicately flavoured shellfish found in British rivers.*

Soup made with river crayfish is considered a great delicacy. A quart of fish stock will be required with 18 crayfish. Remove the gut from the centre fin of the tail of each, shell the fish, and pound the shells and half the tail-meat with 2 oz. butter and 2 boned anchovies wiped free from brine. Put this pounded mixture into a saucepan and stir it with a wooden spoon over the fire until it is hot; add 2 oz. washed rice and fry the whole for 5 min., during which it must not be allowed to colour even slightly.

Add the fish stock and a small onion stuck with 2 cloves; allow these to simmer until the rice is soft, stirring frequently. Soak the soft part of a French roll in milk and add it before rubbing the soup through a hair sieve. Reboil the soup, pour in  $\frac{1}{2}$  gill cream, 1 teaspoonful lemon juice, and some seasoning, finally adding the remainder of the meat from the tails, cut into dice. Serve the soup with croutons or sippets of hot crisp toast. *See Mayonnaise.*

**CRAYON:** How to Use. The variously coloured pencils made of chalk or pipeclay and used for drawing purposes are known as crayons. In addition to the use made of them by artists, etc., they form popular presents for children, especially when accompanied by uncoloured picture books.

Cheap crayons should not be given to children, since they are apt to melt quickly in a warm hand and are a source of real danger if placed in the mouth. Crayon drawings made on paper which is not specially prepared for the purpose easily become smudged. They may, however, be fixed by washing the paper with a strong solution of isinglass. When it is dry, the drawing may be made upon it, after which it should be inverted and held horizontally over steam. The steam melts the size, which absorbs the crayon, and the drawing thus becomes fixed. This process may be repeated several times while the drawing is being made, the effect being increased on each occasion.

**CRAZY PAVING.** The name of crazy paving is applied to stone paths, composed of random or odd-shaped pieces roughly fitted together to preserve a generally straight line at the edges of the path. Crazy paving is not restricted to paths, but has many applications as a paving for courtyards, the surround to the base of a sundial, and for terraces and other ornamental features in the garden.

The materials are often obtainable from housebreakers, or from a stone quarry, while old paving stones are excellent for the purpose when they are available. They generally arrive somewhat broken, which is no detriment, as the success of the crazy

paving depends upon irregularity. No two stones are alike in form or size, but the whole must be so arranged that the boundaries of the pavement are in regular lines. It is not sufficient to lay the pieces of stone directly upon the ground: a properly drained subsoil and a suitable bed for the stones are essential.

*Crazy Paving. Fig. 1. Section of path showing how the flags are set in sand on a foundation of rubble and large stones to ensure proper drainage.*

The proper method of constructing such a path or paved area is first to mark out the site, using pegs and the garden line to define the boundaries. The turf and soft top soil are removed to a depth of at least 6 in., and more on a very light soil. The earth is well rolled or rammed, and broken brick, gravel or other ballast or hard core laid down and covered with a layer of finer but rough material, so as to provide drainage for rain water. Regard must be paid to the falls or levels of the path, and in any hollow places a few rough agricultural drain pipes will prevent pools of water forming on the pathway. In many cases the drain pipes can be so disposed that the rain water is directed towards the flower bed or other location where it will be beneficial.

*Crazy Paving. Fig. 2. Irregularly shaped flags worked into a path and linking up divisions of a large garden.*

The laying of the stones can next be commenced, and it is worth while to sort roughly over the materials and assemble the pieces in groups according to size. The stones vary in thickness, size and shape. For the edge of the path use the straightest edge of the stone and commence by laying a bed of sand upon which to set the stones. The stones are set upon the sand by moving them about slightly and bedding them in, using a trowel to manipulate the sand, and a beetle or heavy rammer to beat down the stone. Every stone must lie firmly without tendency to rocking or movement, otherwise it will never settle. Lay to the outer edges of the path first, and then fill in the centre, but complete the whole width of the path as the work proceeds.

When finished the path should present a level surface; any irregularities in thickness of stones may be compensated by adding more sand underneath to make up for any deficiency in thickness. The stones are sometimes set in cement mortar especially when it is desired to prevent the growth of grass and flowerets between the stones. In this case the cement mortar is laid upon the sand and the surface of the stones brushed over with cement slurry completely to fill all crevices. The path should be washed later on, so that the natural colour of the stones is revealed.

Fig. 3. Crazy paving in a small town garden, the old stones forming an ideal background for flowers throughout the year. (Fig. 2, R. Neal & Sons, Wandsworth; 3. Humphrey & Vera Joel)

An edging of brickwork forms a pleasing finish to a large area of crazy paving. An alternative method is to set larger stones directly upon the grass, when a Japanese or stepping-stone type of path is wanted. To do this the turf is cut away to the shape of the stone, which is then bedded on sand laid directly upon the earth.

A reasonable estimate is that a ton of stone will cover anything between six and ten square yards of crazy paving. See Cement; Concrete; Path; Wall.

**CREAM: Its Food Value.** Cream consists of the fatty globules of milk in which are contained the carbonaceous portion constituting the principal food value. It has been found, on analysis, to contain 74.0 parts water, 2.5 protein, 18.5 fat, 4.5 carbohydrates, .5 ash. All the nutriment contained in cod-liver oil is contained in cream, and invalids and children for whom the former is recommended find in cream a perfect substitute which is much pleasanter to the palate. Consumptives benefit from a diet in which cream has a liberal part, and it is much given to other kinds of invalid.

Cream is separated from milk for commercial purposes by mechanical separators. To separate it at home without mechanical aids, simply allow the milk to stand from 8 to 10 hours. The fatty globules, which contain the cream, are lighter than the other constituents of the milk, and they thus rise to the surface, where they combine and are skimmed off. The milk

should be fresh and immediately placed in a wide, shallow vessel and left to stand in an even temperature of about 52° F. in summer and 60° in winter.

Double cream is obtained by allowing the milk to stand for 24 hours before being skimmed. The vessel in which the milk is placed should on no account be covered so that the air is excluded, but with a piece of muslin in order to protect from dust or flies.

Cream can be kept fresh for two days if it is just brought to boiling-point without being allowed actually to boil. If sugar is added, it will keep in a cool place for about 36 hours. It can be obtained in hermetically sealed tins, and in this form should keep for a considerable time. Once the tin is opened, however, the cream should be emptied into a basin or jug and used immediately.

Whipped cream goes further and is used for many sweets. A little sugar, wine, or flavouring can be added before cream is whipped, if desired. The cream should be poured into a cold basin and whipped with an egg whisk in a cool place or in a current of air, so that cold air can be incorporated into the cream to make it light and stiff. Care must be taken that it is not over-whipped, or it will turn into butter.

Simple contrivances for reconstituting cream from butter and milk are available.

In addition to its chief use for the oily substance that forms on milk, the word cream has several other meanings, all, however, derived from the prime one and all implying some form of excellence. It is used for cosmetics, such as face cream, and for certain mixtures for cleaning boots; also for various preparations in which chocolate is the main ingredient, and for other sweetmeats. *See* Butter; Clotted Cream; Ice; Milk; Trifle, etc.

**CREAM BUN.** These cakes are also known as cream puffs. To make them, melt 2 oz. butter in a saucepan, adding half pint hot water, and let the two boil. Take the pan off the fire and beat in 4 oz. dried and sieved flour. Add a few grains of salt and, with a wooden spoon, beat the mixture briskly until all lumps have disappeared; then put the pan over a slow fire and stir the mixture until it can be rolled about without sticking. If overcooked the butter will ooze out, and the panada, as the mixture is termed, will be spoilt. When cooked let it cool, and beat in 2 whole eggs and 1 extra yolk, adding each egg separately and working it in. Add vanilla essence and castor sugar to taste.

*Cream Bun. Plate of these light cream pastries covered with coffee icing and crystallised flowers.*

To form the cakes use a forcing bag with a plain pipe, but if this is not available use 2 dessertspoons,

forcing or shaping small round heaps of the mixture on to a greased baking sheet and leaving a space of 2 in. between each cake. Bake them in a moderately slow oven for about 30 to 45 min. When cooked they should be light, hollow, and biscuit-coloured.

When cold cut each cake open down one side, and fill in whipped sweetened cream. The buns when cold are coated with chocolate or coffee icing and sprinkled with crystallised flowers. *See Icing.*

**CREAM CHEESE.** While most dairies have their own methods of making cream cheeses from either double cream, containing 50 per cent, of fat, or from thin cream, thickened with rennet before drainage takes place, the following method is a simple one for making about six  $\frac{1}{4}$  lb cheeses from a quart of cream. The cream should be cooled to 65° F. and a drop of rennet, together with a little starter, should be added immediately the cream is cooled. This starter may be either a pure culture of lactic acid bacteria used by most cheesemakers, or it may be a little clean sour milk. On no account should the cream be soured naturally, as the flavour depends on its freshness. The cream is then left for 8 to 12 hours before draining. Salt may be added at the same time as the rennet, one teaspoonful to a quart of cream being ample.

The cream is drained in fine longcloth spread over a wooden form, which is provided with a loose board which can be weighted to press out superfluous moisture. The longcloth is thrown over the form and pressed down to the level of the table on which it stands and the cream then poured in to the depth of 1½ in. covering the inner area of the form. Drainage must be gentle at first, or the mesh of the cloth gets filled with cream. The cloth should be opened once after the first half-hour and scraped down, when the cream should be re-weighted with a 14 lb. weight. The cream should be ready to mould in 3 or 4 hours. The cheese is filled into small moulds lined with parchment paper. A wooden knife should be used. On removal from the mould the separate cream cheeses are wrapped in muslin. *See Cheese.*

**CREAM JELLY.** Prepare half a pint of claret or raspberry jelly, using twice as much gelatine as usual, or, if preferred, use a 1-pint packet of jelly, and prepare it as directed on the packet, but using only half the stated amount of water. Put half a pint of good cream into a basin, whisk it until it thickens, but not sufficiently to make it hang on the whisk. Then whisk it gradually into the warm, but not hot jelly, adding any extra colouring or flavouring desired. Continue to whisk the whole gently until it is on the verge of setting, then pour it into a mould that has been rinsed out with cold water. Leave it until it sets, then dip the mould into hot water and slip the jelly out on to a dish. It may be decorated by putting round the cream a border of chopped sweet jelly, of a contrasting colour.

**CREAM JUG.** The earliest cream jugs known to collectors are silver ones, having a bellied bottom and

straight neck, no lip and simple bow handle. They are sometimes found in sets of three small ones and one somewhat larger. Early in the 18th century the short low-bellied jug with a small lip and bow handle came into use. These jugs stood on a ring foot, but soon they were made with three cast feet, and this type became popular. The body was decorated with chasing, and as other elaborations were introduced the lip became an elongated spout, and for the bow a shaped handle was substituted. The three feet were replaced by a round foot and a short stem, as is seen in two of the illustrations.

*Cream Jug. Antique examples in silver. 1, 3 and 4. Chased and plain jugs, temp, late George I and early George II. 2. Ornamented with heading, classical period, late 18th cent. 5. Cream ewer, dated 1801 (Courtesy of Spink & Son, Ltd.)*

Late in the 18th century, owing to the classical style of decoration in vogue, a less ornate pattern was again adopted. The foot and stem were left, but an oval helmet-shaped body came into fashion. Severity of outline and restrained beaded or reeded ornament were retained, but jugs with fuller bodies and short necks were made. Another style is one in which the foot and part of the body are cut off. Many of these are graceful pieces of work, and many beautiful modern cream jugs are reproductions of 18th century designs. Cream jugs are also obtainable in glass and in china to match services.

**CREAM OF TARTAR.** This is the common name for the bi-tartrate of potassium. Two to six teaspoonfuls in orange marmalade is sometimes used as a purgative. The Imperial drink, a favourite household remedy for slight fever, may be made by adding a teaspoonful of cream of tartar, a little sugar, and a quarter of a lemon to a pint of boiling water. This tends to keep the kidneys active.

**CRÈCHE.** A crèche is a daily boarding establishment for infants and young children under school age. The standard varies according to the income of the parents who wish to have their children cared for during the hours they are unable to look after them.

The mother leaves her child or children at the crèche early in the morning, and pays 2d. or 3d. per child. In many cases she also brings the food it requires for the day. If an infant is breast-fed, arrangements are made for the mother to call in the dinner-hour. The children are cared for by the crèche attendants, and frequently bathed and washed, superintended and fed until the mother or guardian calls for them at about 5 o'clock. They are given as much fresh air as possible, amused and trained in orderly ways. Most large cities have crèches in their midst, and information about them can usually be obtained from the local infant welfare centre.

**CREDIT: The Legal Aspect.** Credit is a matter of agreement. If a lady orders goods and makes no agreement that she is to have credit, the law implies that she is to pay for them on delivery. She should, of course, be allowed an opportunity to examine them before paying. If she wants credit she must agree with the tradesman that she is to have it, and agree how long the credit is to be. Once it is agreed that credit shall be given, the seller of the goods cannot go back on it and demand cash on delivery; neither can he demand payment before the period agreed upon has expired. Thus if the lady buys on the 1st Jan., upon the terms of a month's credit, she has until Feb. 1st in which to pay, and cannot be sued for the money until Feb. 2nd.

The word credit is used by bankers for the money or other reserve which a person has in the bank. In bookkeeping the credit side of the account is the one where payments are entered. *See* Accounts; Banking.

**CREEPER.** A term correctly applied to vigorous self-clinging plants like ivy which are used to cover walls. It is applied to many climbing plants. *See* Canary Creeper; Clematis; Climbing Plant; Wistaria, etc.

**CREEPING JENNY.** This is a good trailing plant and useful alike for window boxes, rockeries and hanging baskets. It thrives in shade and bears yellow flowers in summer. The golden-leaved variety, aurea, is attractive. It is easily propagated by detaching rooted pieces.

*Creeping Jenny. Leaves and golden flowers of this spreading trailing plant.*

**CREEPING SAILOR.** The common name of creeping sailor is given to *Saxifraga sarmentosa*, a pretty creeping plant, which is also known as mother of thousands (q.v.). It may be grown in pots suspended in room, window or greenhouse.

**CREMATION.** When it is desired to have a body cremated, the best course is to telephone or telegraph to one of the cremation companies, who will at once send a representative or give instructions as to what steps should be taken. A special form of application will be supplied, and this must be filled up and signed by an executor or a near relative of the deceased. Among other things the applicant must state that deceased had expressed no objection to being cremated, and whether any near relative of the deceased objects to the proposed cremation; if so, on what grounds.

**Procedure and Regulations.** Two medical certificates are needed. One is filled up by the medical man who attended the deceased in the last illness, and who has seen and identified the body. The second certificate may only be given by a medical practitioner of not less than five years standing who holds one of certain specified appointments, such as medical officer of health, police surgeon, physician or surgeon to a public general hospital containing not less than 50 beds, or has been appointed specially for the purpose. The registrar's certificate of death must also be produced for inspection by the medical referee of the cremation company. When the medical referee of the cremation company is satisfied that all the requirements of the Act have been complied with, he authorises the superintendent of the crematorium to cremate the remains.

Any form of religious service may be conducted before the actual incineration. Friends may see the coffin placed in the chamber, but are not permitted to witness the burning. The ashes are placed in an urn, which may be deposited in a chapel or buried in a grave or handed over to the friends.

The following is a list of the crematoria in Great Britain, with the addresses to which application should be made:

London:

Golders Green: 45, Nottingham Place, W.

Hendon Park: Abney Park Cemetery Co., Stoke Newington, N.

Little Ilford: Guildhall, E.C.

West Norwood: 58, Temple Chambers, Temple Avenue, E.C.  
 Woking: 45, Nottingham Place. W.  
 Birmingham: Kings Court, 115, Colmore Row.  
 Bradford: Scholemoor Cemetery.  
 Bristol: 36, Corn Street.  
 Brighton: Borough Cemetery, Lewes Road.  
 Darlington: 36, Priestgate.  
 Edinburgh: Heriot Hill House, Canonmills.  
 Glasgow: 142, St. Vincent Street.  
 Guernsey: Foulon Cemetery.  
 Hull: Hedon Road Cemetery.  
 Ipswich: Cemetery Gates.  
 Leeds: Lawnswood Cemetery, Adel.  
 Leicester: Gilroes Cemetery.  
 Liverpool: Priory Road, Anfield.  
 Manchester: 37, York Street.  
 Nottingham: Wilford Hill Cemetery.  
 Pontypridd: 31, Gelliwastad Road.  
 Sheffield: City Road Cemetery.  
*See Death; Funeral.*

**CRÊME DE MENTHE.** This is a pleasant and wholesome liqueur made from peppermint. It is of light green colour, and the best brands are highly esteemed as digestives. It should be served after luncheon or dinner in liqueur glasses. A favourite method, especially in hot weather, is to serve it frappé i.e. with crushed ice, when it should be drunk through a straw.

**Crème de Menthe Square.** Take 1 lb. of granulated sugar, 1 teaspoonful peppermint essence, 1 gill water, 1 sheet gelatine, and a little green vegetable colouring. Dissolve the gelatine in half the water in a saucepan, and boil it for 2 or 3 min. Place the sugar with the remainder of the water in another saucepan, and bring it slowly to the boil. Take it off the fire, and when it is slightly cool add the dissolved gelatine, stirring all the time.

Then add the peppermint essence and vegetable colouring to taste. After it has stood for 10-15-min., strain it into a flat tin that has been rinsed out with water. When quite cold it may be unmoulded by dipping the tin into a basin of warm water. Cut the mixture into rounds or squares, or any other shape desired, and roll the pieces in icing sugar. Leave them in the sugar for a day or two, then shake it off, and pack the sweets in boxes between layers of waxed paper.

**CREOSOTE.** An oily and transparent liquid with a strong penetrating odour, creosote is obtained by heating wood or coal tar, and has a strong antiseptic action; it is less caustic than carbolic acid and is very much less poisonous.

Apart from its use in medicine for certain cases of indigestion and for treating painful teeth, it is employed for creosoting timber, and is of value in the household and garden in preventing wood from rotting. Fences are preserved from decay by painting them with creosote, which penetrates the wood and keeps away insects. In the building of pergolas or garden houses,

those portions of the timber which are to be buried in the ground should be treated with creosote. Inside the house, plain furniture and floors can also be so protected, but the penetrating smell is against its use for this purpose. A good disinfectant powder is obtained by mixing one part of creosote with four parts of slaked lime. *See Disinfectant.*

**CRÊPE-DE-CHINE.** Originally made in China and imitated in France, crêpe-de-Chine is now produced in all the silk weaving centres. Its characteristic appearance arises from the use of hard-twisted silk which is woven without removal of the natural gum that forms about a third of the weight of raw silk. This gum is removed after weaving and the threads exhibit a new fullness and lustre. The cloth is dyed after weaving.

What are called schappe crêpes-de-chine are made wholly or in part of spun silk and are generally firmer and more clothly than those made from raw silk. In addition to the self-coloured fabrics selling under this name there are striped sorts, largely of English make, especially suitable for shirt-blouses and washing dresses. This is one of the most suitable silks for wear next the skin, and can be easily laundered at home in a lather of soap flakes and hot water, allowed to grow tepid before using. Squeeze and knead the garments gently in the lather, rubbing only when it is absolutely necessary. Wring them thoroughly, then rinse them into two bowls of warm and one of cold water, adding a tablespoonful of vinegar to the last. In the case of white crêpe-de-chine, a little blue may be substituted for the vinegar.

Coloured crêpe-de-chine should be ironed as soon as possible after washing, otherwise the colours may run. Ironing is best done by laying the material right side up on an ironing-board or table, smoothing it out, and covering it with a piece of muslin. When nearly dry finish ironing on the garment itself.

**CRESOL.** Often known also as cresylic acid, this is a light brown liquid which smells like tar. It is a disinfectant, and is employed to make liquor cresol saponatus, which resembles lysol and is used in the same way. In whooping-cough the frequency of the paroxysms may sometimes be lessened by impregnating the air with vaporised cresol. This can be done by heating a large spoon in the fire and pouring in a teaspoonful of cresol or the drug may be put in the lid of a tin which is fixed over a nightlight. Vaporisers may also be bought for this purpose. Cresol is found in most of the proprietary disinfectants on the market. *See Disinfectant.*

**CRESS.** The term cress is popularly applied both to watercress and the cress which is eaten with the young leaves of the hardy annual mustard plant.

Mustard and cress grow very easily and rapidly, so that a constant supply is always obtainable for small salad. It is a mistake to plant both at the same time, as

the cress grows more slowly than mustard, and should be given a three days' start. *See* Salad.

**CRESTING:** On Furniture. This term is used for any ornamental detail surmounting a piece of furniture and reaching right across from side to side. It refers to a decorative addition only, not to a constructional part. Cresting may be described as a perforated, carved and gilded, or silvered ornament superimposed above the top moulding, such as is found on lacquer cabinets of the late 17th century. In a chair a crest rail refers to a top rail which has some ornamental character. Chairs of the time of Charles II and William and Mary have decorative crest rails.

**CRETINISM.** Feebleness of mind is one of the symptoms of cretinism, a condition originating at birth or developing at any time up to puberty, together with a large and perhaps protruding tongue, poor development of hair, swelling of the abdomen, or dwarfing of the body. The disease is due to lack of function of the thyroid gland, which is situated in the neck just below the Adam's apple.

Treatment consists in giving the thyroid extract to make good the deficiency from which the patient suffers, but it should only be undertaken by a doctor.

Under this treatment rapid increase in height may take place, perhaps 5 or 6 in. in as many months. Early cases receiving prompt thorough treatment may grow up into, apparently, normal individuals, though it may be necessary to continue the treatment at intervals throughout life.

**CRETONNE.** This cotton fabric is un-glazed, and is loomed in several widths, 31 in., 36 in., and 50 in. It is durable and washable and its wide range of patterns and colourings and its soft appearance renders it suitable for curtains and loose covers for furniture, and upholstery. When buying it for furnishing purposes care should be exercised in the choice of the design in order that it may harmonise both in colour and style of pattern with the furniture and decoration of the room. These cretonnes can be obtained in Jacobean designs, in old English flower designs, in bold geometrical patterns, or sprigged with Victorian posies.

As to colour, it should be remembered that deep tones, such as orange or red, are more expensive to produce, and that fabrics in these colourings must be of good quality to obtain pleasing effects. Bright colours in cheap dyes are crude.

When choosing a pattern remember that a large pattern is more costly to make up because the design must be matched in joining the material, thus occasioning more waste than when the pattern is small. Buy rather more material for upholstery purposes than the net quantity obtained by measurement. When making up cretonne into loose covers take measurements and a careful plan of each piece of furniture on hand before attempting to cut the material. Where the widest part of the furniture exceeds the width of the material an extension, or piece to be added by a seam, should be placed on each side,

and not on one side only.

In laundering cretonne, pure curd soap, or soap not containing caustic soda, should be employed; bran-water should be added to the water, the latter being tepid. Cretonne should be starched in boiling-water-starch thinned down, i.e. 3 pints of water to 1 pint of starch. Covers for furniture can be dry cleaned by brushing over them a thick paste made by starch and cold water. *See* Cover; Curtain; Upholstery.

**CRIBBAGE.** This is a card game for two, three, or four persons, but it is most commonly played by two persons only, and the two-handed game is the one that is here described. There are three varieties of cribbage, the five, six, and seven card game, the latter, however, being seldom played. The game is 61, 121, or 181 points up respectively, and a special cribbage board is generally used for scoring purposes.

The full pack of 52 cards is used, and players cut for deal, the one who cuts the lowest card dealing. Ace counts as the lowest card. The cards are dealt one at a time, until five are dealt to each player, and the pack is then placed between the players. Each chooses two cards from his hand, which he places face downwards on the table to form the crib, a hand which belongs to each dealer in turn. As this crib gives a slight advantage to the original dealer, his opponent scores three points or holes, known as three for last to equalise the advantage.

When the cards have been thrown out for the crib the non-dealer cuts the pack and the dealer takes the top card of the bottom half of the cut and turns it up. This card is known as the turn-up, and is used by both players for scoring purposes. If the card happens to be a knave the dealer scores two points, known as two for his heels.

The scoring during the play is as follows, the non-dealer leading the first card. Two points are scored for a pair; that is, if one player puts down a card, say, a three, and his opponent plays a three, the latter scores two for a pair. If the player can follow again with another three, he scores six for a pair-royal, and if his opponent is able to place down the fourth three, he scores 12 for a double pair-royal.

Three or more cards of any suit in numerical succession, as, for example, the three of diamonds, the four of hearts, and five of spades, count one for each card to the last player. Thus a player who completes a run of three counts three points. The run need not be in regular order. Thus in the example given the four might be played, then the five, and lastly the three. If the next player can play a two or a six he scores four points for a run of four, and so on.

When a player plays a card which makes with the cards already exposed a total of 15 pips, he scores two points, 15 two. Thus if a player plays a nine and his opponent a six the latter scores two points. Three or more cards may make up the 15. A score of 15 two and a run may be scored by the same card.

When the total of the pips on the cards approach 31,

the player whose turn it is to put down a card may find that any of the cards in his hand brings the total over 31. In that case he says, "Go," and his opponent has the right of play. If the latter also finds his cards are too high, the player of the last card scores one point for last. If either player can make the total exactly 31 he scores two points. In counting pips on the cards the knave, queen and king count as ten. When both players "Go" or the exact total of 31 is made, the hand terminates, and the two players, beginning with the non-dealer, show their hands and count them.

In this final count the turn up card is also reckoned as part of each player's hand and also as part of the crib. The hands are counted for each 15 they contain, the points being reckoned for each 15 as in play. Every separate combination possible is counted. Thus a king and three fives in a hand count as eight points for 15's, since four distinct 15's may be made. Any pairs count as two points,, any three cards alike as three fives, six points, any four 12 points, independently of the fact that these cards may already have been counted for 15's. Thus three fives count two points for 15's and six points for a pair royal. A run of three, four or five counts three, four or five points. There may be three cards in a sequence and a fourth card which is a duplicate of one of the sequence cards. In that case a double sequence is counted, that is six points, and two points for the pair. Similarly with four cards and the fifth as duplicate. Three of the cards may form a sequence, and the remaining two be duplicates of one card, in which case a treble run of three can be scored; with six points for a pair royal.

When the three cards held by the player are all of one suit he scores three points for a flush, and if the turn-up is also of the same suit, four points. If a player holds a knave of the same suit as the turn-up, he scores an extra point known as one for his nob. The dealer scores his hand after his opponent has done so, and then his crib in the above manner. A flush does not count in crib unless the turn-up is also of the same suit, and then counts five points. A flush counts in addition to any other point also scored. In throwing out cards for crib a player naturally throws from his hand such cards as are likely to be productive of scoring if it is his own crib, and non-productive if his opponent's crib.

**CRICK.** Sudden painful stiffness, occurring in the neck or back, is known as a crick, and is probably due to muscular spasm, though it is also suggested that it may mean rupture of a few fibres of a ligament or muscle. The treatment is gentle massage with the tips of the fingers, using warm oil, a liniment, or the following: methyl salicylate 1 dram; menthol 1 dram; lanolin 3 drams; vaseline to 1 oz.

**CRICKET.** The cricket usually shelters around the kitchen fireplace, often excavating burrows in the mortar between the bricks; these may be made untenable by injecting carbolic acid with a fine syringe. It is a very thirsty creature; and a plate of water to which a few drops of formaldehyde has been added will kill many. It feeds on all sorts of scraps and fragments of

food that have been left accessible to it; a piece of bread covered with the phosphor-paste sold for the destruction of cockroaches will be consumed readily, with fatal results. Any of the remedies suggested under cockroach may also be tried. Crickets especially favour the large open fireplaces often found in old houses.

*Common Cricket of the fireside.*

**CRICKET.** The devotee of this game, which is also played by women and girls, usually provides himself or herself with a bat, and a pair of pads to protect the legs. In addition most players wear gloves to protect the knuckles and the back of the hand, and men wear boots of a special kind. The pads and gloves can be bought in sizes, to suit the needs of the particular individual, from any sporting outfitter.

**The Cricket Bat.** Undoubtedly the best thing to do when buying a bat is to go to a firm of repute, and take the bat which suits, even if the price be the highest. In taking up several bats, one after the other, it will be found that some do not seem to balance well, some seem too heavy, others too light. But in nine cases out of ten one of them will feel as if it were an old friend. If on examination it seems perfect in every way, this is the best bat to take.

Many batsmen have a great objection to knots, and if there are any near the handle it is always safest to discard the bat. Some batsmen prefer a narrow grain in the wood; others like a wide grain. There is no royal road to success in choosing a bat, and despite their experience and skill the greatest of batsmen will occasionally find that, when they have bought their bat, it will not drive as well as a proper bat ought to do. But anyone who has the right instinct, a little common sense, and knows what he wants will very seldom make a mistake.

#### Preservation by Oiling

Not so very many years ago cricketers who bought a new bat treated it almost with reverence. They did not think of using it until it had been well oiled for a long time, and they oiled every part of it, except the handle and splice. To-day good batsmen often use a bat which has just come from the maker or a shop, and it is claimed that by a new process in the manufacture bats are hardened sufficiently for immediate use. Nevertheless, it is certain that no wood of any kind has ever been discovered which does not deteriorate if proper attention is not paid to it. Hence batsmen, or most of them, still look carefully after their bats when they are not in use, and more especially during the winter months.

The usual way of oiling to-day is to spread linseed oil on the surface of the front of the blade with a brush such as is used in oil painting, from the bottom about twelve inches upwards. This is done about once a

month, and then the bat is stored upright, in a place which is neither damp nor too highly heated., The theory is that the oil penetrates right through the bat, and that therefore there is no need to oil the back part. If in wet weather the bat gets very dirty, and the owner does not like its appearance, a little fine sandpaper before oiling will do all that is necessary.

**Cricket Boots.** The most expensive kind of cricket boot is made of white buckskin, but in order to turn out a smart-looking boot at a cheap price, various imitations classed as mock buck are used. There is little to distinguish the real article from the imitation when made up, but most of the latter quickly stretch out of shape and wear into holes. It is better, therefore, to buy good canvas boots, as they are usually more satisfactory in wear and appearance than the mock buck.

As comfort is so essential, the seams on the inside of the boot must not be bumpy or rucked. A chrome sole usually gives longer service than a bark-tanned leather sole, and it is waterproof; but it tends to draw the feet, and persons with hot or perspiring feet should avoid chrome-soled footwear.

Cricket boots are made with and without heels. It is claimed that the heelless variety allows greater foot-flex, but this is really a matter of opinion. The cheapest and most effective cleaning material is pipeclay. In cleaning the boots should not be made too wet. This has a tendency to cause the uppers to shrink if made of canvas, and in the case of buckskin is liable to render the uppers hard and brittle.

**CRINOLINE.** Originally applied to the stiffening of horsehair and cotton or linen threads used to expand women's skirts, the word came to include the steel and whalebone hoops employed for the same purpose.

Crinoline used for women's hats was manufactured from horsehair, but now artificial silk is largely used for this purpose.

**CRIPPLE.** A cripple is a person who suffers from lameness due to some weakness or deformity of the feet or legs. The defect may be primarily in the limbs, or be due to head or spinal injuries or diseases. Some form of apparatus, and in some cases operation, may relieve the condition. *See* Artificial Limbs; Club Foot; Crutch; Deformity.

## CROCHET WORK: IN VARIED STYLES

### Simple, Double, Filet and Picot Stitches Described

For the application of this work readers should consult such entries as Luncheon Set; Tablecloth. Associated articles are Bead; Embroidery; Lace. See also Bell Gauge

First known as Shepherd's Knitting, crochet derives its name from the French word *croc*, meaning hook, as it is performed with a hook of steel for fine work and bone for coarser work. The first stitch is chain-stitch, generally given in directions as the foundation chain,

and all crochet work must have a foundation chain.

The first loop is made with the fingers, thus: Hold the end of the thread with the thumb and forefinger of the left hand, and with the right hand pass the main thread over the end to form a loop, holding both down under the left thumb. Insert the crochet hook from right to left through this loop, and draw the thread through. Draw the loop up close, when the first chain will be made. \*Pass the thread round the hook, and draw it through the chain-stitch on the hook, then repeat from \* for succession of chain-stitches, Fig. 1.

*Crochet. Figs. 1-7. How some of the principal stitches are made.*

Single crochet or slipstitch (Fig. 2) is the same stitch under two names. It is sometimes used to join one stitch to

another, such as at the end of a round, when the last stitch is slipstitched to the first to join; sometimes it is employed to get from one position to another without breaking off the cotton and restarting. To make this stitch, simply put the hook in the stitch and draw the cotton through the stitch and the loop on the hook in one action.

This stitch is employed in every form of crochet, from the finest Irish lace (where it forms a length of chain into a picot) to big garments. When working the

latter in rounds instead of rows, a slipstitch joins the last stitch to the first.

**Double Crochet.** Double crochet is a very useful stitch, and there are two varieties, ribbed and flat, both worked in the same manner, but the hook is placed differently at the beginning. For ribbed double crochet (Fig. 3) put the hook in the back loop of the two seen at the top of the stitch after working one row (in the first row it just goes through the chain), cotton over hook, and draw through the stitch, making another loop on the hook, cotton over, and draw through two loops, completing one double crochet. For flat double crochet take up both the loops seen at the top of the stitch, and work as just described (Fig. 4).

Short treble is shown in Fig. 5. First put the thread round the hook, then hook in one of the foundation chains, thread over hook and draw through. There will now be three loops on the hook; thread over, and draw through all the loops on the hook at once. When this stitch is worked in rows, always put the hook in the loop at the back of the stitch, when there will be a chain stitch running along the surface of the ridges.

Treble stitch (Fig. 6) is worked in two varieties, ribbed and flat. To work ribbed treble, put wool over hook, hook in stitch, and draw the wool through, wool over hook, and draw through two stitches, wool over again, and draw through the last two stitches. There will be two loops at the top of this stitch; and in ribbed treble the hook is put under the back loop. For flat treble put the hook through both loops at the top of the stitch, as shown in Fig. 4 for flat double crochet.

*Crochet. Fig. 8. How to make lacets and bars.*

*Fig. 9. Filet crochet.*

*Figs. 10 and 11. Single and double picot stitch*

*Crochet buttons made according to instructions given in this article.*

Double treble (Fig. 7) is similar to treble, but the cotton is put twice round the hook at the beginning, then all the loops worked off by twos. Sometimes long treble is obtained when the cotton is taken round the hook three and four times, but the

number is generally given in the directions.

Lacets and bars (Fig. 8) are used chiefly to form a background. Sometimes there is a row of lacets, then a row of bars, each bar spanning over a lacet. A lacet is 3 chain, miss 2 stitches, 1 double crochet in next stitch, 3 chain, miss 2 stitches, 1 treble in next stitch. A bar is 5 chain, miss 5 stitches, 1 treble on next stitch. When it spans over a lacet it is necessary to miss the 3 chain, 1 double crochet, and 3 chain, and put the treble on the treble at end of lacet. Lacets and bars are often used alternately along the row forming a pretty background.

**Filet Crochet.** Filet crochet (Fig. 9) consists of groups of trebles and open spaces. The spaces are made thus: \* 2 chain, miss 2 stitches, 1 treble on the next stitch, and repeat from \* for as many spaces as required. Where a group of treble is given, 1 treble is put into each stitch consecutively along the row, whether that stitch be a chain or treble, and these groups form the solid part of the design, the spaces being the background.

Note that the treble finishing the last space before a group is not counted in the group of trebles, because it is already counted in the last space, and if counted twice the symmetry of the design is spoiled. The actual number of trebles should be divisible by 3, besides the one at beginning of the group which finishes the last space or lacet, as the case may be.

When working the first row of filet crochet, the first treble is put into the 8th chain from hook to form the first space, this making 2 chain for the foundation, 3 chain for the treble, and 2 chain for the top of the space. If the work has a treble border, then the row is turned with 3 chain, and this stands for the first treble of the following row. The treble over which this chain stands is not worked into, and when the end of a row is reached always work the last stitch into the top of the 3 chain which is at beginning of previous row. If there is a space at end of row instead, then work into the third chain. When there are directions in brackets, this portion is always worked the number of times stated immediately after the brackets. Take note of the word worked not repeated. The brackets show which part to repeat.

**Picot** (Fig. 10) is a little loop of chain-stitches formed into a ring with a slipstitch, and forms the background of Irish crochet. It usually consists of 5 chain, and a slipstitch into the 5th chain from the hook to form a picot. A single picot loop is made thus: 7 chain, slipstitch into 9th chain from hook, 2 chain, then 1 double crochet on the foundation to fasten down the picot loop. A double picot loop has 2 picots of 5 chain with 2 chain after each.

Two forms of crochet buttons are shown in the illustration. The materials required for making the barrel button are some ordinary crochet cotton (No. 24) and a No. 5 hook.

Begin with 14 chain stitches, work first row thus: Miss one chain, do 1 double crochet into next 13 chain, turn with one chain. For the 2nd row, work 1 double

crochet in each stitch to end, but do not work into the one turning chain. The 3rd row consists of 2 double crochet in the first stitch, and 1 double crochet in each of the next 12 stitches. For the 4th row do 2 double crochet in the first stitch, and 1 double crochet in each of the next 13 stitches, and make the 5th row 1 double crochet in each of first 4 double crochet, 2 double crochet in next stitch, 1 double crochet in each of four more stitches, 2 double crochet in the next double crochet, and 1 double crochet in each of the last five double crochet. The 6th and 7th rows consist of 1 double crochet in each stitch, while the 8th and 9th rows represent 2 double crochet in first stitch, and 1 double crochet in each stitch to end.

The 10th row should be \* 1 double crochet in each of five double crochet, 2 double crochet in sixth stitch; then repeat from \* once, and work 1 double crochet in each remaining stitch. Let the 11th row consist of 1 double crochet in each stitch, and for the 12th row do \* 6 double crochet, miss the seventh; then repeat from \* once and work 1 double crochet in each stitch to end. For the 13th and 14th rows, miss first stitch, 1 double crochet in each stitch to end. For the 15th and 16th rows work 1 double crochet in each stitch and work the 17th row as follows: \* 4 double crochet, miss next stitch, then repeat from \* once, and make 1 double crochet in each stitch, to end. Work the 18th and 19th rows by missing the first stitch and making 1 double crochet in each stitch to end. 20th and 21st should be done in the same way as the 15th and 16th rows. Fasten off. First and last rows form ends of button and these are sewn up, drawing up the middle a little to round it. Sew about three-quarters of the way on the long side (which forms under part of button) then stuff with cotton-wool and sew up the remainder.

The materials required for the barrel button may also be used for the ball button. To make this, begin with 5 chain stitches, and form these into a ring by slipstitching to the first stitch. For the 1st round do 12 double crochet into the ring, and for the second, work \* 2 double crochet into the first stitch, 1 double crochet into next, and then repeat from \* all round. 3rd: \* 2 double into first stitch, 1 double into each of next 2. Repeat from \* all round. 4th: 1st stitch similar, 1 double into each of next 3 stitches. Repeat. 5th: 1 double into each 6th round, \* miss first stitch, work \* 1 double crochet into each of next 4 double crochet, then repeat all round. 7th: As 5th. 8th: \* Miss first stitch, 1 double crochet into each of next 3. Repeat. 9th: \* Miss first, do 1 double into each of next 2 stitches. Repeat all round. 10th: \* Miss first, do 1 double into next. Repeat, 11th: as 10th. Fill the button with cotton-wool. Break off thread, pass into a needle, draw up and fasten off very securely.

**The Crochet Hook.** It is advisable to buy well-made hooks, as any roughness in steel or bone may destroy the texture of fine silk or wool. The blade, throat, and hook parts should all be made in one piece in bone crochet hooks and the throat part should be of even thickness.

Steel hooks run in sizes 00, 0, 1, 1½, mounting in ½

sizes up to 8. No. 00 up to 1 are often used for the finer makes of wool and for artificial silk instead of bone. The finer sizes, 6½ to 8, are only used for very fine Irish crochet, while No. 8 is chiefly used for catching the thread in real Carrickmacross lace. Bone crochet hooks are numbered 1 to 12; 1 and 2 are seldom used except for very coarse rug making. A No. 12 bone is employed with very fine Shetland wool.

**CROCK.** The name is applied to varieties of earthenware jars or pans glazed inside and sometimes outside. The Sussex crock is used for storage of butter, dripping, stock, etc., in the larder. A bread crock is an earthenware pan having a separate cover or lid of the same material.

*Crock. Typical glazed earthenware crock, suitable for larder use.*

The advantage of earthenware lies in the facility with which it can be cleansed, its comparative immunity from absorption, and the absence of rusting. *See Bread Pan: Earthen-ware.*

**CROCKERY: Its Repair.** It is always easier to repair crockery if the job is taken in hand at once, as the fracture is then quite clean. There are various methods, but the simplest is to stick the parts together with one or other of the numerous patent adhesives on the market.

The usual method employed is to coat the edges with the adhesive and press the parts together, holding them in contact while the glue sets, or blocking them up, or strapping the parts together with bands of linen or paper, which are subsequently removed when the cement has set firm.

This method will generally keep the parts in contact, although it seldom results in a thoroughly satisfactory job. Either the joints give when the article is put into service, or the thin film of glue becomes conspicuous by the coating of dust that always accumulates along the line of fracture.

When restoring a valued piece that has broken into many fragments, patience must be exercised and only two pieces joined together at a time, allowing the joints to set hard before attempting to complete the whole piece of work. If a few tiny parts are missing they can often be moulded in fine plaster of Paris made into a cement with liquid glue and just sufficient warm water to make the material into a workable paste. When thoroughly dry it can be smoothed with sandpaper, and coloured to match the original work.

**The Use of Rivets.** The most effective way of re-

pairing crockery so that it can be put into everyday use is by riveting. For this purpose a drill stock specially devised for such work is indispensable, and the general appearance is shown in Fig. 1. Such drills are made with a diamond point, and are far more effective than using a hard steel drill and diamond dust or carborundum as an abrasive. To use the drill, the spindle is twisted so that the cord is wound round the stem; when the crossbar is pressed downwards the cord untwists and rotates the drill. The hand is then raised quickly and the momentum of the drill again winds the cord around the stem, so that by regular and repeated movements of the crossbar the drill can be kept in motion. The drill is worked with the right hand, while the left hand holds the piece of crockery.

*Crockery. Fig. 1. Drill stock employed for making rivet holes in crockery and china (Courtesy of R. Melhuish & Co., Ltd.)*

Commence by moistening the drill point with oil, and then drill a slanting hole downwards into the china and about  $\frac{1}{4}$  in. away from the edge of the fracture. The rivets are simply bent to shape from soft brass wire about  $\frac{1}{16}$  in. diameter, a pair of flat-nosed pliers being handy for this work. The shape of the rivet when made is shown in Fig. 2. Some judgement is needed in placing the rivets so that the fewest number accomplish the required result. On plates and dishes the rivets are best applied to the back, where they are out of sight, but on a jug with a broken spout there is little chance to do more than insert some of the rivets on the inside and the remainder on the outside.

*Crockery. Fig. 2. Diagrams illustrating a china rivet bent for use and the method by which it is inserted in the drilled holes.*

*Crockery. Fig. 3. Bedroom ewer with side and lip mended with rivets.*

To insert a rivet, take care to flatten the inner sur-face of the wire a little so that it bears more effectively on the china, and see that the legs are not too long; they should not quite reach the bottom of the hole, otherwise they will never be flat on the surface of the china. When all is in order the rivet is bedded into the holes with a little plaster of Paris made into a paste with water and a trace of glue. A typical repair is shown in Fig. 3.

**CROCUS.** There are three classes of crocus—spring, autumn and winter flowering: all are hardy. The crocus root is technically known as a corm. Spring crocuses are planted in August or September, 2 in. deep; they look best in grass and flourish beneath large, leaf-losing trees. They also do well in beds and borders, and may be left undisturbed indefinitely. There are several handsome large-flowered named varieties, e.g. Sir Walter Scott, Mont Blanc, King of the Blues. These are worth growing in flower-pots for the greenhouse.

*Crocus. Group of spring-flowering crocus, white veined with purple.*

The corms of autumn and winter flowering crocuses are planted in July and August; they are usually

planted in the rock garden among low-growing tufted plants which prevent the blooms being spoilt by soil splashed up in wet weather. They make charming plants for the unheated greenhouse if grown in pots: this is really the best way to grow the winter crocuses. Of those that bloom in autumn some of the best are:

Asturicus, lilac-mauve; hadriaticus, white; pulchellus, lavender-blue; sativus, violet; and speciosus, lavender-blue. Some of the chief winter-flowering crocuses are chrysanthus, yellow; Imperati, pale with purple stripes; Sieberi, pale purple, and tommasinianus, pale lavender.

## CROQUET AND THE CROQUET LAWN

### The Rules of an Attractive Outdoor Game

Other articles on outdoor games played in the home garden which appear in this Encyclopedia are Badminton; Bowls; Clock Golf; Lawn Tennis

This outdoor game for four players can be played on any level lawn that is of sufficient dimensions. The standard size is 35 yd. in length by 28 yd. in width, but a lesser space can be utilised, provided its length and breadth are in the proportion of 5 to 4. The boundaries are marked with white lines.

The implements required are mallets, one for each player, and four balls that are coloured red, black, blue, and yellow, the mallets being usually marked on the handles to correspond. The balls should be  $3\frac{5}{8}$  in. in diameter, and weigh about 16 oz.,  $16\frac{1}{4}$  being the maximum. Stuck into the ground are six hoops and two posts. Each hoop should stand 12 in. out of the ground and be not more than 4 in. in width across the inside.

Each of the four outer hoops are 7 yd. from the side boundary and 7 from the end of the ground nearest to them. The centre hoops are 7 yd. from each other and 14 from the boundaries on either side. The posts or pegs are in line with the centre hoops, each being 7 yd. from the boundary, and in line across the ground with the side hoops. The posts should be 18 in. high and 1½ in. in diameter.

Sometimes, however, the game is played on a ground set out somewhat differently on a plan known as No. 2 or Willis setting. In this there is only one peg, not two, this being placed in the centre of the ground with the central hoops each 7 yd. from it in a line parallel with the side hoops.

The game is played by two players in partnership against the other two. The pair using the blue and black balls always play those using the red and yellow ones. A game consists in making the balls traverse the course twice, once in each direction, and the pair who finish first win, i.e. both must finish before the second of their opponents does so. All the hoops must be passed through in regular order once on the outward and once on the homeward journey, and the posts must be struck by the balls once each, one when the player is half way round and the other for the finish. The posts may be hit from any direction, but the hoops can only be passed through from the front. The players play in turn, each following an opponent. The usual order is blue, red, black, yellow. The game can also be played by two persons, one against the other. In that case each takes two balls, playing them alternately, as would be the case if there were four players.

Such is the older and popular way of playing croquet, but many play according to rules introduced in 1914. The "either ball" law provides that, as regards the single game, when it is the turn of a player to play, he may play with either ball, blue or black, or red or yellow, as the case may be. In doubles, either player may play the turn. Under another law, passed in 1923, the partners succeed each other in playing any turn after each point is made.

The game is started from balk, i.e. a space behind the first hoop on the left-hand side of the ground. The two hoops in front of him must be taken by each player in turn, after which he crosses the ground and takes the two on the other side, but in the reverse order to the first two. He then makes for one and then the other of the centre hoops, after which he strikes the turning peg, which is at the end of the ground farthest away from balk, with the ball.

The reverse journey is then begun. The two hoops he took first are again taken, but in the other direction, as are the two on the other side of the ground. He then goes to the centre, and this time, leaving the turning peg, passes in turn through the two hoops and finally drives his ball against the winning peg, which is the one near the balk. If, in hitting, a player drives an opponent's ball through the hoop which that player has next to negotiate, the stroke counts, and when his turn comes the opponent plays for the next one. A player can also drive a partner's ball through a hoop, the score counting if the hoop is the next in order of play.

The game begins with the first player driving off from balk. If he succeeds in passing his ball through the first hoop he has another shot and can continue playing until he fails to score a hoop. The game, however, can hardly begin in earnest until all the balls are played, so we will assume this has been done. The first player then plays again. He can either drive his ball through a hoop or hit one of the other balls with it. In either case, provided with the subsequent croquet stroke neither his own ball nor the ball from which croquet is being taken has been driven out of the ground, he is allowed another stroke.

If he has hit another ball this stroke must take the form of a croquet. To croquet he places his own ball against the one he has struck, and hits the former. Having thus moved both, he can play his ball again and again drive it through a hoop or hit another ball with it, and he can continue this as long as he is successful, with the important proviso that he must not croquet off the same ball twice, unless in the meantime the player has passed his own ball through a hoop next in order or scored a peg.

The object of the game is therefore very much as in billiards, to use the other balls as means of scoring, and to be careful to finish with one's opponents' balls, especially that of the opponent who will play next, in disadvantageous positions. This is far more important than an extra score. Formerly this was often done by wiring the ball of the opponent who plays next, i.e. leaving it lying close against a hoop on the side away from the three other balls, the hoop being thus between the next player and his objective. This made a good shot almost impossible. Early in the 20th century an alteration was made in the laws, and now a player whose ball is wired can remove it and play from balk, provided it was put there by an adversary.

**Mallets and Balls.** Croquet mallets consist of two parts, the shaft and the head. For the shaft, hickory is a useful and popular wood, but some are made of malacca cane, and a few of ash and elm. The heads are made of boxwood or lignum vitae, the former having the advantage of being less brittle than the latter. Many mallets are furnished with grips to prevent the hands from slipping. These may be formed by binding the shaft with string, or fitting it with cork or rubber. Of these, cork is perhaps the best, although, like rubber, it lessens slightly the force of the stroke.

In other mallets the player relies for his grip upon the shape of the handle. Such may be octagonal, or oval, or round. The octagonal, with grooves down the side, is for most players the most satisfactory. The oval handle is unsuitable for centre play, and the round one cannot be recommended. The choice of a mallet depends very much upon the style of play adopted. For side play a light implement is desirable, but for centre play a heavier one. The former should not weigh more than 3 lb.; the latter may well weigh ½ lb. more. The length of the shaft should be about 33 in. The head, should measure 9 in. and have a diameter of 3 in.

But whatever the style, a mallet should answer to the following requirements. It must be well balanced and the shaft must be straight. The hole in which the shaft fits into the head must be accurately bored, and the shaft must be set into the head with the grain of the wood at right angles to the head.

*Croquet. Positions of hoops and course of play in the two methods of playing the game.*

Formerly croquet balls were made of wood, and were, therefore, liable to chip, but they are now made of composition, and are thus free from that defect.

Where handicapping is carried out in croquet

tournaments, it is done by means of bisques, i.e. extra turns which a player can take at the conclusion of his ordinary turn. The weakest players are handicapped at 14 bisques and the strongest at—3.

The game is controlled by the Croquet Association, 4, Southampton Row, London, W.C., and under its rules tournaments are held all over the country throughout the summer. The croquet open championships are played at Roehampton, near London, every year in July.

**CROQUETTE.** Scraps of meat, fish or poultry can be utilised to advantage in making croquettes, being minced and blended with various flavourings and some rich thick sauce. A little cooked ham or bacon is always a satisfactory addition. Should the meat be very dark, egg and crumb the croquettes twice.

To use the remains of a cold chicken, remove the skin and bone and chop up enough of the flesh to make  $\frac{3}{4}$  lb. Melt 2 oz. of butter in a saucepan over the fire, stir in 1 oz. of flour, and then add  $\frac{1}{2}$  pint of chicken stock or milk. Stir this sauce over a slow heat until it thickens, then let it cool slightly before adding the chicken,  $\frac{1}{4}$  lb. of cooked and chopped ham, and a teaspoonful of grated lemon rind.

Mix all well, season the mixture carefully with salt, pepper, and nutmeg, and if it is too dry add a little more stock or milk. Turn the whole on to a plate, let it cool, and then mark it into even-sized divisions, forming each into a neat shape. Roll the croquettes in flour, brush them over with beaten egg, and cover them with breadcrumbs. Put 4 oz. of fat in a frying-pan over the fire, and when a blue smoke rises from it put in the croquettes, two or three at a time, and fry them a golden brown. Drain them on paper, and serve garnished with fried parsley. *See Crab.*

**CROSSBANDING.** In furniture design this is a method of using veneered strips at the outer boundaries of the panels. It is done so that the grain runs at right angles to the constructional edges.

**CROSS CUT SAW.** This type of saw is employed for cutting across a log or large piece of timber, or for similar heavy work.

The one-man cross cut saw is adapted for single-handed use, although both hands are generally needed to push the saw. They are made from 3 ft. to 5 ft. in length, and most have a supplementary handle that can be bolted to the end of the saw blade, and are then usable by two men. The two-man cross cut saw is only usable by two operators, each grasping an end of the saw and working in unison. Such saws are made from 4 ft. to 7 ft. in length; the handles are either bolted to the saw blade or fixed into sockets riveted to the ends of the blade.

The tooth shape varies according to the nature of the

work, but for general use the great American type of tooth is the best, advantages being that the set can be put on the small or peg teeth; the deep slots give freedom for the chips, and prevent troubles which would otherwise be caused by local distortion of the blade.

*Cross Cut Saw.*  
*How a two-man cross cut saw is used for cutting tree trunks.*

The teeth are sharpened and set in the usual way. In using such saws a regular, steady stroke is essential, about 20 to 25 strokes per minute being all that is needed. When not in use wipe the blade with a greasy rag, and hang the saw up so that the blade does not get bent or twisted. *See Saw.*

**CROSS-EYE.** This is a condition of squint or strabismus, in which both eyes are not focussed on the point looked at. If something small is held in front of the patient's eyes, say, at about 18 in., it may be readily seen that the gaze of one eye is not directed towards the object. If it is difficult to determine whether this is so or not, a piece of paper should be placed in front of the eye which appears to be looking straight at the object, and the other eye may then be observed to swing into its correct position. The condition may be due to paralysis or weakness of one or more of the muscles which move the eyeball, or it may result from over-action of a muscle when some error of refraction is present. *See Eye; Spectacles; Squint.*

*Cross Garnet Hinge.*  
*Patterns of this door hinge in common use.*

**CROSS GARNET HINGE.** These are extensively used for the commoner variety of doors both indoors and for external work. The ordinary type is made from pressed steel, japanned black, and from 6 in. to 24 in. long. The T-shaped end is screwed to the upright, the long part to the door. Cross garnets are easy to hang, as they are generally screwed on flush with the door and the post. The Lancashire cross garnet type is a superior quality made of wrought iron with a wrought eye at the extremity; they are preferable for heavier doors. Best heavy Lancashire cross garnets are desirable for doors such as those on a garage or stable. They are made from 12 in. to 24 in. long. The 12 in.

weigh about 2 1/4 lb. per pair, the 24 in. about 10 lb. per pair.

In hanging a door on ordinary cross garnets always fix the hinges to the doorpost first, block up the door so that it is tight up against the lintel, then fix the straps of the hinge to the door. On removing the blocks the door will drop slightly on the hinges, and it will then swing properly. *See Hinge.*

**CROSS STITCH.** Lending itself equally well to embroidery on house linen, children's garments, samplers and chair seats, many decorative and useful articles are patterned in cross stitch or completely covered by this work in cotton, silk, or wool. The double stitch employed is formed by two oblique stitches, placed one across the other and crossing each other in the centre. The top stitches in a row must always lie the same way. In the illustration more than one mesh of canvas is used to enlarge the stitch. When embroidering on linen, muslin, etc., a transfer pattern marks the stitches, or the design may be carefully drawn with a pencil.

*Cross Stitch. Position of needle in making the stitch.*

If coarse material be used the threads can be counted, and the cross stitches worked directly on the material; if not, an auxiliary canvas may be used. This should be sewn securely in position over the material; and the pattern worked into the ground material through the canvas, the threads of the latter acting as a guide to the right position only, as they are afterwards pulled away, leaving the completed design behind. Sufficient margin of the canvas must be left so that the threads can be drawn out easily afterwards.

This is useful when borders of simple design are worked on cushions, or for cross stitch embroidery on silk bags and pochettes.

When solid cross stitch is worked for chair seats or stool coverings, etc., the geometrical or floral design is usually worked in colours, so that it forms a contrast with the background stitches. This also applies to figure designs which can be worked by means of a transfer ironed on the canvas in the ordinary way. Canvas can be obtained on which the design is traced. *See Calendar; Canvas; Sampler.*

**CROTON OIL.** One of the most active cathartics (purgatives) used in medicine is croton oil. Usually given 1/2 to 1 drop on a lump of sugar, or in a little pat of butter, croton oil is chiefly used in cases of sudden unconsciousness, paralytic stroke, etc., where it is important to clear out the bowels without delay. The butter is placed on the back of the tongue. Internally

the drug should only be used under the direction of the doctor.

**CROUCH WARE.** This term properly pertains to the early kinds of salt-glaze stoneware made in Staffordshire. The oldest is a drab or buff fabric, but about 1720 crisp, white salt-glaze pottery was produced, and that is the style of Crouch ware which is usually collected. Being mixed with Derbyshire pipeclay, its paste was dense and well finished, at first greenish, but afterwards whiter. Salt-glaze is essentially English, and looks particularly pleasing when it is contrasted with old brass-ware of plain English design. *See Pottery.*

*Crouch Ware. Characteristic bowl in salt-glaze ware, with applied ornamentation, c. 1720.*

**CROUP.** The chief symptom of this ailment of childhood is the peculiar hoarse trumpeting cough and difficulty in breathing. Inflammation of the larynx and trachea is attended by more or less swelling of their lining mucous membrane, and the narrowing of the air passage may be sufficient to produce a croupy cough. In false croup, however, there is a spasm of the vocal cords in addition, and the result is the onset of such difficulty of breathing.

The child may spring up in bed, the attack usually occurring at night. In drawing in the breath the child may make a crowing noise. Suffocation may appear to be imminent. This may go on for an hour or two, and then the child drops into a restless sleep. Next day there is still hoarseness, but otherwise comfort may not be much interfered with. In the night there may be another seizure, but not so severe, and after a few days recovery may be complete.

Frequently there is a tendency to the recurrence of croup. To prevent this the child's throat should be examined, and if the tonsils are enlarged and adenoids present these should be removed. Further, the child should be warmly clad, with flannel underclothing, and should not be allowed to sleep in damp rooms or be exposed to cold winds. The onset of a croupy cough should be brought to the notice of the doctor.

True or membranous croup, in which a membrane forms on and about the vocal cords, may be due to scalding from hot liquids or steam, or to swallowing corrosive poisons; but it is usually due to a micro-organism, in most cases the diphtheria bacillus. Certainly, apart from the scalding cases, one should always treat the case on the assumption of its being diphtheria. In this form the crowing on breathing in may precede the dyspnoea, which usually comes on gradually, though at any time it is liable suddenly to become urgent. On the occurrence of crowing the doctor should be summoned.

In spasmodic croup, or *Laryngismus stridulus*, which is most common during the first two years of life and is associated with rickets, the child suddenly stops breathing and the face becomes purple. Then suddenly the child succeeds in drawing in the breath, making a

peculiar crowing sound. Sometimes there is only the holding of the breath without the crowing. These infants are also liable to convulsions. Recovery is usual.

Treatment consists of trying in every way to build up the general health of the child. Any irregularities of diet should be seen to, constipation should be remedied, and if rickets is present the disease should be actively treated. Should attacks follow close upon one another, place the child in a hot bath and sponge the head and neck at the same time with cold water. *See Bronchitis Kettle; Child; Rickets.*

**CROUSTADE.** For a savoury, small entrée or breakfast dish, croustades of fried bread are a nice way of serving cheese and egg mixtures, tomatoes, sardines, anchovy and egg, or savoury minces. To make, cut circles of stale bread, each about  $\frac{1}{2}$  in. thick and 3 in. in diameter. Mark out an inner circle with a smaller-sized cutter and fry the circles in hot dripping. Take them out of the pan and drain them carefully, then remove the inner ring of bread. The croustades can be then filled with the savoury mixture. *See Curry.*

**CROÛTON.** These thinly cut pieces of bread, variously shaped and fried in hot fat, are used for garnishing such dishes as mince, hash, ragoûts, and savoury dishes of cheese, etc., or cut into dice as an accompaniment to thick soups. When cutting croutons the crusts, which can be used for puddings, are re-moved. When served as a base for a savoury croutons are usually termed *croûtes*.

**Crowfoot.** This is an old English name for the genus *ranunculus* or buttercup.

**CROWING: In Children.** It is mostly in rickety children that the ailment known as crowing occurs, a peculiar spasm in which the child suddenly has great difficulty in drawing its breath, and makes a croaking noise. Frequently there is a liability to convulsions. The mother will often tell the doctor that the crowing begins whenever the child is crossed or excited in any way; or it may follow on waking up or being exposed to a cold draught.

For treatment sponges wrung out of hot water should be placed over the throat, and the chin should be drawn forward. If the child becomes pale and ceases to make any effort to breathe, artificial respiration (q.v.) should be carried out, the child being placed on a rug on the floor for the purpose. Between the attacks the state of the digestion should be looked to.

To begin with, give  $\frac{1}{4}$  to  $\frac{1}{2}$  teaspoonful of confection of senna or a dose of castor oil. The physician may order bromides. If convulsions occur the child should be put in a warm bath. To prevent a return of the condition the general health should be built up, by giving the child more outdoor exercise and plenty of nourishing food, with a fair supply of fats. A teaspoonful or more of some emulsion of cod liver oil,

taken three times a day after meals, is useful. *See* Croup.

The crowing of a cock may constitute a legal nuisance. *See* Animals.

**CROWN DERBY.** It is usual to regard the period of about 30 years after 1784 as pre-eminently the Crown Derby period.

Crown Derby includes the best undecorated biscuit ware ever made in England, comprising rustic and classical figures and groups, besides statuettes of British generals and admirals. Crown Derby Japan shows imitations of Eastern designs. The French sprig or Chantilly pattern, usually a blue corn-flower, sometimes edged with gold, is prized.

*Crown Derby. Beautiful vase made from a classical model, 17 in. high.*

For many lovers of page of old china Crown Derby means the well-known painted and gilded ware, either seen in pieces of elaborate design with decorated pedestals and sometimes with lids and handles, or in the form of dinner and dessert services; also in tall, square-based vases, enriched with blue, canary yellow, pink, or apple-green grounds, and delicate landscape scenes. The modern ware, started in 1877 and styled Royal since 1890, includes reproductions of the characteristic decoration of the old models. *See* China.

**CROWN GALL.** The swellings or galls termed crown gall occur on a great variety of herbaceous and woody plants. The effects of crown gall are seen in dwarfing of growth or direct injury to roots or branches.

It has been shown that the bacteria invade the plant through wounds, and that in all probability they cannot enter an uninjured surface. The greatest care, therefore, should be exercised in not injuring the stocks more than is necessary.

The removal of a gall from a plant does not necessarily free the plant from the disease. The bacteria, in certain plants in any case, spread in the tissues by means of the tumour strands, and, if the gall is merely cut off, the disease may break out again later. On the other hand, if a deeper wound is made with the object of cutting out the whole infected area, it may injure or even kill the tree. If the galls are on the lateral roots and only a few are attacked the affected roots should be cut out, but if badly galled the trees should be burned. This information is given by the Ministry of Agriculture in Leaflet No. 253.

**CROWN IMPERIAL** (*Fritillaria imperialis*). This hardy bulb in spring bears clusters of drooping bell-shaped flowers on the top of a stem about 2 ½ ft. high. The blooms are of various colours, yellow, orange, and reddish. Bulbs should be planted 6 in. deep in early

autumn and left undisturbed, for they become established slowly. This plant likes deep, loamy soil, and does not mind slight shade.

*Crown Imperial, a handsome, hardy, spring flowering bulb.*

## CRUELTY.

Whether practised on human beings or on animals, cruelty is an offence against English law. Persons can be prosecuted and punished if they

starve or otherwise ill-treat children, while dogs, horses, and cats are likewise protected. To ensure conviction a specific act of cruelty, as defined by law, must be proved before a magistrate. Persons who suspect others of acts of cruelty should, in the case of children, inform the National Society for the Prevention of Cruelty to Children, 15, Leicester Square, London, W.C.; and, in the case of animals, the Royal Society for the Prevention of Cruelty to Animals, 105, Jermyn Street, London, S.W. There is a Scottish society at 19, Melville Street, Edinburgh. *See* Animals; Child.

**CRUMB.** Originally a small particle of anything, this word is chiefly used for small, loose particles of bread. It is also used for the soft part of the loaf as opposed to the crust. *See* Bread; Breadcrumbs.

**Crumb Brush.** The cheap brushes made in plain or curved shapes for sweeping up crumbs from the table after meals are composed of fibre, horsehair (drafts), or mixings (bristles). The better qualities, with all bristle knots, drawn into the stocks with wire, will last a lifetime, but in present day households the brush and tray have rather given place to the scoop, which combines both in use. *See* Brush.

**Crumb Scoop.** The design given for a crumb scoop is purposely simple, and intended for easy construction, in any desired metal about 1/32 in. thick. Copper or brass is convenient, as the joints are readily soldered.

The scoop is made by cutting a sheet of the metal to the shape given in the drawings, hammering the rim to shape on a block of hardwood. A raw hide hammer is desirable, as it does not bruise the metal. After bending, the joints must be silver soldered and thoroughly cleaned and scraped. The handle socket is bent to shape round a block of iron, then silver soldered at the joint and to the crumb scoop.

The handle is cut from hardwood, fitted to the socket, and secured with a fine pin driven in after the final polishing and lacquering. The handle should be

**dyed black and wax polished. The final treatment may be by electro-plating and buffing, or by simple lacquering.**

**Crumb Scoop.** *Diagrams showing how to make a simple scoop.*

**CRUMPET.** If yeast is to be used, dissolve 1 oz. of it in a pint of lukewarm water to which a pinch of salt has been added. Stir in sufficient flour to make a light, smooth batter, then cover it and leave it for an hour to rise. Beat the batter, leave it for about 20 min., beat it again, and pour it into greased crumpet rings placed on a baking sheet. It must be cooked well on both sides.

To make crumpets without yeast, use 3 eggs to 1 lb. of self-raising flour and a teacupful of milk. Stir a dessertspoonful of sugar into the flour, and make a hollow in the centre. Mix the eggs with the milk, and lightly stir these into the flour, working the whole up as quickly as possible into a light dough. Then roll it out and cut it into circles each about  $\frac{1}{2}$  in; thick. Prick these with a fork and cook them on a girdle or in the oven until they are firm and light brown in colour. Serve them toasted on both sides and buttered.

**CRUTCH.** A crutch is a staff which may be single throughout or bifurcated for part of the distance, with a concave headpiece to take the weight of the body at the armpit. It should be as light as is consistent with strength. Pressure of the head of a crutch on the nerves in the armpit may bring on paralysis of the upper limb, crutch paralysis, the commonest result being wrist-drop (q.v.), though the whole arm may be affected. A cross-piece for the hands, taking some weight off the armpit, helps to avoid this, also a spring support at the top. A modified crutch may be used which only reaches as high as the middle of the upper arm, which it grips by a horse-shoe metal band. There is a cross-piece for the hand, which takes the weight.

In emergency, a crutch can be extemporised by wrapping the head of a broom in a clean piece of cloth. *See Artificial Limbs; Cripple.*

**CRYSTAL.** Although this word is used to describe glass ware of a fine quality, real crystal is hardly ever made into vases or other ornamental and useful household articles, as it would be too costly. It is chiefly seen decoratively in the form of cut bead necklaces and has many uses in the manufacture of eye glasses lenses for binoculars, and cameras, etc. In the case of large cut glass or crystal ornaments, it is advisable to have small rubber or cork disks cemented on the base to prevent damage when the article is placed on a hard surface. Cut crystal beads may be distinguished from glass imitations by touching one with the lips. Real crystal will remain almost icy cold, whilst glass will quickly become warm when held in the hands and tested against the lips. *See Glass.*

**CRYSTAL DETECTOR.** Certain kinds of mineral ore, when placed in contact with certain metals or other minerals, act as rectifiers or detectors of high-frequency oscillations. The crystal although still used in simple wireless receivers, has been largely superseded by the valve detector which is more sensitive and stable. Zincite and bornite, galena or silicon and brass, carborundum and steel are sensitive combinations, but careful adjustment of the contact pressure is necessary to ensure maximum results. Carborundum is robust, but has the disadvantage of requiring a small battery and potentiometer. *See* Detector.

**Crystal Detector.** Permanent type showing crystals held in contact by springs; surrounding wax has been removed. Left, crystal of carborundum.

**CRYSTALLIZED FRUIT.** Cherries, slices of orange green figs and greengages, small apricots, and lemon, chunks of pineapple, and melon may be crystallized or candied by the following method:

First make a strong syrup by dissolving 1 lb. loaf sugar in  $\frac{1}{2}$  pint water. Then boil it with the lid off the pan, and without stirring it, or the syrup granulates. When it has boiled for about 10 min., or reaches  $245^{\circ}$  on the sugar thermometer, test the syrup by dropping a little of it into very cold water and taking out the little lump that forms. Roll it up in the fingers and see if it will form a firm ball. If so, take the pan off the fire, add a teaspoonful of lemon juice and put the pan over another one containing boiling water to keep the syrup from candying too soon.

Take the prepared fruits up on the point of a fine skewer, or a coarse needle, and immerse each piece in the syrup. Lift them out and drain off the excess of

syrup by laying them on lightly oiled or buttered trays, and dry them off in a warm, dry place. Cherries should be stoned before dipping, and oranges should be peeled and divided into sections without breaking the inner skin, as all fruits must be perfectly dry.

**CUBIC MEASURE.** This is used for measuring volume or capacity. It is as follows: 1,728 cubic in.=1 cubic ft., 27 cubic ft.=1 cubic yard.

**CUCKOO CLOCK.** In the wood-frame cuckoo clock a mechanical toy bird imitates at each hour the sound of the cuckoo, or a hammer strikes the hours on a gong and the bird merely emphasises the time. It is actuated by weights suspended on chains. The pendulum is sometimes hung on a wire loop, which requires frequent oiling.

The striking mechanism has two hammer arbors resembling the ting-tang device in a clock that strikes the quarters. As the hour strikes, the two hammer arbors lift up small bellows in the clock by means of rods. The bellows fall one after the other, and give a puff of wind to a pipe or reed which produces the cuckoo note. The bird is frequently made with a jointed head or beak interconnected with the bellows, and so arranged that the bird makes a movement simultaneously with the sound.

The bellows may sometimes fail, due to a leakage, which can be repaired by re-covering the bellows, or occasionally by sticking a patch over the hole. The connecting wires may be damaged or displaced, but this defect is easily remedied, either by replacing with a new part or by restoring the piece. *See Clock.*

*Cuckoo Clock. Mechanism of the clock, with connexions for striking the gong, working the bellows and making the bird start from its door.*

**Cuckoo Flower.** The popular name of *Cardamine pratensis*, or Lady's Smock (q.v.)

**Cuckoo Pint.** One of the popular names of the wild *Arum maculatum*, which is known also as Lords and Ladies and Wake Robin.

**CUCKOO SPIT.** The presence of frothy, spittle-like masses on many plants in the garden is quite common in summer. If the froth is blown aside, a thick,

bull-headed, greenish insect is revealed. It is the so-called cuckoo-spit or frog-hopper (*Aphrophora spumaria*). It is not very injurious unless present in large quantities, which is unusual. A vigorous syringing with paraffin emulsion will get rid of it.

## CUCUMBERS: THE SEVERAL VARIETIES Growing the Vegetable and Preparing it for the Table

This article describes the cultivation, whether in the open air or in frames, of the vegetable, and gives recipes for serving it. *See also Frame; Kitchen Garden*

Although cucumbers can be raised in the open air, the results are rarely satisfactory, and they are almost invariably produced under glass in Great Britain. The plant is an annual with creeping stems and tendrils, rough heart-shaped leaves, and yellow flowers of two kinds, male and female, the latter producing the fruit.

As it is convenient to have the young plants in separate pots, each seed may be sown in a 3 in. pot with a compost well enriched with leaf-mould. In a warm house or manure-heated pit or frame with a temperature of 60° or upwards the seed will soon germinate. The soil must never be allowed to get dry, nor must the atmosphere be permitted to get arid. The plants may be planted out when 6 in. high, but, except in frame culture, it is usual to transfer them to 5 in. pots and to grow them on.

It is a good plan, when planting, to set them on mounds of lumpy soil. When taken out of the pots they should be planted with the ball of soil and roots entire, taking care not to bury the ball very deeply. As the roots show through fresh soil must be added. A flower stake supports them in the mound until they reach the wires, which should be stretched beneath the glass of the house at a distance of about 1 ft. from it. Once on the wires the plants will make rapid progress. The main shoots should be trained thinly on the wires, but the side shoots should be "stopped."

*Cucumber. Left, short, rough-skinned variety, grown in the open air. Right, specimens raised under glass; they are double the length of the outdoor ones.*

Cucumbers require a warm, saturated atmosphere, which can be maintained by syringing the vines and the surfaces of the house once or twice a day. Water should be used to keep the mounds moist and tepid. When the plants are in full bearing applications of liquid manure twice a week will increase the yield and size of the fruit. Good varieties are Everyday, Delicacy, Improved Telegraph and Boxford Market.

*Cucumber. Diagrams illustrating the culture of the plant. 1. How seed is embedded in sand and sown in loamy soil. 2. Seedling. 3. Stage when ready for repotting. 4. Pinching out, as at a. 5 and 6. Outdoor growing, a, hole filled with manure; b, ridge of soil above manure; c, plant. 7. How to plant in frame. 8. Points of laterals pinched out at X.*

Several fungoid diseases attack the cucumber. If the bed of soil is watered excessively, a stem gangrene called canker commonly starts. The soil should be drawn away and lime or sulphur rubbed in.

Cucumbers are often affected by a malady induced by the root-knot eelworm. The first symptom of attack is a drooping and yellowing of the foliage, followed by the stem becoming limp, and a collapse of the entire plant. To destroy these eelworms the soil must be thoroughly saturated three times, at intervals of a fortnight, with a solution of one part of cresylic, or liquid carbolic acid, in 40 parts of water. The plants that are ruined by the eelworms should be burnt.

**Cucumbers in Frames.** It is quite practicable to

grow excellent cucumbers in an ordinary frame, provided the hotbed has been properly prepared, and steady bottom heat maintained. Inside the frame there should be mounds of soil consisting of loam and leaf-mould, one plant being placed in each mound. The roots must be covered with fresh compost from time to time. Planting is done in April and May. One plant will fill a frame 6 ft. by 4 ft.

Ridge cucumbers can be grown out of doors in summer by putting out the plants in May in rich soil; in a cold, wet season they are liable to fail. Suitable varieties are King of the Ridge and Stockwood, and the gherkin for pickling purposes.

**How to Cook.** Cucumbers may be treated in most of the ways suitable for marrows and aubergines, but are most popular in salads, when they are peeled and very thinly sliced. Thin slices of cucumber are also served with cold salmon. When used as an accompaniment to cold meat, they are usually covered with vinegar, and served in a glass dish. If they are to be eaten raw, cucumbers should be young and firm, and free from seeds.

Stewed cucumber, served with sauce made from the stock in which it was boiled, makes a good dinner vegetable. To prepare it, peel 2 cucumbers, cut them lengthways into quarters, and, if they are old, remove the seeds. Place the pieces in boiling salted water, simmering them there until they are tender; then drain and heat them in a sauce prepared from 1 oz. of margarine, a little cucumber stock, 1 oz. flour, 1 tablespoonful unsweetened condensed milk, and two tablespoonfuls cow's milk.

Melt the margarine, add the flour, and blend the two ingredients well. Pour in the milk gradually, with 5 or 6 tablespoonfuls of stock, stir the whole in a pan over the fire until it boils, and then simmer it for 5 minutes. Lastly, add the condensed milk and the cucumber, heat up the whole, and serve the cucumber with the sauce poured over it.

**Cucumber Cassolettes.** A good way of using up half a cucumber which has been left over from salad making is to peel it thinly, cut it into 4 pieces, and carefully scoop out the centre of each. Stew these very gently until they are tender, in  $\frac{1}{2}$  pint of milk and water, mixed in any proportions, then take them out of the pan and flake  $\frac{1}{2}$  lb. cold salmon or other cooked fish. Season the flakes well, and stuff them into the hollow pieces of cucumber. Thicken the liquor the cucumber was stewed in with  $\frac{1}{2}$  oz. cornflour or barley-flour mixed with a little milk, add 2 teaspoonfuls of chopped parsley, and then pour in a little hot water in which has been melted 2 sheets of gelatine. Add a squeeze of lemon juice, and pour the sauce over the cucumber cassolettes, coating them neatly, and garnishing them with cold peas. Serve cold with potato salad.

A similar dish is prepared by cutting a large

cucumber into rounds each about 2 in. thick, peeling these thinly, and scooping out the insides till a thickness of only  $\frac{1}{2}$  in. is left. Put the rounds into boiling water with a little salt and castor sugar, boil them until tender, and then leave them to cool. When cold, fill them with a mixture composed of peas and some carrots and turnips scooped out about the size of a pea. Before being used for filling the vegetables should be boiled, and when cold mixed with mayonnaise sauce to which some whipped cream has been added.

**Cumin.** The plant of this name, which is brought from the Levant, contains an aromatic oil and acts as a carminative (q.v.).

**CUP: The Drinking Vessel.** One of the oldest of drinking vessels, the cup has taken a number of forms, some of these being known by special names, such as flagon, goblet, loving cup and tankard. Many of these were made by English silversmiths in the 17th and 18th centuries.

Tumbler cups, so-called because they are shaped like a tumbler and are without handles, are found in silver and in Sheffield plate. One example of the time of Charles II is embossed with flowers and foliage. A variant of this cup, known as a taster, is fitted with a handle, and is shallower than the tumbler form. Another variety is the wine cup, which stands on a stem and a foot.

Cups with saucers to match are made in a number of shapes and sizes, but can be divided into three main categories—breakfast, tea, and coffee cups. Most breakfast cups hold about  $\frac{1}{2}$  pint, while teacups hold roughly a gill. They are generally flatter and wider-mouthed than either breakfast or coffee cups, but should not be chosen too wide, as the wider and shallower the cup the sooner the tea will cool. Cups for black coffee usually hold only 2 tablespoonfuls. Special cups for invalids are made with a spout, and with the top partially covered in to prevent the contents from spilling. *See* Breakfast; China; Coffee; Crockery.

**CUP.** This is a kind of drink, made usually from claret or the lighter white wines mixed with soda water, sweetened, and with various herbs and flavourings added. Recipes will be found under the headings of suitable beverages. *See* Cider Cup; Claret Cup; Hock Cup.

### CUPBOARDS AND THEIR CONSTRUCTION

#### Decorative and Useful Pieces Described and Illustrated

Other entries similar in scope are those dealing with Bureau; Wardrobe, etc. *See* also Corner Cupboard and the articles on Amateur Carpentry; Cabinet Making; Drawing. Other forms of cupboard are shown under Bachelor Flat; Bedroom; Bookcase, etc.

The oldest existing cupboards date from the reign of Elizabeth. The original cupboard, known as a court or livery cupboard, was the equivalent of the modern

sideboard or buffet. Such cupboards were used to assist the service of meals, and many were elaborately carved, the lower part being simply a chest, which opened by means of two doors.

Cupboards are divided into two kinds, those built into the house and those that are movable. The built-in cupboard was used in the Queen Anne period for the display of china and pottery. It had fitted shelves and sometimes doors; it was either a corner fixture or built in each side of the chimney breast. This idea is adapted by modern architects for suitable houses, and by decorators in treating corners and recesses in rooms and halls which lend themselves to a Queen Anne or Georgian style of furnishing.

Built-in cupboards increase in importance with space and labour-saving exigencies. Linen cupboards, geyser cupboards, fixture cupboards that shut off sinks, baths, wash-stands and dressing tables in bachelor flats and bed sitting rooms; airing cupboards which make home laundry possible in the small flat, and dining room cupboards painted or panelled to fit in with the decorative scheme and made to contain all the table equipment, dessert, etc., and ingredients for drinks, are cleverly introduced into recesses or form an integral part of the architect's plans for small houses.

With the exception of the corner cupboard, decorative movable cupboards are not much seen to-day. They tend to become severely practical, but are exceedingly useful to supplement landlord's fixtures when the tenancy of a flat or house is only for three years or so. The illustration of a modern dining room cupboard gives a useful idea for the furnishing of a recess in a small room.

*Cupboard. Beautiful old oak Court cupboard. It is of the Elizabethan period and is elaborately carved and inlaid. (Courtesy of M. Harris & Sons)*

**A Hanging Cupboard.** A useful and easily made

cupboard, designed either as a hanging cupboard or for shelves, is shown in Fig. 1. The ends are 1 in. deal, the full height of the job and 1 in. less in width (i.e. 15 in.), the odd inch being taken up by the pilasters fixed on the face of the carcass. These are the same thickness as the door, so that the whole front will line up. The ends, dovetailed to take the top (Fig. 3), are grooved near the bottom (Fig. 4), and the bottom shaping cut to form the feet, as seen in Figs. 1 and 2. A rebate is run at the inside edge in which the back fits, this measuring  $\frac{1}{2}$  in. or  $\frac{3}{8}$  in. for the panels.

## CUPBOARD

Fig. 1

*Figs. 1-4. Useful hanging cupboard, with details of its construction.*

The top and bottom are both the full width of the job, less the thickness of the back panels; they are cut away at the front ends to take the pilasters, and will thus be flush with the front edge of the ends. The top, 3 ft. in length, is through dovetailed, the ends of the dovetails being hidden by the cornice moulding. The length of the bottom will be the inside distance between the ends, plus twice the depth of the groove in the ends. The carcass should be glued up using nails to strengthen the groove joint and corner blocks, as indicated in the diagram at Fig. 4.

*Left. Cupboard. Dining room cupboard in oak with portable table on ball castors for service. The table stands inside the cupboard. (Courtesy of Waring & Gillow, Ltd.)*

When dry, fix the back, which consists of three panels and two muntins, the latter being grooved to take the panels. Now true up the face of the job and fix the pilasters, these being previously cut to shape at the bottom. They are dowelled into the ends and screwed up top and bottom, the screws being hidden by the

mouldings. A corner block, rubbed under the bottom between the pilasters and the ends, will strengthen the feet. Both mouldings should be mitred round, and glued and pinned. The door is mortised together with  $\frac{1}{2}$  in. grooved-in panels and hinged with three butts; a turn-buckle or screw-on lock may be used, with a stop fixed to the inside of the pilaster near the top to prevent the door from pushing in too far. Shelves or hooks may be fixed, the shelves being supported by square fillets screwed to the ends.

Fig. 2

Fig. 3

Fig. 4

## CUPBOARD

**Fig. 5**

*Figs. 5-9. Kitchen or linen cupboard with elevation, plan and diagrams showing details of plinth and fitting of shelves.*

**Kitchen and Linen Cupboards.** The kitchen cupboard, which is illustrated in Figs. 5-8, is a similar type of job to that shown in Fig. 1, except that the doors fit over the carcass and an applied plinth is used. The work proceeds as in Fig. 1, but the ends are cut off about  $2\frac{1}{2}$  in. short at the bottom (Fig. 8). This sketch also shows how the plinth is fixed with screws.

A corner block should be rubbed at the inside of the mitre of the plinth. Three or four shelves are placed at convenient heights, supported by slips screwed to the ends.

A linen cupboard is of similar construction, except that, in place of shelves, a series of slats running from back to front are used to facilitate airing. Fig. 9 shows how these are constructed. Three rails measuring 3 in. by 1 in. are made to run from side to side, and to these rails the slats are screwed.

**Fig. 6****Fig. 7****Fig. 8****Fig. 9**

Figs. 10-13. Corner cupboard for clothes, with diagrams of principal parts.

**A Corner Cupboard.** An example is shown in Fig. 10. The ends or backs do not fit up close to the wall, but stand away 1 in., thus allowing the pilasters to form a close fit to the walls. This is necessary in the case of the angle of the wall not being square, also to allow the pilasters to be scribed over the skirting.

The top and bottom are first prepared. The top, dovetailed into the ends, as in Fig. 12, finishes at the front in a line with the inside of the doors, the frieze being fixed to this. The bottom is grooved into the backs, so that the size will be taken from the inside, adding the depth of the grooves; this also finishes to the inside of the doors. Having cut top and bottom to size, the width of the two backs is taken from them. These are  $\frac{3}{4}$  in. deal, screwed together at the corner (Fig. 12). They occupy the full height of the job and are dovetailed and grooved. When glueing, screw the backs together first, then the top, and finally the bottom, which is nailed from the outside; corner blocks are rubbed underneath.

The pilasters are fixed to the edges of the ends with

dowels; two screws may be put at the top and bottom hidden by the mouldings. The joint is also strengthened with corner blocks (Fig. 13). These pilasters are bevelled on the inner edges, to form a true mitre with the doors. The frieze to the top is screwed to the top, the top of the pilasters being cut, as in Fig. 13, to receive the ends. The shaped plinth is secured in a similar way, putting corner blocks under the, bottom to strengthen it. The three mouldings, i.e. cornice, frieze and plinth, are mitred round, as indicated in Figs. 10 and 11, and fixed with glue and pins. The doors are framed together out of 1 in. stuff and have  $\frac{1}{2}$  in. grooved-in panels. The outer edges are bevelled at the same angle as the pilasters. A centre door stop is fixed behind the frieze, and screw-on bolts and locks used. Three  $2\frac{1}{2}$  in. butts are used for each door. To scribe the pilasters over the skirting, place the job close into the corner and set a pair of dividers to just the width of the opening left above the skirting. Using one point as a gauge, mark the pilasters with the other, drawing the dividers along the face of the skirting.

**Hanging Chippendale Cupboard.** Fig. 14 shows a form of hanging corner cupboard in the Chippendale style, all necessary dimensions being indicated in Fig. 15. Made in mahogany, it embodies the characteristic features of a swan-neck pediment with fretted panel, and a geometrical arrangement of glazing bars. The bottom board is rebated  $\frac{1}{4}$  in. deep to take the sides and back pieces. The top board comes inside the side pieces, and the cornice moulding is planted on it. The pediment moulding is sawn to shape, carved and rebated to take the fretwork panel, the whole being glued and screwed in place. It is shown in detail in Fig. 18.

The stiles and rails, the sides and the bottom board are 1 in. thick. The apron beneath the bottom is of  $\frac{1}{2}$

in. stuff, mitred at corners and fixed with glue blocks. The  $\frac{1}{8}$  in. plywood back boards are nailed to top and bottom, and to rebates in side pieces. The construction is made clear by Fig. 16. A triangular fillet supports the plywood at the angle.

Details of the cornice and door framing are illustrated in Fig. 17. The door stiles extend from top to bottom of the opening, and the rails are tenoned to them. The glazing bars, shown in Fig. 15, are mitred at all joints, glued together, and planted on the glass. Shelves  $\frac{3}{4}$  in. thick have curved fronts, and are glued and nailed to the plywood back. The cabinet, which should be lined inside with velvet, is suspended by four mirror-plates, screwed to the back edges of the top board.

**Figs. 14-18.** Mahogany hanging corner cupboard, Chippendale style, with details of construction.

**A Recess Cupboard.** A recess cupboard is shown in Fig. 19. As the walls of the recess form the back and sides, a framework must be erected at the front. Having decided upon the height, make a framework as in Fig. 20, consisting of a cross-piece tenoned into two uprights of  $1\frac{1}{4}$  in. stuff, 4 in. wide. The cross piece is  $6\frac{1}{2}$  in. wide, the extra  $2\frac{1}{2}$  in. being allowed to take the cornice moulding, which is of this width. This frame is glued together, and when dry should be trued up to fit in position, the lower ends being scribed over the skirting. The fixing depends to a certain extent upon the interior accommodation required. For the example illustrated, a

series of shelves, as in Fig. 21, is intended. Battens or bearers are fixed at each side of the recess, at equal heights, in the position required for the shelves; also for the top. These bearers, 2 in. by 1 in., are as long as the inside depth of the cupboard.

If the recess is of a good depth, allow the face of the frame to stand in sufficiently to permit the cornice moulding to butt into the sides of the recess. This obviates the necessity of making a return end to the moulding. The shelves and top are of 1 in. stuff, all of equal width, and are nailed down to the bearers. To these the frame is nailed, a series of nails being also driven in along the top. The nails should be punched in.

Fig. 19

Fig. 20

Fig. 21

*Cupboard. Fig. 19. Bedroom recess cupboard. Fig. 20. Lintel and framework. Fig. 21. Interior, showing shelves supported by bearers secured to walls.*

**A Boot Cupboard.** The boot cupboard for a bed-sitting room shown in Fig. 22 is made with plywood about  $\frac{1}{2}$  in. thick. The top board is rebated at each end, and the side pieces fitted into them. The cupboard shelf is sawn to size, planed square on the ends, and glued and nailed between the side pieces. The whole of the back is then covered with  $\frac{1}{2}$  in. plywood, glued and nailed to the edges of the shelf, top and side pieces.

The boot racks are pieces of broom handle or similar round wood which fit into holes bored through the side pieces. The ends of the bars are rounded off, and all are glued into place. The cupboard door is made up with "cupboard door moulding," obtainable ready grooved and tenoned. The panel is a piece of  $\frac{3}{16}$  in. plywood. Hang the door on two small hinges, and fit a cupboard turn or lock. A curtain, fitted on a rod beneath the cupboard, conceals the boots and shoes. The cupboard can be finished by staining (and varnishing, or may be treated with a bright enamel.

*Cupboard. Fig. 22. Compact arrangement for holding boots and shoes, useful for a bed-sitting room.*

## CUPBOARDS FOR ALL PURPOSES

*Kitchens, Bedrooms & Linen Stores*

*Two kitchen sets. Above, left: Everything is within easy reach; note the overhanging top row of cupboards, and middle shelves guarded by sliding doors. Right: Conventional hinge-doors on cupboards of all sizes, arranged with architectural economy in a kitchen where space is plentiful.*

*To the left : Cupboard door with lintel and chromium-steel pull-handle. Also an American linen-cupboard, with straps, etc., in orderly arrangement. Above: Bedroom set in white pine. Right: Cupboard-washstand, with mirrors, strip light, shelf and towel rail.*

*Left: Everything possible is built-in—shelves for saucepans, and plate racks. The space beneath the drainage boards accommodates kitchen stools and other things put out of the way. The right-hand lay-out, however, encloses all available space under the sink, but aims at having everything within easy reach.*

*(Photos, Lincoln Collins & Margaret Currant.)*

**CURAÇAO.** This liqueur is made from the peel of a very rare orange which grows in the island of Curaçao. It enters into the composition of many restoratives and tonics.

**Curb.** See Fender; Fireplace.

**CURD.** Curd is the nitrogenous part of milk, the solid substance left when the whey or liquid is separated. When milk sours, the curd coagulates by the action of the lactic acid formed in the milk. Cheese is made from the curd. See Cheese; Junket; Milk.

**CURLY KALE.** An indispensable hardy green winter vegetable. Seeds are sown on a prepared bed of fine soil out of doors in April, the seedlings are transplanted at about 6 in. apart to give them room to develop, and are put out in June or July 2 ft. apart where they are to remain. Curly kale is the name given to the Scotch or curled kale which has densely crisped or curled leaves. There are many other varieties of kale or borecole, e.g. asparagus, cottager's, sprouting, Drumhead and thousand-headed. Cottager's is an old and popular variety. In this the habit is upright and the leaves are plain. The central leaves are tinted blue or reddish purple. All these are useful winter vegetables and need the same treatment as curly kale.

*Curly Kale. A favourite hardy winter vegetable with densely crisped or curled leaves.*

**How to Cook.** To boil it, first wash and trim the kale, ridding it of any hard stalks, and then place it in a pan of boiling water, and boil it rapidly for 5 min. Then change the water for a similar quantity of fresh boiling water, adding a pinch of cooking soda and a teaspoonful of salt to every quart. When tender, drain off the water, press the kale well and chop it up, adding a lump of butter and a little salt and pepper, and mix all together, stirring them in the pan over the fire. Fill a hot vegetable dish with the kale, cutting it across several times with a knife.

Curly kale may be cooked in a casserole. Wash it thoroughly in salted water, and then shred it coarsely and boil for 5 minutes before putting it into an earthenware casserole, together with a gill of water and a lump of fat about the size of a hen's egg; cover the pan and cook its contents gently, stirring them occasionally until the greens are tender. This should take about 1 hour. Finally, season it with pepper and

salt and serve it in the casserole. See Broccoli; Kale.

**CURRENT.** Red and white currants will thrive in any soil that is not too heavy and damp, but black currants give of their best in a moist, heavy soil. The former bear fruit on spurs upon the old wood at the bottom of the previous year's growth. Black currants give their finest fruit on last year's wood, and therefore too much old wood should not be allowed.

Fresh currants of fine quality and quite ripe may be frosted, and in this form provide an attractive dessert dish. Prepare them by sieving some castor sugar on to a saucer or plate, and warming it without letting it melt. In the meantime, beat up the whites of 2 eggs and add to them 3 or 4 dessertspoonfuls of water. Divide  $\frac{3}{4}$  lb. of currants into neat bunches, dip these into the egg mixture, and then into the castor sugar, making sure that they are well coated. Dry on a sheet of paper. See Black Currant; Red Currant; White Currant,

**CURRENT: The Dried Fruit.** Dried currants are a small variety of raisin imported from the Levant, and used in many cakes and puddings, and in mincemeat. They should not be bought in large quantities, as they do not keep well, and should be placed in an airtight tin. To clean currants for use they should be rubbed in a dry, clean cloth on which a little flour has been sprinkled, and shaken on to a sieve so that any stalks can be picked off, or they may be rubbed through a sieve with two or three teaspoonfuls of flour sprinkled over them. Unless there is plenty of time in which to dry them, currants are best cleaned by means of flour instead of by water, for if used while damp they will make the cake or pudding heavy.

**CURRENT SAWFLY.** This is an insect pest called *Nematus Ribesii* which attacks currant and gooseberry bushes. It looks like a small butterfly, and is yellow in colour, with a black patch in the centre of the back. The pest is usually born early in spring, and commences to eat the young leaves of the bushes as they expand. Sometimes a second brood of these caterpillars appears later in the season.

*Current Sawfly.*

*Caterpillars on currant leaf.*

*Right, perfect insects; top, male; bottom, female, both highly magnified.*

Spraying in no uncertain way with paraffin emulsion is the best remedy. In chronic cases it is best to remove all the soil round the bases of infected trees to a depth of 4 in. in winter-time and burn it. This usually destroys the cocoons, which would be the parents of the next season's pests. A dressing of lime to the soil is also recommended.

Consult Ministry of Agriculture Advisory Leaflets Nos. 114 and 176. *See* Black Currant; Gooseberry; Red Currant.

## CURRY: INGREDIENTS AND FLAVOURINGS

Recipes for Meat, Chicken, Fish and Vegetable Curries

The reader interested in cookery may consult the articles Casserole; Chicken; also such entries as Bombay Duck; Chutney; Rice.

If carefully prepared and nicely balanced with regard to flavourings, curry stimulates the appetite and digestion. Many foods are suitable for curry dishes, including meat, poultry and rabbit, cooked or raw; also fish, vegetables and hard-boiled eggs. A number of ingredients are contained in Indian curries, the superior flavour of which is due to the use of fresh and dried spices and fruits instead of the curry powder relied on by many British cooks. Some of these ingredients are obtainable at good stores, as, for example, green ginger, turmeric, chillies, bottled tamarinds, garlic and saffron. A really good imported Indian curry powder should supply deficiencies in home cookery aided by curry paste, coconut milk or shredded coconuts, apple (which can be substituted for tamarinds), pickled gherkins and lemon juice. Flavouring is a question of taste, but no one flavour should be detectable in a well-balanced curry, which should not be too hot, too sweet or too acid.

A curry should never appear on the table with a thin gravy, though there are wet and dry varieties; in the former the sauce is sufficient practically to cover the food curried; in the latter it has been absorbed during cooking by the other ingredients. Boiled rice, grated coconut and chutney should be served, on separate dishes with meat curries; Bombay duck (dried fish) may also accompany these. Rice is often placed as a border on the same dish with small quantities of fish, egg and dry meat curries. Vegetable and fish curries may be served at luncheon or informal suppers in individual pipkins garnished on the top with a spoonful of chutney, a small piece of fried red herring with chopped gherkin, or a slice of hard-boiled egg, surrounded by a little boiled rice. Anything with curry sauce should not be touched by steel; a wooden spoon is best for stirring the mixture in the casserole, and curry should be eaten with a fork, or spoon and fork.

Curries are always best cooked in an earthenware or glass casserole, or in a fireproof dish if the quantity is very small, as this gentle method of braising enhances the flavour, and provides a perfect method of dishing. A metal pan destroys some of the delicately balanced taste. Meat should be cut into cubes. When eggs are used they should be boiled first for fifteen minutes,

shelled, and cut into halves before being heated gently in curry sauce. Small joints of rabbit, chicken or game may be fried in margarine or dripping before adding to the sauce. When fresh coconut milk is not obtainable, substitute the following if wishing to include this ingredient in a curry: Scrape some fresh coconut (or put a large tablespoonful of desiccated coconut) into a basin and pour over it enough boiling water to cover; let it soak for half an hour, and then strain off the liquid for use.

In Indian curries the foundation fat for sauce and frying meats is known as ghee. This is butter into which green mint and cloves are put while it is being clarified which gives to the curry a subtle flavouring.

**Rice for Curries.** Patna is the best rice to use for curry-making, as it has long, pointed grains that separate easily after cooking. It should be perfectly white and dry when served. To prepare it, wash a breakfastcupful thoroughly, and then place it in a pan of salted boiling water. Keep this boiling briskly with the lid off for about 20 min., and stir the rice frequently. When the grains are thoroughly soft, turn the rice into a warmed colander, and then pour boiling water over it. This will separate the grains. When this method is employed it is unnecessary to dry the rice over the stove or in the oven. It should be heaped on to a hot dish, and arranged with a fork.

**Meat Curries.** If fresh meat is used for a curry it is a good plan to fry it in butter or margarine before laying it in the curry sauce. As curry is such an excellent method for doing up left-overs of joints etc., cooked meat is more often used for this purpose. Any of the ingredients already mentioned may be used to flavour the sauce or added to the curry whilst cooking. The recipes given suggest variations suitable for the particular dish.

*Carried Prawns, a savoury dish served with a border of rice.*

For a curry of cold cooked veal, first prepare the sauce. For this, melt in a casserole 2 oz. butter and fry in it, without colouring, a large onion and a medium-sized apple, both prepared and chopped small. Strain off the fat from these and reserve them, then return the fat to the pan. Add a tablespoonful of curry powder mixed with a dessertspoonful of flour and let these cook gently for 12 min. Add the reserved onion and apple and stir in about a pint of white stock. Let the sauce boil up and mix in a dessertspoonful of curry paste,  $\frac{1}{2}$  oz. blanched and chopped almonds,  $\frac{1}{2}$  gill cream or milk, the juice of half a lemon, and seasoning to taste.

Cut 1 lb. of lean cooked veal, previously freed from skin and bone, into cubes, place it in the casserole and simmer gently until thoroughly heated through, but do not allow the curry to boil. Serve with cut lemon, boiled rice and chutney.

A good mutton curry is prepared from the following ingredients: 1 lb. mutton cut into cubes, 2 oz. mint flavoured butter, 1 large shredded onion, 1 tablespoonful each of curry powder and cornflour, 1 finely minced apple, a teaspoonful each of curry paste, lemon juice and chopped gherkin, salt to taste.

Rub an aluminium frying-pan with a crust of bread flavoured with garlic. Place the mint-butter and onions and meat in the pan and fry lightly. Remove meat and onions to casserole, and gently stir into the butter in the frying-pan the curry powder and cornflour. When smooth add  $\frac{3}{4}$  pint stock and salt to taste, and bring to the boil while stirring. Pour this sauce over the meat and onions in the casserole, add the other ingredients, stir the mixture well and allow to simmer until cooked. Serve in the same way as the veal curry, but without sliced lemon.

Kidneys are excellent curried; either calf's or sheep's kidneys may be used, but the former require longer cooking. Split, skin and slice neatly four kidneys and put into the casserole with 1 oz. butter, one thinly-sliced onion, one small chopped apple and a squeeze of lemon juice.

Continue cooking for a few minutes, taking care that the whole does not burn; then stir in  $\frac{1}{2}$  oz. of rice flour,  $\frac{1}{2}$  dessertspoonful of curry powder, a little chutney and seasoning. When these ingredients are thoroughly mixed, pour over them a breakfastcupful of stock, and stew the kidneys for  $\frac{1}{2}$  hour, or until they are tender.

Before taking the curry from the pan, add a little cream to it and serve it with a border of boiled rice.

**Rabbit and Chicken Curries.** To curry a rabbit, cut the flesh into convenient sized pieces, season them to taste, and fry them lightly in a lump of butter about twice the size of a hen's egg. Add 3 or 4 dessertspoonfuls of finely chopped onion, and continue cooking gently for about  $\frac{1}{4}$  hour. Then stir in 2 teaspoonfuls each of flour and curry powder, mixed smoothly with a little, cold water. Add a bunch of mixed herbs, a dessertspoonful of chutney, and  $1\frac{1}{2}$  breakfast-cupfuls of stock. Simmer for about  $\frac{1}{2}$  hour, or until the meat is found to be tender. The bunch of herbs, of course, should be removed before serving.

For curried chicken, having cut the bird into neat joints, dust these with flour. Cut two onions into small pieces, slicing them down from the crown; fry these in 4 oz. of margarine or butter, then strain them and lay them aside. Add 2 tablespoonfuls of curry powder and the pieces of chicken to the butter in the pan, fry these gently for 15 or 20 min., then add a small chopped apple, the fried onions, a few blanched and chopped almonds, a few sultanas, and  $\frac{1}{2}$  pint of white stock. Pour in a teacupful of coconut milk, and add a teaspoonful of curry paste; then season and cook all gently until the liquor is thereby reduced in quantity by

one third.

Before serving, carefully remove all fat from the surface and add a dessertspoonful of lemon juice. Send the dish to the table very hot with boiled rice served on a separate dish. If liked, the chicken may be removed from the casserole, placed round the heaped rice on a dish and the sauce passed through a sieve before being reheated and poured over the pieces of chicken. Any poultry or game may be curried in this way.

**Fish Curries.** A good curry sauce in which fish can be afterwards cooked is prepared by sprinkling a small finely-chopped onion with a little flour, and then frying it in  $\frac{1}{2}$  oz. of butter. When it is light brown, add 1 dessertspoonful of curry powder, and continue frying for a few minutes before putting in 1 dessertspoonful each of chopped chutney and flour. Add  $1\frac{1}{2}$  gills of vegetable stock, and stir the mixture until it boils and becomes of a creamy consistency. Then gradually add  $\frac{1}{2}$  gill or less of cream or milk.

Curried prawns are made with a pint of curry sauce, using fish stock or a stock made from boiling the bruised prawn shells. Add 1 pint of prawns and let them simmer for a few minutes. Serve them on a hot dish with a border of boiled rice. An illustration of this dish is given in the previous page.

To curry lobster cut up the flesh into pieces of a convenient size, heat them in curry sauce and dish in the same way as curried prawns. Chutney should be served separately. Any cooked white fish can be coarsely flaked and reheated in curry sauce, first simmering the latter for 10 minutes. The addition of a little chopped apple and a squeeze of lemon to the curry sauce is sometimes liked.

**Vegetable Curries.** Any vegetables, such as small turnips, onions, carrots, pieces of cauliflower, French beans, peas, and small potatoes, may be used for a vegetable curry. First cook the vegetables until they are soft but not pulpy, and then add them to the curry sauce. Simmer for  $\frac{1}{2}$  hour, add a squeeze of lemon juice and a lump of sugar, serving the curry with boiled rice.

Cooked lentils, butter, or haricot beans may be curried separately. Add 1 pint to sufficient heated curry sauce to cover the vegetables in the casserole. Slice in two scalded and peeled tomatoes, add a teaspoonful of curry paste, and serve in individual pipkins with chopped gherkins and rice.

**Curry Croustades.** A useful way of serving a neat little curried dish at breakfast or supper is to place a tablespoonful of flaked fish or minced meat heated in sufficient curry sauce to flavour, but not to make too moist, in croustades. To prepare these, cut 2 or 3 slices of bread about 2 in. thick and stamp them out into rounds with a plain cutter the size of a wine glass, scooping out the crumb from the centre until only cases of bread remain. Let these soak in a little milk for 3

min., then beat up an egg and brush a little over each case. Cover them with breadcrumbs and try them a golden brown.

*Curry Croustades, which can be made either with flaked fish or with minced meat.*

**CURRY COMB.** This form of comb is used for grooming horses, its object being to free them from the dirt that adheres to the skin. The comb should be used first from the neck to the shoulder; the operation should then be continued downwards to the legs, and finally along the breast and underpart of the animal. *See Horse.*

### **CURTAINS: HOW TO CHOOSE AND MAKE** Decorative and Practical Ideas for Window Treatments

This article concludes with information about the fittings and other accessories of curtains. *See American Cloth; Bay Window; Bedroom; Casement; Colour; Drawing Room, etc.*

Curtain treatments may be simple or elaborate, but they must bear a definite relation to the colour scheme of the surrounding interior. Occasionally a thought should be given to the view through the window. Jade green curtains, for instance, will not look well framing a mass of summer foliage, nor will bluish pinks, or fuchsia shades of red, harmonise with the view of a red brick wall. A certain agreement is also pleasant between the various window curtains of the home as seen from outside. This is easily achieved, without being tied to one colour or fabric, by a lining in one set, by the ground of a cretonne in another, by the pattern in a third and by the solid colour of a fourth, all introducing the same shade, which in turn should contrast happily with exterior paintwork.

**Colour and Pattern.** With regard to interior colour schemes, curtains should accentuate a note in a room or afford a good contrast. Sometimes they may do both, as, for instance, when a patterned material is used which matches the loose covers, but in the case of the curtain is bordered and edged with a plain material, which is repeated for the valance or pelmet; or the pattern may pick up the colours of tiles and paintwork, while the plainer material of the border matches the upholstery. This scheme is a pleasing treatment for printed linen or cretonne with a rep border and is particularly attractive for an informal sitting room or a town bedroom with glass curtains of ivory net woven in square mesh. It may equally well be utilised for a French window, or a double sash window, but in the first case the net curtains are best fitted to each half of the window and held in place at the bottom by a second

rod so that they do not swing out when the windows are unfastened.

For French windows in the more formal room, the type of curtain shown in the first illustration is suitable, especially if the ceiling is low, as the long line of plain fabric with the narrow gracefully braided pelmet gives height. Such curtains would look equally well in shot artificial silk, in satin or, for a dining room, in furnishing velours or velvet. Such pelmets could be trimmed with motifs bought ready embroidered and only requiring to be lightly sewn on, connecting the design with a braid which can be bought to match. For a room with any Chinese lacquer furniture the pelmet could be bordered with strips of Chinese embroidery or with motifs in the dragon design. Hand-worked appliqué designs can be used with great advantage on a pelmet of this type; or it may be simply bound with ribbon of a contrasting colour.

*Curtain. Plain satin curtains frame the French windows of the formal sitting room, while the braided pelmets are designed with curves to correspond with period furniture.*

For the double sash window in a town house long outer curtains may frame lace store curtains to the sill. The advantage of the latter is that they can hide out a depressing view if necessary without obscuring light.

*Curtain. Treatment for a hall or lounge window with braided and tasselled pelmet copied from an Elizabethan design.*

A good formal treatment for a large bay window is to make an outer frame by means of pelmet and long curtains of rich plain fabric. These curtains are pleated on to a band so that they keep their rather narrow line. Practical

curtains in a contrasting colour are hung on an inner rod, bent to the shape of the bay, while lace store curtains fit the windows. This treatment looks well when carried out in deep hyacinth blue for the framing curtains, pelmet and curtains bordered with silver braid, the former having two long silver tassels that hang down over the curtains at the outer edges; the practical curtains are of artificial taffeta shot with a lighter blue and mauve and the store curtains are an ivory shade. Whatever the colour scheme selected to suit the room the framing curtains should be unpatterned and of darker tone than the practical ones. Vitrage laces may be utilised instead of store curtains for bay windows. These laces are made in panels and can be cut along the joins, one or more panels adjusting themselves to the fitting of narrow or wide windows. Brise-bise nets can be used for casements, or for lower sashes of bedroom windows with outer curtains to the sill. Crisp effects can be obtained by the use of organdie muslin, self-fitted.

*Curtains and pelmet to suit a country cottage  
(Margaret Currant Studio)*

Striped artificial silk fabrics bring a gay note into a room otherwise neutral in tone. A small dining room, carpeted with brown, and having parchment-coloured walls and a cold north light, was transformed by window curtains in bold stripes of orange with narrower stripes of gold, blue, green and chestnut-brown. The valance was composed of two layers of scalloped material, each scallop measuring six inches across. The points between the scallops were well defined, the lower scallop being placed beneath the cut up point of the top layer. This top layer was of chestnut-brown (which colour also lined the curtains), and the under layer of the predominating orange stripe. A sunny glow was introduced into the room with fine artificial silk net curtains in pale gold across the window. Beautiful curtain fabrics for lounge or dining room can also be had in patterned damasks and tapestries. The latter need plain walls to show off their beauty.

**Short Curtains.** For easement windows, the frilled or pleated valance with short curtains will look well in thinner materials. Valances may be box pleated on to a tape to which small rings are attached at close inter-

vals. Hooks can then be screwed into the valance board so that the valance can be hung and not nailed to the board. If no valance or pelmet is used the curtains must be very neatly gathered into a heading at the top, or ugly gaps may be an eyesore between curtain and rod. If the top of the curtain is firmly pleated to a depth of several inches by means of rows of stitching it will give a delightfully neat heading. Cretonne gathered valances need not be lined, but straight scalloped valances or pelmets in any material require this additional support and stiffness.

Bedroom curtains are better lined if they are practical and blinds are done away with; also, with the exception of taffeta and furnishing satin, fabrics hang better when lined. Short chintz, check gingham, bordered casement cloth, or coloured bolton sheeting curtains do not require lining unless it is particularly desired to darken the room at night. Pale coloured voile or spotted muslin are dainty fabrics for glass curtains in simply furnished bedrooms.

The second illustration shows a charming treatment for a hall window, the diamond points of the pelmet being trimmed with gold tassels, while gold braid is used to make the design. Either velvet, velours on heavy artificial silk rep would lend itself to the making of these curtains, which would look equally well in a small sitting room.

Plywood pelmets are sometimes seen with short curtains, and have cleanliness and neatness to recommend them as well as possibilities of decorative treatment. They can be painted the same colour as the woodwork of the room, decorated with a stencil pattern, or repeat the groundwork of cretonne curtains. The edge of such a pelmet can be left straight or curves can be introduced by means of a fret saw. Painted with gold or silver metallic paint and outlined with a colour, they are decorative in a modern room. They are right for the up-to-date kitchenette where coloured paint is to be used for woodwork, and also for the nursery with stencilled animals or fairy tale characters. They may combine successfully with American cloth, cretonne or chintz for these rooms. The third illustration shows a curtain treatment that is particularly suitable for a bungalow window, having a painted plywood pelmet decorated with two lines of colour.

Bathroom curtains may be of brightly patterned towelling, rubberised cotton fabric or oiled silk, though washable checked or striped materials are also suitable.

**Details for Making.** Several labour-saving devices are on the market which simplify making and washing. A heading tape can be obtained in three sizes for light, medium and heavy curtains which only requires to be machined to the back of the curtain heading and then drawn up to the width required when finished. Rings and hooks are sold with it which may be detached or fixed in a moment, while the headings can be let out so that when the curtains are washed and ironed they are straight. A curtain gliding rail is also obtainable which

simplifies hanging light or heavy curtains and can be supplied with a valance extension. The hooks on the heading tape fit into the rings on the rail, so that the problem of taking curtains down for cleaning or washing and putting them up again is reduced to a minimum.

Flexible and adjustable wires with rings at the ends which fix on to small hooks on the window frame are the best means for hanging lace and net glass curtains. These wires are simply threaded through a hem and, being stretched to the width of the windows, keep the top of the curtains taut.

**Poles and Rods.** Curtain poles averaging 1 in. or more in diameter are adapted for large windows, doorways and openings. Curtain rods are of smaller diameter, used generally for casement windows. The materials are brass-cased iron tube and wooden dowel rods, the latter from 5/16 to 1/2 in. diameter, up to 6 ft. long. The patent curtain rod brackets shown in Fig. 1 may be used for supporting rods up to 3/4 in. diameter.

When it is only possible to fit the rod between the jambs of a window opening, the fitting shown in Fig. 2 is especially useful. The brass ferrule is arranged to unscrew from the base to facilitate removal of the curtain rod. This type of

fitting is available for rods from 1/2 in. to 3/4 in. diameter.

For fitting two curtain rods parallel to each other, one for the curtain and the other for the valance, a double bracket fitting, as in Fig. 3, is most convenient. It is adjustable, and the inner rod can be 3/8 in. from the window frame, while the outer rod extends another 3 in. The other ends of the rods are carried in simple projecting brackets, as shown in Fig. 4. All these fittings are screwed to the window frame with countersunk brass screws. The fitting of curtains to a small bay window or oriel is greatly simplified by using spring

wire, bought by the foot from any ironmonger, with the hooks for supporting the wire and the eyes for screwing into the ends of the spring wire. The hooks are fixed at each angle of the window frame, the spring wire passing over them.

**The Valance Board.** In a house with concrete walls and metal-framed casement windows, to which the usual curtain fittings cannot be screwed in the ordinary way, the plan is to fix a valance board on brackets screwed to the wall on the Rawlplug system. Where there is no pelmet or valance board long curtains are generally attached to a number of wood or brass rings, free to slide along the horizontal pole supported on brackets at the top of the window frame. The pole is provided with detachable ornamental ends large enough to keep the rings from sliding off.

In the case of a plain pole and no cords the curtains have to be pulled or jerked along by hand when opening or closing. An improvement is to have pulleys fitted to the ends of the pole and cords hanging from them and connected to the rings, so that the latter can be drawn along the pole by the cord. With a pair of curtains divided in the middle this movement must be in opposite directions, and the pulleys are arranged so that the pulling of one cord accomplishes this. The principle is indicated in Fig. 5.

Fig. 5. Device for opening and closing curtains.

This is done by using the opposite directions of travel of the cord, which goes to the far end of the pole, passes over a pulley, and comes back. The middle two rings, A B, of the set are attached to the cord, so that in its travel it pulls one in one direction and the other in the opposite. The pulleys are generally fitted into slots in the pole. In other cases the pulleys are attached to the brackets, an example of which is shown in Fig. 6. For bay windows the pole must be in lengths and at angles to suit the bay. A typical example is shown in Fig. 7, the required dimensions being marked D. A is the pole, and C C the supporting brackets. The angle joints B must be cut to the correct angle, which can be ascertained as follows: On a sheet of paper draw the two parallel lines, E F, G H (Fig. 8), the distance between them being equal to the diameter of the curtain rod. Then cut a card template to the angle of the window, as at L°, and draw lines, A B, C D.

The points of intersection, marked K J, should now be joined with another line, which shows the exact angle to which to cut the ends. When cutting the rod keep the end faces perpendicular, otherwise the rod

## CURVATURE OF THE SPINE.

The predisposing cause of scoliosis is weakness of the back muscles and general debility; the curvature may be induced by habitual faulty postures or by carrying weights which overtax the strength. Examples of this are: writing at a

In angular curvature, or Pott's Disease, tuberculosis attacks one or more of the vertebrae, as a result of which the bones as well as one or more of the cartilaginous disks between them soften and crumble away. The part of the backbone above the point of disease then settles down on the part below, and bending forward results. The disease may occur at any age, but is most frequent in children. Frequently it follows a blow on the back or a strain.

In treating Pott's Disease the usual measures for tuberculosis in any part of the body are to be carried out, and complete rest must be secured for the spine. The patient's room should be airy and sunny, and he should be carried into the open air as much as possible. His diet must be abundant and nutritious. *See Spine.*

## Pleasing and Colourful Aids to Comfort

**Helpful information will also be found under the headings Appliqué; Embroidery; Raffia; Woodwork. See also Drawing Room.**

Although cushions were formerly considered merely as general aids to comfort, to-day they should be chosen to form a vital part of the colour scheme and general furnishing of the room in which they are to be used. It is the greatest mistake to allow the cushions in a room to bring in colour notes that are not in harmony with the whole. A divan covered in some neutral coloured material or in a fabric that tones with the walls of the room will provide a good setting for piles of cushions, each one covered in one of the colours used in the main colour scheme (q.v.). Whatever

colours are chosen for these cushions the material should be plain.

It should be a golden rule that when chair and settee covers are made in a patterned material the cushions should be covered either in the same material or in a plain fabric in one of the colours included in the pattern.

When chairs are covered in cretonne chintz or upholstery linen, the cushions to go with them should be in a similar linen or cotton fabric and not in silk or satin. These latter fabrics would be quite in keeping, of course, with chairs covered in heavy upholstery satins, damasks or taffetas.

One of the most effective ways of bringing cushions into line with the general colour scheme of a room is the following: Choose some gaily patterned linen or chintz for curtains. Bright flowers in natural colours on a cream ground always look well. To go with this, chair and settee covers in a heavy linen to tone with the background of the curtain material can be piped with one of the bright flower colours in the design. Then the scheme can be further worked out by introducing the remaining flower colours and the green of the leaves in plain linen covers for the cushions.

Quilted satin and silk cushions are very fashionable nowadays for rooms where curtains are of any type of furnishing silk, satin, damask or velvet. *See Quilting.*

With  $1\frac{1}{4}$  yards of 31-inch material, either a round or square cushion of average size can be covered. Cut two circles,  $21\frac{1}{2}$  inches in diameter (a paper pattern can be cut first from the cushion to be covered), or two squares of  $21\frac{1}{2}$  inches each, and also a band 4 inches deep to be set all round the sides to make the cushions mattress shape. The seams may be piped to match or with a contrasting colour. If to be appliqué or embroidered the one side of the cushion will be worked before making up. Such cushions lend themselves to an endless variety of designs. Terry towelling makes delightful nursery cushions either patterned or in plain bright colours.

**Garden Cushions.** Raffia cloth in the natural colour is a good covering for outdoor cushions, with a lining of sateen or other close fabric, and bias binding for the edges if rounded. Simple wool or raffia embroidery can be used to trim such cushions. Hessian is another excellent covering material. This coarse canvas may be stencilled or lends itself to embroidery in cross-stitch; simple garden or flower bed designs look well and transfers are obtainable which are quickly worked in wools. Crash cushions embroidered with a group of circles in darning stitch are also suitable. The circles can be traced on the crash by pencilling round the inverted edges of small cups and saucers. American cloth provides a damp-proof reverse side for garden pouffes and mattress cushions. Water-proof cretonne cushions are obtainable to match the coverings of deck chairs.

To brighten cane or canvas chairs for the verandah, loggia or garden, a useful and attractive cushion can be made in the form of a Japanese lantern. This has an appliqué design of three little Japanese lanterns which might be carried out in pink, green and yellow

respectively, and is made of either crash or casement cloth in a contrasting colour. Two oval pieces of the material are cut 20 inches by 16 inches for the body of the cushion, and two pieces of black sateen for the top and bottom of the cushion, measuring  $8\frac{1}{2}$  by 3 inches each. The three small lanterns are applied with stem-stitch, and apparently hang from a spray easily drawn on the material with pencil and also to be stem-stitched and decorated with a few little pink flowers in buttonhole-stitch.

*Cushion. Lantern cushion for a garden chair. The design is appliqué with stem-stitch.*

*Left. Cushion. A many-coloured quilted cushion made by miners' wives in the "Special Areas."*

*Left: cretonne-covered, with frill, kapok-filled, Jacobean design.*

*Right: vivid Indian hand-embroidered wool; brown hessian back.*

*Left: fringed folk-weave, darned and tufted, in many different colours.*

To make up the cushion these two ovals are joined together with a piping inserted while the two black satin oblongs are placed in the middle of the long sides of the oval pieces to represent the top and bottom of the lantern. A black cord is attached by which the cushion is suspended to the back of the chair. This obviates constant slipping when the occupant moves. Leather, dyed chamois, or air cushions are most suitable for cars.

**Cushions in Richer Fabrics.** For the more formal type of sitting room, lounge or dining room where the furniture is upholstered in velvet, silk rep, leather, or damask richer materials are needed for suitable cushions. On a dining room settee with brown velvet loose seat cushions, large round brown velvet extra

cushions will look well trimmed with leather panels in a contrasting colour. Round cushions are also often particularly suitable for a window seat, as they help to reduce the apparent squareness of an old-fashioned window. Oval and pillow-shaped satin cushions look right with 18th century styles. Floor cushions give a luxuriously comfortable look to the hearthrug in winter. These should be large, deep, and made of a suitable heavy material such as damask, furnishing velours or rep.

Although cushions for rooms in period or special styles should be of rich materials they need not be costly. Setting aside for the fine needlewoman the beautifully embroidered designs, there are some effective methods of trimming which demand no special skill. For a room with lacquer pieces of furniture Chinese strips, rounds or squares of embroidery can be used, either placed to form a pattern on a plain coloured or black cushion and applied by means of a narrow galon, or (as in the case of rounds and squares) laid flat in the centre of the cushion, and the silk, or other material with which the cushion is to be covered gathered round it on a gauging cord.

A bolster cushion shape can be bought and covered in velvet, with ends either cut into rounds and piped to fit the bolster, or pleated into a button to hold the folds in place.

Gold-coloured cushions in crinkly satin have the appearance of being tissue-covered, but are soft and do not tarnish. This satin is good trimmed with self piping on a thick cord, and coloured wooden beads devised into tassels, or into flat ornaments at three of the corners, with a large dangling one of padded satin and beads over the edge of a sofa for the fourth.

Round, square or bolster cushions covered with satin or shot taffeta are ornamental, especially for using on a couch or divan in alliance with smaller cushions covered in contrasting fabrics. Lace or beautifully embroidered muslin can be used as covers for small head cushions, which look their best piled on divans or day beds with larger cushions in various shapes. These add considerably to the comfort of large armchairs, and fill up odd corners; they lend support to a tired back, or act as an extra support for the back of the head. Covered in muslin on embroidered linen, they are often provided on beds. Round or square cushions can be trimmed with appliqué or covered with patchwork in geometrical patterns. This costs nothing where there is a scrap drawer containing odd pieces of silks, satins, ribbons and tinsel brocades. The simpler he designs the better. They are cut out first in paper, pinned on the cushion cover to judge the effect, and then cut out in the various materials. Designs may be traced or drawn freehand before cutting out.

**CUSPARIA BARK.** In medicine cusparia bark, which is an aromatic bitter obtained from a S. American tree, can be employed to increase appetite. Two preparations are used, of which the doses are: Infusion of cusparia, 1 to 2 fluid oz.; concentrate of cusparia, ½ to 1 fluid dram.

**CUSTARD.** To make a simple boiled custard, allow 2 eggs to 1 pint milk, and use 2 dessertspoonfuls castor sugar, with flavouring to taste. Beat the eggs well and stir in the sugar. Bring the milk to the boil and then pour it gradually on to the eggs, stirring all the time. Pour all into a stone jar or a jug and put this into a pan of boiling water. Stir the custard until it thickens. Then remove it from the pan, add flavouring essence, and pour it into a bowl to cool. If lemon flavour is desired, let a little lemon rind boil with the milk.

Confectioner's custard is sometimes used as a substitute for cream in filling chocolate éclairs, etc. It is prepared by mixing a little more than 1 oz. cornflour with ¾ pint milk and stirring the paste in a small saucepan over the fire until it boils. Then let it simmer for several minutes, afterwards adding the yolks of 3 eggs, 1½ oz. sugar, and a little vanilla essence. Cook the custard slowly, stirring it all the time, and when it thickens take it from the fire and allow it to cool.

**Custard Powder.** A custard powder can be made at home from cornflour and riceflour. These should be mixed in equal parts, and it is essential that the ingredients should be quite dry and that they should be sieved to ensure their being free from lumps. The powder can be coloured yellow with powdered turmeric. One tablespooouful of custard powder should be used to every pint of milk. The powder should be mixed to a smooth paste with a little cold milk, and the remainder of the milk brought to the boil and then poured on to the paste, stirring being continued all the time. Flavouring and sweetening are added to the mixture as the milk boils.

**Steamed Custard.** To prepare a steamed custard pudding, beat up 2 eggs with sugar to taste, and add a pint of milk and the desired flavouring. Pour the whole into a greased basin, cover it with greased paper, and put it into a steamer or into a pan half filled with boiling water. Let the water simmer very gently for about half an hour, until the pudding is set.

A good variant from plain custard pudding is provided by this recipe. Put ¼ lb. jam into the bottom of a greased pie-dish, and sprinkle over it a tumblerful of breadcrumbs. Pour over the whole a pint of custard made as above, taking care not to disturb the jam at the bottom of the dish, and bake the pudding in a moderately hot oven for 20 to 30 min.

**Custard Tartlet.** The pastry for these tartlets is prepared by sieving 8 oz. flour, adding a pinch of salt, and then rubbing in 2 oz. margarine and the same quantity of lard. Add enough cold water to mix the whole to a stiff paste. Roll it out till it is about ⅛ in. thick, then cut it into small rounds and line some deep tartlet tins with it. Line each case with a piece of greased paper and then fill it up with uncooked rice to

prevent it from rising in the centre. Bake the cases for about 15 min., or until they are lightly browned. Then take out the paper and rice, and leave the cases on a sieve to cool. Make  $\frac{3}{4}$  pint of thick custard, flavour it with vanilla and leave it to cool. Then put it into the cases, and grate a little nutmeg over the top of each. A little raspberry jam may be placed in the bottom of each case before the custard.

*Custard Tartlet. Dish of these deep tarts filled with thick custard and sprinkled with nutmeg.*

Another variety of custard tartlet is prepared by lining patty pans with a short crust, and three-parts filling them with custard. Bake them until slightly browned and leave them to cool on a sieve. Make some sugar icing by mixing the whipped white of 1 egg with 1 oz. of castor sugar, spread this over the tartlets, sprinkle some more sugar on top, and then bake them slowly until the icing is crisp. These tartlets can be made still richer if a little jam is put into the cases under the custard.

**CUT:** How to Treat. Slight clean-out wounds, such as are made with a knife, should be cleansed by holding under a tap for a few moments, or by bathing the part with clean cold water, or, preferably, carbolic acid lotion (1 in 40) or a solution of boric acid. Lint, cotton, wool, or clean linen should be used for the purpose. As soon as bleeding stops bring the edges accurately together, sprinkle on a thin covering of boracic powder, a dressing of lint or clean linen, and bandage. A little boric ointment may be applied, or the wound may be covered with flexible collodion. Whenever festering occurs, dress with some antiseptic, such as boric, salicylic, or cyanide gauze, after thoroughly washing with one of the above mentioned or another antiseptic lotion.

A cut of any size, or a deep cut which bleeds profusely, should be covered over with a towel soaked in cold water (or, better still, a 1 in 40 solution of carbolic acid and water) while waiting the doctor's arrival. Efforts should be made to control the bleeding by applying pressure over the wound, or, if this does not succeed, on the main vessel supplying the part. If there is any delay in the doctor's arrival a tourniquet may be put on. *See Bandage; Bleeding; First Aid; Tourniquet.*

## CUTLERY AND THE CUTLERY CANTEEN

### Directions for Making a Useful Receptacle

Detailed information about the various kinds of cutlery

will be found under the headings Fork; Knife; Spoon, etc. See also Cabinet Making; Drawer, etc.

Under this general name all small cutting instruments are included, such as scissors, razors, knives and carvers for fish, poultry and meat. Table cutlery sold in sets in a canteen or cutlery cabinet may, in addition to knives in two sizes, contain forks and spoons, fish and fruit knives and forks, tablespoons, gravy spoons and carvers. Sets may contain sufficient articles for twelve or six persons.

**Making a Canteen.** A cutlery canteen, as at Figs. 1 and 2, has much to recommend it. Fig. 1 shows the cabinet closed by means of locking pilasters, sunk handles being fitted to drawers and also to the cabinet ends for lifting purposes. Fig. 2 shows the cabinet opened out, including a lift-up lid with well immediately under it, and also a couple of drawers or pull-out trays.

*Cutlery Canteen. Figs. 1 and 2. The canteen, which is in polished wood and has a tray and two drawers, shown closed and open.*

It can be made in oak, well seasoned and sound, stained to a rich nut-brown colour and polished. An inlaid tablet of brass on the lid will heighten the finished effect.

The length of cabinet is 1 ft.  $3\frac{1}{2}$  in. by  $12\frac{1}{2}$  in. wide by  $8\frac{1}{4}$  in. over all. The lift-up lid is  $1\frac{1}{2}$  in. deep outside, to be fitted as a tray for cheese knives. The upper well is  $1\frac{1}{4}$  in. deep, with special fittings. The upper drawer should be allowed  $1\frac{7}{8}$  in. deep over outside front, and the lower one  $2\frac{3}{4}$  in. deep. Each of the latter has special fittings for the various items to be contained in compact dozens or half-dozens.

Two sides of the case can first be got out to finish  $11\frac{3}{4}$  in. by  $6\frac{1}{4}$  in. by  $\frac{5}{8}$  in. thick after planing up clean and true. For the back a piece of equal thickness to finish  $15\frac{1}{2}$  by  $6\frac{1}{4}$  in. will be required, these parts being preferably mitre-dovetailed together, or housed and screwed or dowed together. The front has a top rail  $1\frac{1}{2}$  in. by  $\frac{3}{4}$  in. dovetailed into position for preference, but may be tenoned or dowed instead to the sides. The upper tray bottom can be of  $\frac{1}{4}$  in. wood cleaned up and grooved into sides and back, and the front edge rebated, glued and panel-pinned into front rail. A bearer rail under the upper drawer to finish  $\frac{3}{8}$  in. thick may be continued from front to back to form a

dustboard. The bottom, to allow the locking pilasters to close in flush, will project  $\frac{3}{4}$  in. at front and finish  $\frac{1}{2}$  in. thick, to fit flush at sides and back. It should be screwed up to sides and back with brass screws.

The drawers (or pull-out trays) should be made as dust-tight as possible. Fronts had best finish  $\frac{3}{4}$  in. thick: sides and backs  $\frac{3}{8}$  in. thick, bottoms  $\frac{1}{4}$  in. thick, let in flush.

The fronts, sides and backs of the drawers are dovetailed together, each front being fitted with a sunk or flush brass handle or a cup handle. All should close in flush ready for locking the pilasters. These finish  $6\frac{1}{4}$  in. long, hinged with brass piano hinges. A  $\frac{1}{4}$  in. hole with brass bush is also sunk into each top edge of same. The finishing depth of the upper tray will be  $1\frac{1}{4}$  in. inside, of the upper drawer  $1\frac{3}{8}$  in. full, and lower drawer  $2\frac{1}{4}$  in. full. These receptacles should have bottoms and sides covered with green baize or a suitable cloth. If the bottom is lined first, the sides and back can be fitted with cloth-covered slips of three-ply.

For the lid, two pieces  $15\frac{1}{2}$  in. by  $1\frac{1}{4}$  in. net will be needed, and two pieces  $12\frac{1}{2}$  in. by  $1\frac{3}{8}$  in. net for the sides. The top finishes  $15\frac{1}{2}$  in. by  $12\frac{1}{2}$  in. by  $\frac{3}{8}$  in. thick. The sides should be mitre-dovetailed together, and the top rebated in  $\frac{1}{4}$  in. deep, the remaining  $\frac{1}{8}$  in. forming the top edge, to be rounded or bevelled off.

*Cutlery Canteen. Details for making the cabinet shown above. Fig. 3. Lid. Fig. 4. Top tray. Fig. 5. Plan of top drawer. Fig. 6. Plan of bottom drawer.*

The hinges should be a special kind of quadrant box hinge, as at Fig. 8. The lock is fitted to a block inside centre of front of lid, to permit the lid to close down flush with the closed pilasters. A corresponding link plate is fitted to front rail of case. A couple of brass pin plates are also fitted to lid so that they drop into the holes in top edge of pilasters previously referred to. The fittings are slips of deal cut out with a fretsaw, then covered with cloth, using liquid glue, ordinary glue, or shoemakers' paste as an adhesive.

The lid, Fig. 3, can be fitted for 12 cheese knives, each fitting being about  $1\frac{3}{4}$  in. wide by 1 in. high, and

shown to larger scale at Figs. 9 and 10. The slip will be a shade under  $\frac{7}{8}$  in. high, notched out at intervals  $\frac{7}{8}$  in. wide by  $\frac{5}{8}$  in. high, to receive the handles. The capping can be of three-ply with a  $\frac{3}{4}$  in. slip of same to lift up and be fastened down by clips as Fig. 3. The blades enter notches  $\frac{7}{8}$  in. by  $\frac{1}{2}$  in., as Fig. 10, the fitting being cloth-covered before inserting into position.

*Fig. 7. Slips for carvers. Fig. 8. Quadrant hinge for lid.*

*Figs. 9 and 10. Fittings for lid.*

The top tray of case (Fig. 4) will have fittings for carving knives, steel and forks, and 12 table knives, the blades of which interlie. An enlarged detail of slips is shown at Fig. 7 for carvers

and steel, the cuts being  $4\frac{3}{4}$  in. by  $\frac{1}{8}$  in.; 3 in. by  $\frac{3}{8}$  in.;  $2\frac{3}{4}$  in. by  $\frac{1}{4}$  in., and 1 in. by  $\frac{1}{8}$  in., out of slips  $1\frac{1}{2}$  in. high,  $\frac{3}{4}$  in. thick, with the cuts right through. The table knives can be in slips as Figs. 13 and 14, height being  $1\frac{1}{4}$  in. full and thickness  $\frac{5}{8}$  in. for Fig. 13, with the cuts  $\frac{3}{16}$  in. wide by  $\frac{1}{4}$  in. apart; and for Fig. 14 cuts are  $\frac{11}{16}$  in. high by  $\frac{1}{2}$  in. and  $\frac{1}{8}$  in. alternately, each cut being  $\frac{1}{4}$  in. apart.

*Fig. 11. Slips for dessert forks. Fig. 12. For table spoons. Figs. 13 and 14 (below). Slips for table knives.*

The upper drawer can be fitted for, say, 6 teaspoons, 12 dessert forks, and 12 table forks. Size for slips is  $1\frac{1}{4}$  in. high by  $\frac{5}{8}$  in. thick. The bottom drawer would take 6 table spoons, 12 dessert spoons, and the remaining 6 teaspoons. Slips can be  $2\frac{1}{8}$  in. high. A plan of drawers is seen at Figs. 5 and 6. An enlarged repeat of the slips for these items is given at Figs. 11 and 12. The locking

pilasters are shown closed and open respectively in Figs. 1 and 2.

**CUTLET: How to Cook.** To prepare cutlets, trim away all pieces of fat, and if there is any bone in the centre cut this away. The bone at the end must be scraped bare and free from fat. Beat the cutlets with a wet cutlet bat or rolling-pin to make them tender and to improve the shape. They should not be more than  $\frac{1}{2}$  in. thick. Dust with flour that has been seasoned with salt and pepper, then coat with egg and breadcrumbs, and fry them. The cutlets can be dipped into melted butter and breadcrumbs, instead of egg. Cutlets can also be stewed in a casserole or plainly grilled.

*Cutlet. Dish of grilled mutton cutlets, garnished with green peas and decorated with paper frills.*

Cutlets are usually served on a mound of mashed potatoes, the cutlets being arranged with the bones pointing in one direction and wrapped round with paper frills. Various sauces can be served with them. Veal cutlets should be garnished with slices of cut lemon, lamb and mutton cutlets with chopped parsley.

Tomatoes, grilled or made into a purée, spinach sauté in butter, or green peas, are usually served with cutlets.

To make cutlets from the remains of cold veal, lamb, mutton, or fowl, mince the meat finely, season, add chopped parsley or any flavouring desired, and mix with the yolks of eggs until a firm mixture is obtained. Shape the mixture into cutlet form, coat with egg and breadcrumbs, and fry them. Cooked and flaked remains of fish can be treated in the same way. *See Casserole; Mutton.*

**CUTTING GAUGE.** This tool is for cutting lines on woodwork, making small rebates and for similar purposes, and serves the same purpose as a marking gauge. It consists of a steel cutter fixed to a hardwood stock or bar by means of a wedge. A sliding head moves on the bar, and is fixed at any desired position from the cutter by means of a wooden thumbscrew.

Its general form is seen in the illustration. It is used by grasping the stock with the left hand when marking out work, in the right hand when cutting a rebate. The method is to adjust the distance between the cutter and the face of the head, which determines the width of the rebate. The cutter is set to the requisite depth by loosening the wedge, pushing the cutter through the stock as far as needed, and firmly wedging it in place. A rebate is formed by backward and forward strokes with the gauge, cutting on the forward stroke. When

one face of the work has been so cut, it is turned over, and the same procedure repeated. The cutter should be ground and sharpened in the same way as a chisel.

*Cutting Gauge. How the tool is used for cutting a rebate on a piece of wood.*

**CUTTING-OUT.** As applied to tailored clothing for men and women, cutting-out is a highly skilled trade, but the process of cutting out simple dresses, undergarments, etc., is easy with a good paper pattern to work from.

Three pairs of scissors are necessary, viz., a large, sharp pair for cutting large garments or thick cloth, a smaller pair for moderate-sized garments and silk, and also for cutting round curves, while a small pair is wanted for slots, slits, buttonholes, etc. A measuring tape is necessary for measuring the material and taking measurements of the pattern, to compare it with the size wanted, and also for measuring any straight or cross way strips that may have to be cut for frills or trimming bands.

As a rule it is easy to determine which is the right and which is the wrong side of a material. Woollen materials are generally bought folded with selvages together, with the right side folded inside, while longcloth and similar cotton fabrics are folded with the right side out. If materials are of single width, and therefore not folded with selvages together when bought, the right side can generally be determined, as it is smoother than the wrong side. The right side of serge, gabardine, or any cloth with a fine crossway grain can be determined by holding a length down with selvages right and left, and one cut end under the chin. If right side is outermost, the grain should run from left down towards the right.

Some materials are woven to be made up so that a certain way hangs downwards. Thus worn, it wears longer and looks better.

This up-and-down way, is so pronounced in some fabrics that they have a bloom, which means that viewed from one end of the length the material shades lighter than it does when looked at from the opposite end. To determine the right way down of a material, lay it out flat on the table, and pass the palm of the hand first up one way then down the other. It should be smoother one way than the other, and should be made up into the garment so that the cloth smooths downwards.

Velvet and Velveteen. Materials which have an up-and-down shading or bloom are made up so that, the dark way shades down, and the darker way can be ascertained by folding the length of material to bring the two ends together, but side by side, and holding these under the chin, so that the loop hangs downwards. By looking down the stuff while it is held in this position it is easy to determine which is the darker way. It should be remembered that the smooth way down is not necessarily the dark way down too. In velvets and velveteens very often the reverse is the case, and no attention is paid to the smooth way of the stuff, for it is made up so that the dark way shades downwards, and a richer effect is obtained.

Before actually cutting out a garment, fit the pattern to the figure. Having made any necessary alterations, pin the pattern to the material firmly, so that it will not slip out of position during the cutting process. A weight is sometimes used in the case of velvet which marks easily, or needles may be substituted for pins. When cutting, cut in even strokes, so as to get a good line to the garment, and do not lift the material from the table with the scissors more than is necessary.

A piece of tailor's chalk is useful for marking cloth or dark cotton materials round the pattern edges after cutting out. When the pattern is removed from the material there are correct lines which may be placed together, the stitches taken along them, and the right amount of turnings allowed for seams is taken up. On many materials, such as light-coloured cottons or silks, for instance, chalk cannot be used. For these a tracing wheel or coloured tacking cotton is desirable.

A table large enough to take the entire length of material to be used makes cutting out simpler, as the whole pattern may be set on it at one time. The pieces may be fitted in better than they could be otherwise arranged. In paper patterns, as a rule, only one side of the garment is given. Set the pattern on double material, so that both sides of garment may be cut in one process. The double layer can be obtained by folding a piece of material to bring the selvages together: or, if the full width of the material is necessary, owing to the large size of the pattern, by setting two full widths together. If the latter plan is followed, however, it must be ascertained that either the right sides of the two layers face one another, or else that the wrong sides face. See Dressmaking; Pattern.

**CUTTINGS:** For the Garden. Where seed is unobtainable or where it is desired to keep a plant true to type, propagation by means of cuttings is employed, and these are of five kinds, soft-wooded, hard-wooded, heeled, root, and leaf. The first named is generally the easiest to strike.

As a rule, a soft-wooded cutting should be severed just below a joint, and should consist of the upper part of a growing, not flowering, shoot, with three or four leaves. In some cases the wood should be young, in others half-ripe, in others quite firm. In nearly all cases the best compost for soft-wooded cuttings is loam, with about a third of leaf-mould, and enough sand to make the whole of the compost thoroughly gritty and porous.

The cutting is made firm at the base by pressing it with the blunt edge of a lead pencil passed diagonally through the soil. Cuttings strike best round the edges of a pot.

*Cuttings. Diagrams illustrating typical methods of treatment. 1. Geranium, of good growth. 2. Same cutting trimmed for planting. 3. Cutting planted with sand at base. 4. How to avoid "damping off." a. Cutting planted in small pot filled with moss. b. Layer of sand. c. Soil. 5. Rooted cutting ready for potting-on. 6. Fuchsia cuttings, several of which, as in 7, are planted in a large pot and plunged into a box of ashes covered with glass. 8. Viola cutting. 9. Pink cutting. 10. Root cuttings of anchusa starting into growth under a hand-light, a. Layer of sand.*

Acacia, boronia, epacris, and erica are examples of hard-wooded cuttings. On the whole they are less reliable than the soft-wooded. In most cases the usual favourable conditions are: small pieces of the upper parts of non-flowering shoots, a compost of peat and sand, wood fairly firm and ripe, bell-glass covering. A heel is a small strip of the older wood, about an inch

long. The cutting of young wood is pulled or cut off with this strip instead of being cut clean across under a joint. Some plants root better and are less liable to damp off with than without a heel. By leaf cuttings are not meant leaves laid on the soil, but leaves with the stalk inserted. The indiarubber plant is a familiar example. They require a good deal of moist heat. Gloxinias, begonia Gloire de Lorraine, and pelargoniums generally root when thus propagated.

Evergreen shrubs are increased by cuttings placed in sandy soil in a frame in August. Leaf-losing trees and shrubs are propagated by cuttings set out of doors in October-November. Certain plants, e.g. seakale, anchusa, Japanese anemone, oriental poppy, are propagated by pieces of the root which are inserted as cuttings. *See* Apple; Gooseberry; Grafting; Raspberry.

**CUTWORM.** The larvae of the turnip moth, the heart-and-dart moth, the yellow underwing and others are known as cutworms or surface caterpillars, and cause much damage to cultivated plants. As a rule cutworms spend the day in the surface layer of the soil or hidden under leaves, thick grass or stones. At night they come out and feed, sometimes on the leaves of plants, but more often on their stems, both above and below ground, and are specially fond of the thick, fleshy parts of such crops as mangolds, turnips and potatoes. They also bite through the stems of plants.

*Cutworm. 1. Male and, 2, caterpillar of turnip moth. Right, potatoes damaged by the caterpillar. 3. Male of heart-and-dart moth. 4. Male yellow under wing moth. (By permission of H.M. Stationery Office and the Ministry of Agriculture)*

Since the caterpillars are often of the same colour as the soil on or in which they live, they are not easily seen. An examination of the crop after dark is perhaps the simplest way. They are often specially troublesome on foul, weedy land, and potatoes are likely to be attacked. When crops of potatoes or mangolds have been badly attacked it is risky to sow winter wheat unless the pests have first been destroyed.

Undoubtedly, the best method of dealing with cutworm-infested land is to run poultry upon it, and wherever this is possible it should have precedence over all other treatments. When young root crops are being attacked above ground, the plants may be sprayed with lead arsenate (1 lb. lead arsenate paste to 25 gallons water). Provided the plants are small so that the greater part of the root has yet to be made, there will be no risk of poisoning stock when the roots are finally eaten. Lead arsenate is poisonous to man and domestic animals and must be carefully used.

In allotments hand-picking is often the most simple method of dealing with the pests, which can generally be scraped out of the soil near the plants last attacked by means of a blunt knife or pointed stick. They may also be collected at night when they are feeding or crawling about on the surface of the soil. These measures are advised in Leaflet 225 issued by the Ministry of Agriculture. *See* Cabbage; Potato; etc.

**CYCLAMEN:** *How to Grow.* The Persian cyclamen is a valuable greenhouse flowering plant in full beauty in early spring. Hardy cyclamen are low-growing plants which flourish out of doors and bear small flowers in autumn and spring.

*Cyclamen. The Persian cyclamen, a beautiful greenhouse plant.*

The Persian cyclamen is raised from seeds sown in August in a well drained box of sifted compost of loam, leaf-mould and sand placed in a frame. When large enough the seedlings are placed singly in 3-in. flower pots, and when well rooted in those they are potted finally in 5-in. or 6-in. pots, in which they will bloom. During the winter months they should be kept in a greenhouse temperature of about 50 degrees. In the summer they thrive best on a bed of ashes in a cold frame; they need cool, moist conditions. From seeds sown in August the plants will bloom in the following February twelvemonth. When potting cyclamen care must be taken to keep the corm on the surface. Well drained pots are necessary, and a suitable compost for the final potting consists of loam, two-thirds, leaf-mould and decayed manure one-third, with a scattering of sand and crushed charcoal.

When cyclamens have finished flowering they should be dried off by gradually giving less water. When the leaves have fallen the soil must be kept dry and the pots placed in a sunny greenhouse or frame. Late in July the corms should be taken out of the soil, repotted in fresh compost, watered and set in a frame. They will soon start into fresh growth. These plants are long lived and may be kept for many years. They are often grown successfully as window plants. There are many varieties, with flowers in crimson, rose, salmon, and other colours.

Hardy cyclamen should be planted out of doors in well drained soil with which leaf-mould and mortar rubble have been mixed freely: they like slight shade. The corms need only a slight covering of soil except those of *Cyclamen neapolitanum* and *africanum*, which should be set an inch or so deep. Some of the chief kinds are: *africanum*, reddish flowers, September; *coum*, rose-red, April; *europaeum*, rose, August; *ibericum*, rose-red, March; *neapolitanum* (*hederaefolium*), reddish, September; *repandum*, reddish, spring. The corms of the autumn flowering cyclamen are planted in July-August: the others in September. Pron. Sik-la-men.

**CYCLE.** Both a tricycle and a bicycle are called a cycle, while cycle shed and bicycle shed are interchangeable terms. *See* Bicycle; Motor Cycle; Tricycle.

**Cycle Car.** *See* Three-Wheeled Car.

**CYMBIDIUM.** A beautiful winter and spring-flowering orchid of which innumerable new varieties have been raised in recent years. The flowers, in shades of rose, buff, pink, and green on long arching spikes, are most decorative. They are vigorous plants and are grown in pots in a mixture of loam and peat with sand. They thrive in the intermediate house in which a minimum temperature of 55—60 degrees is maintained. Pron. Sim-bid'i-um.

*Cypress. A favourite conifer, Cupressus lawsoniana.*

**CYPRESS.** The cypress is a graceful evergreen conifer of which there are many species, some of them are ideal lawn trees. They flourish best in moist districts in deep loamy soil; they are less satisfactory in gardens near large towns where the air is impure, or on very chalky land. One of the chief species is *Cupressus lawsoniana*, of which there are many varieties, e.g. *lutea* and *Stewartii*, with yellow leaves, *Silver Queen*, with silvery-green leaves, and *gracilis pendula* of drooping growth. *Cupressus macrocarpa* is a beautiful quick-growing conifer and its yellow leaved variety *lutea* is attractive; both these are better suited to comparatively

mild than cold districts. *Sempervirens*, of distinct columnar growth, so conspicuous in Italian gardens, is less hardy than others.

**DAB: The Fish.** This small flat fish of the flounder species, seasonable all the year, is found in abundance round the coast of Great Britain. To fry, the dab should be cleansed, well dried, and rubbed with salt an hour or two before cooking, and dipped into egg or milk and breadcrumbs. It should then be garnished with fried parsley.

To boil a dab sufficient water is needed to cover the fish, a little salt and vinegar being added. About 10 min. is the time required, and any fish sauce can be served.

**DACE.** A fresh-water fish, resembling the roach, found in abundance in English streams. The flesh is somewhat coarse but it can be fried or boiled.

**DACHSHUND.** In spite of his unprepossessing appearance, the dachshund has a high reputation as a domestic pet, being affectionate in disposition, a splendid playmate for young children, and a good watchdog. Although not used for sport in Great Britain, his German name, signifying badger-dog, indicates the purpose for which originally he was bred.

*Dachshund, a short-haired breed of German dog.*

The body of the dachshund is exceedingly long, and the legs very short, the front pair crooked. The long head tapers to the sharp muzzle, and the ample ears hang flat beside the cheeks. The tapering tail of the animal is carried with a rather low curve. The type usually seen in Great Britain has a short, close coat which may be some tint of red, black, brown, or grey, or a combination of two colours. There are also long-haired and rough-haired breeds. *See* Dog.

**Daddy Long Legs.** This is the popular name applied to several of the larger kinds of crane flies. *See* Crane Fly.

**DADO: For Decoration.** Where there is a dado there should not be a frieze is a rule which holds good in average homes, but occasionally both are seen in the case of exceptionally large and lofty rooms, or on a staircase where there exists a wide expanse of wall between the stairs and the ceiling.

The dado, which may be described as a decorated space between a base consisting of a skirting and a moulding, may be of one of various materials. About 3 ft. to 4 ft. 6 in. is an ordinary depth from the floor to

*(Continued in page 605)*

### 'C' RECIPES. A SELECTION SHOWN IN ACTUAL COLOUR

**Canterbury Pudding.** Put slices of stale sponge cake in a buttered mould in layers, each sprinkled with castor sugar and cinnamon. Beat up 3 eggs and strain into  $\frac{1}{2}$  pt. milk. Pour into basin and leave to soak. Steam gently. Serve quickly with fruit or sweet sauce. **Carrot Cheesecake.** Any good pastry filled with 4 oz. boiled carrots (yellow centres only), rubbed through sieve, mixed with 1 oz. warmed butter, 1 tablespoonful each of currants and spongecake crumbs, 2 of castor sugar, grated lemon-rind, a little grated nutmeg, and a well-beaten egg. Serve hot.

## 'C' RECIPES: A FURTHER SELECTION SHOWN IN ACTUAL COLOUR

**Crepinettes.** Savoury mince baked or fried inside strips of pig's caul and served on spinach or other green vegetable. Remains of fowl, veal or lamb may be used. Egg and breadcrumb and then fry or bake. **Cornflour Muffins**—to make:  $\frac{1}{2}$  lb. each of wheaten flour and cornflour, 2 oz. each of melted butter and castor sugar, 2 teaspoonfuls baking-powder,  $\frac{3}{4}$  pt. warm milk and 2 eggs. For method of cooking, see under Muffin. **Coconut Kisses:** made like Coconut Ice, but shaped like rock cakes. **Cumberland Pudding:** 6 oz. each of breadcrumbs, suet, sugar, chopped apple and sultanas or currants. A little candied peel and nutmeg and finely chopped peel of 1 lemon; 6 beaten eggs mixed with other ingredients. Put into mould, cover with cloth and boil 3 hr. Serve with white sauce (made with water] flavoured with sugar, nutmeg, lemon-juice, and a little sherry or brandy.

the dado-moulding. The dado has a tendency to cut the height of a room, especially when there is marked contrast in colour or tone between it and the rest of the walls. Panelled wood is used in oak colour for staircase, hall and lounge, and is a saving precaution against dirty marks on light-coloured walls, where there are children. Hand-made Japanese embossed leather papers make a substitute for such panelling. They are good in colour, and durable, being impervious to the action of smoke and gas.

Decoration for rooms in Adam or Queen Anne styles utilizes the dado in wooden panelling, while above the dado rail the walls are painted and mouldings applied to simulate the big panels of those periods.

A tiled dado is clean and labour-saving in kitchen or bathroom. *See Anaglypta; Decoration; Moulding.*

**DAFFODIL.** The best hardy spring-flowering bulb, suitable for planting in flower beds and borders, in grass and for cultivation in pots in the greenhouse and in bowls indoors. Forced bulbs will bloom in January and a succession of flowers can be maintained until March, when the earliest of those out of doors come into bloom.

*Daffodil. 1. Chalice-cupped Sir Watkin. 2. King Alfred.*

Daffodil is the popular name of the trumpet variety of narcissus, such as Emperor and Empress. A modern classification describes ten groups of narcissus. The classification is based on the comparative length of the outer or perianth segments and that of the central part, which is variously described as trumpet, cup or crown according to its length. The chief classes are as follows:

Trumpet daffodils, in which the trumpet or crown is as long as or longer than the segments of the perianth. Favourite yellow varieties are Emperor, Golden Spur, Lord Roberts, King Alfred and Maximus. White varieties are Madame de Graaff, Peter Barr, Beersheba, Alice Knight, and W. P. Milner. Others with white perianth and yellow trumpet (called bicolors) are Horsfieldii, Empress, Weardale Perfection and J. B. M. Camm.

*3. Poeticus narcissus. 4. Variety known as the Hoop Petticoat daffodil.*

**Chalice Cupped or Incomparabilis:** the cup or crown is not less than one-third the length of the perianth segments. A few good varieties are Sir

Watkin, Gloria Mundi and Blackwell.

**Star, Barri or Short Cupped:** the cup or crown is less than one-third the length of the perianth segments; the perianth is yellow or white and the cup is coloured. Favourite varieties of this type of daffodil are Barrii conspicuus, Red Beacon and Red Chief.

*Daffodil.*

*Diagram showing how the bulb should be grown. 1 and 2. Relative depths to plant in light and heavy soil. 3. Distances apart for planting. 4. Dibber, with depth for planting marked at a. 5. Unsuitability of pointed dibber, which leaves water pocket below bulb, a. 6. Bulbs planted in fibre. 7. Pot culture: a, drainage; b, soil; c, sand, and 8. How to place bulbs. 9. Pot, covered with another, buried in fine ashes b, on cinders, a. 10. After flowering, bulbs are placed in a trench until foliage is dead. 11. A good type of bulb.*

Eucharis-flowered or Leedsii: distinguished from the star narcissi by having a white perianth and white or pale cup or crown. Duchess of Westminster, Mrs. Langtry, Maid of Athens, and Snowsprite are typical ones.

The remaining groups consist of varieties of Narcissus triandrus, cyclamineus (both of these are miniature kinds), jonquil, the bunch-flowered Narcissus tazetta, Poet's Narcissus and the double narcissi.

Daffodils never look better than when grouped in grass; the bulbs are planted in September-October

about 3 inches deep. Suitable varieties for this purpose are Emperor, Empress, Pallidus praecox, Barrii conspicuus, Mrs. Langtry and Sir Watkin. For planting in formal flower beds Emperor, King Alfred, Empress and innumerable others are used.

The miniature hoop petticoat daffodil (*bulbocodium*), cyclamen-flowered (*cyclamineus*), angel's tears (*triandrus*), are suitable for the rock garden; they need well-drained soil.

Varieties for cultivation in flower pots under glass to supply early blooms are Golden Spur, Horsfieldii, maximus, Victoria, jonquil, W. P. Milner and the bunch-flowered or poetaz varieties. The bulbs should be potted early in September, placed under old ashes out of doors for 6 weeks and then brought under glass, a few at a time, to provide a succession of bloom.

**Daffodil Pests.** Two main troubles afflict daffodils. First, there is the narcissus fly, which lays eggs on the leaves in May and June, and the grubs that hatch eat out the heart of the bulbs. The flies resemble small dark humble-bees, but being true flies have only two wings and have no visible antennae on their heads. They should be netted on bright sunny days. The bulbs should be examined at lifting time, and gently pinched; if soft they should be cut open and the grub destroyed. The other disease has been proved to be due to eelworm, which, in addition, is particularly troublesome in connexion with cucumbers and similar plants. See Bulb; Cucumber; Flower Garden.

**DAHLIA.** There are many types of dahlia, and some are more useful for garden decoration than others. Those chiefly to be recommended for this purpose are the star, charm or dwarf peony-flowered, mignon, decorative, collarette, tall peony-flowered, single and some of the cactus varieties. Other types are the show, pompon and fancy.

*Dahlia. 1. Sapho, a single variety.*

*2. A characteristic show dahlia.*

*3. Yeoman, cactus dahlia.*

*4. Patrol, a collarette variety.*

The tubers of the dahlia are not hardy, therefore they

must be lifted as soon as the tops of the plants have been cut down by frost and stored in a frost-proof place for the winter. They keep well in boxes of soil or sand. In April the old tubers may be planted out of doors; they provide a profusion of bloom. Finer flowers are obtained by starting the tubers into growth under glass in February and taking cuttings from the young shoots. These are inserted in pots of sandy soil; after having been hardened off in May they are planted out of doors early in June. Dahlias may also be raised from seeds sown in a heated greenhouse in January-February; they will bloom late in the summer. There are innumerable varieties of the types referred to above, and fresh ones are introduced annually. They are described in catalogues.

*Dahlia. Diagrams illustrating methods of culture.*

*1. Root in frame. 2. Roots drying on shelf. 3. Roots in box, kept from frost. 4. Sprouting tubers, for cuttings. 5 and 6. Types of cuttings, ready for potting, as in 7. 8. Sprouting tuber. 9. Same cut to fit pot. 10. Potted cutting in frame, for rooting.*

Dahlias need deeply dug and manured soil, a sunny position and full room for development. They must be staked carefully, for the shoots are brittle. The best display is assured by removing many of the side shoots.

**DAIRY.** To fit up a small dairy is by no means a difficult matter. A building can often be altered to fulfil the necessary conditions, such as a shed about 15 ft. by 12 ft. It should be situated at a sufficient distance from the cowshed, the dungheap, or other source of contamination. The aspect should be northern, if possible, as this keeps the dairy cooler during the hot weather. The entrance to the room should be from the open air, and not from the cowshed or other farm building, and the room should be used for no other purpose than for the treatment of the milk. A separate room is desirable for the washing up of the utensils, and this is arranged quite easily by putting up a thin partition.

Windows that will open can be placed on one or more sides of the dairy, as ample light is highly desirable. Fine wire gauze or similar material can be fixed outside the windows to keep out insects, while allowing air to circulate freely. The dairy should be provided with ventilators, preferably both below and above, in the walls. The walls should be smooth, which can be accomplished by cementing the interior; they can be either washed down frequently, or, better still, they can be lime washed. The roof should be easily cleaned. There should be no inside drains, but the floor should be made with a slight fall, 1 in. in 8 ft., towards a gutter at the side of the wall, and an outlet through the wall should lead to a properly trapped gully outside. The best material for the floor is cement.

In a small dairy a copper should be placed in the washing-up room, and there should also be a washing-up sink. The copper can be adapted for sterilizing purposes by boring a hole through the centre of a wooden lid and fitting a plug in. The steam from a properly boiling copper is sufficient to sterilize the utensils in 5 min. Pails and churns can be sterilized by inverting them over the opening in the lid, and smaller articles by placing them in a steamer, which may be improvised by using the receiver of a milk cooler or separator, placing it over the opening and covering it up with a thick cloth. Alternatively all the utensils can be put into boiling water for several minutes.

After use, all utensils should be rinsed with cold water as soon as possible, thoroughly scrubbed inside and out with hot water, and then scalded or steamed and inverted on a rack provided for the purpose. Floors should be washed and scrubbed with a brush, swilled with boiling water, and dried with a cloth or squeegee. *See Butter. Cheese; Churn; Cream; Milk, etc.*

**DAISY.** The named varieties are showy flowers for spring beds. Rob Roy, Alice, Dresden China, and Pink Beauty are favourites. For giant double daisies sow seeds in June. The seedlings are put on a reserve border and planted finally in autumn. They should be lifted and divided after flowering; the pieces are grown on a reserve border during the summer. The variety popularly termed the hen-and-chickens daisy has the peculiarity of forming small flowers round a large central bloom.

**DAISY CREAMS.** To make these, cut a fresh Swiss roll weighing 1 lb. into slices about  $\frac{1}{2}$  in thick.

Prepare  $\frac{1}{2}$  pint jelly in the usual way, then chop it rather finely and put a heap of it on each slice. Whip  $\frac{1}{4}$  pint cream and mix it lightly with a stiffly-whipped white of egg. With this the jelly should be covered. Then blanch 1 oz. of sweet almonds, splitting each in half lengthways, and cut 2 or 3 candied apricots into small, thin rounds, each about the size of a threepenny piece. Soak a little angelica in warm water till it is soft, then cut out from it a number of diamond shapes to represent leaves. On the top of each sweet put a daisy formed from the halved almonds, using these as petals, and a round of apricot for the yellow centre. The angelica should be arranged to form stalks and leaves.

*Daisy Creams, an attractive sweet.*

**DALMATIAN.** In certain respects the Dalmatian dog resembles a spotted pointer, and from the numerous dark spots on his white coat he has been called the plum pudding or spotted dog. He is usually very clean-built, strong, and agile, with straight legs and feet, powerful loins, deep chest, and nicely-moulded neck, the short coat, sleek, glossy, and easily groomed. Weighing about 55 lb. on the average, the Dalmatian is of medium size, and not too big for an indoor companion. He is not noisy, seldom barking when it is not his duty to do so; but if he does bark, his deep voice is an effectual warning to strangers. In choosing one, remember that the markings may be either black or liver-coloured on a brilliant white ground. Experts insist upon the spots being clearly defined, without touching one another, and in proportions they may vary from that of a sixpence to a florin. They should be pure in colour, not having any white hairs mixed with them. The dog is hardy, easily kept in condition, and an excellent breed in every respect. *See Dog.*

*Dalmatian Dog, a large breed of carriage dog, also known as the plum pudding dog, a powerful, agile and companionable breed.*

**DAMAGES:** The Law. Anyone who breaks a contract or who by his trespass, or nuisance, or negligence causes injury to another in person or property must pay damages. In some classes of cases, e.g. libel or slander, the damages awarded may be punitive or exemplary; that is to say, they bear no relation to any monetary loss sustained by the person aggrieved.

The same is true in claims for assault or breach of promise. But in most cases the damages to be awarded are such a sum as will make up to the individual the actual loss sustained by reason of the wrong or the breach of contract. In the case of personal injuries, a man may claim what it has cost him for doctor's fees, special food, the cost of a holiday to recuperate, earnings lost, and, in addition, a fair sum for the pain and suffering he has undergone, and for any permanent injury.

When a husband, wife, child, father, or mother is killed by somebody's negligence, or otherwise, under such circumstances that if he or she had only been injured and not killed, an action for damages could have been brought against the wrongdoer, the widow, children, widower, or either parent, can recover damages proportionate to the pecuniary loss sustained. In addition, the personal representatives of the deceased can recover damages for the death. These damages will include a sum in compensation for the shortening of the life of the deceased. Nothing is allowed for injured feelings.

A person breaking a contract is liable to pay some damages, even though the other party has suffered no loss; but these may only be nominal—a few shillings. But the other party to the contract can also recover any pecuniary damage for any loss which was the natural and reasonable and direct result of the breach of contract. If anyone agrees to supply goods and does not send them, the buyer is entitled to purchase them elsewhere, and if he has to pay a higher price, he can claim the difference. If a householder orders work by a tradesman at a price, and the work is badly done, the householder is entitled to have it put right by another man and claim from the first man as damages what he had to pay to the second *See Accidents; Contract; Employer's Liability; Servant.*

**DAMASK:** The Fabric. There are linen, cotton, silk and wool damasks, and the feature common to them all is the method of construction. The patterns are usually large and floral, and are formed of satin-like twills in reversed directions.

Damasks are made more for household and furnishing purposes than for dress. Silk damasks made for church use have stood for centuries. Victorian worsted damasks, used as winter window curtains, and tablecloths, have, in many instances, stood 50 years of wear with little harm. There are two kinds of linen table damask known as double and single damask. The latter has the stronger weave. Cotton damask tablecloths are made in the same patterns as linens, but they lack firmness and brightness.

**DAMASK ROSE.** A very old type of rose, said to

have been introduced into Great Britain in the 16th century. Damask roses do well as dwarfs, but are not suitable for growing as standards. They require generous cultivation, and all their weak growth should be thinned out in March or April, leaving strong shoots pruned to about one-fourth their length.

Several varieties are obtainable, among the best being: Lady Curzon, large single pink; Crimson Damask, bright crimson; York and Lancaster, white, striped red; Old Rose Damask, red. The Damask rose is largely used abroad for the purpose of making attar of roses. *See Rose.*

**Dame's Violet.** *See Rocket.*

**DAMP:** Precautions Against. Excess of moisture or damp may be present in the soil, the dwelling, the atmosphere, or the clothing, and so affect health. A cold, damp climate, dwelling or workshop favours the development of rheumatism and chest complaints, including consumption. Sitting in damp clothes predisposes to chills.

In the house damp needs to be carefully guarded against, and during the winter no room containing a piano or any other musical instrument, valuable pictures, or furniture that is heavily padded, should be left long without a fire. If the drawing room is not used daily, a fire should be lighted in it once or twice a week. Pictures that have been hanging on a damp wall should be taken down, the moisture wiped off with a clean duster, and then placed with their faces to the wall in a warm room. Furniture or perishable articles which are being stored in a cellar should be placed on battens and should not be pushed close against a wall.

Beds left unoccupied for several days can be kept free from damp if hot-water bottles are placed between the sheets at frequent intervals. This obviates the need for removing the bedding and airing it before the fire. Damp in beds can be detected by placing a mirror in the bedclothes. If it remains unclouded, the bed is dry enough to be slept in. If damp cupboards are sprinkled with quicklime and then left for two or three days, the moisture will be absorbed.

**Damp in Walls.** The cause of damp in the house is not always easy to discover at first, although the general position of the trouble will often indicate its probable source. For instance, if the wet patch is at or near the top of the room, and a gutter is just outside, the gutter will probably be found to have got choked up with leaves and rubbish, thus impeding the free flow of the water, and causing it to overflow. It may do this on the wall side of the gutter, when the dampness will appear near the top of the room, or it may overflow on the outer side of the gutter, and be driven by the wind on to the wall at a considerable distance away.

Another cause of dampness is the failure of the gutter brackets, which may work loose and sag down, or even be broken off altogether. The trouble will probably disappear when the slack brackets are

wedged and cemented up, or rescrewed to woodwork. Care must be taken to see that the guttering has a sufficient and regular fall. Should a section of gutter sag badly, it will cause a pocket in which water will accumulate when a heavy rainstorm puts extra pressure on the gutters.

Some old-fashioned houses with curb roofs, those with a mansard roof, or a brick or masonry parapet, have inconveniently arranged internal gutterings, generally made or covered with sheet lead or zinc. These either perish with age or, more frequently, are punctured by falling matter, or the passage of someone wearing hobnailed boots. When dealing with this class of gutter, always wear felt slippers or something soft, such as a rubber golosh over the boots, or take care to walk on duck boards laid down for the purpose.

Holes are very difficult to locate in such gutters; the only thing to do is to brush or clean all suspected parts, and persevere until the perforation is found. It can then be repaired by means of a wiped joint, a new section can be laid, or a temporary repair effected by applying one of the many compounds sold for the purpose of rendering leaky roofs watertight.

Damaged slates and tiles are obvious causes of dampness; but it does not follow that a damp place on a wall is necessarily made because a tile is missing immediately above it. A displaced tile may allow rain to drive in, or, worse still, to flow in by convection; it may then drip off on to, say, a rafter, and run down the rafter for a distance of several feet before it finally drips on to the wall. Generally, however, it is the tiles at the eaves that should be suspected; all those that are damaged must be replaced, or the cracks and holes made good with cement, mortar, or slurry. The rain-water heads and down-pipes may be choked with debris, and cause damp places on the wall, the plain remedy being to clear away all obstructions.

**Treatment of Porous Bricks.** When a house has been built with inferior or porous bricks, the wet may drive through the wall. The cure is by rendering with cement mortar, rough casting, or by a coat of one of the waterproof compositions. A waterproofer known as Pudlo may be added to the cement used for rendering a damp wall. This preparation is mixed with the cement in the proportion of one part in twenty, in the dry state, before the cement is added to the sand. A preparation of emulsified paraffin wax, painted or sprayed on to walls in warm, dry weather, will fill up the pores, and render them impervious to damp. Sold under the name of Sprawax, this can be obtained from ironmongers and builders' merchants. It is also available for inside work. Another method is to apply two or three coats of silicate petrifying liquid to the outside wall.

Besides dampness due to falling water and driving rain, another cause of trouble is found in defective damp courses, which allow the wet to rise upwards by suction in the bricks or by convection. In addition there are purely local causes, such as a burst waterpipe or an unexpected flood in the district. Treatment must be determined by circumstances. First ascertain that there is a damp course by examination of the lower courses of

brickwork. If there is, and the defective spot can be located, it can be remedied by removing the brick course above and below the damp course, and resetting a new one.

An additional precaution in houses situated in a damp locality is to provide adequate surface drainage. This ensures that the land in the vicinity is relieved of all surplus water, and any chance of sodden or waterlogged ground eliminated. *See Cottage; Gutter; House; Roof, etc.*

**DAMP COURSE.** This is a layer of impermeable material built into all walls to prevent the damp from rising out of the earth. Suitable materials for use comprise slates, sheet lead, asphalt, or bitumen.

*Damp Course. Fig. 1 illustrates the arrangement of a simple horizontal damp-proof course.*

*Fig. 2 shows various courses for a floor beneath the ground level.*

In all probability slates are cheapest and best in the long run. They are purchased in convenient sizes and known as D.C. slates, generally measuring 18 in. long and 9 in. wide for the ordinary 9 in. wall. They are laid in two courses, breaking joint and well bedded in

cement mortar. Asphalt and bitumen damp coursing is generally used in the form of long sheets, the end of one sheet overlapping that of the next. It should be laid on a bed of cement mortar floated off smooth, and care taken that the material is not punctured or torn while being laid. It is advisable to use only the best quality. Tarred roofing felt, which is sometimes employed as a damp coursing, is an inadequate protection for the walls of a building.

Horizontal damp courses of all kinds must be laid on walls, piers, chimney breasts, sleeper and fender walls; they must cover the full width and be laid beneath the lowest timbers, and at a height not exceeding 12 in. nor less than 6 in. above the ground. Fig. 1 shows a simple horizontal damp course. When the floor level is below the ground level, three damp courses are needed—first a damp course 6 in. above the ground level; secondly, one below the wood sleeper plates of the lowest floor, and the third is a vertical damp course connecting the others, thus preventing any possible passage of dampness (Fig. 2).

Damp courses may also be necessary in or near the top of walls to prevent rain water working downwards, as for example a garden wall that abuts on the house. Slate damp courses are laid in chimney stacks at the point where they rise above the roof, for the same reason. *See* Air Brick; Architecture; Brick; Bungalow; House; Wall, etc.

**Damper.** *See* Range; Stove.

**DAMPING-OFF.** In gardening this term is commonly applied to the premature decay of seedlings, cuttings and tender plants. It is caused by a fungus disease which in the main is the result of overcrowding and careless watering. Seedlings should be watered by immersing the flower pot almost to the rim for a few minutes in a vessel of water.

**DAMSON:** Tree and Fruit. Being very hardy, the damson thrives in bleak places, and does not suffer from strong winds to the same extent as most other cultivated fruits. It is consequently often planted on the outsides of plantations, generally as a standard.

The treatment advised for plums quite suits the damson. It succeeds in most fertile soils, but best in ground containing lime. After the trees have been shortened once, or perhaps twice, in their early days, they require practically no pruning. Propagation is generally by budding and grafting on to plum stocks. The best varieties are the Merry-weather, Bradley's King, Shropshire Prune, and Farleigh Prolific.

*Damson. Fruit of Farleigh, one of the best varieties.*

**How to Cook.** The small purple fruit improves with

cooking, but requires plenty of sugar to be cooked with it. Sugar added after the damsons are cooked will not remove the acidity. To stew damsons, pick over and rinse 1 lb., and simmer them in a stewpan with 3 heaped tablespoonfuls sugar and a breakfastcupful of water. If the damsons are first slit with a knife they will cook more quickly. Any stones rising to the top should be removed. The flavour will be improved if apples are mixed with them,  $\frac{1}{2}$  lb. apples to 1 lb. damsons.

Damsons are excellent when prepared in this manner for flans, tartlets and pies. A damson pudding is made in a similar way to other fruit puddings. Line the basin with a suet crust, and fill it with sound damsons, or damsons and apples, and sugar. Two pounds of fruit will need five tablespoonfuls of sugar and a teacupful of water. Cover the basin with a round of the crust, tie over it a scalded, floured pudding-cloth, and steam it for 3-3  $\frac{1}{2}$  hours.

**Damson Preserves.** Damsons make good preserves. The following is a recipe for making damson jam without stones: Take 8 lb. ripe damsons, and boil them in a stewpan with a very little water until tender. Strain them through a coarse sieve to remove the stones, and add to the pulp 6 lb. preserving sugar. Let the whole boil until a little of the jam will set when dropped on a plate, then pour it into dry, warmed jars and cover at once.

The following alternative recipe is given with apples, which should be used in either case as desired. Split open 6 lb. ripe damsons, and put them in a stewpan with  $\frac{1}{2}$  pt. water and 3 lb. peeled and chopped apples.

Stew them for half an hour or more, stirring frequently, and removing any stones that separate from the fruit. Then add 8 lb. of sugar and continue the process until the jam is done.

A very stiff jelly made with damsons is known as Damson Cheese, and eaten as a preserve. To make it, pick over some sound, ripe damsons, and put them in a covered jar in a saucepan of cold water. Bring the water to the boil, and let it boil for 2—3 hours, re-plenishing it with more hot water as it boils away. When the damsons are tender, remove them from the juice and strain them through a coarse sieve to get rid of stones and skins.

Weigh the pulp, and add sugar in the proportion of  $\frac{1}{2}$  lb. or more to every lb. of pulp. Put this, with the juice, into an enamelled pan, and let it boil fast, stirring frequently, until it becomes a stiff paste, so stiff that it will leave the pan clean when it sticks to the spoon. Have ready some shallow, buttered moulds—odd saucers will do—and pour the cheese quickly into them. If covered with jam paper when cold it will keep well.

**DANCE:** How to Give. One of the most popular entertainments that a hostess can give is a dance. If a very big dance or ball is given, a large number of invitations are sent out, an elaborate supper is offered,

the floral decorations are on a grand scale, and bands provide the music for dancing.

Such a dance can only be given in a house with very large rooms, and it is generally necessary to hire a hall or assembly rooms. Many hotels have a suite of rooms kept for the purpose, and when a dance is given the hostess can lessen her responsibilities by leaving the lighting, decoration and arrangement of the rooms to be done by the hotel.

In the hostess' own house the refreshment arrangements can be entrusted to a firm of caterers, who make a fixed charge per head and take the whole responsibility of seeing that the food, service, and general details are suitable and adequate. There are many hostesses who feel that, provided their house is large enough, nothing is really more enjoyable than a private dance given in a private house, and they do not mind the trouble it entails.

The largest room is set apart for dancing. It should be completely emptied, and where there is parquet flooring covered with rugs it is an easy matter to roll up and put aside the latter and polish the floor until it provides a good surface for dancing. The lighting arrangements must be adequate, for the gaiety of a dance does to some extent depend on the brilliancy of the scene. At a New Year dance a feature in the programme may be a 'Twilight' dance, during which lights are switched off, with the exception of coloured electric bulbs in the evergreen decorations.

Besides the room set apart for dancing, suitable provision must be made for sitting out and for cloak-room accommodation. If people who do not dance are also asked, it is a good plan to arrange for bridge to be played in another room. There may be a band, or several musicians; though a good gramophone is often successfully used for a small dance in a private house.

The invitations are sent out two or three weeks beforehand, and, if the dance is very small, may take the form of a little note. For larger dances, printed at-home cards are used, with the time the guests are expected and the word dancing written at the bottom right-hand corner of the card. It is usual for girls only to be invited with a partner. This arrangement saves the hostess much trouble.

A Cinderella dance ends at 12 o'clock, begins at 9, and supper would be served at 10.30. Other dances may be carried on to the small hours of the morning. A cotillon may be introduced, but this calls on the hostess for presents or the distribution of favours. Just before the guests depart it is usual to offer each a cup of hot soup or coffee.

#### DANCING: ITS FUNDAMENTAL PRINCIPLES

##### Some Modern Ideas on an Ancient Art

In addition to this general article, our Encyclopedia has entries on the various dances, e.g. Fox Trot; Quick Step; Waltz. See also the preceding article on Dance.

Correct ballroom dancing is one of the most beneficial of pastimes, it uses the muscles in a natural manner and is conducive to preserving a good figure.

But the form of dancing must be correct, balance and ease of movement being essential.

Formerly far fewer muscles were used, and dancing was done almost always on the ball of the foot. This last was a most injurious practice, not only because of the unnatural strain on the leg muscles, but on the big toe joint as well, causing in many cases the malformation of the joint. Now the heel comes into play and the ankle is used naturally as in walking; in fact all modern ballroom dancing is based on natural movement. A good teacher endeavours to make a pupil dance as naturally and comfortably as he or she walks; and to a certain degree adapts the steps, or rather the size and manner of the steps, to the habitual walk of the pupil, providing, of course, that it is a good walk. Therefore anything in dancing that seems uncomfortable and awkward for the person to perform must be wrong, whether the fault is on the side of the girl following or the man leading.

*Dancing in action: the correct hold. Left: the woman's hand is placed just below the man's shoulder, the fingers resting gracefully but naturally.*

*Right:*

*the correct position for the man's hand, just above the small of his partner's back. (Courtesy of "The Dancing Times")*

Before taking up dancing it is an excellent plan for anyone to make sure that his walk is correct. The back should be straight and the stride coming from the hips; feet should be neither turned out nor in, and should be close together when one foot passes the other, as close as if walking on a plank.

**Basic Movements.** Dancing, like any other sport or pastime, has its rules, etiquette and technique, and if the basic movements are learned correctly in the beginning more complicated movements are easily performed later. The person who has thoroughly mastered the groundwork can learn a series of new steps in a quarter the time it takes a person who has never learnt the basic movements, but dances "naturally." This applies to any dance, whether it is one of the established dances such as the waltz and slow fox trot, or the new and short-lived crazes that come and go during the dancing season.

The movement is always from the hips, the legs swinging like a pendulum. The girl and man should both stand erect and naturally, the girl resting her left hand along her partner's right arm near the shoulder, the man holding her firmly, but without strain or

effort, just under her left shoulder blade, his left arm held so that his hand is on a level with his ear. One of the chief faults seen in the man's hold is that he clamps his arms from shoulder to elbow to his body, instead of holding them easily in a nice straight line from the shoulder.

*Dancing: the Quarter Turn. A useful step for the occasional dancer. First movement: right foot forward, turning on it to right; left foot to side, still turning. Second: close R.F. to L.F., step diagonally back with L.F. Third and Fourth: R.F. back, turning on it to L.; close L.F. back to R.F., turning to L. on R. heel pivot.*

### Correct Hold in Dancing

The fact that one of the partners is very tall or short should make no difference to the form of the hold. A tall man should guard against clamping a short girl or straining at a tall one. He need only alter the position of his arm from the elbow to the wrist, just raising or lowering it a little, as the individual may need. The position of the upper part of the arm should remain the same. The actual formation made by the hands, whether the girl's or man's, is immaterial, or rather it relies, like many other things, on the individual sense of good taste, being neither clumsy nor affected. The man's hand should rest on the girl's back in a light natural position, and the girl's hand should be the same, not spreading the fingers nor yet "curling" them.

The hips of both partners are always slightly forward

in dancing, as they respectively lead and follow from the hips, not by means of the man squeezing and clutching with both arms and the girl hanging on with both hands. If this hip movement is tried it will be seen at once that the girl must know what step is coming next, without any extra pressure of the hand on her back. The only time when this may be needed is when the man decides to do an outside step, then the very slightest pressure with two fingers is enough to indicate this change. The girl must not, under any circumstances, anticipate, but must remain supple and ready to follow. To enable her to do this easily, the man must lead definitely and from the hips.

**Poise and Balance.** Balance is obtained principally by correct distribution of weight, and this is a simple walk backwards which the beginner can practise. Done correctly it will ensure accurate balance, which is more than half the secret of graceful deportment, whether in walking or dancing. Take a long step from the hip, the ball of the back foot meeting the floor; keep the pressure of the front foot on the heel whilst travelling backwards, and never let the back heel drop until the front foot passes it. The knees must never be stiff in dancing, but never really bent. They must be straight and relaxed alternately, the travelling leg being straight and the knee of the supporting leg relaxed. Here, again, one must remember that dancing is natural movement, and this straightening and relaxing of the knee alternately is exactly what should occur whether a person is walking in the street or running on a tennis court.

This naturalness in dancing can scarcely be over-emphasized. A "natural" dancer with an inborn sense of rhythm is preferable to one who is over-anxious to practise complicated steps.

The direction for all dances is anti-clockwise. For the comfort of others on the floor it is correct to travel around on the outside of the floor, and everything in dancing has been composed with the view of making all movements progressive. It is when two people either try to invent new steps, or the man's dancing consists of a few steps forwards, a turn, and a few steps backwards, that "crushes" occur and second lines are made in the ballroom. Generally speaking the line of dance is oblique, the steps and combinations of steps forming a zig-zag pattern around the room; in the case of the tango these lines are curved.

**Style and Rhythm.** With regard to etiquette, apart from the position of the hands, which has already been dealt with, good manners and the comfort of others should be the guiding rule. It is not etiquette to make up fancy steps if they interfere with the progress of the others. Nor should any deviation from the occupation of correct ballroom dancing occur, for it usually means bumping into another couple, which is as bad a breach of good manners as if it happened in the street.

In modern ballroom dancing the feet are always

parallel, unless performing a twist, e.g. the Charleston. In this case the feet are in a straight line with the toes, and neither foot is turned out. The rule for placing the feet in a forward movement is heel first, except when two quick steps follow each other. This is contrary to the old form of dancing, which was always "point toe," and is just the same as a natural walk, which is always "heel first." The only difference between the natural walk and the modern ballroom dancing step is that the latter glides along more.

There are two ways of turning, right hand, or natural, and left hand, or reverse. Contrary body movement is turning the body from the hips so that the opposite hip and shoulder move forward, or back, if stepping back with the moving feet. This movement applies chiefly to slow steps, and curves are governed by that. When a foot has to move from an open—that is, feet apart—position to another open position it must pass close to the stationary foot on the way. This is known as brushing.

There are three popular times for dance music, 4/4, which embraces the slow foxtrot, quickstep, blues, mid-way rhythm: 3/4, which is waltz time; and 2/4 for the tango.

**DANDELION.** In a cultivated state the dandelion makes an excellent salad, and the improved varieties, such as large-leaved French, are grown in many large gardens. They are raised from seed sown in spring and thinned to a foot apart.

In late autumn the roots may be lifted, placed in boxes of soil and forced into growth in a dark, warm place. Or the fresh spring growth can be blanched by covering the plants with pots.

The dandelion as a weed on the lawn must be dug or spudded out, and a little salt or weedkiller dropped into the hole. One way of destroying is to dip an iron skewer into sulphuric acid and force it into the heart of the plant. In medicine the dandelion, or taraxacum, is sometimes used as a simple bitter and stomachic. It is also laxative. The common preparations are: extract of fresh dandelion root, dose 5 to 15 grains; liquid extract of dandelion root, dose  $\frac{1}{2}$  to 2 drams; juice of dandelion root, 1 to 2 drams.

**DANDIE DINMONT.** The affectionate and intelligent little terrier known by this name is often confused with the Aberdeen and the Skye terriers.

*Dandie Dinmont. "Leydon Piper," a prizewinner of this favourite breed of small Scotch terrier.*

The head is large, the muzzle strong and the nose black. The broad-based, tapering ears hang closely to the cheeks. The legs are short, and the rather short, feathered tail with a slight curve is carried little higher than the line of the back. The hard, but not wiry, coat is about 2 in. long, and has a mixture of softer hair. On

the head the hair is silky. The colours of the terrier range from bluish black to silver grey, and from red brown to pale fawn. If the upper parts are black or grey (pepper), the legs should be brown or fawn; if brown is the upper colour (mustard), the head should be creamy white, and the legs a shade darker than the head. The height at shoulder should be from 8 in. to 11 in., and the weight 14 lb. to 24 lb., but preferably about 18 lb. *See Dog.*

**DANDRUFF** or Scurf. Dandruff is due to inflammation of the scalp caused by microbes, and shows itself as an accumulation of yellow or grey scales, which consist of the horny cells of the skin, produced in excess and thrown off. In treatment the first step is to remove, as far as possible, the crusts and scales on the scalp. Shampoo the head well with tincture of green soap, which can be obtained from any chemist. It is important to remove all the soap from the hair, so the head should be rinsed with several changes of clean water. The following sulphur ointment should be rubbed thoroughly through the roots of the hair:

Precipitated sulphur	20 grains
Salicylic acid	10 grains
White vaseline to make	1 oz.

The treatment is repeated as often as may be necessary to keep the scalp clear of scales. *See Baldness; Hair; Shampoo.*

**DANIELL'S CELL.** This is a form of electric cell designed to obtain constant voltage. It consists of a glass jar in which is a copper plate usually bent into the form of a cylinder of such size as to stand in the jar and leave plenty of room in the middle. Inside the copper cylinder stands a porous pot, that is to say, a jar made of unglazed earthenware, and inside it is a zinc rod.

*Daniell's Cell. Diagram of the component parts.*

The porous pot is filled with a dilute solution of sulphuric acid, and the space between the glass jar and the porous pot is filled with a saturated solution of copper sulphate. The copper sulphate solution is kept saturated

by adding a number of crystals of copper sulphate; these must be added from time to time, as they

dissolve when the cell is in operation. A shelf is sometimes fixed to the copper cylinder to receive the supply of copper sulphate crystals.

The voltage of a Darnell's cell is just over one volt. They are particularly suitable for heavy and continuous work and are employed for closed circuit burglar alarm systems. When a Daniell's cell has been charged with electrolyte the two terminals should be connected by a piece of thick copper wire so as to short circuit the cell, leaving it thus for twelve hours or more. See Burglar Alarm.

**DAPHNE.** Of the hardy daphnes the favourite is the mezereum (*Daphne mezereum*), a slow-growing shrub 3 ft. or more high, which bears reddish-purple fragrant flowers in Feb.-Mar. It is suitable for the rock garden or the front of the shrubby border. It likes soil containing lime. *Daphne eneorum* (alpine garland flower) with fragrant, rose-coloured blooms, and *blagayana*, cream-coloured flowers, flourish in the rock garden in peaty soil; the branches of the latter should be pegged down. *Daphne laureola*, spurge laurel, is an evergreen which will thrive in the shade. The height is from 3 to 4 ft. It is commonly raised from seed, and has glossy leaves and yellowish-green flower in winter. *Daphne indica* is a favourite winter greenhouse plant with fragrant flowers.

*Daphne mezereum*, a hardy species of the flowering shrub which will thrive in the open.

## THE DARK ROOM AND ITS FITTINGS

### How to Adapt or Construct a Room for Photographic Work

The processes carried out in the Dark Room are described under Developing; Enlarging; Printing, etc.

Although there are systems of developing photographic films or plates in full daylight, a dark room is a necessity for photographic work.

It is quite practicable to do almost any kind of photographic work in an ordinary room which is temporarily darkened. Several patterns of darkroom cabinet are sold. They provide a convenient and not unsightly storage place for dishes, bottles, etc., whilst the door of the cabinet, in some models, forms a bench or table. A bathroom is most convenient for use in this occasional way.

In fitting up an ordinary room for photographic use any window has to be blocked up. It is best to do this so that the full light from the window can be quickly obtained if required, for there are many operations that are preferably done by daylight, and also it is then much easier to keep the room in its necessary state of cleanliness. Most windows can be fitted with a wooden frame covered with two thicknesses, of stout brown

paper or black blind material. A few wooden wedges will prove sufficient to keep it in place.

An effective and easily fitted dark room blind can be contrived with an Acme or similar type spring roller fixed on brackets well above the window frame (Fig. 1). Down each side of the window hinged shutters are fitted to exclude light at the sides when the blind is drawn (Fig. 2). Dimensions will vary with the size of the window, but the blind should be arranged to overlap the inner shutter (Fig. 1, A) at least 1 ½ in. The blind should be made of thoroughly opaque material, such as un-glazed American cloth fastened to the roller with glue. This does not prevent the use of ordinary curtains and blinds.

**Dark Room.** Fig. 1. Blind for making a temporary dark room.

**Fig. 2.** Details of light-excluding shutters for use with the blind.

**Fig. 3.** Folding table placed over a bath.

Ventilation must not be neglected. If the room has a fireplace, this will be sufficient; but if there is none, an inlet and outlet of air must be contrived somewhere, if only in the top and bottom of the door. Right-angle tube-pieces, like stove pipes but rather smaller, can be bought for dark room ventilation and can be fitted to the covered frame which is used to close a window.

Much labour is saved if a water-tap sink and waste

pipe can be provided: but these are not absolute necessities. If water cannot be laid on, an excellent substitute is a tank holding a few gallons fixed on a stout shelf a foot or two above a sink. Such a tank of zinc fitted with a tap, is a stock article. The sink should be shallow (about 3 or 4 in.) and of fair size, about 3 ft. by 2 ft. It is either of earthenware or of lead in a wooden casing. If a pipe for carrying off the waste water cannot be arranged, a large bucket serves the purpose, a rubber hose being fitted to the sink outlet. If constant flow and escape of water are not available, washing of negatives or prints can be easily and readily done in the domestic bathroom.

It is convenient to support the sink on a pair of cupboards; those sold as ordinary meat safes answer well and serve for the keeping of dishes, tanks, etc. The sink itself should be covered with a rack of stout wooden slats, which forms the work bench and allows all drippings of solutions to pass through and drain away. Some narrow shelving, not more than 3 in. wide, for the bottles of solutions completes the fitting of the work bench. It should be placed so that it stands on a firm support, any nails serving to hold it upright on the wall just above the work bench.

Lighting is most important and it is economy in the long run to pay for the best. The small oil or candle ruby lamps sold for a shilling or two are useless. The essential is to have plenty of light, and that of a kind which is safe for the particular kind of sensitive material. The lamp should be fairly large; the size of the safe-light, which is the coloured screen of the lamp, should be about 10 by 8 in.

The most convenient form of dark room lamp is electric with a two-way switch, by which a bulb outside the lamp can be instantly brought into operation whenever white light is required. For bench use the lamp should be of the pattern in which the front is vertical or slopes slightly forward. A hanging lamp in which the safelight is horizontal gives a flood of light straight down on to the work-bench. This form is by far the best for the development of prints, the progress of which is judged by looking on them, not through them, as with negatives.

If gas has to be used, it is necessary to buy a large lamp on account of the heat which is developed, and if the dark room is very small it is advisable to place the gas burner itself outside, fixing the safelight as a window. The same considerations apply to an oil lamp.

When the bathroom is used as a dark room it will be found very tiring to lean over the bath or kneel down in front of it for lengthy periods. This can be avoided by arranging a hinged table over the bath at the height of a person sitting (Fig. 3). The methods of construction are shown clearly in the diagrams. Sizes will vary according to the width of the bath and the height of the table.

Make the table of slats of wood about  $\frac{1}{2}$  in. apart, so that spilt liquid may fall straight into the bath. If a trickle of water from the bath tap is allowed to run there will be no risk of staining the bath enamel with developer. Hypo has no effect on enamel. If possible, dishes should be kept in the bathroom, and a plate rack

or slatted shelving put up to provide easy drainage and to keep them free from dust. Dust is the photographer's principal enemy.

**A Portable Dark Room.** A small dark room, as is shown in Fig. 4, made in sections so that it can be moved from place to place, is extremely useful to the amateur photographer. The door is arranged to fit into one section, and virtually forms one wall of the building. The other sections are covered on the outside with weatherboard, and lined on the inside with 3-ply wood.

The floor rests upon 3 in. by 2 in. floor joists, to which it is securely nailed with 2 in. oval brads. The roof is formed of  $\frac{3}{4}$  in. matchboards, nailed to 2 in. by 2 in. rafters, and bolted to the frame of the building. It should be covered on the outside with good waterproofed material. The window is formed opposite the door, and should be glazed with clear glass. Separate frames are made to fit over the window frame; these are covered with fabric or glass of any desired colour, and may be rebated and fitted with a panel of safelight coloured glass. These frames are held in place by turn-buttons, securely screwed to the window framing and arranged to bear on wedge-shaped slips of hardwood fixed to the removable frames, as shown in Fig. 5. The edges of the frame may be covered with felt, so that when the turn-buttons are twisted they bear on the wedge-shaped slips and thus close the frame up tightly. Details of construction are shown in Figs. 6-10. The joints are simple, being merely halved together. The door (Figs. 7 and 9) is made double by first constructing an ordinary ledged and braced door, and covering the inside with ordinary 3-ply board, having previously glued and nailed make-up pieces to the inside of the door in the manner indicated in the drawings. A good stopping of 1 in. square stuff is requisite, and it should be faced with felt to exclude all light.

To allow for ventilation, an air inlet is provided (Fig. 10), and slotted and so fixed that air can enter but light cannot pass.

*Dark Room.

Fig. 8. Back frame.

Fig. 9. Door.

Fig. 10. Air inlet.

**DARK SLIDE.** The old-fashioned wooden double dark slide opening like a book is now largely displaced by the single metal sheath holding one plate. These metal slides should not be allowed to become rusty, and should always be carefully dusted out before inserting fresh plates. Attention should be paid to the strip of velvet on the top of the plate-holder which traps the light when the slide is withdrawn during exposure in the camera. If the velvet is worn or flattened, light will leak past and fog the plate; if the velvet is brushed up after unloading a slide, it will not only be kept free from dust, but will be less liable to allow light to enter.

To blacken slides when worn, wash in strong soda water, which removes rust and grease, followed by immersion in a weak sulphuric acid solution in the proportion of 1 dram of strong sulphuric acid to 1 pint of water. They are then blackened by boiling in the following solution:

Hyposulphite of soda	180 grains
Copper sulphate	120 grains
Water	10 oz.

*See Camera; Photography.*

**DARNING.** Too heavy a mending yarn pulls and strains the material to be darned, and soon leads to further holes; too fine a one only fills the rents with twice as much labour as is necessary, and does not last long. The idea is to counterfeit the weaving of the material, first one way and then the other, till the hole is filled with closely interlaced threads going over and under each other at right angles.

Start on sound material well outside the edges of the hole, running the needle (threaded double for all but small repairs) in and out of the stuff in a straight line. Return as close as possible to the first line, going under the stuff where that went over, and vice versa. At the end of each line do not pull the thread tight, but leave a tiny loop, Fig. 1; this allows for the shrinking of the new thread in the wash. Continue darning up and down till well outside the hole on the far side and on sound stuff again. Then darn closely across at right angles, alternately under and over the original lines of stitches, Fig. 2, until the hole is completely filled. Thin, places should never be allowed to run into holes. If they are darned one way only they will last for a long time.

When mending a ladder stop the dropped stitch from running with a temporary stitch. An ordinary crochet hook will assist the repair, as shown in Fig. 3. Note that the hook draws each line of thread through the stitch separately and restores the actual pattern. Darning balls or eggs, over which the hole can be stretched smoothly while in course of repair, make the work easier and less cramping to the hand. Anything of a delicate nature should be repaired before being laundered.

On woollen garments of a uniform colour a piece of canvas large enough to overlap the edges of the hole should be cut out and tacked in place on the wrong side of the material, so that the lines of the canvas run exactly parallel with those of the weaving. This may be

coarse or fine, according to the texture of the material. The raw edges of the tear are cut away to form a square, and the wool is darned across, backwards and forwards, stitches being caught into the material, on either side, as in Figs. 1 and 2.

*Darning. Figs. 1 and 2. Method of darning a hole, illustrated on open-mesh canvas to show stitches.*

*Darning. Fig. 3. Mending a ladder with an ordinary crochet hook.*

**Darning Stitch.** The straight darning stitch for simple embroidery is shown in Fig. 4. The rule for straight darning is to take up half as much material as that passed over, the latter forming the length of stitch. In fancy darning the stitches are spaced to suit the design. *See Mending; Stocking; Wool.*

*Fig. 4. Straight darning stitch used in embroidery.*

**DART: In Dressmaking.** A dart is a wedge-shaped piece of material taken up on the inner side of a garment, to remove any unnecessary fullness. It must be carefully made by taking up just the amount of material that is not required and gradually sloping it off to the point where the dart is to finish.

**DARTS.** This game, played indoors with a wall target and small darts, is one of the finest games of skill, demanding a keen eye, a steady hand, mental judgement and a head for figures. Its extraordinary popularity has now extended from the public to the private house, for all the year round.

The dart-board is circular, 18 inches in diameter, made usually of elm 2 inches thick, marked on both sides; when a side gets badly pocked it is restored by soaking in water.

The faces of the board are divided by wires nailed to the surface into 20 segments, numbered from 1 to 20, but in irregular sequence, unlike a clock face. Thus, for instance, No. 2 is at "5 o'clock," No. 19 at "7 o'clock."

**Darts.** *The type of dart-board most generally used.*

The bull's-eye, a  $\frac{1}{2}$ -inch circle in the centre called the "dosser," counts 50, and round it is an "outer" worth 25. Round the edge of the board is a metal strip  $\frac{3}{8}$ -inch thick, counting double the number concerned; halfway to the "dosser" is a similar circle, counting treble.

Each player in turn throws 3 darts. The usual form of the game starts and finishes on the double strip. The score required is always an odd number: 1,001 in team games, 101 or 201 in duels and 301 or 501 for four-somes. "301 up" is usual.

**Scoring.** Before a player can score, a dart must be lodged in the narrow "double-strip." After this, darts score the number of the segment in which it is lodged. Each score is subtracted from the agreed total; and victory goes to the player who first reduces his total to exactly nothing with a "double." For example, if he has 20 left he must get a double 10; if 9 left, a small odd number—say 1—and then a double 4. Exceptionally skilled players get 101 with the first three darts: e.g. 38 (double 19), 13 and 50 (double 25).

Of other variations of the game, Shanghai, Oxo, Cricket, Shoveha'penny, etc., the best is "Round the Clock." The player must get one dart in each segment in numerical sequence (1, 2, 3, 4, etc.), and finally one in double 20 (or 50, by arrangement). The starter carries on until he fails to improve his position in any one series of 3 darts. Then his opponent throws. First to get final "double" wins.

In the home, Darts is an admirable game for an informal party. There are infinite variations and local conventions of the game in different parts of England. There are at least 5 different types of board: compressed paper and cork boards are little used now, but "pig-bristle" is a good material into which darts sink deeply but not too easily. Lighting should be brilliant but shielded -from the eyes. Some players prefer to carry their own darts; beginners should use light wooden ones, graduating after experience to heavy brass darts. Weighted or unweighted feather darts have individual advantages. They cost about 10½d. a set, and should be withdrawn gently from the board to preserve their condition. The player generally stands 9 feet from the board, whose centre is usually 5 ft. 8 in. from the ground. Tossing a coin or "who throws nearest the dosser" decides who shall start. The game abounds in technical terms (e.g. Bed-and-Breakfast= 26); these and the full rules may be obtained from the London Darts Club, or from Mr. Rupert Croft-Cooke's exhaustive monograph on the game. Everyone develops his own style. Most players, however, throw from eye-level with legs apart.

**DATE: The Fruit.** The dessert varieties of this fruit are generally bought in boxes weighing between  $\frac{1}{2}$  lb. and 1 lb. These dates should be a shiny, golden brown in colour, large and soft. Cooking dates are usually bought by the pound. Before using them, the dates should be separated and washed in tepid water. They will improve if soaked in cold water overnight.

To stew dates, split open 1 lb. of them, and remove the stones. Put them in a saucepan, cover with cold water, and simmer them until they are soft. They need no sugar.

*Date. Dish of appetising sweets made from this fruit.*

Attractive sweets can easily be made if some good dessert dates are split open, the stones removed, and a roll of almond paste, coloured with cochineal, etc., inserted instead. The stuffed dates should be warmed in an oven for 15 min. in order to set the paste, then allowed to cool, and put into paper cases.

A blancmange can be flavoured with chopped dates, and this fruit also makes a good compôte. Stone  $1\frac{1}{2}$  lb. dates, and put them into a clean jar containing the strained juice of a large lemon, 6 oz. sugar, and  $1\frac{1}{2}$  gills Malaga. Have ready a pan of boiling water, place the covered jar in this, and then cook its contents as slowly as possible over a very low fire, or at the side of the gas-stove. Leave it thus for an hour or more, and let it get cold before serving.

**DATE PLUM.** These are small yellow plums, extremely astringent before ripe, but sweet and of good flavour when ripe. In America the date plum is known as persimmon. It is used in the same way as other plums, and can be eaten raw or cooked. For jam-making, 1 lb. of sugar should be allowed to each lb. of fruit. *See Jam; Plum.*

**DATE PUDDING.** Peel and chop up finely a good-sized apple, and mix it with  $\frac{3}{4}$  lb. of washed, stoned, and roughly-chopped dates. Make a suet crust, using about 5 oz. flour, and roll it out fairly thin. Line a greased pudding basin with the pastry, then fill it up with alternate layers of date and crust, pastry being on the top. This pudding, which will need steaming for 2 hours or more, should be turned out and served hot with boiled custard.

Another date pudding is made by chopping  $\frac{1}{2}$  lb. dates very small, and mixing them well with 3 oz. sugar, 6 oz. breadcrumbs, 4 oz. flour, a little baking-powder and a good pinch of salt. Now beat up together 4 oz. of dripping or lard, 1 gill milk, 1 tablespoonful treacle, and 1 egg. Mix the wet with the dry ingredients, and put the whole into a greased pudding

basin so that it fills only  $\frac{3}{4}$  of it. Twist some greased paper over it and steam for a good 3 hours.

**DATURA: The Thorn Apple.** The datura is a half hardy annual and shrub belonging to the potato family. Of the shrubs the favourites are *Datura (brugmansia) suaveolens*, with white, and *sanguinea* with red flowers in late summer, they may be grown in tubs or large pots and placed out of doors for the summer, but must be brought under glass in autumn. The annual daturas are raised from seeds sown in slight heat in February-March and planted out of doors in May. A few of the best are *cornucopia*, double flowers, purplish white; *Metel*, white scented blooms; and *ceratocaula*, white fragrant flowers. These bloom in summer and grow 2 to 3 feet high. The common thorn apple (*stramonium*) has white flowers which are followed by spiny fruits.

**DAVENPORT TABLE.** This type of writing table, or *escritoire*, is chiefly associated with Victorian furniture, and consists of a desk placed upon a pedestal, below which are a set of drawers. These do not open at the front, but at the side. The desk is the same width as the pedestal, but is made to slide forward, so that a person can sit and write at it in comfort. It has a hinged lid, below which is a receptacle for papers, etc., and in which small drawers are sometimes fitted.

In some of the pieces there is also a sliding shelf that draws out at the side and is used to hold paper, etc. These desks are usually covered with leather and have a low rail round the top to prevent the pens from falling. *See Bureau; Writing Table.*

**DAVENPORT WARE.** This Staffordshire ware, including porcelain, stone china and earthenware, was produced by a family of that name at Longport for about a century after 1793, and usually bears the potter's surname, either with an anchor or sometimes with the place-name.

*Davenport Ware. Porcelain plate and sugar bowl, with delicate floral design, c. 1815. The mark, an anchor and the word Davenport, is printed in red.*

*(By permission of the Director, British Museum)*

The porcelain is a fine bone-paste, sometimes white, cream-coloured and blue-printed. Collectors usually look out for the tea and dessert services with deep blue, rose du Barry or apple-green grounds, and attractive panels of scenic and floral subjects. There are also choicely painted vases, and all have massive gilding on the rims, handles and feet. Except for the mark, such

ware is not easily distinguished from Derby or Coalport china of the same period.

The willow pattern with only 25 apples on the tree is readily recognized, as the corresponding Wedgwood, Spode and Adams patterns have no fewer than 32 apples. Davenport ware has a tendency to become covered with minute surface cracks, and some of the cups appear as if tea-stained, a defect which cannot be removed. *See China; Staffordshire Ware.*

**DAY LILY (Hemerocallis).** This lily is a beautiful hardy flowering plant, 2 to 3 feet high; in June and July it bears lily-like flowers in shades of yellow and orange. It thrives in ordinary soil in a sunny or slightly shady border, and is increased by division in early autumn. Some of the best sorts are *aurantiaca*, apricot, *flava*, *fulva* and *Queen of May*. Although the individual blooms last only for a day, the plant continues to flower throughout several weeks. *See Lily.*

**DAYLIGHT SAVING.** This term is used for the system, known also as *Summer Time*, of putting forward the clock by one hour at the beginning of summer and putting it back an hour at its end. The nominal time remains the same, thus avoiding all changes in time-tables and the like.

Daylight saving was introduced into Great Britain in 1916, but it was not made permanent until later. For some years the opening and closing dates of Summer Time varied, but in 1922 uniformity was introduced. As the law now stands Summer Time begins at 2 o'clock in the morning of the day after the third Saturday in April, unless that day is Easter Day. If it is, Summer Time begins on the day after the second Saturday in April. It ends at 2 o'clock on the morning of the day after the first Saturday in October. This means that the clock is put forward one hour on the appointed day in April and put back one hour on the appointed day in October.

The law applies to Great Britain, Northern Ireland, the Channel Islands and the Isle of Man, but not to the Irish Free State. France and Belgium have adopted the same period of summer time.

**DEADLY NIGHTSHADE.** The common name for the belladonna plant is the deadly nightshade. Medicinal preparations are obtained from the leaves and the root, but the active principle, atropine, is found also in the berries, and poisoning has resulted from eating these; they are about the size of a small cherry, violet-black in colour, and have a sweetish taste. If the patient is able to swallow while waiting for the doctor, vomiting should be induced at once by tickling the back of the throat or by an emetic. He should be given draughts of strong hot tea, and kept warm in bed with hot water bottles. *See Atropine; Belladonna.*

**DEAD NETTLE.** (*Lamium maculatum*). This wild plant has purplish flowers. The yellow-leaved variety aureum and puralbum, which has pinkish flowers, are sometimes grown in gardens.

**DEAFNESS.** Injury or disease of any of the three portions into which the hearing apparatus is divided may cause deafness, or it may result from a foreign body blocking up the outer passage of the ear, and in this way preventing sound waves from touching the drum.

Children frequently cause the latter variety of deafness by poking buttons or hard peas, etc., into their ears. No attempt should be made to remove the foreign body by means of a hatpin. The child should be taken to a doctor, and if the foreign body is a pea or bean, no one must attempt to syringe it out. In the case of a live insect, however, a little warm oil may be put in the ear.

Frequently the obstruction of the passage is due to an accumulation of ear wax. A little warm almond or olive oil in the ear overnight and gentle syringing with a ten per cent solution of boracic acid and warm water the next morning may be the only treatment needed. Care should be taken not to push the point of the syringe into the ear passage. The stream should be pointed not directly against the drum but against the back wall of the passage, while the ear is drawn upwards and backwards.

*If the wax does not come away easily, never attempt to remove it with a hatpin, or otherwise, nor by forcible syringing. See the doctor about it.*

The deafness from a cold and the frequent attacks of deafness in children who suffer from adenoids is accounted for by catarrhai swelling of the Eustachian tube which connects throat and ear. But in this latter case and also in any condition of catarrh of the nose and throat, either acute or chronic, inflammation may extend up the Eustachian tube actually into the ear itself.

Suppuration may take place and may lead to the perforation of the drum and disease and destruction of the bones connecting this with the inner ear. Here again there is deafness; but much more serious than the deafness is the suppurative process going on in such close proximity to the brain. Sometimes there is acute inflammation without suppuration, and frequently the effects of this do not clear up properly, and some degree of deafness results. The risk of this happening will be lessened by seeing the doctor at once.

In other cases is found an increasing deafness due to chronic catarrh of the middle ear, in children and young persons, accompanied by an exudation, but in older people taking the form of "dry catarrh." These cases are practically always associated with catarrh in the nose and throat, and it is clearly of the greatest importance that adenoids and other conditions which provoke this catarrh should be early and efficiently dealt with. Diphtheria, scarlet fever, and other in-

fectious disorders are often complicated by middle-ear disease. In long-standing chronic inflammation of the middle ear, with persistent discharge, the hearing usually becomes gravely affected. In all cases of acute or chronic catarrh or inflammation the utmost pains must be taken, under the doctor's directions, to clean up the ear.

Where there is internal ear deafness, the actual nervous structures, as distinguished from the merely conducting structures of the ear, are at fault. This nerve deafness may also be due to the action of drugs, e.g. quinine, salicin, etc., and particularly in those whose ears were otherwise affected. *See Ear.*

**Care of the Deaf and Dumb.** Where a child is born deaf, mutism, or inability to acquire speech by ordinary methods, necessarily follows, though the vocal organs may be quite normal. This is due to the fact that all children learn to speak by imitation; the deaf child, hearing no spoken language, acquires none, and instead develops a series of natural gestures. This led in the past to silent methods of finger spelling and signing; but the methods now employed have in view to teach the deaf to understand what is said to them by means of speech reading, or, as it is commonly called, lip-reading.

A simple and effective method of testing the hearing is the following. Place the child with its back towards you, and step backwards, two steps, roughly about 6 ft., then whisper some simple command or question. If the child does not respond, it is deaf or partially deaf, and the case should be reported to the local education authority, whose duty it is to see that the child is placed in a suitable school, either for the deaf or the hard-of-hearing. The deaf child is entitled to free education, though if this entails removal to a residential school, the parents may be required to contribute.

The child should be treated as nearly as possible as a normal boy or girl. Bad habits, a shuffling gait, mouth noises, ugly grimacing and gesturing, should be checked. He should be spoken to a little more slowly than other children, and his attention should be directed towards the lips. Every member of the family should try to keep up his interest in persons, places, and things, just as though he could hear. During the last years at school there will have been some definite trade bent in the manual instruction received, and the boys readily find occupation in carpentry, cabinet making, bakery, bootmaking, etc., while the girls secure openings at laundry-work, dressmaking, millinery, fancywork, etc. Usually an Aftercare Association will assist in placing the deaf child, and will further continue to visit and report on its progress during the first years of employment. There is also usually an agency or mission which provides special services for the deaf. In London this agency is the Royal Association in Aid of the Deaf and Dumb, at 413, Oxford Street, W.1.

Deafness occurring late in life may involve loss of employment. Nothing has so beneficial an effect in such cases as a course of lessons in lip-reading, which

renders the loss of hearing much less noticeable, and so helps to give the deaf person more confidence in himself. Classes in lip-reading are provided in most large towns, and instruction may also be arranged privately through the Royal Association above mentioned or the National Institute for the Deaf, 105, Gower Street, London, W.C.1. Much may be said with regard to artificial aids, but each case must be treated by a skilled aurist.

*Deafness. Deaf and dumb manual alphabet, using both hands, a method of communication now largely superseded by lip-reading (By permission of Mr. B. H. Payne)*

**DEAL:** Uses of the Wood. The wood obtained from the pine or fir tree is called deal and is generally of three varieties—red, white, or yellow. Planks 2 in. to 3 in. thick by 7 in. to 11 in. wide are known as deals. Most of these come from the Baltic ports. Deal is the cheapest and most commonly used wood, and is soft and light, but very durable. It is employed in house building for joists, rafters, floorboards, doors, window frames, match boarding, outdoor structures of all kinds, also for the cheaper kinds of furniture.

Red deal, which has a slightly reddish tinge, is considered a little superior to white, which is often called spruce. Yellow pine is a superior class of wood, and is not generally regarded as deal. It is not stronger nor more durable, but it has fewer knots, is easier to

work, and less liable to warp. Spruce generally has many knots, which makes the wood troublesome to plane. *See Amateur Carpentry; Fir; Wood.*

**DEATH.** The symptoms of death are usually not to be mistaken when sudden pallor overspreads the face as the heart stops beating and breathing ceases. Rigor mortis, or stiffening of the body, may come on quickly, but on the average it appears in about six hours, and lasts for about 24 hours.

In view of the fact that a state of trance closely resembles death, and to avoid any possibility of the person being buried alive, certain signs that life is extinct should always be looked for. A mirror held before the mouth and nose may become dimmed, perhaps very slightly, but sufficient to show that breathing is taking place. By using a stethoscope the doctor may be able to hear very faint beats of the heart, or by tying a ligature tightly round a finger he may find that the end of the finger becomes red, while on the removal, of the ligature a white mark is left—thus showing the presence of some circulation of blood.

**The Legal Side.** Every death must be notified to the local registrar of births and deaths within five days of the event, under a penalty not exceeding £10. The person to give the information to the registrar is first of all the nearest relative present at the death or in attendance during the last illness. If no such relatives, then any relative of the deceased living in the same registrar's subdistrict. If none, then the occupier of the house where the death took place; and if he does not, then every inmate of the house is bound to see to it.

One of the next things to be done is to find out whether the deceased had made a will, and, if so, who is the executor, as the latter is the only person to look after the property and effects of a deceased person. If there is no will, or a will but no executor named in it, or the executor is dead, then the proper thing to be done is to see that letters of administration are taken out as soon as possible. The administrator then becomes the proper person to take care of and distribute the property and effects.

Death puts an end to all contracts of agency, so that, for example, a widow who orders goods for herself or the household after her husband's death, does so at her own expense, and has no claim to be reimbursed out of his estate. A banker may not honour his customer's cheque after he knows of the customer's death. Every contract depending in any way involving personal qualifications for carrying it out, comes to an end by the death of a contracting party.

If two people are killed in the same accident, e.g. a railway collision, the younger is presumed to have survived the elder. This is sometimes important in questions of family inheritance. The death of a member of a family on whom other members are dependent sometimes gives rise to a claim for damages on the part of the dependents.

**Laying Out the Dead.** When death takes place

under natural conditions from illness or old age, and there is no necessity for the immediate inspection of the body by a doctor or the police, certain duties should be at once performed by those in attendance.

If the deceased person is already in bed such duties are simplified, but if death has taken place in other than a bedroom it is better to select and prepare a bed before the body is laid upon it. When possible a mackintosh should be placed over the mattress, or if that is not obtainable thick brown paper or a spare piece of linoleum or American cloth. This can be covered by a clean sheet. If death has taken place in bed, it is presumed that some such provision has been made. Pillows, bolsters, water-beds, hot bottles, and any surgical appliances should be removed. The body should be divested of all garments and laid quite straight, the arms to the side and the ankles tied together.

A small pillow for the head can be kept if required, but it is better at first to use none. The head can be turned gently on one side to allow any fluid in the mouth to escape. The eyelids should be closed and kept in position by pads of wet cotton-wool, or a heavy coin. False teeth and rings should be removed, if required. A bandage or cloth should be tied under the chin around the head to keep the jaw in position until rigor mortis has set in. Cover the body and leave it, if possible, for half to one hour.

This time can be spent in clearing the room of unnecessary fittings and signs of illness, preparing a clean gown and sheets, and dressings if required, a basin of clean water, soap and towel. The body should then be washed and cleaned all over, and the hair brushed, parted and plaited as occasion requires. Avoid the use of pins of all kinds. Small plugs of wool may be used in the ears and nostrils. Any wound or sore should be covered with a wet dressing of strong disinfectant, and a thick pad of wool bandaged securely over.

The deceased should then be clothed in a shirt or gown, or if preferred wrapped in a sheet. White socks or stockings may be used on the feet and a small pillow placed under the head. Cover the body completely with a clean sheet, or, alternatively, the sheet may be turned down on the bed in the usual way, and a handkerchief used over the face. It is better to keep pads or weights over the eyes for the first 24 hours. If the body is a heavy one it is of great assistance to the undertaker if towels are laid under the shoulders, hips and feet. *See* Cremation; Executor; Funeral; Mourning; Will.

**DEATH DUTIES.** This is a collective name for the duties paid on the property left by a dead person. In the United Kingdom, since 1894, they have consisted of the estate duty and the legacy duty. Australia, Canada, and other parts of the British Empire raise revenue by death duties of various kinds. The payment of the death duties is the business of the executors, who are responsible for the valuation of the estate and must satisfy the inland revenue authorities about the accuracy of their figures. *See* Estate Duty; Executor; Intestacy; Legacy Duty; Will.

**DEATH RATTLE.** When vitality is very low fluid collects in the windpipe and bronchial tubes, and the air entering or leaving the chest in breathing, passing through this fluid, produces a gurgling sound, popularly named the death rattle.

**DEATH'S HEAD MOTH.** The largest of British moths may be known by its grey-brown fore-wings mottled with yellow, the yellow hind wings crossed by a broad and a narrow dark band, and by the black-belted yellow hind-body with its central stripe of blue. Most striking is the yellowish patch on the fore-body, which has a curious resemblance, stronger in some specimens than in others, to a human skull. The usually yellow-green caterpillar when fully grown is nearly 5 in. long and thicker than one's finger. It feeds chiefly upon potato-haulm, also on the tea tree and snowberry.

*Death's Head Moth and pupa.*

It does not appear in such numbers or so commonly as to constitute a menace to the potato crop, but the moth has a bad reputation as a honey stealer. In all stages the insect is so large that hand-picking is the surest means of controlling it. *See* Moth.

**DEBT: In Law.** In law a debt is a sum of money which one has contracted to pay as distinct from damages, which is a sum one is ordered to pay for some wrongful act or breach of contract. A debt is due the moment it is contracted, but if it is to be paid on a future date, or on the happening of some event, it is not payable until the date arrives or the event happened.

A debt cannot be sued for until it is both due and payable. Unless there is a contract to that effect, a creditor is not bound to go to his debtor, or to ask him for the money; it is the debtor's business to go to the creditor and pay him. If there is any dispute as to how much is owing, the debtor should tender in cash (not a cheque) the amount he says he owes. A husband is very often sued for debts contracted by his wife. If a wife contracts debts of her own, her husband is not liable for them; but if she purports to act as his agent, he will be liable in certain circumstances. Thus, if she manages his household, she has implied authority to order on his behalf such household requisites, including food and clothing for herself and the children, as are reasonably necessary, having regard to the husband's position in life.

If a husband turns his wife away, or by his cruelty or misconduct compels her to leave him, he is still, unless he makes her a reasonable allowance, liable to pay for board, lodging, and clothing to a reasonable extent, that is, for necessities. If they are separated owing to her misconduct he is not liable for anything.

When husband and wife are living together, and he makes her an allowance for housekeeping or for dress, she cannot pledge his credit. When a wife has once contracted debts with a tradesman, and the husband pays, and he afterwards puts her on a cash allowance, he must warn the tradesman to give no more credit. It is also better to warn the local trade protection society, so that they can circularize their members.

An infant, that is to say in law a person under 21, is, as a rule, not liable under his contracts; but an infant is liable for debts contracted for necessities. These include food, drink, clothing, lodging, and instruction according to the infant's rank in life. Even when an infant owes a debt for clothes (say) which are suitable to his station, the debt may not be enforceable, because the infant may plead that he was already supplied. For instance, if an undergraduate at Oxford ordered an evening suit he would, *prima facie*, be liable to pay for it; but if he could show that he already had two evening suits in good condition, he is not liable to pay for the third. Debts can be attached, i.e. if A owes money to B and B owes money to C, C, being unable to get his debt paid by B, can apply to the court for an order compelling A to pay the debt to him instead of to B, or such part as will satisfy his claim. This is known as a garnishee order. Debts can be assigned by one person to another; but in such cases the assignment must be absolute and in writing.

**DECANTER.** The decanter developed from the wine flasks made in Italy in the 16th century. In the 17th they were made in England, and those of the early 18th century long remained the standard type. In the middle of the century some decanters were made with the vine pattern of grapes and leaves, while others of about the same time belong to sets of Jacobite glass.

*Decanter. Antique decanters in cut glass, showing three of the many beautiful and graceful shapes that are obtainable.*

A little later came the decanter with rings round the neck, this variety, like many of its predecessors, being of finely cut glass. Small decanters were also made to go with a set of liqueur glasses. For them ruby coloured

glass was popular in the early part of the 19th century.

A decanter stand or coaster is an article sought by collectors whether made of silver or old Sheffield plate. They were fashioned to hold a decanter and so prevent the wine from staining the table, and first appeared in England about 1770. Most of them have wooden bottoms and the sides are ornamented in various ways. *See Glass; Sheffield Plate; Silver.*

**DECARBONIZING.** This is the term employed for the removal of the carbon deposit which forms on the inside of internal combustion engines. After a motor car or a motor cycle has been driven for a distance varying between 3,000 and 8,000 miles or so, the engine will show a steady falling off in power, a tendency to overheat and to knock on hills, chiefly due to the deposit that has been formed in the cylinder and on the piston. Such deposit is removable in several ways: by hand, by means of oxygen, or by a mechanical process. The deposit on the piston head can be scraped off with a blunt knife or a screwdriver. It will often be found that a deposit is formed on the piston ring grooves, and this should be carefully removed.

*Decarbonizing. Black and Decker process, in which carbon deposit is removed from the cylinder head by means of a rotating wire brush. (Courtesy of A. Ferraris, Ltd.)*

To remove the deposit on the cylinder head by hand is often a laborious job. The usual tool for the purpose is an ordinary long screwdriver, with which the deposit is carefully chipped off. The greatest care must be taken during the whole operation not to scratch the walls of the cylinder. Much of the deposit formed is due to road matter getting through the carburetter, and the fitting on of a new gauze will often lessen the trouble considerably. The use of the correct oil and avoidance of over-oiling will also go a long way to obviate carbon deposit in the engine.

If a motor car engine has a removable head it is easy to take this off, and then chip and scrape out the deposit in it, and also on the top of the piston. If the engine has not a removable head, a simple, but not very thorough, method is to remove the valve caps; then with a straight scraper the tops of the pistons can be reached, and with a bent one the ends of the cylinders. Scrapers for the purpose can be purchased.

If it is decided to remove the cylinders, they should be raised bodily off the pistons, and then the block can be laid on a bench and the deposit removed. While the pistons are exposed, the opportunity should be taken

to make certain that their rings are free in the grooves, and that the gudgeon pins are tight. When cleaning the tops of the pistons, pieces of rag should be stuffed in the openings of the crankcase, so that the charred matter does not fall into the latter and mix with the oil.

The oxygen process for removing carbon deposit is quicker and sometimes more effective and it obviates the need for dismantling the cylinder. The process depends upon burning the carbon away by the use of an oxygen jet.

The Black & Decker method of decarbonizing, available at a number of garages, consists in the use of wire brushes which are rotated by a powerful high speed electric drill. This method is very much quicker than the ordinary hand scraping process, and the job of decarbonizing can be completed in a day. An allied process is used for cleaning the valves and guides, and reconditioning the valve seats. *See* Internal Combustion Engine; Motor Car; Motor Cycle.

**DECEASED WIFE'S SISTER.** Marriage with the sister of a deceased wife is now lawful in England, as it has been for many years in most British dominions, but a clergyman of the Church of England cannot be compelled to celebrate such a marriage. It is also lawful for a woman to marry her deceased husband's brother. It should be observed that it is still unlawful for a man to marry the sister of a woman from whom he has been divorced, so long as the divorced wife is living. The Act of Parliament legalising marriage with a deceased wife's sister came into force in 1907.

**DECIMAL SYSTEM.** The decimal system of coinage and of weights and measures, also known as the metric system, and so called because it is based upon an arbitrary unit, the metre, is one by which everything is reckoned in tens and multiples of ten. It has not been adopted in Great Britain, but the traveller meets with it when he goes to France and some other foreign countries. The franc consists of 100 centimes, and goods are weighed by the gramme and measured by the metre, as for length and breadth, and by the litre as for volume, all these being used also in multiples of ten and in divisions of ten, for example, decalitre, decimetre.

**DECK CHAIR.** This name is used for a light chair which folds up. The frame is made of crossed pieces of wood, across which canvas is nailed to form the seat. Some are made with a canopy for protection from the sun and some without, but in both cases the framework is the same.

A chair of this kind is easy to make. A rough idea of the finished chair is seen at Fig. 1. From Fig. 3 the general method of construction will be clear, and the plan at Fig. 2 shows exactly how the article (without canopy) will appear when folded. These chairs are made in ash, beech, birch, and sometimes oak. Any tough wood will serve the purpose, but obviously the timber must be sound. The parts required are few, and

are given in the cutting list appended.

*Deck Chair. Fig. 1. Folding chair and canopy which can be easily made by the amateur.*

The two seat rails (A) are shown 17½ in. apart over all, and are joined at the ground end by a turned rail (D). At the seat end they are joined by the flat rail (E). The seat rails (A) are notched with, say, five notches, which adjust the lean of the back. These notches must be deep enough to take the square part of cross bar (J) without any chance of slipping. The leg rails (B) are 19 in. apart over all. At the ground end they are joined by the turned rail (F), and at the top end by the flat rail (G). The leg rails are pivoted to the seat rails at H (Figs. 2. and 3) by means of bolts. The position must be determined after the framework is made, but the bolts come approximately 12 in. from the front end of A, and 13½ in. from the lower end of B.

Thus far it will be seen that the chair is made of two frames: the inner one consisting of A, D, and E, and the outer one of B, F, and G. This may be followed from the plan, Fig. 2. The frames should fit closely, but sufficiently free to permit of metal washers being placed between them at the bolts.

From a glance at Fig. 2 it will be seen that the chair has a kind of third frame, consisting of the two support rails (C) and their cross bar (J). The support rails are bolted to the legs (B) about 16½ in. from the top end, and are joined by a cross bar (J) which engages the notches cut in the seat rails (A). The cross bar is usually turned, but with square blocks left to rest on the notches. If this plan is adopted it should be 1 ¼ in. square; otherwise it may be ⅞ in., turned throughout.

A sketch of the usual method of bolting is given at Fig. 5. To prevent friction, the inner disk of the bolt is sunk into the wood, and the end of the bolt riveted to the disk. A thin washer is placed between the rails. The canvas selected for the seat ought to be stout and durable. It is folded over the rails (E and G) and firmly tacked (as Fig. 6). When the seat is folded (as Fig. 2) the canvas should lie practically flat, but not strained tight.

A canopy is somewhat cumbersome and is apt to attract earwigs and other insects, but in bright weather it is of great advantage when reading out of doors. If a canopy is wanted, the parts required are these (Fig. 4): The arms (K and L) are bolted to the leg rails (B) about 9 in. from the end, the method of bolting being indicated at Fig. 7. Each pair of arms is joined by a turned rod (M and N), and the canvas covering—say 6 in. deep—may be tacked on or left loose.

## DECK CHAIR

	Long		Wide	Thick
	ft.	in.	in.	in.
2 seat rails (A)	3	4	1½	¾ or ⅞
2 leg rails (B)	3	10	1½	¾ or ⅞
2 support rails (C)	1	9½	1½	¾
Cross turned rail (D)	1	5½	⅞ diag.	
Cross seat rail (E)	1	5½	1½	¾
Cross turned rail (F)	1	7	⅞ diag.	
Top rail (G)	1	7	1½	¾
Cross bar (J)	1	9	1¼	1¼

## THE PARTS REQUIRED FOR FIG. 4:

	Long		Wide	Thick
	ft.	in.	in.	in.
2 back arms (K)	1	4	1¼	⅝
2 front arms (L)	1	10	1¼	⅝
Back turned rod (M)	1	9	⅝ diam.	
Front turned rod (N)	1	10½	⅝ diam.	

*Deck Chair. Figs. 2-7. Constructional diagrams showing how the various parts of the folding chair and canopy should be joined and fitted together.*

# DECEMBER

## What to do in the Garden

### Flowers

Minimum temperature for greenhouse 45°

Hyacinths for forcing in fibre may still be planted

Water all plants sparingly; dry heat is better than moist

Pot up seedlings of cyclamen, cineraria, and calceolaria, also autumn cuttings of fuchsia and pelargonium. i.e. geranium

Give as much air as possible when the shade temperature outside the house is well above freezing point

Plants which have been temporarily shifted from the greenhouse to the drawing room, for the purposes of table and other decoration, should be sprayed with tepid water when they are replaced in the house

### Fruit

Prune all trees during mild spells of weather

Train and shape wall trees in the desired directions

In severe weather cover the stems of stone wall fruit, i.e. peaches, etc., with hay or straw bands

Plunge vines in pots of leaf-mould for early forcing, and put them in a temperature of 70° for fruit in spring

Spray fruit trees with one of the tar-oil washes to cleanse the branches and kill the eggs of pests

Prune vines under glass by cutting back last summer's shoots to within two buds of the base

Planting of all fruit trees may be proceeded with in the open air, so

long as the ground is free from the effects of frost

### Vegetables

Dig, trench, and manure ground freely, so that the frost may percolate and sweeten it

Seakale roots may be forced in boxes of soot in a dark, rather warm place

Celery plants should have the last earthing up

Cauliflower may be cut and stored on the concrete floor of a shed if severe frost is threatened

Rhubarb, asparagus, and radishes may be forced now

Start early potatoes under glass in moderate heat for planting out

## Food in Season

### Fish

Barbel; bream; brill; carp; cod; dory; eels; flounders; gurnet; haddock; hake; halibut; herrings; ling; mackerel; mullet; perch; pike; plaice; salmon (Dutch and Canadian); skate; smelts; soles; sprats; tench; turbot; whiting

### Shellfish

Crabs; crayfish; lobsters; mussels; oysters; prawns; scallops; shrimps

### Meat

Beef; house lamb; mutton; pork; veal; venison

### Poultry and Game

Black game; capercaillie (till 20th); capons; chickens; ducks; fowls; geese; grouse (till 18th); hares; landrails; larks; partridges; pheasants; pigeons; pintail; plover; ptarmigan; pullets; rabbits; snipe; teal; turkey poults; turkeys; wildgeon; woodcock

### Vegetables

Artichokes (globe. Japanese and Jerusalem); beetroots; broccoli; Brussels sprouts; cabbages; red cabbage; cardoons; carrots; cauli-

flowers; celeriac; celery; chervil; chicory; endive; horse-radish; greens; leeks; mushrooms (cultivated); onions; parsnips; potatoes; salsify; savoy; Scotch kale; seakale; winter spinach; tomatoes; turnip tops; and watercress

### Fruit

Almonds; apples; bananas; chestnuts; cranberries; dates; figs; filberts; grapes; hazelnuts; lemons; medlars; melons; oranges; pears; pineapples; plums (Californian); pomegranates; raisins; rhubarb (forced); walnuts

## Notes for the Month

DECEMBER 25.—Christmas Day. Quarter Day

DECEMBER 26.—Boxing Day. Bank Holiday (not in Scotland)

DECEMBER 31.—End of the year. Various licences expire

**DECORATION:** In Cookery. The appetising appearance of food is enhanced by decoration and garnishes. The former term usually denotes ornamental colour touches to the food itself, while the latter more particularly refers to accompanying fruit, vegetables, forcemeat balls, croûtons, parsley, etc., which trim the dish.

To decorate hors d'oeuvres coloured savoury butters such as anchovy or maître d'hôtel may be put through a forcer. Coralline pepper, strips of pimento, shredded anchovies, finely chopped parsley, gherkins and truffles, the white of hard-boiled egg cut into shapes and the sieved yolk are all useful for ornamenting cold savoury dishes. Olives are decorative when stuffed with anchovy butter and placed on a ring of white of egg, a larger ring of beetroot and a round of brown bread and butter. Radishes may be cut into flower shapes, with pieces of olive to form leaves and used to decorate the centre of small individual Russian or other salads. A glacé cherry or a black grape is placed in the centre of a prepared grape fruit, which may also be cut into points round the edge with a sharp garnishing knife.

Soups may be given a decorative touch by using a pleasing colour contrast. Chopped parsley is suitable for a tomato or white purée, chopped mint for pea soup, cooked asparagus heads or green peas for fish soups, small fancy shapes of Italian pastes or dried vegetables for clear soups.

Even the usual trimmings of lemon and parsley can be tastefully placed on whole fish such as turbot or plaice served hot. The lemon should be cut into very thin half slices which overlap each other down the centre, broad way on, and down the sides are placed so that the semicircles make a scalloped edge to the fish resting on a parsley border.

**Decorating Cold Service Dishes.** Mayonnaise of lobster or salmon lends itself to effective dishing. The sauce may be reddened with the aid of tomato puree or greened with vegetable colouring. A flower design can quickly be made by using beetroot cut into thin petals for red flowers and shredded almonds for white petals, with yolk of egg for flower centres, pieces of cucumber peel or gherkin can be cut for leaves or stalks, while capers maybe used for buds. A basket effect for the flowers can be made with crossed strips of anchovy. Such finishing touches bring distinction to a buffet supper party or a summer luncheon. Aspic jelly cut into leaves supplies ornament for galantines and pressed beef, together with vegetables, cut into dice and stars, and butternut through a forcer.

Cold sweets such as flans, trifles and fruit jellies can be decorated in much the same way as cakes, except that whipped cream may be more lavishly used. Besides patterns made from crystallized fruits and angelica (q.v.), crystallized flowers are a suitable decoration in such cookery and also for chocolate and other confectionery. These flowers can be obtained at any good grocery store, and they need to be of good quality, inferior preparations often being either faded or are too highly coloured.

The process of crystallizing requires care and some

knowledge of sugar boiling, but it is not too difficult to be done at home. Rose petals, orange flowers, lilac, cowslips and violets may all be crystallized. A simple method is to pour over the flower or flower petals a cooled syrup made from refined sugar and water, allowing 3 lb. sugar to each lb. flower petals. The syrup must be boiled to 230°. Then place the petals in a cool oven; when they begin to candy lift them out on to tray and sprinkle with sugar.

Such flowers with candied fruits cut into small pieces form effective decorations with thin strips of angelica arranged to resemble stalks and leaves. Chopped nuts that are sprinkled with a little colouring liquid are also useful.

**Ornament for Cakes.** For Christmas or birthday cakes any greeting can be written on the top of the cake with the aid of a forcing tube and a little icing. Candle-holders in sugar icing are obtainable for children's birthday cakes in the form of tiny roses. Large decorated cakes usually have a groundwork either of royal or French icing before the ornamentation is arranged in place.

*Decoration. Cake ornamented with flowers in icing.*

If crystallized fruits and flowers form the main decoration, what little piping is required should harmonize with the colours of the fruit or flowers. When decorations are laid on the icing they will adhere if it is not quite dry, otherwise they must be fastened with a small portion of royal icing or joined by piping in a pattern. Chopped nuts are secured with warmed jelly or jam lightly brushed over the cake before they are sprinkled on.

Sandwich or layer cakes have a cream or rich filling between each layer of cake. French or butter cream icing forms the covering, and they are decorated in a manner suitable to the distinctive character of the flavouring. A walnut cake, for instance, would have halves of walnut to ornament it, or a coffee cake would be finished with coffee icing.

Almost any description of icing can be ornamented with a fancy piping, silver dragees, coloured sugars or comfits. Almonds and pistachios sliced and formed

into the petals and leaves of flowers are attractive. Small cakes may either be baked in various-shaped little tins or may be cut out of a slab of Genoese, sponge or chocolate mixture, and the trimmings formed into Russian cake. Small portions of the Genoese may also be shaped, moistened with sherry, coated with marzipan and coloured to resemble such fruits as apples and peaches, with pieces of almond or angelica for stalks.

## DECORATION: IDEAS FOR THE HOME

### Some Aspects of the Trend of Style

For further information see the articles Ceiling; Painting; Panelling; Paperhanging. See also Christmas; Colour; and the entries on Adam Style; Chippendale Style; Queen Anne Style, etc.

Never before this period has there been such a general interest in attractive homes and such conscious desire to achieve good interior decoration by simple means. It is in the comparatively small houses and flats that the great movement towards practical beauty is being quietly carried on. To-day, as in the day of Robert and James Adam, beautiful houses are being designed—equally expressive of our time as theirs were of the 18th century. Built and decorated by noted architects, in spite of their costly nature such houses are not so far removed to-day from general appreciation as their prototypes were then. They are described and pictured in magazines and papers, while the ideas and designs originating in these buildings percolate through the brains of the army of artists and workers in the decorative trades. These in turn all help to place quickly on the market, by the aid of modern machinery, effective adaptations which will be within reach of the ordinary homemaker.

Sometimes old houses are reconstructed beyond recognition inside and out, or the architect-decorator will merely get rid of offending interior features and bring all else into, a pleasing scheme by clever adaptations and innovations suitable for life to-day. Again these useful and beautiful ideas are handed on for inspiration to the many.

**Architectural Decorations.** In quite a number of the small recently built houses architects have made the choice of decorations, and even of furnishings, comparatively simple. Natural and artificial lighting has been considered, also the well-balanced heights of ceilings, and doors, and the sizes and shapes of windows. Where there is a horizontal line of panelled dado it is frequently continued in built-in cupboards, fireplace and corner seat.

In another type of room with light, painted walls, bookshelves are a decoration in themselves. They are placed either side of the chimney piece in recesses, the tops of which are architecturally designed to suit the style of the furniture, and the back of the shelves and borders of the recess painted in a colour contrast to the walls and to match the skirting. Such recesses, or built-

in cupboards with glazed doors, somewhat reminiscent of Queen Anne style, are also utilized in dining rooms to hold glass and china, and a delightfully decorative touch is given to them, especially if they are placed in dark corners, by an inside coating of silver paint, the silver note being repeated elsewhere in the room in lighting fittings, curtain trimmings, or other paintwork. In yet another style the architect will, with utmost severity, insist on square effects, even refusing architraves to doors and windows and a shelf to the chimney piece, but making up for this by beauty of texture in woodwork and flooring.

A home to be lovable and livable in to-day cannot be like a museum, however keen the owner is on a period style. On the other hand, not to avail oneself of the rich heritage of past beauty in architecture, decoration and furnishing designs is to be either lacking in culture, or an extremist in the craze for startling novelty at all costs. Strictly period rooms become absurd when provision has to be made for the wireless, the gramophone, the radiator, or even the telephone and electric lighting fixtures, while there is something too unfriendly to most homeloving people in the room of squared lines, the elimination of all gracious movable furniture, and in substitutes reminiscent of ship's cabins and saloons.

*Decoration. Papers of various designs and textures. Top left: imitation pine. Right: green wavy lines on silver, vertical grain. Centre: imitation folk-weave in browns and fawn. Lower left: modern flower design, red and green on beige. Right: scraped gold and cream, washable. (Courtesy of Sanderson & Co.)*

**Texture as Decorative Patterns.** Apart from extremes, one of the pleasantest things about the various materials now largely employed in decoration is that they can form beautiful backgrounds for

genuine old furniture, for reproductions, for Oriental pieces and for modern chairs and tables. There is already a breaking away from startling colour schemes—except on rare occasions when the furniture demands it, in the extra sitting room where experiments are interesting, and in otherwise gloomy halls, where such decorations may be cheery and inviting and do not weary the inmates of a house as they might in a living-room in constant use. Another exception is when brilliant wall paintings are executed by a mural artist, but such a decorative treatment is necessarily rare in the ordinary home.

Colour for decorations should be pure and beautiful. The trend is away from fierce contrasts or primary hues—except here and there as colour notes—and towards delicate blendings, tone-in-tone effects in woven fabrics, marbled, mottled, grained, blurred texture effects in paint, woodwork, plaster, wallpapers and floorings. Pale colours are usual, but white is no longer considered helpful in the decoration of ceilings, friezes or woodwork. Rough surfaces, which respond to the play of light and shade, are seen above pine panelling, stripped and waxed. Where walls are painted, a subtle colour pattern is sometimes obtained by an undercoat of a deeper shade than that eventually required, and over this two thin coats of white paint, which in turn is rubbed down to let the original colour show through at the edges of panels and on mouldings. Marble texture is imitated, or two shades of a neutral tone are stippled, to give variety to the walls; or again the grain of a wood is copied by means of paint or reproduced in wallpaper designs. Surfaces are not merely flatly covered, but interestingly broken up by patterns founded on texture.

**Motifs and Pilasters.** Wallpapers, too, have advanced in practical use and beauty, and are now obtainable in really washable varieties. For those who do not wish for the expense of painted walls, there is the choice of a patterned paper in one of the simple restful designs, using a paler shade of the ground colour with which to distemper the ceiling; or a paper in a mottled, flecked or woven texture effect may be selected in a cream or pale shade with an applied decoration. The first illustration shows various textures and patterns of modern wallpaper with which intricate colour schemes may be built up. Large designs and bright colours are well suited to the proportions of large rooms. Strong contrasts are often helpful in a poorly lighted room. (*See Colour Schemes.*) Here modern wallpaper can be most valuable: choose a paper containing several colours and an interesting motif, repeat these in paintwork, chair covers, curtains and carpets, and you have a surprisingly harmonious room. Nature provides endless suggestions for such schemes.

The other illustration shows a panel, or pilaster, which can be placed to create interest where desired. The styling, or strips, with which such panels are bordered is obtainable with an outline of gold to emphasise a gold-flecked wallpaper suitable for the decoration of a charming sitting room with paintwork

in the softest shade of delphinium blue. These pilasters are also designed with other tall flowers, such as foxgloves. Plain wall space is essential on either side of such a decoration, which should not be overdone—two pilasters in a small room may be sufficient. Applied decorations can also be obtained which are cut out to form central sprays for simulated panels, or groups as skirting or frieze borders. Motif sprays for corners of walls and extending over the ceiling corners may also be used with decorative effect, but discretion is necessary in blending the whole scheme of the room harmoniously, or such ornamentation may be disturbing rather than pleasing.

*Panel effect obtained upon a gold-flecked wallpaper by an applied decoration of delphiniums. The borders are outlined in gold and should have plain wall space on either side. All paintwork is in soft blue. (Courtesy of Sander-son & Co. and Thomas Wallis & Co., Ltd.)*

**DEED:** In Law. A deed is a document which is sealed and delivered by the person or persons executing it. A deed is necessary for a lease of upwards of three years; for a conveyance of land; and for a contract or promise made without valuable consideration. By valuable consideration is meant money or money's worth, and future but not existing marriage—marriage is always reckoned valuable consideration. If a husband desires to settle anything on his wife after marriage, it should always be done by deed.

The sealing of a deed is generally done by a wafer or piece of sealing-wax being affixed to the paper or parchment, the maker of the deed touching it with his finger; but this, though advisable, is not necessary.

In addition to sealing, a deed requires delivery before it becomes operative. By delivery is meant that the maker of the deed parts with it unconditionally. So that if anyone signs and seals a deed purporting to sell his house, and hands it to his solicitor, not to be parted with by him until he gets the money, there is no effective delivery of the deed; it is only delivered when the solicitor hands it over to the purchaser or his agent in exchange for the money. *See Agreement.*

**DEERHOUND.** The deerhound is a member of the greyhound family, resembling the coursing dog in general lines, but of more robust build, and standing several inches higher. The coat is shaggy, harsh and

wiry, the length being about 3 or 4 in. A soft, woolly coat is undesirable. A dark blue-grey is preferred, but also recognized are dark and light greys, brindle, yellow and sandy-red or red-fawn. White often appears on the chest or toes, but it is not liked, and a white blaze on the head or a white collar would disqualify in the show ring.

*Deerhound. A fine specimen of this graceful breed. (Photo: Ralph Robinson)*

The front legs must be perfectly straight, hind legs well bent, with great length from hip to hock, very deep chest, and a well-arched loin. The neck should be long and shoulders sloping. Deerhounds are somewhat delicate as puppies, but when once through distemper they are hardy. A dog measures from 28 in. to 30 in. at the shoulders, bitches being usually about 2 or 3 in. less. *See Dog.*

**DEFORMITY.** A departure from the normal shape or position affecting the body, or any part of it, is a deformity, e.g. dwarfism, spinal curvature, club foot, wry neck, fingers in excess of the usual number, hammer toes, etc. Deformities may be congenital, or may be acquired in the course of life through injury or disease. In addition to unsightliness, most deformities interfere to a varying extent with the proper function or use of the part. Various methods of treatment may be adopted according to the nature of the case, including operations, the use of an apparatus, exercises of all sorts, massage, electricity, etc. *See Artificial Limbs; Club Foot; Hammer Toe, etc.*

**DELAINE.** Originally called mousseline delaine, or wool muslin, delaine is not invariably all wool. The weave is plain, the fabric is crisp to the touch, and usually bears a printed design somewhat like a cotton voile. The crispness is the outcome of a chemical process which makes the fabric nearly unshrinkable.

Good delaine wears well, and does not easily soil; it creases less and is warmer than cotton. Used as casement curtains, it requires washing less often than cotton.

Delaine requires careful washing if it is to retain its softness. Launder in the same way as flannels, and in order to brighten up the colour add a little ammonia to the last rinsing water. Iron delaine while slightly damp.

**DELFT WARE.** As introduced at the Dutch town of that name in the 17th century, Delft ware was a soft-paste faience with a tin-enamel surface which skilfully imitated the effect of Chinese porcelain before it was successfully reproduced in true glazed hard-paste china at Dresden. The secret of real Delft is the tin-

enamel, usually painted in blue on the white surface while still soft. Its vogue lasted to the end of the 18th century, when it was displaced by the technical improvements of the Staffordshire potters.

*Delft. Dish of Dutch earthenware, Oriental design, dating from the 18th century (Victoria and Albert Museum)*

The earliest pieces, in red clay, had biblical and rustic scenes in blue, or blue and purple.

Some excellent work was produced on a yellow or pale-brown body, enamelled in rich colours, with polychrome imitations of Japanese designs. Old Delft is recognizable by its smooth enamel, which seldom crazed, whereas modern Dutch tiles are ordinary glazed earthenware. Among more than 150 marks, mostly initials, dates and other devices, only one shows the place-name.

The manufacture of enamelled Delft became popular in England early in the 18th century, before porcelain was attempted. The first in the field was Lambeth, whose fabric was harder, coarser, and with a more opaque, enamel than Dutch. From this it can be distinguished by its being decorated after firing the enamel, by its rosy tinge, and by its slight glaze.

The Delft ware which started later at Bristol often has a bluish-green tinge in the thin enamel. Chinese imitations were favoured styles, and fireplaces were adorned with pairs of dog and cat pictures, each of nine tiles. Liverpool later still produced Delft ware. *See Faience; Lambeth Ware; Liverpool Pottery.*

**DELIRIUM.** The state of mental excitement occurring in acute febrile disorders, e.g. pneumonia and other conditions, is known as delirium. The onset may be sudden, or to begin with the patient may talk in his sleep and may be somewhat confused when he wakes. He fancies he sees strange things about the room. If spoken to he may answer apparently rationally, but almost at once he wishes to talk of his fears and fancies. All this time he is tossing restlessly, and may attempt to get out of bed, and too often such patients have managed to throw themselves out of a window. He may imagine that someone in attendance on him is an enemy who is attempting to do him an injury, as by putting poison in his food. This state may go on for some days, and then the patient begins to sleep and may wake up more rational.

Children who are fevered become delirious very easily, but this need occasion no undue alarm. Delirium may come on after severe injuries in healthy people quite apart from any addiction to alcohol. It begins after about 48 hours and is usually associated with septic poisoning. Poisoning with belladonna and

similar drugs almost always produces this condition. Acute delirium, or Bell's mania, is a form which affects women mainly, and a family history of insanity is common.

The treatment will be supervised by the doctor. The room should be kept well aired, darkened, and as quiet as possible. The patient must be constantly watched, lest he do harm to himself or anyone else. Sponging with warm water, a pack, or, when practicable, a warm bath, are useful soothing measures. The forehead may be bathed with vinegar and water, or an ice bag may be applied to the head. A sleeping draught may be necessary. The diet should be fluid.

Sometimes active delirium passes into what is known as the typhoid state, and this also occurs apart from previous active delirium at the end of any severe illness when the vital powers are sinking low. The patient lies with the eyes half open and keeps muttering to himself. The fingers are constantly picking at the bed-clothes, and he may make movements in the air as if he were attempting to catch imaginary flies. The tongue is dry and covered with brown fur. Here the whole aim is to maintain the patient's strength. Nourishment, in liquid form, must be given at short intervals night and day. The sick-room must be aired, but it should also be warm, and hot water bottles must be used if necessary, especially in the early hours of the morning.

**DELIRIUM TREMENS.** This is an acute temporary insanity developing in the habitual drinker. The common symptoms are delusions of a suspicious and fearsome character. There is a constant babbling or shouting, a trembling of the hand and tongue, and inability to sleep. The patient struggles violently with his attendants, and frequently resists all attempts to feed him. Occasionally there is fever, the pulse is weak, and finally the patient may pass into a state of dangerous exhaustion.

Every effort must be made to make him sleep. He should be kept flat on his bed, if necessary by straps or long bath towels, tying down his arms and legs to the sides of the bed. Unremitting observation and care are essential, as if left to himself the patient may commit suicide, or do some act of violence to another person. He must be carefully guarded from chill and exposure, and his strength kept up by giving every two hours small amounts of strong soups, meat broths, and milk. Chloral or some other hypnotic may be required to induce sleep; but such a remedy will only be used by the doctor's direction. An attack of delirium tremens usually passes off in from two to three days under appropriate treatment.

**DELPHINIUM** (Perennial Larkspur). The delphinium is one of the most beautiful of all hardy herbaceous perennials. The plants grow from 3 to 6 feet, or more, high, and bear tall spires of bloom in shades of lavender, blue, purple and mauve. They should be planted in autumn or in spring in deeply dug and well manured soil and left undisturbed for many years. If an increased stock is required it is better to

raise seedlings from seeds sown in frame or greenhouse in March than to disturb old plants. Or the young shoots may be taken off in spring, when about 3 inches high, for insertion as cuttings in pots of sandy soil under a propagating case in frame or greenhouse. When well developed, delphiniums make a magnificent show and are in full beauty in June. An annual top-dressing of manure in spring is beneficial. When the young shoots are pushing through the soil in spring they are apt to be eaten by slugs. A layer of ashes placed round about them affords protection from these pests.

There are two chief types of delphinium, the tall, vigorous varieties, and those of the belladonna type, which are of branching, slender growth and 3 to 4 feet high. Beautiful varieties of the latter are Capri, sky blue; Lamartine, purple-blue; Moerheimii, white; and grandiflorum, light blue.

*Delphinium. Double variety of this handsome border plant.*

Varieties of the vigorous tall-growing delphinium are innumerable and every year fresh ones are introduced. The following are particularly fine: Blue Boy, blue; Millicent Blackmore, light blue and mauve; Mrs. Townley Parker, blue and white; Sir Douglas Haig, dark blue and purple; Rev. E. Lascelles, dark blue and white; Nora Ferguson, light blue, mauve and rose.

The annual delphinium, popularly called larkspur, is raised from seeds sown out of doors in March-April where the plants are to bloom in summer. They reach a height of 2 to 3 feet and have flowers of various colours. One of the most beautiful is the rose-pink variety. *See Border.*

**DELTA METAL.** The alloy known as delta metal, and noted for its strength and toughness, consists mainly of copper and zinc with some iron and tin. It can be cast, drawn, or rolled, and can be forged at a dull red heat. When finished it takes a high polish, and does not tarnish so readily as brass, nor is it so susceptible to verdigris. Delta metal is used in the manufacture of certain types of wire rope. When drawn to various sections or extruded, it is suitable for ornamental mouldings found on shop fronts.

**DELUSION.** In every form of mental unsoundness delusions may be present, arising chiefly from inability to correct the imagination by what should be the

normal judgement. The person drifting into delusional insanity is often at first very suspicious, touchy, and eccentric.

Although delusions are of infinite variety, they roughly group themselves into two classes—delusions of persecution and delusions of exaltation. To the former class belong those of the person who thinks that other people are conspiring to injure him. A man in this state is often very dangerous, for he may attack anyone whom he suspects. In delusions of exaltation a person has extraordinary ideas of his own greatness. He may believe himself to be a prophet, a king, the greatest orator, poet, military genius, etc., in the world. Very often these delusions of exaltation follow delusions of persecution.

In the case of old people making their wills, it is often a matter of great importance to decide whether they are influenced by delusions; for a man may believe that he is made of glass, and yet make his will with sound judgement. But if he suffers from insane delusions with regard to the conduct of his relatives or the amount of his property, his will is likely to be faulty. *See* Insanity.

**DEMULCENT.** White of egg, honey, starch, glycerin, gelatine, liquorice, olive oil, are examples of demulcents used in medicine. Their object is to protect and thus lessen irritation of mucous membranes; so in corrosive and irritant poisoning thin arrowroot or gruel, white of egg, or olive oil is given freely. *See* Gelatine; Honey; Starch.

**DENTIFRICE.** A preparation for cleaning the teeth may be in the form of powder, paste, or liquid. In the first of the following recipes for a powder the carbolic acid should be mixed with a little of the kaolin in a mortar before adding the other ingredients. It is necessary to sift the powder through a fine sieve. The antiseptic tooth paste is made into a paste with as much as may be required of a mixture of glycerin 4 oz. and water 1 oz.

#### CARBOLIC

Kaolin, 6 oz.; infusorial earth, 2 oz.; quillaia extract, 1 dram; carbolic acid, 2 drams.

#### SAPONACEOUS

Powdered white soap, 1 oz.; powdered orris root, 2 oz.; precipitated chalk, 5 oz.; rose geranium oil, 10 drops.

#### ANTISEPTIC TOOTH PASTE

Precipitated chalk, 5 oz.; powdered soap, 5 oz.; salicylate of soda, 2 drams; rose geranium oil, 30 drops; wintergreen oil, 20 drops.

#### LIQUID DENTIFRICE

Quillaia bark, 4 oz.; glycerin, 3 oz.; alcohol, 5 oz.; carbolic acid, 1 dram; rose geranium oil, 10 drops; clove oil, 10 drops; cassia oil, 10 drops; tincture of rhatany, 1½ oz.; rose water, 1½ pints.

The quillaia bark, glycerin and alcohol are shaken together occasionally for 4 days and then the other

ingredients are added. These are again shaken occasionally for a period of 4 days, and then the liquid is filtered through absorbent paper. A few drops of the liquid dentifrice on a wet toothbrush is used night and morning. *See* Artificial Teeth; Teeth.

**DENTIL.** Dentils are the small toothlike ornaments found in furniture fashioned by Chippendale, Hepplewhite, Sheraton, and their imitators. Sometimes each tooth is cut away in the centre, thus leaving a raised or filleted edge, and less frequently there are dentils which are deeply undercut. One of the most frequent blemishes found on pieces of furniture of the late 18th century is the absence of a few of these dentils, which have been knocked off through careless handling.

**DEODORANT: Its Uses.** Substances which mask or absorb foul odours are termed deodorants. Examples are smoke from brown paper or tobacco; perfumes like eau de Cologne; oil of eucalyptus and thymol; hydrogen peroxide, wood charcoal, potassium permanganate and chloride of lime. *See* Antiseptic; Disinfectant.

**DEPILATORY.** A preparation that is used for removing superfluous hair is known as a depilatory.

Barium sulphide is the active principle of most of the depilatories on the market. The following is a simple prescription, cheap and readily made up:

Barium sulphide	2 parts
Starch	4 "
Orris root	2 "

Make a little into a paste with water and apply to the hairy parts. Leave on for 5 min., or until the skin begins to tingle slightly, then scrape off with a bone knife and wash the part with cold water. Dry, and apply a little boracic ointment or cold cream to the skin.

The treatment may be repeated from time to time as the hairs grow again. The paste should not be left on longer than 5 min., and it should not be persisted with if it causes irritation of the skin. With shaving, it shares the disadvantage of possibly making the hairs grow stronger and stiffer. *See* Electrolysis; Hair.

**DEPOSIT: Of Money.** A deposit is a sum of money placed in a bank with the intention that it shall remain there for some time. This distinguishes it from money put into a current account. Banks give receipts for money taken on deposit and pay interest on it, generally 1 per cent, below bank rate. Money placed on deposit cannot be drawn out by cheque, nor usually without notice being given. In another sense a deposit is a sum of money paid down when a contract is made to show that the purchaser is in earnest and as a guarantee that he will carry out his share of the undertaking. It may take the form of 5 or 10 per cent, on the amount of the purchase money. *See* Banking; Contract; Savings Bank.

**DERBYSHIRE NECK.** This name is sometimes used for the complaint known as goitre. It was believed to be specially prevalent in that county, and was due to the peculiar properties of the water. *See* Goitre.

**DERMATITIS: A Skin Affection.** The general name of dermatitis is used to denote any inflammation of the skin. The area affected may be reddened, swollen, hot and painful, as is the face after severe sunburn; but in other cases more or less numerous papules appear. These may be small, like pimples, or considerably larger; or blisters may be found, a small blister being known as a vesicle and a large one as a bulla. If a vesicle is filled with pus or matter it is described as a pustule. After the skin has been reddened, with or apart from the formation of papules, it may become scaly if vesicles or pustules are present they will dry up as crusts or scabs. Itching may possibly accompany any of these changes.

Some forms of inflammation are given distinctive names. A chronic inflammation with papules covered by silvery scales is known as psoriasis. Grouped vesicles such as often occur at the corner of the mouth with a bad cold constitute herpes, and inflammation which is characterised by large bullae is styled pemphigus. Eczema is an inflammation of the skin in which the skin is reddened and in which papules, vesicles, and pustules may all appear.

The term dermatitis is used in speaking of inflammation when it has been produced by a definite known agent. This may be heat, light, X-rays, cold, drugs taken inwardly, e.g. bromides, iodides or arsenic. It may be due to the action of poisonous plants, e.g. some primulas or poisonous ivy when they come into contact with the skin, or the handling of irritating substances in the course of many occupations, as by paraffin workers, steel grinders, etc.

Other forms of the condition are dermatitis exfoliation, in which the skin all over the body throws off crops of large and small scales; dermatitis herpetiformis, so called because its inflammatory manifestations tend to be grouped like the vesicles in herpes; and seborrhoeic dermatitis, in which rounded reddish or salmon-pink scaly patches appear on the back, chest, face or elsewhere. It is associated with dandruff. Much may be done by scrupulous cleanliness to prevent the occupational form of the disease. Unless the case is very slight the doctor should be consulted. In slight cases zinc ointment may be useful. *See* Eczema; Skin.

**DESENSITIZER.** Desensitizers are substances which reduce the light sensitivity of photographic emulsions. Their chief application is in the lowering, before or during development, of the high speed of modern negative materials, so that these may be developed without risk of fog in a light of greater brightness than that which must be used for the non-desensitized materials. Panchromatic plates and films, for example, are so colour sensitive that normally they have to be developed in darkness. After desensitizing,

however, development can be carried out in a light of sufficient brightness to enable the operator to see the development process clearly.

The ideal desensitizer should be a stable, colourless or non-staining substance, without any harmful action on the exposed plate or film, and should be equally effective in solution as a fore-bath or as an addition to the developer. This ideal desensitizer has still to be found, but a few practical substances are available commercially, the most widely used being Desensitol (marketed by Ilford, Ltd.), Pinacryptol Green and Pinacryptol Yellow.

Desensitol stains the negative a deep red, but this is got rid of by increasing the period of washing; a faint pinky stain does no harm to the negative beyond increasing the time in printing. Any difficulty in getting rid of the red stain can be overcome by the addition of an acetic acid and alum clearing solution to the fixing bath.

Pinacryptol Green is an efficient and rapid desensitizer, and shows little tendency to stain. Its disadvantages are a tendency to cause chemical fog and slight loss of image density. Pinacryptol Yellow is probably the most successful desensitizer, being rapid and powerful in action, with no staining action, and can be used safely with colour plates or films.

Remember, however, that no desensitizer destroys completely the original sensitivity of the photographic material. *See* Developing.

**DESERTION: In Law.** In England, desertion for three years is one of the grounds for divorce by either husband or wife under the Matrimonial Causes Act, 1937. If a wife is deserted at all, she is entitled to an order from the magistrates for maintenance. A husband who goes abroad temporarily on lawful business, or State service, though absent for three years, is not guilty of desertion, because it must be proved that he has deserted (i.e. abandoned) his wife, and not merely that he has been absent from her, which absence may have been due to business or some other perfectly legitimate reason.

A father who deserts his children can be summoned for not maintaining them, provided they are under 16 years of age or are, by reason of infirmity, whether mental or bodily, incapable of maintaining themselves. *See* Child; Cruelty; Divorce; Separation Order.

**DESICCATION.** This manufacturing process is applied to articles of food to render them suitable for storage. All moisture being extracted, the articles are considerably reduced in bulk. Desiccated coconut is the commonest commodity thus produced.

**DESK.** In its origin a desk is a table for writing on, some being flat and others sloping. While the plain form was retained for use in schools, something more elaborate was introduced into the home. A drawer was added, and there are some fine examples in which the table with a single drawer beneath it is supported by carved legs or columns. Some beautiful pieces of this

type were made in Buhl work. From this the familiar writing-table was evolved, the pedestals or supports being formed by drawers, one upon another, on either side, leaving a space for the knees between.

The bureau is one form of desk, while another is the roll-top desk, the idea of which originated in France in the 18th century. The bureau du roi, which has been described as the finest piece of furniture in existence, is of this type. It was made for Louis XV by several of the greatest artists and designers of the day, and is now in the Louvre. *See Bureau; Writing Table.*

**DESPATCH BOX.** A despatch box is made of tin or sheet metal, and usually contains separate compartments for stationery and a lift-out tray, beneath which is a space for storage of important documents. The best qualities are fitted with a reliable lever lock, and have a rolled edge reinforced with an iron or steel bar and a strongly fitted bottom. The lid in particular should be stiff and ridged.

Another type of despatch box is strongly made of leather, and usually fitted with an inkwell, blotting-pad, spaces for pens and pencils, and divisions for paper and envelopes. These are more appropriate when travelling or for personal use.

**DESSERT:** How to Serve. The last course at dinner is often omitted when the meal concludes with a sweet of the fruit salad or ice type, but where a savoury is included in the menu, dessert usually follows.

In winter, when flowers are scarce and expensive, fresh fruit in ornamental dishes of pottery, china, glass or silver, or in gilt baskets, forms a charming table decoration. A centrepiece can be arranged with mandarins and ordinary oranges (supplies from West Indies and South Africa are sweetest), pale, shiny, yellow Newtown pippins, a few brilliantly crimson apples for contrast, russet winter pears, and bunches of black and white grapes.

In addition, for the ordinary dessert, a dish containing either pulled figs, almonds and raisins, crystallized fruits, or French plums or dates with walnut or marzipan stuffing, and one of nuts, with two smaller dishes of chocolates and fancy sweets, would be sufficient; but for a larger party a pineapple and a dish of South African cherries might be added. Ginger preserved in syrup is best served in its own jar. Salted almonds, which may be bought ready prepared in bottles, are always popular, so also are a few small silver dishes of marrons glacés and other bonbons.

In summer the more juicy fruits should be arranged in separate dishes. Strawberries may form a complete course. Remove the calyx from each berry, pile them in shallow bowls and serve them with cream and sugar.

**Dessert Services.** The charm of this course is greatly aided by attractive ware. A service usually consists of six or 12 plates and three or five fruit dishes. In old china it is often highly decorated, Coalport, Worcester and Crown Derby services being unexcelled

The old green-leaf service (vine or lotus is the usual

pattern) can often be picked up more or less complete at a bric-à-brac shop, and has a decorative value with its malachite green on a polished table. Venetian glass services are beautiful and costly, and there are other glass varieties in plain crystal, coloured or gilt patterned at more moderate prices. Italian fruit-painted pottery has a gay appearance, and there are many good varieties of English china and semi-porcelain fruit sets.

Dessert sets of knives and forks can be obtained with twisted pearl handles, plain or filigree encased. Green-stained ivory and silver gilt also make a good handle, also black, silver mounted. A dessert set comprises a dozen pairs. *See Cutlery; Silver; Spoon; Table.*

**DESTRUCTOR.** A furnace which is used by a district for burning up its refuse is known as a destructor. The refuse burns itself; the heat provided may be used for generating steam, and the ashes, which are known as clinker, have various uses. Small destructors may be used in the home, but their power of consuming refuse is very much less than the large ones, and in any case the kitchen fire is usually able to burn up domestic refuse. In the case of a large house and garden, a small destructor in the grounds is of value to deal with the garden waste and all house refuse as well. *See Refuse.*

**DETECTOR.** A device that is essential to the operation of a broadcast wireless receiver. Its purpose is to change the high-frequency current that is generated in the aerial by the broadcasting station into the low-frequency impulses which are needed to work headphones or a loudspeaker.

In many sets the high-frequency current is amplified in "H.F. stages" before being passed to the detector. Either a thermionic valve or a crystal detector may be employed. The crystal, although simple and economical, is comparatively inconsistent in its action, whereas the three-electrode valve or triode is both consistent and sensitive.

Among the various methods of valve detection are leaky or cumulative grid, anode or lower band and diode rectification. A leaky grid detector utilizes a fixed condenser having a value of .0001-.0003 mfd., and a grid leak which generally has a resistance of 1 or 2 megohms. One end of the grid leak is usually connected to a point in the circuit at positive potential in respect to earth. In the case of an anode bend detector a negative potential of 1½ volts or more is applied to the grid of the valve, and a grid leak and condenser may or may not be employed.

The diode detector is very efficient in regard to quality, for it provides detection with a minimum of distortion. But it is relatively insensitive and, therefore, its use is normally confined to super-heterodyne and other such sets as employ a considerable degree of H.F. amplification. *See Broadcast Receiver; Valve.*

**DEUTZIA.** This is a beautiful, easily-grown hardy flowering shrub. Deutzias thrive in ordinary well-tilled

soil and benefit by being top-dressed with manure annually in spring. They are pruned by thinning out the oldest shoots as soon as the flowers have faded. A few of the best are *gracilis*, *scabra*, *crenata* and *corymbosa*, all having white flowers. The best pink-flowered kind is *longifolia veitchii*, and *magnifica* has double white flowers. Several noteworthy large-flowered sorts have been raised; some of the best are

*candidissima*, *magnifica*, and *Pride of Rochester*. *Deutzia gracilis* is a favourite shrub for forcing; if potted in early autumn and placed in a heated greenhouse in December it will be in full bloom in the springtime.

*Deutzia. Flowering spray of D. crenata, a hardy shrub.*

## DEVELOPER:

**In Photography.** So far as all ordinary plates and films are concerned the selection of a developer is principally a matter of convenience. Any good standard developer, used correctly, will give similar printing results. Some stain the negative, others give a good black-looking negative, but so long as development has been properly carried out the result in print or enlargement will not vary to an appreciable degree.

It is a sound plan to select a developer and adhere to it. Uniform results cannot be expected and failures must be increased if the amateur repeatedly changes his developer.

*Developer. Two practical methods of dissolving developers or other photographic chemicals.*

In dissolving powders, tablet developers or other photographic chemicals, useful methods to adopt are shown in Figs. 1 and 2. As the solution is formed it falls and fresh water is continually coming into contact with the powder until the solution is complete. The method shown in Fig. 2 is particularly suitable for the solution of amidol, pyro and metol, filtration being effected at the same time. These developers are not easily soluble, and if undissolved particles are permitted in the dish bad spots will occur in the negatives.

Here is a brief account of the normal characteristics

of the best-known developers:

**Amidol.** Requires no alkali. An excellent general-purpose developer for negatives or bromide papers. Gives soft negatives and good blacks in bromide prints. This developer will not keep in solution.

**Glycin.** Free from liability to stain or fog. Excellent for the development of warm tone chloro-bromide papers, and for miniature films on account of its fine grain qualities.

**Hydroquinone.** Used in combination with metol, when it is popularly termed "M.Q.," this is a universal developer for both negatives and positives of all kinds. Cannot work satisfactorily at a temperature below 65° F. Good for maximum contrast.

**Paraminophenol.** Commercially prepared formulae of this developing agent are sold under the trade names Azol, Certinal and Rodinal. Image inclines to delicacy rather than contrast.

**Pyrogalllic Acid.** "Pyro" as it is usually called is the developer *par excellence* for obtaining a negative of printing strength from under-exposures. It gives a characteristic yellow stain, and so can be used only for negatives.

In all cases formulae for making up developers are given by their makers and also by manufacturers of films, plates and papers.

Once a developing solution is made up it must be used and not kept. Stale developer is certain to give bad results. About 10 oz. of solution is necessary to develop six  $\frac{1}{4}$  plates at one time, and if a further batch of plates is to be developed fresh solution must be used. Amidol, metol and pyrogalllic acid must be kept in well-stoppered bottles and not exposed to the air longer than is necessary, to avoid deterioration. See *Developing; Photography.*

## DEVELOPING PHOTO PLATES AND FILMS Methods Which Give the Amateur the Best Results

Associated articles are Film; Fixing; Photography; Plate; Washing; etc.

Developing is purely a chemical process, and therefore precision and absolute cleanliness are required, but the systems which have been evolved make it a matter of ease and simplicity. Negatives or films may be developed by one of three methods: by observation, by factors, and by time and temperature.

By the first method each exposure is developed separately in a dish, observing the progress of development by means of a red or other actinically safe light, and judging the point at which development should be stopped. To develop plates or flat films by this method, take the plate from the dark slide or

sheath (taking particular care not to touch the sensitive surface with the fingers) and lay it film side (creamy surface) upwards in the dish; next pour on the developing solution in an even sweep so as to cover the whole surface of the plate as evenly and as quickly as possible. Then rock the dish very gently so that the solution is kept moving over the plate. Care is also taken to see that air bubbles do not cling to the emulsion surface of the plate, since they will cause round holes in the finished negative.

After 3 or 4 min. the progress of development is observed by holding the negative up to the red light and looking through it for a second or so. It must be viewed by transmitted light in this way, since in most cases it will appear black in the dish, and all signs of the image will have disappeared some time before development is complete.

*Developing. Fig. 1. Workbench prepared for film pack development by tank. In the foreground: curved sheaths for roll films and rack for plates. The film pack tank holds twelve plates or films. Behind: rectangular container with screw cap for the developer.*

This method is one that requires a good deal of experience, and moreover suffers from the disadvantage that with modern fast plates and films the necessary exposure to red light is liable to cause fogging. It cannot be used at all with panchromatic plates, which are specially sensitive to red light, unless a desensitizing solution is used. If development is likely to be slow, cover the developing dish with a piece of cardboard. The edges of the plate which have been covered by the edges of the dark slide should be clear glass when fixed. If they are at all grey the plate has been fogged, the reason probably being undue exposure to the dark room light.

If a flat (not roll) film is to be developed by the observation method in a dish, first fill the developing dish with clean water and immerse the flat film until it becomes thoroughly wet on both sides and fairly limp, then pour off the water and apply the developing solution as is done for plates.

If a roll film is to be developed by hand in a flat dish, do not make any attempt to cut it up before developing, but develop the whole strip at one time. Fill a fairly deep developing dish with developer, say, to a depth of 1. to 2 in., then unwind the film from the spool, cast

aside the black paper covering and thoroughly wet the film in the basin of cold water.

After allowing the film to soak for about a minute, take the two extreme ends of the film, one in each hand, so that the film hangs in the form of a loop, like the letter U. Take the film from the water and pass it to and fro through the developer in the dish, raising one hand and lowering the other, keeping up the see-saw movement so that the whole strip of film may be acted upon by the developer. A special type of dish is required.

**The Factorial Method.** The second and better method is Watkins' factorial development. This consists in noting accurately the time which elapses between the flooding of the plate with developer and the first appearance of the image. This time is then multiplied by a factor for the particular developer used, thus obtaining the total time for development of that particular negative. Since the factorial method presupposes a correctly exposed negative, it has largely given way to the increasingly popular tank method of development, by time and temperature.

**Time and Temperature Method.** The third, and on the whole the soundest, method for the amateur is that known as development by time and temperature. Makers of practically all the standard developers on the market have now published tables showing the times required for development at different temperatures of all the standard plates.

Scientific research has demonstrated that for all ordinary purposes, given a particular plate and a particular developer at a certain temperature, the time required for complete development cannot usefully be varied, whether exposure of the negative has been accurately judged or not. To get good results negatives must always be properly exposed. Under-exposed negatives may be intensified and over-exposed negatives reduced, but the results never equal those obtained from a correctly exposed negative, and no matter how carefully after processes are performed there is always a risk of damaging the negative.

The time and temperature method can be used for either the development of single negatives in a dish or for batches in a developing tank.

**Tank Development.** A developing tank is a light-tight receptacle in which exposed plates or films can be placed and the necessary developing and fixing solutions poured in and out again without light entering. By this means, the whole process of developing, fixing and washing can be carried out without touching the negatives with the hands, and so a fruitful source of stains and scratches is avoided.

Tanks for the development of plates and film packs, or cutfilm, are usually in the form of boxes of nickel steel or stainless steel, the negatives being loaded into special holders placed inside the box, after which the lid is closed and the solutions poured through a light-

trapped opening. A typical example is the Dallan tank, seen in Fig. 1.

*Developing. Figs. 3 and 4. Correx tank with "agitator" for removing air bubbles. Right, film and apron secured by clip are dropped into tank.*

Among the tanks used for developing roll-film, one of the best-known is the Correx (Figs. 3 and 4). This makes use of an "apron" of non-absorbent material, the edges of which are corrugated to allow the developer to pass freely between film and apron. Procedure for development is as follows: In the dark room remove the backing paper from the film and insert one end of it under the spring clip fastened to the axle of the reel. Wind on the film quite loosely and clip the other end of the apron to the edge of the reel. The reel with the film on it is then dropped into the bakelite container, and the lid fastened down securely. White light can now be switched on.

*Fig. 4. Film and apron, secured by clip, is dropped into tank. The components (see text for details).*

Pour the developer, which should be at a temperature between 65° and 68° F. gently into the tank. When the tank is full, tap gently to dislodge any air bubbles and then from

time to time turn the film in the developer by means of the milled knob at the top, in order to prevent "tide marks" on the negative. The time of development is ascertained from tables supplied by the makers of the developer.

When this time has elapsed, pour off the developer, rinse the film with water and then pour in the fixing solution. The time necessary for complete fixation is about a quarter of an hour, after which the film can be taken out of the tank and washed thoroughly in running water.

*Developing. Fig. 2. Agfa Rondinax tank, which can be used in daylight.*

Another type of roll film tank is the Carbine (Fig. 5). The spool in the holder is inserted in the tank previously filled with developer. The lid is put on with the long plunger withdrawn. Next, the plunger is pushed down, extending the film. This tank is

practically automatic, very simple, and can be used entirely in daylight. Made in solid brass, enamelled and plated, it has no changing box, apron or grooves. Developer required, about 37 oz.

The methods of inserting, unrolling and treating a film in a tank are very ingenious and vary according to the make of the tank. All makers of tanks, however, supply booklets giving full details.

**Stand Development of Plates.** For stand development of glass negatives or flat films a large dish is required to take six or more negatives lying flat on the bottom of the dish. The negatives are unloaded from the dark slides (preferably in the dark), the developer having been prepared in a large jug beforehand. Make up plenty of solution so that the negatives are well covered, pour it over the negatives without delay, counting the seconds from the moment that the negatives are wetted.

When all the developer has been poured into the dish make sure that none of the negatives have been disturbed or are over laying one another, and cover the dish with a card or piece of board; take the total of the seconds counted during these operations and, turning on or going to the light, note the time when development began (i.e. when the negatives were first wetted) and the time when, according to the table for the developer used and temperature of the solution, development will be completed.

*Developing. Fig. 5. Ensign Carbine tank, for various spools, showing plunger for stretching out film.*

As in any case the developer in the dish will acquire the temperature of the room before development is complete, have it ready half an hour or so before it is required and test its temperature just before use.

This will be found a particularly useful method for developing panchromatic plates where no red light can be used at all, and in most cases total darkness is essential. A very little practice is required to gain confidence in handling the negatives in the dark. It is only necessary to have everything conveniently to hand on the bench.

In most cases the tables for time development by the time and temperature method given by the makers of developers and plates are calculated for what is known as "normal contrast." This produces a negative which, if it has been properly exposed gives a print on gaslight paper which has the amount of contrast of light and shade most suitable for the amateur's ordinary snapshots. If the negatives are to be used for enlarging, or if they are portraits, shorter time is needed for development. All that is necessary in the second case is to deduct 25 p.c. We thus get what is known as a thin negative. In general, developers work best at a

temperature between 60° and 70° F. Hydroquinone hardly acts at all below 60° F.

In all photographic work, but particularly in developing, absolute cleanliness of dishes and measures is of the greatest importance. Always wash out dishes thoroughly immediately after use; never leave them until the following morning. It is best to keep separate dishes for developer and fixer. Also, after washing a dish rinse it with a solution of spirits of salt, which can be kept and used repeatedly. By care in these directions mysterious stains and markings can be avoided.

**DEVILLING:** In Cookery. The name is given to a method of cooking in which cayenne pepper or hot spices are used. The legs of a cooked turkey or chicken are very suitable for devilling. They are first soaked in a sauce prepared from equal quantities of Worcester sauce, vinegar and melted butter, to which is added enough mustard, cayenne and salt to make the sauce hot and appetising. After being soaked well in the sauce the legs are fried and served hot with toast.

To prepare devilled game the remains of a cooked bird should be cut into neat joints, rubbed over with margarine, sprinkled with salt and cayenne, and then grilled lightly. A sauce is prepared from one tablespoonful vinegar, one shallot, one dessertspoonful each tomato sauce and margarine, a pinch of cayenne and a teacupful stock or gravy. The vinegar is brought to the boil with the cayenne and the finely chopped shallot, and the other ingredients added with the exception of the margarine. Bring the whole to the boil again, take the sauce from the fire and stir in the margarine. The sauce is then poured round the game, which is served on rounds of toast.

**Devilled Savouries.** Fried and boned sardines dipped in sauce described above and served on croûtons of fried bread make a good savoury. Finely chopped ham may be used for the same purpose with a little devilled sauce.

Good after-dinner savouries are also prepared by mixing  $\frac{1}{2}$  oz. butter with a small pinch of cayenne pepper,  $\frac{1}{2}$  teaspoonful made mustard, and a teaspoonful curry paste. Spread the mixture on one side only on some dry, unsweetened, finger-shaped biscuits, dredge them well with grated cheese, and then cook them on a baking sheet in a sharp oven or under the grill. When lightly browned they are ready for serving.

**DEVON WARE.** The potteries in Devonshire are the outcome of the art movement which set in during the late-Victorian age. On the south coast Watcombe ware, made near Torquay, includes green and straw pieces, and barbotine designs of marine objects. Aller Vale is noted for its motto ware, brown inside and yellow outside, besides a crocus pattern, and the simple, dignified Sandringham ware.

North Devon clays are used at Barnstaple for the favourite Barum ware, which comprises simple shapes treated with bold coloured-slip designs, or with applied

mouldings, such as dragons and sea creatures. A variation made at Fremington possesses an iridescent glaze of local creation. This may be used in fruit dishes, puzzle jugs and other forms. See Pottery.

*Devon Ware: characteristic example. Aller Vale jug with motto.*

**DEWBERRY.** A variety of bramble or blackberry is the dewberry, which grows abundantly in the woods and hedgerows of England. The fruit, large and glaucous black with a pleasant acid taste, can be used for the same purposes as blackberries. See Blackberry.

**DEXTRINE:** Its Adhesive Uses. Known also as British gum, dextrine is prepared by heating starch that has been previously moistened with dilute acids. The chief use of dextrine is in the manufacture of textiles, but it is an adhesive which finds favour with photographers for mounting purposes. A suitable mountant is made by heating 2 oz of white dextrine with 6 oz. of boiling water until it is dissolved, then allowing it to become nearly cold and stirring in an ounce of methylated spirit to act as a preservative. See Mounting.

**DIABETES.** There are two varieties of diabetes, in both of which the patient passes constantly large amounts of urine. Diabetes mellitus, generally referred to simply as diabetes, is characterized by rapid wasting and the passing of sugar in the urine in the form of glucose, and complete recovery is rare. In diabetes insipidus there is no such passing of sugar, and it is mostly children and young adults who are affected.

Men are more likely to develop diabetes mellitus than women, and it is commonest in middle life. A tendency to fatness in youth, a highly nervous disposition, a too strenuous business life, an undue fondness for the good things of the table, have all been suggested as predisposing causes of diabetes.

There is a close connexion between the health and activity of groups of cells in the pancreas or sweetbread and the symptoms of this disease. These cells secrete and pour into the blood a substance to which the name insulin has been given, and its function appears to be to ensure the burning up of sugar in the body. The injection of insulin into patients who are suffering from diabetes has been followed by the disappearance of sugar from the urine and marked improvement in the general condition.

**Advice on Diet.** The basis of diabetic treatment is to restrict carbohydrates (starch and sugar) in the diet, and sometimes also the proteins (lean meat, etc.), as sugar may be formed from them. What must be done in any particular case is to find out the amount of

carbohydrate which the patient can take without sugar appearing; in other words, the sugar tolerance. One method is to put the patient on a diet of meat, eggs, green vegetables, and a limited allowance of carbohydrate—say, 4 oz. of bread. It is known how much sugar is produced by this allowance, and if the sugar appearing is less, it shows that there is some tolerance. If the amount is taken without the appearance of sugar, it is gradually increased. This increase is also made possible by the daily use of insulin, the requisite number of units being injected under the skin, usually before the morning and evening meals. Insulin has proved of immense value in cases of diabetic coma, a condition of blood poisoning commonly called acidosis, which results from the perverted body chemistry.

The diet should be as varied as possible. The following may be given: Clear soup, tea and coffee (without milk or sugar), soda water, unsweetened lemon drinks, bread and biscuits made with almond, gluten or bran, cucumbers, celery (sparingly), tomatoes, asparagus (the green part), and all green vegetables, all kinds of fish and shellfish (except cod's liver), all meats (except liver), and poultry, milk (very moderately), eggs and butter, and all acid fruits, particularly oranges, currants and sour berries.

The following may not be given: Bread of all kinds, rice, tapioca, potatoes, beets, turnips, vegetable marrows, parsnips, artichokes, all malted liquors including beer, ale, stout, sweet wines and sweetened beverages. Saccharin tablets or powder may be used in order to sweeten tea, coffee, and lemonade, etc., and may also take the place of sugar in cooked dishes.

**DIACHYLON PLASTER.** This is a lead plaster, used to give support and protection to the skin and superficial tissues over which it is applied and so promote healing. It may thus be used for bruises and sprains. It enters into most other plasters, e.g. resin or adhesive plaster. Mixed with an equal amount of vaseline it forms diachylon ointment, which is employed in eczema.

**DIAMONDS: How to Choose.** When selecting diamond jewelry, the soundest investment is to purchase good quality stones. Blue-white stones of fine quality always have a good market value, no matter what their size may be, but large stones which are not of good colour and which have flaws in them are never really good investments, no matter how advantageously they may have been acquired.

The setting of diamonds requires special consideration. The stone should be set in platinum, but on account of the high cost it is usual for the setting to be of platinum, backed with a mount, either of white or ordinary 18-carat gold. The most effective diamonds are round in shape and deep; but in higher-priced ornaments oblong-shaped or pearl-shaped brilliants are used which, if blue-white and without flaws, are extremely valuable.

**Methods of Cleaning.** The simplest way to keep

diamonds clean is to brush them lightly with warm water with a little soap or soda added, and then to dry out the moisture from the back of the stones by means of cotton wool, which can be easily fixed on some pointed article, such as an orange stick used for manicuring. Another way is to brush the back and front of the stones with a soft brush and a little gin or whisky, after which there is no necessity to dry the stones, as the spirit is quickly absorbed.

**Dianthus.** Botanical name of the carnation, pink and sweet william. They are all described under those headings.

**DIAPER.** Little more than a name for a woven design, diaper at one time implied linen cloth with a diamond or lozenge pattern. Linen and cotton tablecloths, napkins, and towels woven in small geometrical designs, alternately bright and dull, are called diaper indiscriminately, and are made in all qualities of material.

In furniture design diaper is the repeating pattern in which the repeat is small in comparison with the space occupied. It is not applied to anything repeated on a large scale. Diaper is frequently seen in marquetry on furniture of the later part of the 18th century.

**DIAPHORETICS.** These are substances that are used to increase perspiration. One purpose of sweating is to lessen the temperature of the body and keep it at its normal level. If, then, we increase perspiration in fevers, we benefit the patient by reducing the fever. Another purpose of sweating is to get rid of the waste products, and when the kidneys are inactive, as in Bright's disease, increased sweating will relieve the strain on the kidneys and remove from the blood substances where retention is dangerous. The simplest means of inducing perspiration is to wrap the patient in hot blankets, giving him at the same time plain water to drink. A very hot bath, followed by half an hour in bed with plenty of bedclothes, will usually bring on profuse perspiration. Turkish or Russian baths or dry hot air baths or hot vapour baths are very efficient means of inducing perspiration.

Among the most useful diaphoretic drugs are the solution of ammonium acetate, dose 2—6 drams, and sweet spirits of nitre, dose 15-60 minims. Dover's powder, a combination of opium and ipecacuanha, is much used as a diaphoretic. At the beginning of a feverish cold an otherwise healthy adult may take 5 grains at bedtime, washing it down with a glass of hot lemonade or hot whisky and water. Within a short time profuse perspiration will set in, and care should be taken that the patient does not throw off his bedclothes and contract a fresh chill in the night. *See* Bath; Perspiration.

**Diaphragm.** *See* Stop.

**DIARRHOEA.** The commonest causes of

diarrhoea or looseness of the bowels are the ingestion of poisonous substances or unsuitable food, chill and fright or excitement. The condition may occur as a symptom in the course of some specific disease, such as cholera, typhoid or dysentery. Colicky pains, rumblings in the intestines, a coated, furred tongue, great thirst, and more or less weakness and collapse are the chief symptoms.

Where the attack has come on suddenly and unsuitable food is probably the cause, a  $\frac{1}{2}$  oz. or 1 oz. of castor oil, or a smaller dose in the case of children, may be given at once. If this does not produce speedy improvement, or the pain is severe, the patient should be put to bed between warm blankets with a hot-water bag or fomentations on the abdomen, and the doctor should be sent for. The diet should be milk, to which an equal amount of soda water or lime water may be added. In hot summer weather the milk should be boiled. As the attack gradually passes off arrowroot and smooth milk puddings may be added, then poached eggs, steamed fish, leading up to ordinary diet; but precautions should be taken for some time to keep out things like tough, stringy meat, fruit skins and similar indigestible substances.

Chronic diarrhoea may follow an attack of acute diarrhoea or may result from chronic indigestion, disease of the pancreas, or from chronic ulceration of the intestinal lining, as in tuberculosis. The physician should be called in, as it is only by a skilled examination that a correct diagnosis can be made.

**The Complaint in Children.** Diarrhoea in infancy may take the form of infantile cholera or of simple acute diarrhoea. The latter is commonest in the summer months, and is usually due to indigestion brought on by improper or excessive feeding. It may also follow chill or a sudden change in the weather. If the child is feverish from any cause, e.g. teething, diarrhoea is a common accompaniment.

In a mild case of simple acute diarrhoea, careful protection from chill or from overheating, a cutting down of the amount of milk and diluting it further, perhaps with barley water, and a teaspoonful of castor oil comprise the treatment. In all cases of chronic diarrhoea medical advice is urgently essential. The child should be kept comfortably warm and carefully protected from all chill or exposure.

Infantile cholera, a very fatal form of diarrhoea, occurring during hot weather, affects children mostly in the first two years of life, chiefly those who are hand-fed and brought up in squalid surroundings. It is due to germs in the milk which is impure or has been kept too long. A noteworthy symptom is loss of elasticity in the skin of the abdomen, and there is violent sickness and diarrhoea with a temperature rising to  $102^{\circ}$  to  $104^{\circ}$  F., and dropping perhaps to  $98^{\circ}$  with extreme prostration.

Preventive measures are of the utmost importance. At the beginning of any hot spell, more than ordinary precautions should be taken over the baby's food. Its bottles and nipples should be thoroughly scalded after each feeding, the milk should be perfectly fresh, and should be sterilized. All milk should be kept in tightly

closed receptacles in a cool place, and it is better to buy half the daily quantity needed morning and evening than the whole day's supply at once. The use of a baby's comforter is highly dangerous.

The baby should be seen by the doctor as soon as possible, but in the meantime a pack may be used. A towel or piece of sheeting is wrung out of cold water and wrapped round the child from the armpits downwards. Then a blanket is wrapped round and the baby is tucked up in its cot. Till vomiting has ceased only cooled boiled water should be given; but after that albumen or whey is allowed. If signs of collapse appear, put the child in a hot bath and give it a very little weak brandy.

**DIBBER.** This small gardening instrument is used for planting potatoes, bulbs, green crops, etc. The most useful form is the handle of a disused spade cut down to about 12 or 15 in. The point should be shod with iron, as it keeps cleaner, works easier and lasts longer. If not shod, the point should be charred with fire and then rubbed down with sandpaper. A foot-driven dibber is sometimes used for planting potatoes, but it is not recommended by the best authorities. *See* Cabbage; Chrysanthemum; Daffodil.

**DICE.** Dice are used in several games of chance, for instance, backgammon; also in the class of games known as race games. They are small pieces of ivory or wood, each having six equal sides. On each side are dots, or pips, 1, 2, 3, 4, 5 and 6 in number respectively, these being arranged so that those on opposite sides shall together total 7. Thus 3 is opposite 4 and 1 is opposite 6.

The dice, generally two but sometimes more in number, are thrown by the players in turn, either from the hand or from a dice box, and the player receives the numbers that are uppermost as the dice lie on the table. Dice can be made by cutting pieces of wood into the necessary shape and marking them with ink to make the dots. Great care should be taken that the pieces are cut quite evenly; otherwise the dice will be unreliable and should not be used. *See* Backgammon.

**DIE.** The word die is applied to various tools. The die used to stamp an address upon notepaper is known as an embossing die, being engraved with the letters to be embossed on the paper. It is fixed in a cast-iron frame, having a hand lever at the upper part which when depressed forces the die down on to the paper. The paper is placed upon a counterpart having corresponding letters raised on its surface. Dies for cutting screw threads are dealt with in the article Stocks and Dies. *See* Screw Plate.

**DIELECTRIC.** This is the non-conductor or insulating substance which separates the plates of a condenser. The actual capacity of a condenser depends

upon the nature of the dielectric, i.e. upon the dielectric constant, which for air is one, while for mica it may vary from 4 to 8 (according to the type of mica used).

Thus the capacity of a condenser having a mica dielectric might be as much as eight times that of a similar condenser employing air as the dielectric. *See Capacity; Condenser.*

### DIET: ITS SCIENTIFIC PRINCIPLES

#### Cardinal Rules Governing the Nutrition of the Body

The correct balance of the constituents of a dietary is discussed here. Particular aspects of the subject are treated under such headings as Egg; Milk; while information on special diets required in disease will be found in the articles Consumption; Diabetes; etc. *See also Digestion; Eating; Food.*

The essentials of a proper diet are that it should provide for growth and for the replacement of waste, that it should furnish the heat and energy required by the body, and that it should furnish also a measure of stimulation to metabolism and to the functions of the alimentary tract. An analysis of foodstuffs shows that they are made up of certain constituents, namely, proteins or nitrogenous substances, carbohydrates, fats, salts, vitamins and water.

The proteins, of which white of egg and lean meat are examples, are the tissue-builders and make good the loss of tissue due to the wear and tear of living; they also go to the making of the secretions of the body. A growing person requires a liberal allowance of proteins. These substances are contained in flesh, fish and fowl and also in wheat and other vegetable foods, but those of animal origin have in addition a certain dynamic quality which explains the craving for animal food in cold climates, and the lessened inclination for it among dwellers in temperate climes during the hotter weather. Proteins also furnish a certain amount of heat and energy, but the proper sources of most of our requirements of these are carbohydrates and fats.

#### Calorie the Unit of Energy

The amount of heat, and incidentally of energy, as heat and energy are convertible into one another, furnished to the body by fixed amounts of protein, fat and carbohydrate can be estimated by burning them outside the body. The amount of heat is calculated according to a unit known as a calorie, or, as is usual when dealing with foodstuffs, a large, or kilogramme, calorie.

A calorie, or small calorie, is the quantity of heat required to raise the temperature of 1 gramme of water through 1° C.; a large calorie, that required to raise the temperature of 1 kilogramme, or 1 litre, of water also through 1° C. In what follows, when the term calorie is used it is the large calorie that is meant.

It has been found then that 1 gramme of either protein or carbohydrate produces 4 calories, while the same amount of fat produces 9 calories. The excellence of fat as a source of heat is apparent, and, for a reason

to be mentioned hereafter when treating of vitamins, fat is an essential part of any diet. It might appear then, that fat might be used altogether in place of carbohydrate, but this is not so; the body cannot burn up fat properly unless in the presence of a relatively large amount of carbohydrate. Otherwise poisonous substances accumulate in the blood. The optimum balance differs, however, with circumstances. In cold climates and in cold weather an increase of fat is indicated.

From experiments it has been found that the number of calories expended and required in the 24 hours by various classes of persons are as follows:

Man doing hard muscular work	4,000 calories
Man doing moderate muscular work	3,500 „
Man doing light muscular work	3,000 „
Man doing sedentary work	2,500 „
Average woman	2,500 „
Man in bed, feeding	1,850 „
Man in bed, fasting	1,700 „

Different opinions have been expressed regarding the relative proportions of the three food constituents which should be represented in the diet. Two scales which have been suggested as suitable for a man doing light muscular work, that is, requiring 3,000 calories, are as follows:

Protein	Carbohydrate	Fat	Actual Calorie value
120 grammes	500 grammes	50 grammes	3,007
100 „	350 „	100 „	3,090

The salts in foodstuffs include those of iron, calcium, magnesium, sodium and potassium, and are necessary in tissue building or, in various ways, in the chemical processes which go on in the body.

Even should a diet be corrected, however, in all the particulars mentioned up to this point, it will not be a good diet, unless the foods included contain certain substances known as accessory food factors or vitamins. Several of these vitamins have been recognized, namely, three which are soluble in fat, but not in water, and known respectively as A, D and E, and three which are soluble in water and known as B, B2 and C.

Fat soluble A prevents xerophthalmia, D prevents rickets, and E has been shown to be necessary to reproduction in rats fed on an artificial diet in which A and D were present; the absence of water-soluble B leads to beriberi, and it is therefore also known as the anti-neuritic vitamin; B2 prevents pellagra; while the absence of water-soluble C leads to scurvy and it is therefore called the anti-scorbutic vitamin. It is probable that ill-defined diseases occurring in those who feed on artificial foods is explained by vitamin starvation.

In the following table the vitamin content of various foods is set out:

Foodstuff	Fat Soluble A	Water Soluble B	Water Soluble C
Milk .. ..	+	+	+
Butter .. ..	+	+	+
Cream .. ..	+	+	+
Egg yolk .. ..	+	+	+
Beef fat .. ..	+	+	+
Mutton fat .. ..	+	+	+
Lard .. ..	+	+	+
Pork .. ..	+	+	+
White fish .. ..	+	+	+
Herring .. ..	+	+	+
Cod-liver oil .. ..	+	+	+
Margarine (containing animal fat) .. ..	+	+	+
Vegetable oils .. ..	+	+	+
Wheat (whole grain) .. ..	+	+	+
White flour .. ..	+	+	+
Polished rice .. ..	+	+	+
Fresh fruit (especially orange, lemon, grape fruit, tomato) .. ..	+	+	+
Nuts .. ..	+	+	+
Green vegetables (raw) .. ..	+	+	+
Green vegetables (cooked for a short time) .. ..	+	+	+
Potato .. ..	+	+	+
Swede turnip .. ..	+	+	+
Yeast .. ..	+	+	+

+ + += abundant supply; + + = moderate supply; + = fair supply; - = none.

Foods which contain vitamin A generally contain D also, and the statements in the first column above, regarding the presence and richness of vitamin A, may be taken as applying equally to vitamin D. There is very little vitamin D in green vegetables, however, and conversely the body fat of fish contains no vitamin A but a fair proportion of vitamin D, so that herrings, for example, may be used as a source of the latter. What is said about vitamin B above applies more or less to vitamin B2, but milk, which does not contain the former contains the latter, and this also occurs in lean meat, fish, cheese and eggs.

Other characteristics of a good diet remain to be considered. It must excite the digestive functions and must contain a sufficient amount of indigestible material, or, as it is called, roughage, to stimulate the muscular movements of the gut and so promote regularity in the action of the bowels.

Appetite and digestion are improved by variety in the diet and by good cooking. Foods which require chewing are helpful because they allow time for the action of saliva, and the act of chewing stimulates the flow of gastric juice. Moreover, it should be recognized that chewing crisp food, such as an apple, is a natural method of cleansing the teeth. Roughage is supplied chiefly by the cellulose contained in vegetables and fruits.

An excessive diet strains the digestive and excretory apparatus of the body, leading to indigestion and auto-intoxication. Some of the excess is laid down as fat, and a flabby obesity is also the common result of an ex-

cessive consumption of carbohydrates, another result being flatulent indigestion. In some diseases adjustment of the diet is the most important part of the treatment.

After a person has passed middle age his dietary should be reviewed frequently and the quantity should diminish *pari-passu* with his output of work as the years go on. For old age food must be simple and easily digested and as the body heat is less easily maintained, it should contain an adequate amount of fats and carbohydrates.

**DIFFERENTIAL GEAR.** The differential, or balance, gear as now used in a motor car is always incorporated in the live axle. The differential is employed so that the relative movement of the back wheels (or front wheels in the case of front-wheel drive) shall be capable of self-adjustment to the needs of the moment. When the vehicle is turning a corner the wheel on the inside of the curve is travelling slower than the outside wheel.

**Two Designs of the Gear.** There are two designs of differential gears employed, viz. the bevel and spur pinion types. The better-known and more easily understood is the bevel. First of all it has to be remembered that the road wheels control the differential.

In the diagram, A is the crown wheel driven by the bevel pinion B. The crown wheel A is mounted solid with the differential case C, which rotates on the same centres, but independently of the axle-shafts D and E. The differential case C carries the bearing pin F, on which the two small bevel pinions G are mounted. These pinions are capable of independent rotation, but are both in mesh with the large bevel pinions mounted solid on the axle shafts D and E. Therefore, so long as the axle shafts D and E are rotating at an equal speed (owing to the car travelling in a straight line) there will be no movement of the pinions G, the whole rotating as though solid through the medium of the crown wheel A, which is a part of the differential case C.

**Differential Gear.** Diagram showing the working of the bevel gear type.

Now, assume that the car is travelling to the right of the page and so is turning to the right. During this

movement of the car the road wheel that is a part of the axle shaft D will have to make a greater number of revolutions, as it is on the outside of the curve, than the road wheel that is a part of the axle shaft E, and is on the inside of the curve. To allow of this movement, it will be obvious that the two small bevels G will be turned through the medium of the large bevel pinion, on the axle shaft D, in the direction of the two curved arrows shown in the small diagram, thereby allowing the relative differences of speed between the two axle shafts D and E to take place.

The two small bevel pinions G are in reality a compensating coupling between the axle shafts D and E, their movement being governed solely by the variations of speed between the two road wheels. In all other respects they act as the driving medium to the axle shafts so long as the road wheels are in contact with the ground.

If, however, one of the wheels should be lifted free of the ground, and the crown wheel A rotated, then the small pinions G will be free to rotate, and by so doing will reverse the direction of rotation of the wheel that is lifted free, the other wheel remaining stationary. On high-powered vehicles three or four of the small pinions G are employed. *See Gear; Motor Car.*

**DIGESTER:** Use in Cooking. Strong iron boilers used for making soups, etc., are known as digesters. They have lids which screw down tightly so as to confine all the steam, and by this means the water may be heated several degrees higher than boiling point. So that the vessel will not burst, the lid is fitted with a safety valve by which the heat of the steam can be regulated. Meat cooked in these boilers may be entirely dissolved and bones reduced to jelly.

A special type of digester allows the steam to escape through the valve on the lid, and for this reason should be only three parts filled with water. When cooking begins, it should be placed near a slow fire and its contents allowed to simmer for 8-10 hours. The soup should then be strained through a hair sieve or colander, put back into the digester, vegetables and seasoning added, and the whole boiled for 1-2 hours. Digesters of this kind vary in capacity from 4 quarts to 10 gallons. Saucepan and stewpan digesters made on the same principles hold from 1-8 quarts. To clean digesters, wash them in hot water to which a little soda has been added, and then scrub them inside and out. Finally rinse them and dry them with a clean cloth. The digester has been largely superseded by the casserole, at least as far as stews are concerned. *See Casserole; Soup; Stockpot.*

**DIGESTION:** Its Functions. The food that we eat would fail of its purpose were it not altered into products suitable for the nourishment of every part of our bodies. These products are carried in the blood and must, therefore, be soluble. The process of alteration is known as digestion. The changes involved are many and complicated, but all are supervised, without conscious effort, by the nervous system, which has

filaments at every point of the canal, 30 ft. long, traversed by the food.

In the mouth, digestion of starchy foods is begun by the saliva, while movements of cheek and tongue aid the teeth in crushing the food into a soft rounded mass or bolus. Swallowing is begun by the tongue pushing back the bolus into the grasp of the muscles surrounding the throat. These pass it quickly over the air passage, which is protected by a small flap called the epiglottis. The muscles of the oesophagus next push the food into the stomach.

The stomach is a sensitive muscular tube changing frequently in shape and position. Its lining produces gastric juice, which renders the food acid and digests to a large extent the meaty portion of the diet. The formation of gastric juices is increased when one sees food and when chewing takes place, as well as at the time of its arrival in the stomach. Hence the importance of food being cooked in an appetizing way and attractively served.

An ordinary meal remains for some four hours in the stomach and is then pressed out, in a liquid state, into the upper end of the small intestine, or duodenum. A short distance down, a duct brings to it the secretions of the liver and pancreas. The fluid formed by the liver is called bile, and this is an important agent in digesting fatty foods. The pancreatic juice acts on starchy or farinaceous substances and also causes further disintegration of meat products.

The long coils of the small intestine lie in many loops packed in the central part of the abdomen, and the absorption of feeding-stuffs mainly occurs while the food is being propelled by regular waves of contraction, called peristalsis, along the seven yards of these coils.

In addition to the digestive juices mentioned above, there is a secretion from multitudinous small glands which dot the lining membrane of this tube. This secretion aids digestion and makes the food alkaline. The lining membrane is also corrugated into transverse ridges, so that an extensive surface is presented to the digesting food and its rate of flow delayed. All over the surface occur minute projections which have inside them a network of bloodvessels and lacteals. These villi, being bathed in digested food, suck out from it the nourishment which serves to renovate all parts of the body. The special function of the lacteal vessels is to collect the digested fats. These are carried into the thoracic duct, which discharges them into the great veins near the heart.

The contents of the small intestine pass into the large intestine, at the commencement of which is situated the vermiform appendix. This is the worm-like blind pouch so well known as the site of appendicitis. The large intestine is provided with many mucous glands, and single lymphoid glands which probably serve to drain off deleterious substances. It measures about 2 yards in length and terminates in the rectum, where the undigested remnants of food and the remains of digesting fluids collect until voided. Regularity in passing the excretions should be taught in infancy. If

such errors as insufficient exercise, undue restriction of drinking water and the use of tight clothing are avoided, the habit will remain regular provided the diet is reasonable in quantity and quality. *See* Diet; Indigestion.

**DIGESTIVE.** A substance which reinforces the digestive juices of the body, and therefore is useful in dyspepsia and digestive weakness generally, is termed a digestive. The digestive may be given inwardly to be of assistance in the process going on in the alimentary tract, or, as in the peptonizing of milk, etc., it is added to the food and allowed to act for a certain time before this is taken.

Some digest the proteins, like lean meat and white of egg, e.g. pepsin. This ferment, dose 5 to 10 grains, may be given in powder, pill, cachet, or tablet, or in liquid form as the glycerin of pepsin, dose 1 to 2 drams, and in this case is usually combined with a little dilute hydrochloric acid. Pancreatic solution, dose 1 to 2 drams, contains trypsin, which is a protein digestant, and also a ferment which digests starch.

Benger's food contains wheaten flour, with the addition of the digestive ferments of pancreatic juice, which convert its contained starch into sugar, while the milk used in the preparation of the food is partially peptonized. The food as prepared can be graded to the patient's digestive powers by allowing a longer or shorter time for the action of the ferments, before finally stopping this by bringing the food to the boil.

Among other digestives of starch, mention may be made of taka-diastrase, obtainable in capsules, dose 1 to 5 grains, and extract of malt, dose 1 to 4 drams. The latter may be useful in dyspepsia in children in a dose of a teaspoonful thrice daily.

**DIGGING.** The successful management of plants depends chiefly on deep cultivation of the soil by digging and trenching. Trenching cultivates the soil three spits (a spit is the depth of soil removed by the spade when thrust straight down); double digging cultivates it two spits, and in ordinary digging the surface only is turned over.

The way to dig a piece of cultivated ground is to take out a trench 2 ft. deep across one end of the plot and to place the soil at the opposite end of the plot. The bottom of the trench is forked over and garden refuse or strawy manure is mixed in. The top layer of the next 2 ft. strip of ground is then placed in the bottom of the first trench and stable or farmyard manure, if available, is forked into it. The second layer of soil is placed on top of it, thus filling the first and opening the second trench. And so the work is continued until the end of the plot is reached, when the soil excavated from the first trench is used to fill the last one. This method of cultivation is sufficient for general purposes; those who grow produce for exhibition sometimes trench the ground three spits deep; manure is placed in the second spit of soil and rough garden refuse, or coarse manure, in the bottom of the trench.

A different practice is followed when dealing with

fresh land—that is land which has not been previously cultivated as a garden. If it is covered with turf this should be stripped off about 3 in. deep and stacked for a year. It may then be dug into the ground. A 2 ft. wide trench is dug across one end of the plot and the soil taken out is placed at the end as already described. But the next detail is different, because it is essential that the top soil and subsoil be kept in the same respective positions.

This is assured by taking off the top spit from the second 2 ft. strip of ground and placing it also at the opposite end of the plot. Thus the first trench is empty and the second trench is half empty. The subsoil from the second trench is then placed in the bottom of the first trench and the top soil from the next strip of ground is put on it. Thus the first trench is full, the second is empty, and the third is half empty. The method keeps the subsoil and the top soil in the same positions as they were before. In subsequent years their positions may be reversed by adopting the ordinary method of trenching as already described.

**The Diagrams Explained.** The accompanying diagrams picture three methods of digging. Figs. 1 to 4 cover what is known as double digging, which, although entailing much hard work, ensures perfect preparation of the soil. Commence by taking out a trench two spits deep and carry the soil to the spot where digging will end. Break up the subsoil A, transfer the top soil B on to this, and then lift the second spit C on top. Fig. 2 shows the resulting position. Now break up the subsoil at the bottom of the new trench, dig down the top soil E to second place, and again transfer the second spit to the surface. Continue the operation in this order until the whole plot is completely dug.

The position at the end of the first digging is shown in Fig. 3; the subsoil A is broken and loosened, the good top soil has taken the place of the original second spit, while the whole of the second spit has been brought to the surface for weathering. This first digging is done during the autumn. In spring the second digging is carried out in precisely the same manner, which restores the freshened underspit to its original position and brings the old top spit to the surface again. The soil taken from the first trench is used to fill the vacant trench left at the end.

Figs. 5 to 10 show a single digging method which will be found highly satisfactory when time cannot be devoted to double digging. Take out a trench one spit deep, as in Fig. 5, follow with another half the width (Fig. 6), and conclude by breaking up the bottom spit, as in Fig. 7. Dig over the second spit D, as in Fig. 8, and then loosen the bottom spit E. Now lift the top soil F on to D (Fig. 9), which refills and completes the first trench (Fig. 10.) The operation is continued in the same manner—that is to say, the next portion of undug second spit is put above the broken bottom spit, the next top spit carried to the surface, and so on. Fill the last hole with the soil taken from the original trench.

**Digging.** Figs. 1-12. Diagrams illustrating effective ways of digging a kitchen garden. Figs. 1-4. Double digging. Figs. 5-10. Single digging. Fig. 11. Emergency digging. 12. How to dig a large plot.

Another method, easier still, is shown in Fig. 11. Simply take out a trench one spit deep and break up and manure the soil beneath. Dig the next top spit on to this, continuing as directed by the arrows in the sketch.

An excellent way to dig a large surface methodically and regularly is to divide the plot into three sections, as pictured in Fig 12. Commence by taking out a trench at A, and deposit the soil at A A. Step backwards and transfer B into trench A, and work down to C, as directed by the arrows. An empty trench will consequently result at C, and into this dig the soil from D. Then face the open trench at D, and continue until you have an open trench at F. Now face this trench, and dig on in the same order until the end of the plot is reached. An open trench, of course, results at G, and into this place the soil A A from the original trench. *See Garden; Spade.*

**DIGITALIS.** This powerful and useful drug is obtained from the foxglove. Its chief action is to slow the beat of the heart and to increase blood pressure. It is often used when the blood pressure is low, and is of value in cases of heart disease and dropsy. But when taken over a period it may accumulate in the body and lead to poisoning. The first symptoms are palpitation and unevenness of the heart beat. In severe cases the patient turns livid, with shortness of breath, and should be put to bed at once, avoiding all exertion until the doctor arrives. Strong hot tea, diluted spirits, or sal volatile should be given. When poisoning is due to an overdose, an emetic must be given to start with, and vomiting encouraged by draughts of tepid water. See Foxglove; Heart. Pron. Dij'i-tā-lis.

**DILAPIDATIONS.** This is a subject of increased importance to the householder owing to the high cost of labour and the consequent necessity of doing his own renovating wherever possible.

In purchasing a house, due regard should be paid to those parts which are likely to prove vulnerable from the standpoint of dilapidations. Externally, these may be summed up as the brickwork and the roof. Re-pointing brickwork that has perhaps become unsound enough to be no longer weatherproof, owing to percolation of the mortar, the bricks themselves, or both, is an expensive business, and can hardly be tackled by anybody not possessing practical knowledge of building; nor is the replacing of slates or tiles any less an expert's job.

Internally, however, there are certain dilapidations which can be put right without much trouble. Papering and painting are among them. Other dilapidations likely to call for attention more frequently than the walls or woodwork are those of door handles, electric or other bells, the stained parts of floors, the catches of windows, painted metal baths, etc. These are comparatively small matters which can be dealt with as occasion demands. The major dilapidations involving papering and painting lose much of their formidableness if they are taken in hand gradually and systematically. See Building; Cottage; Lease; Repairs.

**DILL.** Aromatic herb with finely divided foliage resembling fennel, but of much smaller growth. It may be raised from seed sown in spring, the plants being thinned to about 1 ft. apart. The leaves are used for flavouring soups and sauces, and the seed for distilling oil of dill and for making the carminative known as dill water.

**Dill Water.** For infants and children a useful carminative is found in dill water, which is prepared from the dried seed of the plant. The dose is 1 to 2 fluid oz.; for children, a teaspoonful. For flatulence and hiccough an infant may be given half a teaspoonful with a little pinch of bicarbonate of soda added.

**DIMORPHOTHECA** (Namaqualand daisy or star of the veldt). This is a beautiful hardy annual

bearing daisy-like flowers in orange, yellow, salmon, apricot, and blush. The seeds are sown out of doors in April where the plants are to bloom in summer; they like a sunny position and well drained soil. Star of the veldt also makes a good pot plant for the greenhouse. Seeds are sown thinly in 5 inch pots of soil and the seedlings are thinned out, not transplanted.

**THE DINING ROOM AND ITS FURNISHING**  
**Practical Suggestions for Small and Large Houses**  
 The entries on the various pieces of furniture should be consulted, e.g. Chair; Sideboard; Table. See also Alcove; Carpet; Colour; Cupboard; Curtain; Decoration, etc.; while attention is drawn to the article Dinner.

In recently-built houses the position of the dining room is generally decided with due regard to aspect. Under other circumstances, where choice is possible, a window facing east is a desirable feature in the room selected as a dining room, in order to get the advantage of any sunshine at breakfast time.

The ideal arrangement in a detached house is a corner room with a window facing south and another east, especially if possessing French casements opening on to a veranda or loggia so that the dining room may be practically extended in the summer by meals being taken outside. A useful piece of furniture for this is a three-tiered service trolley, obtainable with a locking device, which when released allows the three tiers to swing into a level position, forming a table at which several people can be seated comfortably for a meal, the trolley being loaded with requirements and easily wheeled from the kitchen, thus facilitating service.

**Aids to Service.** The most practical consideration in connexion with the dining room is service with the kitchen. In the small house, where the room is next to the kitchen and one maid is kept, a service hatch saves many footsteps in the day. It may be arranged, as shown in the third illustration, with a china cupboard to balance it on the other side of the oak Welsh dresser. In this case the hatch in itself forms a useful place for storing china and glass. On the lower shelf on the dining room side glass is kept, while china is stored on the glazed upper portion on the kitchen side.

A service feature in some of the smaller modern dining rooms is a built-in sideboard with a hatch forming its upper part which on the kitchen side, is part of the dresser. When the cutlery and china have been washed up they are placed on shelves accessible from the dining room side so that they are ready for laying the next meal. Sometimes the service hatch looks like a small wall cupboard which, when opened in the dining room, reveals circular trays, revolved when necessary on a central pivot.

For dining rooms which are not on the same floor as the kitchen, a small service lift either worked by electricity or hand-power with pulley ropes, is the only method of obviating the necessity of loaded trays. Such

lifts can be installed without much difficulty if the dining room is directly above the kitchen and there are no restrictions to preclude it. For the long corridor in a flat or house between kitchen and dining room the tiered service wagon is practically a necessity.

In the larger type of dining room, a good arrangement is for a hatch to open into a small pantry, which amounts to a cut-off lobby separating the kitchen from the dining room. Such a pantry should be well ventilated, and fitted with shelves and a sink.

**Attractive Schemes.** Styles in decoration and furnishing for dining rooms are so many that choice is almost bewildering when confronted with this problem in a fresh home. The type of house, size of room and question of expense will all be decisive factors. If a house has been fairly recently designed it will probably be equipped with a built-in sideboard. Should cupboards and a window seat also have been added, the flooring be laid parquet and the walls panelled, the furnishing question merely resolves itself into suitable table and chairs, with well designed carpet and curtains. In such a room beautiful effects are simply obtained by the use of browns and shades of cream to orange. The frieze and ceiling could be distempered a creamy apricot. Dinner services should always be chosen with regard to the decorative scheme of the dining room.

When dining rooms are not panelled a tinted plaster or other roughly textured effect is often used for the walls. A room in Spanish style is shown in Fig. 1. The nail-studded leather upholstered chairs, wrought iron sconces, and table setting stress the Spanish note. A dining room inspired by this scheme could have tiles in black and grey marble rubber flooring, salmon pink tinted plaster walls and curtains in velvet of a dark olive green.

**Dining Room. Fig. 1.** Room in Spanish style, this note being struck in the tiled floor, distinctive table equipment, nail-studded leather chairs and wrought iron sconces.

Extreme styles in furnishing include a dining table with a heavy pedestal instead of legs, and chairs with steel tubes instead of

woodwork and cane upholstery. More universally admired are charming rooms with a suggestion of period setting like that seen in Fig. 2, with its simple yet formal Empire style. The ropes and huge tassel instead of a pelmet are a happy thought, as they exclude no light, while the treatment of the chimney piece is in perfect taste.

Such a furnishing would be suitable for a smaller

dining room in a flat and would be one of which the inmates would not tire. The colour of the wall paper could be in two shades of grey, a black note for the medallions and plaques, the paintwork in the deeper grey scumbled over a silver powder undercoat and finished with eggshell gloss varnish. The line of moulding between ceiling and walls would be in black, which would be repeated for the cords and tassels, while the curtains brighten the colour scheme with deep coral pink, a paler shade being used to distemper the ceiling.

**Fig. 2.** Small dining room in Empire style. The prevailing tones in this room are shades of grey, deep coral pink and black, with furniture in accord with the period.

Fig. 3 also shows a scheme of furnishing suitable for a small room, but of less formal type with its gate-legged oak table, Welsh dresser and rush-seated chairs. An oak chest and brick fireplace would complete the scheme, which would be pleasant carried out in a golden amber shade of water paint for the walls, with a paler shade for ceiling, a Wilton carpet in Persian design and curtains of shot fabric suitably blending the colours of the carpet.

**Dining Room. Fig. 3.** Design for a small room with light walls and oak furniture. There is a china cupboard and service hatch on either side of the dresser. (Courtesy of Our Homes & Gardens)

In Fig. 4 is illustrated a good arrangement for the tiny bungalow dining room, or a hall dining room, sometimes met with in a small flat. The simple oak stools are enriched with maroon coloured velvet cushions, having gold tassels at the corners; the golden note could be picked up in the brass candlesticks and the lantern-shaped lighting fitting. The walls of the room and ceiling could be distempered a pinkish stone and frieze moulding of light brown to match the weathered oak colour of door and furniture. The

carpet would be of natural haircord. carpet would be of natural haircord. For the winter there would be curtains of maroon velours.

*Fig. 4. Charming arrangement where space is limited.*

### DINING TABLES, PRACTICAL AND PLEASING With Details about the Construction of Expanding Tables

Further articles in this work deal with other types of table, e.g. Bed Table; Console Table; Table; Writing Table. See too Billiard Table; Sideboard. The craftsman should consult the entries Amateur Carpentry; Cabinet Making; Joint, etc.

The first dining table was just an ordinary table put to this use, square and solid, and quite plain. Dining tables soon became more elaborate articles of furniture, made to harmonize with the other pieces in the room. They were of oak, mahogany, cedar or chestnut, but the cheaper woods soon came into use.

At the end of the 18th century the dining table was, as a rule, extremely well made. The usual type in the best houses was one supported upon pillars and claws, four claws to each pillar, and running upon brass castors. By this time the idea of the expanding table had been evolved, and patents for this were taken out before 1800. Then came the expanding table worked by means of a long screw. By turning this the table can be opened out and loose leaves inserted therein, thus, if necessary, doubling the length of the original table. In

the 19th century a circular or oval expanding table was introduced into the English dining room.

*Circular table in Chippendale style with claw and ball feet (Courtesy of W. Whiteley, Ltd.)*

**Making a Table.** Of all the various types of extending tables, the draw table (Fig. 1) is still in many respects the best. It is simple in action, durable and absolutely rigid, and has passed the test of time, as is amply proved by the inspection of the old 16th century

draw tables. Their only disadvantage compared with the telescopic type is that whereas the latter can be extended to over four times its normal length, the draw type will only open to nearly double the length. However, this is ample for ordinary purposes.

*Dining Table. Extending table made in the Adam style.*

Differing from other types, the legs and underframing remain stationary, while the leaves or extensions are contained under the main top and are pulled out at each end when required, being supported by bearers tapering towards their extremities. These bearers are screwed to the extensions and fit into notches cut in the end rails of the table. When pulled out the effect is to raise the extensions up to the height of the main top, which is loose, forming a flush join. The top, however, cannot be lifted off or moved sideways, as it is kept in position by guides. To close the table, the main top is lifted to allow the extensions to pass underneath.

Success lies in the correct making of the bearers, and it is advisable to set these out full size before commencing the job. The legs are cut from 4 in. squares and are mortised to take the rails, the tenons of which should be as long as possible to obtain the maximum strength. They are also pinned. Note that at one end the notches for the bearers occur immediately against the legs, so that the width of the tenon will only be from the bottom of the notch to the bottom of the rail (Fig. 3). A grooved moulding is worked on the rails, though this may be omitted if desired; the same applies to the lower rails or stretchers. Having turned the legs, the table may be glued together; the underframing does not differ from that of an ordinary table except that allowance is made in the height for the thickness of two tops.

Below the main top and between the two extensions is now fixed a centre cross piece (Fig. 2). This measures in length just the width of the top; it is 1 ft. wide, and the same thickness as the top. Two slots are cut, as in Fig. 4, to take the two top guides; the cross piece is screwed to the rails. The top and two extensions are now made as in Figs. 5 and 6. The 1 in. framing is mitred and tongued at the corners, with two centre cross rails tenoned between and having  $\frac{3}{4}$  in. panels tongued and grooved between them; panels are not glued.

When the framing is glued together, the whole should be trued up and thickened, making sure that it is perfectly straight and flat and out of winding. Two

*(Continued in page 652)*

*Left: sideboard and table in scrubbed oak; the mirror is built up of four pieces of vitrolite, cast-metal figure in centre. Right: cellulosed chairs covered in ivory or crimson hide, with vitrolite-topped table. Note illuminated opaque glass cupboards.*

### DINING ROOM: FURNISHING DESIGN AND EQUIPMENT New Styles and Old in Modern Houses and Flats

*For a modern flat: waxed walnut table with a cupboard underneath and folding top. The chairs are covered in repp, the spotted design contrasting with the general impression of squareness.*

*A small round table offers plenty of leg room. Observe also the modern sideboard of Nigerian cherry mahogany with white bone handles, in which the curve of the table is repeated.*

*Here is shown the fashion for butting the dining-table against the wall to save space. Note Viennese vogue of strip-lighted wallbrackets for flowers, also heavy-cretonned chairs.*

*Two dining rooms from Chelsea flats, one of restrained modernity, the other a period piece. Left: view from living room set apart by velvet curtains. Notice the natural oak surround to the division, also attractive arrangement of shelves. The whole dispenses with an ugly partition.*

*Right: lavender grey and white walls in a Regency room, with rich red damask curtains and red and white damask Regency chairs. (Photos: Margaret Currant. Humphrey and Vera Joel, and Lincoln Collins)*

### ***DINING ROOM: HARMONIOUS COLOUR SCHEMES FOR MODERATE INCOMES***

*In illustration No. 1 is shown a dining room of which the predominating tones are blue and brown. The general line is simple and beautiful, and care has been taken that the room should not be overcrowded; but the two armchairs in the ingle nook ensure comfort. No. 3 shows the bow window of the same room, with upholstered seat and blue curtains to shade with the carpet. A built-in dresser provides a further attraction. In No. 2 is seen another style of dining room carried out in red and brown. This room is less spacious, but its possibilities have been well exploited. Note the curtains which can be drawn across the ingle nook to give added cosiness when the room is being used as a sitting room. General hints as to the planning, furnishing and arrangement of dining rooms are given in the text together with further illustrations.*

packing pieces are then fixed to the centre panel at the sides so as to obtain extra thickness for the two top guides which are stub-tenoned underneath. These guides are  $3\frac{1}{2}$  in. deep with slots cut near the bottom into which stops are fitted after the top is put in position, thus preventing any possibility of the top being lifted right off.

The bearers are cut from  $1\frac{1}{4}$  in. stuff, 2 in. thick, and tapered at one end Fig. 2 shows where taper commences. As the top is 1 in. thick, it will be required to taper the bearers 1 in. so that the extensions will be raised just this amount. The taper commences about  $\frac{3}{4}$  in. in front of the inner edge of the extension, so that when open the main top will rest upon the same surface as the extension (In the middle, of course, the top is supported by the centre cross piece.)

The notches are now cut in the end rails of the table, so positioned that the bearers at one end will fit just inside those at the other end; in depth they are cut just the thickness of the bearers at that point when the table is closed. The bearers are now screwed to the extensions and the whole job is assembled.

Guides are fixed as in Fig 4; these are deep enough to take the cross pieces, which are screwed on to prevent the extensions from being lifted up. Apart from this they take no actual strain, the whole weight being divided between the end rails and the centre cross piece (Fig. 2). Stops are fitted to the underside of the bearers to prevent them from being pulled right out. When the movement is tested, the table should be tried to see that when opened the whole top is in a straight line; also that the extensions bed right down firmly without any give in any of the corners. A good lubricant for the bearers is ordinary candle grease.

**A Telescopic Table.** Fig. 7 is an example of the telescopic table. To open, it is simply pulled out at each end and a loose leaf inserted in the centre. In this case the legs move with the top, there being two rails at each side, kept rigid by a tongue.

A table of this description could, by the addition of extra rails or slides, be made to extend considerably, being operated by means of a revolving screw.

The legs are made out of 4 in. mahogany, and are marked out for the mortises, allowance being made in the height for the castors. It should be noticed that in the one pair of legs the mortises are set nearer to the middle to take the inner rails (Fig. 12). The mortises are  $\frac{5}{8}$  in. wide and should meet; the legs are then marked out to shape and tapered accordingly. The end and outer rails are 4 in. by  $1\frac{1}{4}$  in., and the inner rails 3 in. by  $1\frac{1}{4}$  in. The reason for the latter being 1 in. less in width will be obvious from Figs. 8 and 9, since the cross rail fastened to the outer rails will have to pass under them.

The tenons of all the rails are marked out and cut, and it will be observed that those of the inner and outer rails occur at one end only, the other ends being cut off square. The grooves in the rails are gauged from the top edges and ploughed to a depth of  $\frac{1}{2}$  in.; they are  $\frac{3}{4}$

in. wide. The tongue is then glued into the groove of the inner rails and allowed thoroughly to set. All rails and tongues should be of hardwood, which is essential for all work of this kind.

At a distance of  $1\frac{1}{2}$  in. from the square ends of the rails cross rails are dovetailed underneath (Fig. 10). It is essential that these cross rails should be marked out to the exact length, as one pair of rails must fit just inside the other, forming two sets of exactly parallel rails (Figs. 11 and 12). The dovetails are supplemented with screws.

The various parts are now glued up, each pair of legs with its accompanying rails forming a complete set. When dry the two parts are fitted into each other and two stops screwed to the top of the lower cross rail (Fig. 11). When fixing these, allowance must be made for the table to open about 1 in. more than is required when the leaf is put in, as this is fitted with short dowels (Fig. 13). The moulding is then glued to the outer rails, as indicated in Fig 10.

For the top thoroughly seasoned timber must be used; it will be necessary to joint this, the shape being cut afterwards. The best way to mark this out is to use a thin lath with a pin driven through near one end to use as a centre, and revolve the lath round this, holding a pencil at the other end. The two fixed tops are pocket-screwed to the rails, as in Fig. 10. Short dowels are glued into one side, and fit into corresponding holes at the other (Fig. 13). The leaf is also dowelled at one side, and with holes at the other, so that it will always be put in the same position whatever size of table is required.

Having screwed the top on, the joint is planed level with a trying plane; the leaf is also put in and levelled. The ends of the leaf are quite straight, and form a continuous line with the semicircular shape of the fixed tops. The edge is rounded off, as in Fig. 10, while the leaf is in, thus ensuring their coinciding. Candle grease is a good lubricant to use should the slides run stiffly; oil or any other liquid tends to expand the wood, thus making them run more tightly, which may perhaps cause them to jam.

## DINNER AND DINNER PARTY

### Suggestions that Housewife and Hostess will Appreciate

The reader may with advantage consult the article Table and the entries on the various dishes mentioned in the contribution below. See also Dining Room; Service Wagon.

The home dinner need not be elaborate, and the dishes may contain very simple ingredients; but the cooking should be good, the hot food served really hot, and the table should be attractively laid.

The meal should be served punctually. In many homes the dining room has to serve several purposes besides its use at mealtimes, and will need a little tidying and readjustment before it is ready for the family dinner. During the winter the fire should be made up and the hearth swept before the table is laid, and the windows opened to ventilate the room.

Menus should be as varied as possible, and the likes and dislikes of the members of the family considered. A good arrangement when a three-course meal is taken is to have soup, grapefruit or melon, followed by a joint, savoury or dessert, three evenings of the week, and fish, entrée, or a vegetable dish such as asparagus or salsify, and a sweet on the alternate evenings.

For evenings when the cook is out, or time for the preparation of dinner is short, soup can be prepared, a meat pie or stew that only needs re-heating left ready, and a cold sweet made in the morning.

The Sunday evening dinner usually becomes in reality supper. Soup may be the first course, and cold meat or a pie can be served with an inviting salad or sliced beetroot and hot potatoes baked in their skins: or a mayonnaise is generally liked in summer. In winter a casserole meat dish is more suitable than cold food, and a tart or steamed pudding can soon be warmed up, while a cold extra sweet can be prepared and served in the event of unexpected guests, and also additional dessert.

Such arrangements serve for an informal dinner with one or two guests, but the formal dinner party needs careful planning.

**Dinner Party Etiquette.** Dullness should be guarded against by inviting the right persons to meet, in the case of a small party, or by arranging the table, in the case of a large party, so as to bring together the people who are likely to have subjects of conversation in common. Another important factor of success is to give a well-cooked and well-chosen dinner; also to see that any wines to be drunk are good of their kind, and the service smooth and efficient.

In England, in large towns, the time of invitation varies between 8 and 8.45; in the country, between 7.30 and 8; about 10 minutes' grace being allowed for the guests to collect in the drawing room. Men on arrival leave their coats and hats in the hall or in a cloak-room; women are taken by a maid to a bedroom to remove their wraps. The host and hostess receive the

guests in the drawing room, where they are announced by a servant. Cocktails are usually offered.

At a ceremonious party all the arrangements of guests at the dinner table, and the order of precedence into the dining room, are carefully worked out beforehand according to rank and importance. When dinner is announced the host offers his right arm to the most important woman present and takes her into the dining room. The hostess pairs off the other guests in the order of their social precedence, with the exception of the most important man present, who goes in last with her. The host places the woman he takes in on his right at the bottom of the table, the woman of second social importance being on his left. He stands until the guests are seated. The hostess sits at the top of table, with the man who has taken her in on her left.

At large parties it is quite usual to put a card with the name of a guest in each place, but where this is not done the host would tell each couple as they entered the dining room where they should sit. The necessary carving of joint, game, or poultry is done by a servant, unless the host prefers to do it, other dishes being handed round, from which the guests help themselves. The guests on either side of the host are served first, and then straight along, or round, the table to each guest in turn, finishing with the host.

If champagne is to be drunk, it is first offered after the fish, the same rule applying to claret or light white wines, and any of these would be drunk until the savoury. At dessert it is customary to place decanters containing port, sherry and claret in front of the host. If a cloth is used, it is generally removed for dessert, and in any case peppers, salts, etc., pieces of bread, crumbs and glasses are cleared away, and fresh wineglasses are placed with the dessert plates and finger-bowls. After dessert is on the table, the servants withdraw.

At the end of dinner the hostess bows to the most important woman guest and rises. This is the signal for the women to leave the dining room, the hostess going out last. Coffee is served with liqueurs and cigarettes in the drawing room and dining room. At less formal parties coffee may be served before the women leave the dining room; otherwise the men join them in the drawing room in about a quarter of an hour. In town houses, when the regular staff is not large it is sometimes supplemented by engaging skilled assistance. There are able women who specialize in cooking for dinner parties at a moderate fee, and private waiters can be obtained.

To give a successful party the hostess must not be worried over the dinner while it is in progress. It is better to think out a small menu of well-chosen dishes, comprising a soup, fish course, entree, game or poultry, cold sweets and savoury, within the scope of her resources, than to attempt a banquet, which may be spoilt.

**Dinner Service.** A well laid table is essential to entertaining and the charm of this is enhanced by a good dinner service. These are usually made for twelve

or six persons, and can be had at moderate prices in earthenware or semi-porcelain. The regulation service for 12 persons starts with three sets of plates—meat, pudding, and cheese, two or three dishes, two vegetable dishes with covers, and either a sauce-boat or saucetureen with cover and stand. To this may be added 12 fish plates, soup plates, and a tureen with dish and cover. In small households and when entertaining the last item is often dispensed with, soup being served directly from the kitchen into plates, special cups or sets of bowls.

As with a breakfast service, the stock pattern may be recommended, with the suggestion, where economy of space has to be considered, of choosing the same pattern for breakfast and dinner service. In any case thought must be given to colouring and style to ensure harmony with the room or any coloured glass that may be intended for use with the service.

For better services, modern Wedgwood and Coalport china are in perfect taste and are decorated with many of the old designs.

**DIPHTHERIA.** The bacillus known as the Klebs-Loeffler is the germ of diphtheria, and the most striking local symptom of the disease is the formation of a greyish-white or yellow membrane on mucous surfaces, most frequently at the back of the throat and tonsils. The disease is highly contagious. Germs may be found in the throats of apparently healthy people, and in some the microbe is not virulent, but in others it is, and they are diphtheria carriers.

The disease may begin with chilliness and other signs of fever, the temperature being raised 2 or 3 degrees. Next day the throat is sore, angry and red, and some hours later there is a grey or yellowish patch on the tonsils or the back of the throat. Frequently there is no complaint of sore throat, and diphtheria may exist for several days without its presence being suspected. Parents would probably save much trouble if they would make a practice of looking at the throats of young children when they are "off colour."

*The earlier the anti-toxin is given the better. If given on the first day, the disease is almost always cut short. The prospects become rapidly worse, however, the longer serum treatment is delayed.*

On the first suspicion of Diphtheria the patient should be isolated, preferably in a large top-floor room with plenty of fresh air. One person only, who is to look after the case throughout, should be allowed to visit him. Clothing should be put to soak in a disinfecting solution before removal from the room.

It is important throughout the disease and sometimes well into convalescence to keep the child constantly lying down in bed, as there is always a risk of heart failure occurring. After the second week paralysis of various muscles may set in. If it affects the soft palate there is a regurgitation through the nose of any fluid the child may be drinking; if of accommodation, near objects such as print cannot be seen distinctly; if of the limbs, there is weakness in using

them.

Cleansing the throat is not necessary after anti-toxin has been given unless there is foetor, when the throat may be swabbed or sprayed with boracic lotion. If the child struggles against swabbing it is better to discontinue it rather than risk exhaustion. The nurse should wear a mask or protect the eyes with goggles, and if any mucus is spluttered on her face it should be washed off with an antiseptic lotion. Swabs of cotton wool should be used for wiping the face and cleansing the nose. They should be burnt at once. If a croupy cough develops, a bronchitis kettle (q.v.) should be used. To relieve the pain and swelling in the throat, hot applications may be applied to the neck, or cloths wrung out in iced water. The diet should be entirely liquid, milk and broths, and as much water as the patient wishes. Steel drops or tincture of perchloride of iron is a useful medicine in doses of 3 to 5 minims.

The patient is not allowed out of isolation till 3 weeks after the throat is normal in appearance, and not till 2 swab tests at 3 days' interval are negative. Persons who have been in contact with cases should be in quarantine for a week, and each day the throat should be inspected for evidence of the disease. "Carriers" must have their throats disinfected. By inoculations into the skin, in the Schick test, it can be determined whether or not a person is very liable to contract the disease. Protective inoculations can be given to those who show little or no resistance. *See* Disinfection; Notification.

**DIPPING FORK.** A two-pronged fork that is known among manufacturing confectioners as a dipping fork is considered essential for sweet-making purposes. It is used for lifting out centres which have been dipped in chocolate or some other coating mixture and placing them aside to dry. Dipping forks can be obtained at small cost from any ironmonger's. *See* Chocolate.

**DIPSOMANIA.** Periodical attacks of an uncontrollable craving for alcohol, coming on at intervals of a few weeks to a year, and due to hereditary influences, are the symptoms of dipsomania. Between the attacks the victim has no desire for alcohol and may even dislike it. An alteration may be noticed in the patient just before he is overwhelmed—differences in his behaviour, sleeplessness, and loss of appetite. After having taken a certain amount a distaste may arise, and the drinking stops, or retching and vomiting may come on and determine the attack, or he may drink himself into delirium tremens.

Apomorphine, by producing nausea or sickness, may be successful in preventing or cutting short the attack. Capsicum and cinchona have been suggested as a useful substitute for alcohol in relieving the craving, as in the following mixture: Tincture of capsicum, 1½ drams; fluid extract of anchona, 2 drams; syrup of ginger ½ oz.; chloroform water to 6 oz. Take a tablespoonful, when necessary, in a wineglassful of water. When employed by experts, hypnotism has been

most successful in some cases in combating the craving and preventing attacks. *See* Delirium Tremens.

**DIRECT CURRENT.** This is an electric current which flows round a circuit in one direction, as distinct from alternating current (q.v.), which is constantly changing its direction. *See* Electricity.

**DIRECTOIRE:** The Style. This style of furniture originated in France at the time of the Directory (1795-99). It was based on a study of Greek ideas, and its artists used in the main the constructional lines of Louis XVI furniture. The ornaments, however, were discarded and griffons, caryatides, honeysuckles and other classical figures were substituted. After Napoleon's return from Egypt the sphinx and other Egyptian decorations were introduced. During the period marquetry was no longer in demand, but chased bronze mounts in ormolu were the principal mode of decoration. Carving was mainly used in gilded imitation of ormolu work. Mouldings were comparatively little in favour. The Directoire was succeeded by the Empire style. *See* Empire Style.

*Disbudding. Diagrams indicating where this operation is carried out on typical plants. 1. Rose. 2. Dahlia. 3. Carnation. 4. Tomato. 5. Chrysanthemum. (By special arrangement with Amateur Gardening)*

**DISBUDDING.** This means the removal of surplus shoots or flower buds so that those left on the plant shall have full room for development. Disbudding is an important detail in the cultivation of peach and nectarine trees and vines, for many more shoots grow than are needed. "Taking" the buds of chrysanthemums grown to provide large blooms means disbudding or removing the small shoots which appear beneath the flower buds in August. Disbudding is practised on carnations, roses and other flowers grown

for exhibition; many of the flower buds are taken off in order to ensure that those left shall furnish large blossoms.

**DISH:** In Various Wares. Dishes with covers for entrees are made in silver and Sheffield plate. Plain or cut-glass dishes are used for serving dessert, trifles, jellies, etc., while earthenware and china dishes are included in dinner services or may be purchased separately in many stock patterns and in plain kitchen ware. Fireproof dishes are to be had in glass, china and earthenware with covers to match.

**Dish Cover.** The heavy silver or plated covers of the Victorian era are seldom seen now on account of the cleaning involved. Plain electro-plated covers are used for joints, fish or poultry dishes when necessary.

The well-equipped kitchen has a supply of wire-mesh dish covers. These should be used to cover all kinds of fresh food, cooked remains of dishes, and anything which might be disturbed by flies, beetles, mice, or other vermin. After being washed in warm, soapy water they should be shaken and dried, and then placed over the rack above the range to dry thoroughly. *See* Entree; Fireproof Ware; Washing-up.

**DISH:** In Photography. Dishes for photographic work must be kept scrupulously (i.e. chemically) clean. If a trace of fixing solution is left behind in a dish which is afterwards used for developing, mysterious stains will appear on the negatives or prints being developed. The best plan is to keep each dish for one purpose only.

Dishes should be thoroughly washed out immediately after use, and not allowed to stand all night with the stale developing solution in them. After washing they should be rinsed out with a strong solution of spirits of salt (hydrochloric acid). This need not be thrown away, but can be used repeatedly. Earthenware or china dishes are easier to keep clean than enamelled iron dishes, which are liable to chip; but the latter are less expensive. In either case it is well to see that they have flat bottoms. Curved dishes require more solution, and plates and paper do not lie well in them. *See* Developing.

**DISINFECTANT.** Disinfectants are agents used for destroying the germs of disease and so preventing the occurrence and spread of illness. These germs may be present in the air, in furniture, in clothing, and a variety of means may have to be employed to secure disinfection. Sunlight and fresh air kill most germs, while plenty of soap and water is one of the cheapest and most efficient methods to prevent their growth. Polluted water may be made safe for drinking if boiled for 10 min. Infected articles of no value should be burnt.

Chemical disinfectants include carbolic acid, corrosive sublimate (perchloride of mercury), biniodide of mercury, lysol and other substances

derived from coal tar, permanganate of potash, etc. Formalin is a liquid with a strong, irritating odour. It is usually used in a strength of one part to 20 parts of water. Lime is a good disinfectant, employed when diseased animals are buried, a thick layer of the lime being made to surround the carcass.

Linen may be disinfected in many ways. Exposure to steam for a lengthened period, repeated boiling, or boiling in soap and water and then exposing the linen to the sunshine for several days, are some effective methods. A good means of disinfecting is to soak the linen for an hour in a solution of carbolic acid, using one pint of prepared carbolic to 20 parts of water. *See Carbolic Acid; Formalin.*

**DISINFECTION: Of the House.** After an infectious illness it is necessary to have a house or a room disinfected. The problem is much simplified if the room has been previously prepared for the reception of such a patient. The carpet will have been replaced by one or two light rugs, heavy hangings by washable curtains. Unnecessary furniture and all books and pictures will have been removed. The only books allowed should be such as can afterwards be burnt.

In the sick room sputum and nasal discharges are best collected in paper and burnt in the fire. Infective faeces and urine should be received in a bed pan containing some carbolic or a coal tar disinfectant.

Sulphur is easiest to use as a fumigant, and for every 1,000 cubic ft. of space 4 lb. of roll sulphur should be used, or it can be obtained in the form of sulphur candles. The walls and floor should be well sprinkled with water, as sulphur vapour is only active in the presence of moisture. The sulphur is placed on a shovel, preferably at some height above the floor, moistened with methylated spirit and ignited. The door is then closed and the margins of the door and the keyhole sealed with gummed paper.

If the local authority undertakes disinfection the sanitary inspector assumes responsibility for the treatment of the room. He may destroy infected articles and compensate the owner. *See Contagion; Formalin; Fumigation, etc.*

**DISLOCATION.** Displacement of one or more bones at a joint is the general meaning of dislocation. The ligaments which hold the bones in position are torn; the synovial membrane or lining of the joint and the blood vessels and nerves may also be injured.

First-aid consists in sending for the doctor and putting the parts at rest by slings, cushions, and, if necessary, splints, and cold applications to relieve pain. If shock is present, warmth should be applied by hot-water bottles and blankets. No attempt should be made to reduce the dislocation, that is, to put back the bones into their normal positions. This must be left to the doctor to perform, as unskilled efforts may aggravate the injury.

**DISTEMPER: How to Apply.** Before distempering the walls of a room they must be free from nail

holes and similar blemishes. If the room to be redecorated has previously been papered, the walls must be stripped, and any picture nails removed.

Having done this, mix some plaster of Paris with cold water to the consistency of thick cream, and with it stop all the nail holes, cracks, etc., in the surface of the plaster.

The distemper may be purchased loose from any oil and colourman, but it is more satisfactory to purchase a well-advertised brand of washable distemper. Careful mixing is required to ensure an even texture. Three-parts fill an old bucket with cold water, and add the powder a little at a time; stir well with a stick. It is important not to add all the package at once, or to put the distemper in first. The liquid should be of the consistency of whitewash when ready for use, and the first coat should be applied evenly with a distemper brush. Make the strokes horizontally and work the distemper well into the wall, as when painting wood. The distemper should be stirred well during use. *See Colour; Cottage; Decoration; House; Paint; Paper-hanging; Wallpaper, etc.*

*Distemper. 1. How to take a full brush of distemper from the pail.*

*2. Correct way to apply distemper is by working at arm's length.*

**DISTEMPER: In Dogs.** The deadliest disease from which dogs suffer is distemper. If a young dog shows signs of ailing and is indifferent to food, he should be watched. A husky cough follows a rise of temperature, and usually there is a discharge from the nose.

To treat a dog suffering from this disease, put the animal in a moderately warm place, well ventilated, but free from draughts, and coat him in flannel; take an old blanket about the right size, and make two holes 6 or 9 in. from one end, through which the front legs are placed. Sew it up along the back, while it is all the better if the chest and sides are further protected with gamgee wool. Diet with nourishing slops, no solids.

If food is refused, he must have it poured down. Put the fluid in a wide-mouthed bottle. Hold the lips on one side, and on the other insert the bottle, drawing up the lips to prevent spilling. Several times daily cleanse the

nostrils, and wash the gums and inside the mouth with a solution of permanganate of potash. Cleanse the eyes with warm boracic lotion. On no account get on to solid food or permit exercise until temperature has been normal for nearly a week. If the case becomes serious a vet should be called in. *See Dog.*

**DISTILLED WATER.** This water is used for making up hair washes. It should be employed for dissolving shampoo powders, as ordinary water tends to destroy the efficacy of the powder. In making up boracic lotion for inflamed eyes distilled water should always be employed. It is also used for the accumulator of a motor car. *See Accumulator.*

In photographic work the use of distilled water is highly desirable. *See Developing.*

**Preparing the Water.** A simple means of making small quantities of distilled water, such as are required for developers and for other purposes, is provided by the kettle. The spout is inserted in a thistle funnel, obtained from a chemist or dealer in scientific apparatus, which is bent at right angles in the flame of a Bunsen or methylated spirit burner. It passes through a large tin, which has a hole cut in the bottom fitted with a cork; through this a hole, just large enough to allow the tube of the thistle funnel to be pushed through, is bored with a red-hot nail. This tin is kept filled with cold water.

**DISTRAINT: The Law Of.** The law regarding distraint has been modified by the Rent Restriction Acts, passed during and since the Great War. Under them no distress may be issued for the rent of any houses to which the Acts apply without the leave of the county court. Such houses are those of which either the recoverable rent or the rateable value in 1931 did not exceed £45 in the Metropolitan Police district, £45 in Scotland, and £35 elsewhere.

Apart from these temporary exceptions the law allows the landlord whose rent is overdue to enter the house by himself or by a certified bailiff between sunrise and sunset, seize the goods found there, with certain exceptions, and ultimately sell them to pay the rent and the expenses of the distraint. Rent is overdue the day after it ought to be paid. All goods and chattels on the premises may be seized in distress, except certain pictures, fittings and personal necessities actually in use.

If a lodger's goods are seized, he may get them back by giving notice in writing to the landlord or bailiff. He must send a list of what he claims as his, and state that the tenant has no interest in them. Then, if the landlord refuses to return them, the lodger may at once proceed against him in the police-court, for which purpose it is better to employ a solicitor. But the lodger must also state in his notice what his rent is, and if he owes anything; and the landlord can then insist on the lodger paying future rent and arrears.

If a tenant fraudulently removes his goods so as to evade a distress, the landlord may follow the goods and

distrain, and may even break open doors or windows to get at them. But he must do this within 30 days of the fraudulent removal. Goods distrained on may be sold by the landlord after five clear days from the distraint. It is a criminal offence to take away goods which have been impounded, i.e. distrained upon. *See Rent.*

**DIURETIC.** A substance which increases the secretion of urine by the kidneys is termed a diuretic. Water, bland mineral waters, and milk are diuretics.

Diuretics are called for in the state of fever, and the following prescription would be useful. The dose is  $\frac{1}{2}$  to 1 tablespoonful every 3 hours.

Solution of ammonium acetate	3 drams
Potassium citrate	1½ „
Spirit of nitrous ether	1 dram
Syrup	1 „
Peppermint water to make	8 oz.

**DIVAN: How to Construct.** A method of making a divan is to use a box spring mattress and mount it on feet. Fig. 1 shows the method of fixing these. The bottom canvas or covering is stripped off at the corners and a 2½ in. block rubbed into the inside corner, the grain running vertically. It may also be screwed into place. Four feet are then turned (or they may be bought already turned, having a ¾ in. dowel), and a corresponding hole bored into the block, and the foot glued into this. The canvas is cut to fit and tacked back.

**Making the Mattress.** Our illustrations (Figs. 1 to 4) show methods of constructing a box mattress suitable for the divan.

*Divan. Fig. 1. Method of attaching feet to box spring mattress.*

*Figs. 2-4. Diagrams*

*showing construction of mattress frame and how it is sprung and stuffed.*

These box spring mattresses usually finish about 10 in. to 12 in. high, and are based on a sort of tray frame (Fig. 2). A series of stretcher rails is cut in flush and screwed to under edge of sides—numbering seven, including the

two end pieces, and each about  $3\frac{1}{2}$  in. wide. In some cases, instead of all sides being of equal width, the head and foot sides are higher, say 7 in. wide, and the blocks are prolonged to form feet of required height, the sides being notched or let into them and screwed (Fig. 3).

The springs are placed on the rails and screwed to them by staples, and the tops of the springs are tied together with cord to counteract lateral play. They are then covered with canvas, and above this the stuffing is packed to form the mattress and also covered with canvas (Fig. 4). The whole surface is then covered with the outside ticking, which finishes at the bottom edges of the sides, the bottom of frame being neatly covered with canvas.

It will be understood from the above description that the completed box-spring is compressible at the extreme corners in addition to the centre, or not, according to the style of frame which is adopted.

Fig. 4.

*Divan. Fig. 5. Divan bed which can be made from an ottoman and a mattress. It serves the purpose of a seat during the day (Courtesy of Williamson & Cole).*

**Divan Bed.** A divan bed, as it is called (Fig. 5) is one that serves the dual purpose of a seat by day and a bed by night. It can be made of a box ottoman (q.v.) and a mattress. The ottoman should have a stout wooden frame, padded and covered with figured material, the box being used as a receptacle for the bedding. The lid of the box should consist of a spring mattress on which the loose mattress is placed. The latter should be covered on the top with the same material as the ottoman, but underneath it should have an ordinary mattress covering. The ottoman should be fitted with castors so that it can be moved easily. By day, with the mattress for the seat and cushions placed thereon, the piece will serve as a divan. *See Attic; Bedroom; Bed-Sitting Room; Sofa, etc.*

**DIVIDERS.** These are measuring instruments, with which the utmost precision can be obtained from hand work. Typical dividers consist of two legs of equal length, joined together at one end, and finished with a fine point at the others.

*Dividers. Use of spring dividers for setting out wood-work.*

Draughtsman's dividers are frequently fitted with a fine adjustment device, consisting of a small milled-headed screw, which,

when turned, moves one leg to-wards or away from the other. For marking out woodwork the ordinary black spring dividers are made from one piece of steel, the action of the dividing legs being provided by the springiness of the metal. A long screw and a butterfly-nut provide a fine adjustment.

Dividers are used to set out and measure a piece of work, accurately to determine limits and proportions of a design and by them almost all geometrical problems can be solved. *See Compasses; Drawing.*

**DIVISION: In Gardening.** This is the term given to the method of propagation practised in increasing the stock of hardy herbaceous perennials and a few shrubs. Plants which bloom in spring or early summer are divided in autumn; those which bloom in late summer and autumn are divided in spring. The work is carried out by lifting the plants, separating them into pieces each with roots attached, discarding the old inner pieces and replanting only the young outer portions. Most of the favourite border plants, e.g. Michaelmas daisy, helenium, Shasta daisy, phlox, flag iris, erigeron or summer starwort, perennial sunflower, and coneflower or rudbeckia are increased in this way.

*Division. Diagrams showing various methods of dividing. 1. How to treat perennials, the divisions being replanted in groups, as in 2. 3. Potato divisions, each containing an eye. 4. Dahlia root, points of division indicated by arrows. 5. Fern crown, divided for replanting. 6. Loganberry sucker, rooted and divided as shown by arrow. (By special arrangement with Amateur Gardening)*

**DIVORCE.** Divorce in England is granted, under the Matrimonial Causes Act, 1937, to either husband or wife for:

(1) Adultery; (2) Desertion for three years; (3) Cruelty; (4) Incurable insanity for five years.

Except in very special circumstances no petition for divorce can be presented until three years after the marriage.

If the offended spouse, with knowledge of the offence, continues to have marital relations with the offender, the offence is said to be condoned; but, if a new offence is committed, the old offence revives. Husband and wife must not act in collusion to get a divorce if they do, they lose the right to one.

At the trial, if successful, the petitioning party obtains a decree nisi, that is, a decree which does not dissolve the marriage, but the matter comes before the Court again in about six months' time, and then, unless the King's Proctor intervenes, the decree is made absolute and the marriage is at an end. It should be noticed that until the decree absolute is pronounced the marriage vows are still in force, and must be faithfully kept, otherwise the King's Proctor may intervene.

Sometimes husband or wife petitions for a divorce who has, on an occasion, been unfaithful to the marriage vows. In such a case, if he (or she) makes a clean breast of it to the judge, his lordship may grant the divorce notwithstanding the petitioner's own guilt. In all divorce cases it is hopeless to proceed without legal assistance. Petitions for divorce can be heard at various assize towns in the provinces, as well as in London and Edinburgh.

Persons who have less than £50 (in some cases £100) and whose usual income is less than £2 (in some cases £4) a week may apply for a divorce as poor persons. In this case the costs will be very small. Application should be made to the Poor Persons Department at the Royal Courts of Justice, Strand, London, W.C.2, or to a local registry. *See* Desertion; Husband; Marriage; Separation Order.

**DIZZINESS** or Vertigo. Any passing attack of giddiness is probably due to disorder of the digestion or constipation, but it may be the result of any one of a large number of causes. Chronic gastritis is very likely to be accompanied by dizziness.

In these cases the patient should carefully inquire into his diet, the state of his teeth, and his habits with regard to taking food. In some cases it will be found that abstaining from liquids at meals, and taking them only between meals, is helpful. Fats and pastry should be taken moderately. Old people should eat sparingly. Haste at meals often causes digestive trouble. If necessary one may take an occasional mild aperient (q.v.). Excess of tea, alcohol or tobacco may be responsible.

In neurasthenia dizziness is a common symptom. Treatment must be directed to the cause. People getting on in years whose arteries are becoming inelastic, find that they often suffer from dizziness. It is not wise for

them to get up quickly when sitting or lying down; to empty the bladder immediately on getting out of bed in the morning; to make any sudden violent movement such as jumping on an omnibus. Excitement should be avoided as far as possible, and the food should be light and nutritious.

**Ear and Eye Trouble.** The ear is often a source of this trouble. Collections of hardened wax, mixed as they frequently are with hairs and dust, may for a long time be the unsuspected cause of dizziness. The wax should be removed by soaking for a night with oil and gently syringing with warm water. A running ear may be accompanied by dizziness. In Menière's disease of the ear, dizziness is a most prominent symptom.

The eye may also be the cause of the dizziness. Errors of refraction are indeed a very common cause of a slight degree of this trouble which is cured by suitable glasses. Dizziness is associated with many serious affections, such as disease of the heart, tumours of the brain, syphilitic affection of the brain, epilepsy, etc. Much worry will be saved by a timely visit to a doctor, as in the great majority of cases the cause is one which can easily be remedied.

**DOESKIN.** A material much used for gloves, doeskin is a leather which has been degrained by the removal of the upper surface. Thicker and fuller than ordinary kid, it is less heavy than buckskin, and is obtained from the skins of various animals. *See* Glove.

#### **DOGS: CHOOSING, TRAINING AND FEEDING** With Information on Other Matters of Daily Interest to Dog Owners

This entry is supplemented by articles throughout the work on the various breeds of dog, e.g. Airedale; Collie; Retriever; Sealyham, etc., where the illustrations of the various types appear. *See* also Animals; Distemper; Kennel.

At the present time between 80 and 90 different breeds of dog are recognized by the Kennel Club. There is thus a very large selection from which to make a choice but a great deal depends upon individual taste, as well as the accommodation at hand. The heavy breeds comprise the St. Bernard, Newfoundland, mastiff, Great Dane and the bull mastiff, all of which are costly to keep and require a fair amount of exercise to keep fit and well. Any one of them will cost from 8s. to 10s. per week to keep, no matter how carefully fed. The mastiff, the bull mastiff and the Great Dane are smooth-coated dogs and so give less trouble with regard to grooming than do the St. Bernard and the Newfoundland. All are equally useful as guardians of personal property, and the Newfoundland is an excellent water dog.

Following these dogs in point of size, mention must be made of the Alsatian wolf dog, Irish wolf hound, deerhound, Afghan hound, bloodhound, Old English sheep dog, elkhound, greyhound and collie. All these

dogs can be trained for companionship or specifically as guards. Their cost of keep ranges from 5s. to 8s. 6d. per week. The most popular of all is the Alsatian, if we except the greyhound and the retriever.

The retrievers and spaniels are particularly useful dogs. Perhaps the most useful all-round dogs are the terriers, which comprise the Airedale, Bedlington, Border, Cairn, Scottish, Dandie Dinmont, West Highland White, Skye, Fox (smooth and rough), Irish, Kerry Blue, Sealyham, Bull Terrier and Manchester. Here we have a group of first-class dogs, equally good for waterside work or for watching and companionship. The terriers cost very little to keep and make excellent friends with man. Two terriers recently introduced are the Schnauzer and Lakeland. The terriers of Scotland are all short legged, big boned and broken coated, but the bull terrier and the Manchester terrier, likewise the smooth fox terrier, are smooth coated. Handy little dogs are the Cairn terriers, likewise the Sealyham and Welsh terriers, but perhaps the most popular are the Kerry Blues, the wire-haired Fox Terrier and the Sealyhams. The Dalmatian, the collie, the chow-chow, the bull dog, the Pekingese, the Brussels griffons, the King Charles spaniel, pugs, poodles, Pomeranians, whippets, French bull dogs, Dachshunds, Keeshonds and Samoyeds, are admired by many people, and it is purely a matter of personal choice as to which of these may be selected.

**Feeding.** Given the ordinary standard of health and not less than a year old, a dog should be fed once a day, and the best time for this purpose is between one and four p.m. If it is convenient it is a good plan to exercise the animal beforehand. Dogs differ considerably in their habits of feeding. The pet should not be spoiled by feeding it on tit bits, but should be trained to eat properly cooked flesh food, which all dogs must have in order to maintain health. Supplemental foods such as dog biscuits, boiled rice, bread, etc., are useful for giving bulk to the food, but the use of oatmeal or maize meal will sooner or later lead to the production of skin trouble. Such dogs as retrievers, spaniels and collies, etc., should have one pound of flesh per day, the terriers  $\frac{1}{2}$  to  $\frac{3}{4}$  lb., whilst toy dogs  $\frac{1}{4}$  lb. to 2 oz., with or without bread, hound meal, etc. Dry foods are better for dogs than those of a sloppy nature, more especially old dogs, but it is generally necessary to mix the meat with soaked, stale bread or hound meal, squeezing out any excess of water.

Table scraps and bones commonly form part of the domestic dog's menu, but the dog's stomach should not be made a receptacle for the kitchen refuse. One large bone per week may, however, be allowed for a tooth brush and to assist digestion. Dangerous bones are found in chickens, hares, rabbits and fish, and these are liable to become lodged in the back part of the mouth or throat, whilst their sharp edges may easily lacerate the gullet, perhaps with fatal results. Boiled carrots are the best vegetable of all and improve the condition of some dogs. Dog biscuits in their various forms usually contain dried meat and are extensively used (either dry or soaked) as a food for dogs.

**Water for Dogs.** Dogs that are free drinkers generally thrive better than those that take very little water. No matter whether a dog is kept in or out of doors, it must always have a plentiful supply of fresh water. In summer all dogs drink more water than in winter, so the water trough should be refilled at least twice a day and kept in the shade. Both milk and tea are very good for dogs, the former being an excellent nutrient and the latter a mild stimulant. From 1 gill to 1 pint of milk per day will increase the weight of a debilitated dog.

**Exercise.** Road traffic renders the highway very dangerous for dogs and quite a number of people exercise their dogs on the leash only. This does not take the place of freedom, but it is better than no exercise at all. Facilities for exercising vary, and the majority of dogs can be easily exercised, whereas greyhounds and whippets require training on hard roads in order to keep their toe nails properly worn down. Dogs that are too fat must have gradually increased exercise in order to tone up heart, lungs and muscles. Never exercise a dog behind a motor car, or at such a speed as will entail suffering. Sore feet may easily be produced by prolonged exercise, especially on flinty or sandy ground.

**Training the Dog.** The sooner the training of a puppy commences the better, whether to be trained for work with the gun, for ratting or for some other particular purpose such as minding sheep or cattle, the guardianship of person or property, etc. Every dog must be taught to be clean in its kennel and in the house, which can be done by the force of habit and suggestion obtained and obtainable by the repetition of exercise at frequent intervals and by feeding the animal at the same time daily. Dogs have a desire to urinate frequently, and when two or more are kept together one or the other will suggest this act and become a nuisance, especially if living in the house. It is, therefore, very much better to keep them apart or in separate kennels if this can be done. Further, allow very little liquid after 4 p.m. Puppies are, of course, nearly always urinating, so that they require to be lifted and taken into the open four or five times a day.

Every dog must be trained to follow at heel, as this constitutes the basis of obedience, and training to follow in and out of traffic is the best safeguard against accidents. This schooling may begin when the puppy is two or three months old. Put a collar on him and to this fix a check cord, say three or four yards in length, so that you can gradually shorten the cord as each lesson proceeds; bring the puppy closer and closer to heel at the word of command, which is "Come to heel," gradually substituting the word "heel." To prevent the puppy from chasing other dogs, cats, fowls, etc., use the word Ware (pronounced war) thus "ware cat," etc., the frequent repetition of which will prevent the puppy from breaking away and render it free from chase.

Never allow a dog to roam the streets, as this leads to most objectionable habits.

**Grooming.** A healthy coat means a healthy skin, and the health of the latter depends upon a healthy constitution. The appliances necessary for keeping the coat in proper order comprise a dandy brush, or one with stout bristles, a hair glove, a chamois, a comb, and a stripping comb. This appliance has very fine and short teeth; therefore it must be used with a certain amount of care in order to avoid abrading the skin. Pass the comb through the long, soft hair and at the same time use the fingers to remove it, so that plucking and combing run together. The shoulders, around the ears, behind the elbows and the hind quarters should receive special attention.

When a dog comes in wet and muddy it should be allowed to go into a deep bed of straw, and when thoroughly dry should be rubbed down with a wisp of straw and the mud brushed off with a dandy brush. If a long-coated dog is not combed daily, the coat and leathering become felted and then trouble begins. A coat that is healthy has a pleasant feel, whilst the skin is soft and pliant, and free from any redness or irritation, or causes which produce the latter, such as fleas, lice, ticks, etc. Take particular care to see that the inside of the ears are kept clean by sponging them out occasionally with equal parts of hydrogen peroxide and water.

**Care of the Teeth.** Never neglect to make periodical examination of the dog's teeth; otherwise trouble may arise, as nothing can be worse than offensive breath from a foul mouth. Incrustations upon the teeth are common and the discoloration of the latter frequently occurs during distemper, but can be minimised by cleaning the teeth with equal parts of hydrogen peroxide and water. Loose teeth, spongy and bleeding gums (pyorrhoea) are the precursors of digestive disturbance.

**The Dog's Bath.** Grooming should obviate the necessity for frequent bathing, but the bath sometimes becomes a necessity. Soap and water will cleanse the coat, but it renders the hair soft, and in course of time destroys its texture. Under ordinary circumstances a bath at the commencement of the four seasons of the year ought to be sufficient for any dog. The proper manner to bath a dog is to wet thoroughly the back and hind quarters, under the tail, between the thighs, and on the belly freely with warm water; then rub in the soap with the fingers, leaving no part untouched. For adult dogs a good carbohc soap is the best. Repeat this process on the fore part—then rinse the soap out with warm water. This will kill the fleas if the work has been properly done. A medicated bath consists of the addition of some drugs, such as 4 oz. of Epsom salts to each gallon of water for the cure of simple skin irritation, or else 2 oz. of sulphurated potash to each gallon of hot water, but it is much better to dissolve this in a quart of boiling water and then add to bath. This last remedy is

useful for destroying lice, fleas, etc., but it must be repeated at least twice weekly for three weeks in order to render it efficient.

**Administering Medicines.** Dogs, like all other animals, are liable to a variety of diseases and accidents. To give a dog medicine, either in powder, pill or liquid form, is usually, but not always, a simple enough matter to those who have had practice. The pill and the tabloid are the simplest to administer. First of all open the mouth with the left hand, take the pill between the tips of the index and second finger of the right hand and then, with dexterity, place it on the extreme back part of the tongue, closing the mouth almost simultaneously, keeping it shut until the dog swallows. Some dogs will hold their medicine a long time: others swallow immediately.

Powders are usually simple to give and may be dropped on the back part of the tongue, whereas liquids require to be given slowly. To administer the latter put the fluid in a small vial and with the right hand insert the neck of the bottle into a pouch formed by the dog's cheek on the right hand side, keeping it in position by encircling the bottle neck and cheek with the fingers. Sometimes tasteless medicine can be mixed with the food, or dissolved in the drinking water, whilst a very good way to give pills and tablets is to camouflage them by sinking them into a piece of meat. Worm medicines usually require to be given on the empty stomach, or one that is partially so; therefore adult dogs should be fasted 24 hours beforehand, but puppies need only to be kept without food from six to twelve hours. These are commonly infested with round worms, and the best remedy is santonin given in oil, say castor oil. The dose ranges from  $\frac{1}{4}$  to 2 grams for puppies about one month old. A common medicine is areca nut in powder and the dose is 1 grain, or 2 grains for each pound weight of the dog, given in milk or mixed with butter to form a bolus.

The normal temperature of the dog may be said to be 101° F., but slight variations up to 102° F. are common and the temperature rises during exercise. Temperatures of 104° F and 105° F are frequent in febrile affections. The clinical thermometer is used for taking the temperature, and the right situation to ascertain the body heat of the dog is the lower end of the bowel, i.e. the rectum.

**Diet in Sickness.** When a dog is ill it is necessary to devote attention to its food and feeding, in fact in severe illness everything depends upon attention to this matter. For instance, if a dog is troubled with vomiting, it must have small quantities of milk and soda water, keeping it entirely without water. Boiled fish, boiled tripe, malted milk, Brand's essence, Valentine's meat juice, Ovaltine, etc., should constitute the sick dog's diet and the greatest point of all is that of giving the nourishment in small quantities and often. The white of egg beaten up is excellent in stomach and bowel troubles, whilst for urinary affections barley water is best.

**Diseases and Accidents.** Catarrhal diseases affecting the dog are distemper, catarrh, laryngitis, bronchitis, and pneumonia. The commonest of these is distemper (q.v.)

Intestinal maladies comprise worms, diarrhoea, dysentery, inflammation of the bowels or stomach and vomiting. Jaundice or the yellows is not uncommon in the dog; in fact, it has been the hound master's bane.

Cutaneous affections are very common amongst dogs, more especially those which are fed on unsuitable food and lead sedentary lives. These skin complaints are known under various titles such as red mange, blotch, surfeit, eczema, etc., most of which are constitutional in their origin. In these cases professional advice is necessary.

Eye affections are fairly frequent in dogs, and comprise ophthalmia, opacity, ulceration of the cornea, and cataract. Cataract is a disease of the crystalline lens and mostly occurs in old dogs, as senile cataract. It causes partial or complete blindness. Eye troubles, like those of the ear and skin, require professional skill for their proper treatment.

Fractures and contusions are usually the result of direct violence. A fracture may be simple or compound. In the latter case there is a wound in addition to the broken bone, and this complicates matters. Very often the organs contained in the chest or belly are contused; therefore it is necessary to take the dog to a veterinary surgeon.

**Wounds.** These are usually produced either through fighting or direct violence, and owners should always be careful to ascertain the extent of the injury. A wound may appear to be a slight one externally, yet considerable laceration may have occurred. First of all cut the hair off all around the wound, and soak it well with tincture of iodine, but do not wash it. The bleeding must be stopped. Wounds on the ear, especially the margin, as a rule bleed very freely; therefore dress with iodine and fasten on a compress by means of glue or seccotine, leaving this dressing on until it drops off, unless circumstances demand other treatment.

**Poisoning.** Dogs are sometimes accidentally or maliciously poisoned, and very often through rat or mouse poison, though occasionally by strychnine. As a rule the best plan is to give a smart emetic, for which purpose there is nothing better than ipecacuanha or antimonial wine given in doses from 1 dessertspoonful to 2 tablespoonfuls without water. The dog will usually vomit shortly afterwards.

**Mother and Puppies.** The normal period of gestation in the bitch is 63 days, but a few days before or after the prescribed period for labour to occur is common. It may, however, be delayed through the death of the puppies or some other cause. If the owner has any suspicion that all is not well he should immediately consult a veterinary surgeon. The signs of approaching labour are restlessness, lacteal secretion, and abdominal pain. Owners should always prepare

suitable accommodation for a bitch about to become a mother, and this ought to be in a quiet place. Disturb her as little as possible, but as soon as she has completed her task give her a dose of castor oil, cleanse her with soap and water, and take care to feed her generously on cooked meat and broth, boiled rice, etc. Wean the puppies when they are four weeks old, and as soon as weaned feed four times per day on milk and farinaceous food with a little minced meat. Later on feed three times per day on more solid food.

**Homes for Dogs.** There are several homes to which dogs can be sent, the oldest being at Battersea, London. Anyone losing a dog in the metropolitan area should at once inform the police, and then visit the Home, where all strays are taken except those found in certain parts of north and east London; these are sent to Willesden and East Ham. Unless they are diseased they are kept for seven days, and may then be sold or destroyed. All dogs not claimed within the seven days become the absolute property of the committee. A purchaser will have to give an undertaking that the dog is not to be used either for experimental or for stage purposes.

At Shooters' Hill, London, S.E., the Blue Cross Society have kennels for dogs that must go into quarantine. The society also take charge, for a fee, of dogs when their owners go away from home. Many veterinary surgeons also take in dogs at such times.

**Clubs and Shows.** The chief club for dogs is the Kennel Club at 84, Piccadilly, London, W. Another is the Tailwaggers' Club at 58, Mark Lane, London, E.C.3, and, in addition, there are a number of others, some being specifically devoted to the interests of a particular breed.

The breeding of dogs is encouraged by numerous shows. Some of these are general, while others are devoted to a single breed. The chief show is Graft's Dog Show, which is held in the Agricultural Hall, Islington, every February. It was started in 1886 for terriers only, and has now nearly 10,000 entries, these including every recognized breed of dog.

**Licences for Dogs.** Throughout Great Britain every person who keeps a dog over six months old must take out a licence, obtainable at any post office. This is not necessary in the case of farmers, who may keep up to two dogs to assist them on their farms, for the purpose of tending sheep or cattle. A sheep farmer may obtain exemption for more than two dogs. Exemption must be obtained by making a declaration, the form for which may be obtained from the local post office. Dogs used by the blind are exempt; so are hounds under 12 months if they belong to a master of hounds. The cost of the licence is 7/6 in Great Britain and 5/- in Northern Ireland.

If any person is found in custody or charge of a dog, or the animal is found in his house or premises, he will be deemed to be the person who keeps the dog, unless the contrary is proved. The penalty may be as high as £5: and any excise officer or police constable is entitled

to ask him to produce his licence, and he may be fined up to £5 if he does not comply with this demand within a reasonable time.

**The Law About Dogs.** For some purposes a dog is not property, i.e. it cannot be stolen at common law, but in 1861 it was made an offence punishable by six months' imprisonment to steal a dog.

The Ministry of Agriculture and Fisheries may make orders providing for the regulating and muzzling of dogs and keeping them under control in any particular district, and for prescribing and regulating the seizure, detention and disposal (including slaughter) of stray dogs and dogs not muzzled or under proper control. A local authority may, if satisfied that there is a mad dog, or one suspected of being mad, in its area, make an order placing such restrictions as they think expedient on all dogs which are not under the control of any person during the period of the order. Such an order must be published prominently. Anyone who thereafter contravenes it is liable to a fine of 20s. The owner of a dog alleged to be dangerous may be summoned before a magistrate's court and ordered either to keep it under proper control or to have it destroyed. Any person failing to obey such an order is liable to a fine not exceeding 20s. a day.

Stray dogs must not be kept by the persons finding them, but must be either returned to the owner or taken to the nearest police station. If the finder wishes to keep the dog he can obtain a certificate stating full particulars of the dog. In this case he must keep the dog in his possession for at least one month. Police officers have the right to seize dogs which appear to be stray dogs, and detain them until the owners claim them and pay the expenses. Should any stray dog so seized be wearing a collar giving the address of its owner, or should the police know who is the owner of the dog, due notice must be given to the owner in writing saying that the dog will be sold or destroyed if not claimed within seven clear days. Imported dogs may be ordered to be detained in quarantine for a particular time. Such orders are commonly made in an outbreak of rabies.

Every dog in a public place must wear a collar with the name and address of its owner. This does not apply to dogs used for sporting purposes, for destroying vermin or for driving sheep or cattle. A dog without a collar is liable to be treated as a stray dog. The owner and the person in charge are also liable to a fine up to a maximum of £50.

Any motorist who runs over or injures a dog must stop and give his name and address to the owner or person in charge. Otherwise, he must report the accident to a police constable or police station within 24 hours. (Maximum penalty—first offence, £20.)

Every dog which is suspected of having rabies may be slaughtered. When there is an outbreak of foot and mouth disease an order prohibiting the removal of animals may include dogs. It is illegal to use dogs as draught animals.

Damage done by dogs is the subject of a rather

curious order. At common law the owner of a dog was not liable if it bit or worried any person or animals unless he knew that it was a vicious animal.

Later the owner was made liable for any damage done to cattle or sheep, without proof of knowledge, and in 1928 the principle was further extended. In Great Britain the owner of a dog is now liable for any injury done by it to poultry, just as he is for injury done to cattle, horses and sheep.

**DOG: In Woodwork.** Employed for temporarily holding two pieces of woodwork together, a dog consists of a bar of steel bent over and pointed at each end. The ends are driven into the wood. The dog is placed so that one end is fixed into the standing part and the other end into the other piece, so far as possible in a diagonal manner.

*Dog. Flooring dog, showing how it is used to close up floorboards.*

Many otherwise difficult jobs can be put together with dogs, such as the erection of a framed building; the first section is erected, and the next held in place with the dogs while the bolts are adjusted, the dogs being then removed.

Flooring dogs, employed when laying a flooring of boards, have two prongs formed on the end of a bar, which is tapped to take a screwed rod having a handle at one end and a pad piece at the other. The prongs grip the floor joists, and the screw is used to tighten the boards in the manner shown in the diagram, one dog at each end of the board. This ensures a good tight joint, and is of advantage when the timber is not perfectly seasoned.

**DOG CART.** This is a high, open, two-wheeled vehicle drawn by one horse. It has two seats, placed back to back and each holding two persons. The rear seat usually folds up, and the back footboard can be fixed up so as to enclose the body of the vehicle. This type of carriage is very suitable for persons who wish to get about the roads quickly. *See Carriage; Driving.*

**DOG FISH.** Belonging to the species of smaller sharks found off the British Isles, the dog fish is so named from its habit of pursuing in packs the smaller fish on which it feeds. It is dreaded by fishermen, the value of whose catch is frequently seriously diminished

owing to the dog fish biting at the fish hanging on the line and attacking and damaging the nets.

### DOG'S TOOTH VIOLET (*Erythronium*).

These are beautiful little spring-flowering bulbs suitable for planting in the rock garden. They thrive best in peaty or leafy soil in slight shade. The popular name is derived from the shape of the bulb which bears some resemblance to a dog's tooth. The flowers of the common kind (*dens-canis*) are of various colours, rose, purplish-pink, etc.; they are on stems 6 inches or so high. The American Dog's Tooth violets, which need a sunnier place, are finer and more varied in colour. Some of the best are *Hendersonii*, pale purple; *revolutum*, purplish pink, and *Hartwegii*, yellow. The bulbs ought to be planted in September or October about 2 inches deep.

*Dog's Tooth Violet. Clump of flowering plants of the European species, dens-canis.*

**DOGWOOD** (*Cornus*). These are hardy shrubs or small trees which are valued for their flowers, ornamental leaves or coloured bark. The commonest of the flowering kinds is the cornel or Cornelian cherry (*cornus mas*) which grows wild in Britain: it makes a big bush and bears a profusion of small yellow flowers in February-March. *Cornus Nuttallii*, which bears large white flower-like bracts and autumn-tinted leaves, is very beautiful, but, being less hardy than some others it needs a sheltered position. *Florida*, *macrophylla* and *kousa* are others which produce attractive, pale, flower-like bracts. They need a sunny sheltered spot.

Of the dogwoods, grown for the sake of their coloured leaves, the two finest are *Cornus alba Spaethii* with green and yellow, and *alba variegata* with green and white leaves. *Cornus alba* and *stolonifera* have red stems, those of *flamiramea* are yellow. These, which are beautiful in winter, should be hard pruned annually in March for the bark of the new shoots is more brightly coloured than that of the old stems. Propagation is by layers in summer or by cuttings inserted out of doors in autumn.

**DOILY.** Doilies may be round or square, and are made for dessert use of real lace, Irish crochet, hand-painted gauze, oriental embroidery on muslin or silk. Lace paper doilies can be bought in varying sizes in

silver and gold paper as well as in white. Their use should not be overdone. For cake plates they are not necessary, but they are a good finishing touch for serving small savouries, sandwiches and pastries. *See Luncheon Set.*

### DOLLS AND THEIR HOMES

#### With Details for Making these Fascinating Playthings

This article describes how to make a simple doll, a doll's house and also its furniture. For other information of a similar kind see *Christmas; Knitted Toys* also *Toys and Toymaking*.

While freakish dolls, sophisticated dolls in fancy dress and purposeful dolls, whose wired crinolines conceal a telephone or a bottle, are a matter of passing fashion for the grown up, the real toy doll retains a permanent position as a nursery favourite. It may be of rubber or wood, or soft and cuddly of the knitted wool or plush-covered variety; it may be made completely of wax, china or composition or have its face, arms and legs of one of these fabrics and the rest of its body of linen stuffed with horsehair or other material; it may possess an automatic equipment for walking and speaking, a wig of real hair and almost deceptive eyebrows, eyelashes and teeth, or it may be merely a sixpenny doll with no merit but the one common to any of the others, its capability of becoming the intimate friend of its possessor.

When grown beyond the stage of her first cuddly toys, a little girl is normally attracted by a doll dressed more or less as herself; small boys quite often like dolls dressed as soldiers, sailors, or Red Indians. It is certain that many girls who love their dolls do not want to bother about dressing or undressing them, but young children of both sexes will frequently be interested for hours playing with a doll's house and its furniture.

**Easily Made Dolls.** Printed covers for rag dolls, ready to be cut out, made up and stuffed can be bought at many toy stores. Having laid such a cover flat on the table, with sharp scissors cut round the outline, leaving a narrow margin for making up. This is turned in and if the seams are neatly oversewn on the right side stuffing can be done as the sewing proceeds. Kapok (vegetable down) is the best filling to use and should be well worked into the cover.

Another method, which can be used when an old bought stuffed doll is available, is to unpick the doll, remove the stuffing, iron the case to smooth out creases, and take the pattern of the old doll. It may not be necessary to go to the trouble of unpicking it, for if the shape is simple the pattern can be obtained by measurement. The old stuffing, provided it is quite clean, can be used to fill the new doll. The accompanying diagrams give ideas which can be supplemented by individual taste.

Fig. 1 shows how to cut out and place pattern on material to make a doll. For one of medium size the

distance from shoulder to knee should measure 10 in., and across hips 4 in. The leg and foot are cut in a separate piece, also the arm (A, C, and B). For making the body-case, holland, glazed linen, or wash-leather are suitable. When the pattern is cut out place back and front together, right side inside, and stitch all round, leaving  $\frac{1}{4}$  in. turnings. Leave the neck open for stuffing.

*Doll. Left, composition doll with bobbed hair. Right, jointed doll with eyes that open and close (Selfridge & Co., Ltd.)*

There are many different materials besides kapok that are suitable for stuffing dolls. Brown rugging wool, provided it is clean, is a cheap and soft filling. Flock is another material which can be used. Sawdust and bran give a good shape to the doll when filled. Before using, care must be taken that the tilling is dry; this especially applies to bran, which, if packed damp, soon goes mouldy and smells unpleasant. Fine wood wool is much employed for stuffing dolls, and is suitable for big ones that will be subjected to hard wear. This can be bought at glass and china shops.

Whatever filling is used, it must be packed in tightly. Force it well down into the legs, using a pencil. When both legs are well filled and a good shape, machine or stitch by hand a straight line across the body; this forms the hip line (Fig. 1). Continue to fill in the same way until the trunk is firm and a good shape. Close the neck with strong stitches placed closely together.

*Doll. Fig. 1. Stuffed doll, showing how to cut out the various pieces. The method of making a movable joint is shown at D.*

The lower leg and foot should next be made. When

filled the leg is ready to attach to knee. The following contrivance, which is extremely simple, makes the knee move as though jointed (Fig. 1, D). Do not attach the lower leg directly to the upper leg, but instead stitch on a piece of the same material,  $1\frac{1}{2}$  in. deep, from which the body was made around the bottom of the upper leg. Sew the top of the lower leg to the outer edge of this band of material. This leaves about  $\frac{3}{4}$  in. between the two limbs, and will allow for movement sideways as well as backwards and forwards. The arms can be entirely made of material, or the lower arm, wrist, and hand can be bought made in composition or plaster, and glued to the upper arm. Attach both arms to the neck.

As this particular doll is intended to be for older children who would appreciate a realistic one, it is better to buy a head, obtainable at toy shops at varied prices. The heads are provided with good shoulder pieces, which must be glued over the top of trunk and arms, thus doing away with any unsightliness where the arms join the body.

**Clothing for the Dolls.** Clothes for dolls may be copied from national or fancy dresses, but are more often merely reproductions on a small scale of those made for girls, babies, and, to a lesser extent, boys. Their making is therefore only an adaptation of the ordinary principles of dressmaking, knitting, etc. Usually the more nearly the doll's clothes resemble those of its prospective owner the greater pleasure will it give; and for some children the larger its wardrobe, the greater amount of interesting occupation it will supply.

Socks can be made on fine needles, just a straight strip decreasing a little towards the end; when sewn together at the back, and pulled on to the doll's leg, they will shape themselves. Shoes may be made from old gloves and fastened on with a button and loop. A vest can be knitted or crocheted. A straight piece of knitting with stitches cast off in the centre for the neck and shoulders and picked up again to complete the back is all that is necessary. A crocheted border for the neck will allow of a ribbon or string to pull it up.

Patterns of dolls' clothes, together with detailed instructions for cutting out, etc., are sometimes issued with fashion periodicals, while various books and papers dealing almost exclusively with clothing for dolls and everything pertaining to the toy are obtainable.

Dolls for Christmas trees, party favours, etc., can be dressed in crepe paper. This can be bought from most toy stores in rolls of various sizes and in a wide range of colours. A combination of different shades is often successful.

Because of its fragile nature, crêpe paper should be sewn with care and a fine needle used. This precaution applies particularly to gathers where the thread has to be drawn up very gently.

**Renovations and Repairs.** There are certain doll's hospitals in London and the provinces to which a

damaged doll can be sent for repair. New wigs can be supplied quite inexpensively, new limbs, new eyes, and new heads. The body of a large well-made doll will stand two or even three decapitations, and be worth re-heading at intervals. It is quite possible to repair a broken doll at home provided the face is not cracked and ruined. Very often the back of the head gets crushed in. The best remedy is to stuff the head with paper or cotton wool and glue over the whole aperture a fairly large wig. The jointed limbs of dolls can often be fixed in again. In the case of a hair, wool or sawdust stuffed doll, the detached limb can be sewn on again securely.

If the body is of celluloid or composition the limb can be securely tied on with strong thread or very fine elastic. The latter is knotted through one limb, threaded through a coarse darning, and then drawn through the doll's body, and the limb on the other side attached. If the outer covering of the hair or wool or sawdust stuffed body becomes torn, a neat patch sewn over the hole prevents the doll from "bleeding to death." In the case of a cracked face, the only remedy is to melt a little wax from a candle and pour it into the crack, smoothing it first before it sets to make it look as even as possible.

**The Doll's House.** An inexpensive, quickly made, strong and attractive doll's house is shown at Fig. 1. Oddments and three-ply board are almost wholly employed in the construction of these houses, the whole nailed together, and the walls and roof covered with doll's-house paper.

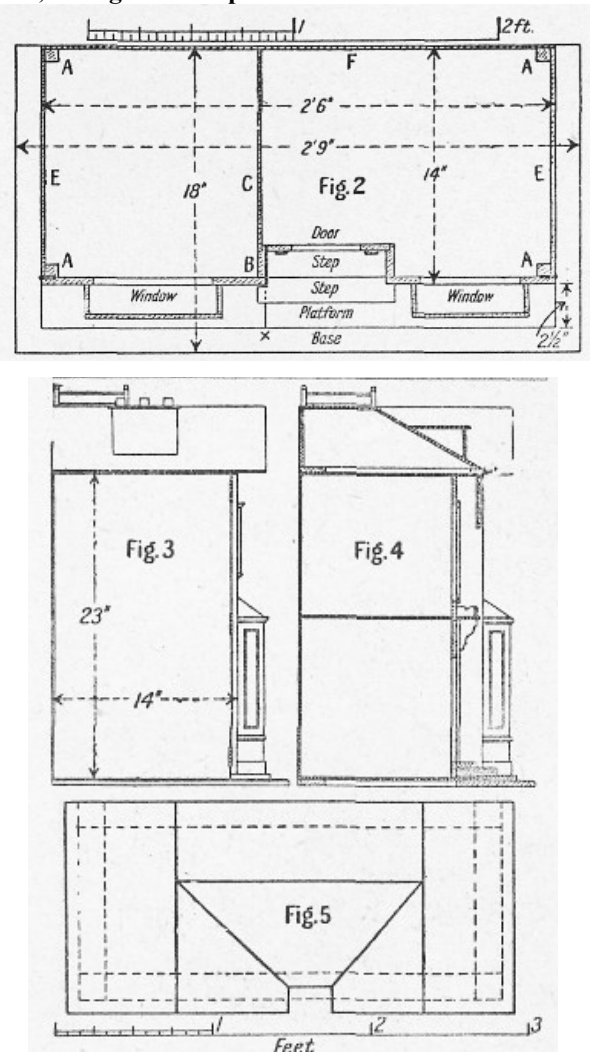

*Doll's House. Fig. 1. Easily constructed doll's house.*

The entire front is constructed as two large doors which open over the ends and disclose the whole interior with four roomy compartments. On the ground floor is a kitchen at the left, and at the right a lounge living-room. The first floor may be used for two bedrooms; or the right-hand half may have a partition across, making space for a bathroom. In the lower lounge there is room for a neat staircase. The roof is so built that it may be lifted off; elevations and plans shown are drawn to scale. The elevations and plan at Figs. 2, 3, and 4 will give sizes and quantity of timber. Fig. 6 shows how the skeleton framework is built. There are four corner posts (A), for which lengths of

about 2 ft. by  $\frac{3}{4}$  in. square will be wanted. The middle upright (B) is the same length, but 2 in. wide by  $\frac{1}{2}$  in. thick, and is rebated for the partition (C), which will be 3-ply board. The bottom (D), ends (E), and back (F) are three-ply, nailed on. The top (not shown in this sketch) is also 3-ply, the same size as the bottom.

The 3-ply floors (G) are cut at the corners to fit the posts, and fixed to narrow mould nailed to the 3-ply sides and partition. The right-hand floor (G) should be cut back in the middle as indicated to allow for the recessed doorway part.

The front is a pair of large doors, hinged to the posts (A), and opening from bottom to top. The left-hand door, 13 in. wide, shuts on the upright (B), which is a fixture. The right-hand door is 17 in. wide, and includes the recessed doorway portion of the house. Thus, the right-hand opening front is not flat, but has a break (Fig. 8). The fronts of the house may be of  $\frac{3}{8}$  in. wood, strengthened top and bottom with battens.

*Fig. 2. Plan. Figs. 3-5. End and sectional elevations and plan of roof.*

Screwed to the underside of each opening front is a  $\frac{1}{2}$  in. platform which carries the bay windows. This platform is 30 in. long by 3 in. wide; but, as it opens out

with the doors, it must be cut across as at X on plan (Fig. 2). At Fig. 8 are given outline perspective sketches of the left and right opening fronts as they will appear in carcass. The bay windows and doorway are not shown on this sketch. The narrow break piece (H) should be of  $\frac{3}{8}$  in. wood, nailed to the main parts of the little building.

Figs. 6-7. Carcass of house and details of roof.

Figs. 8-10. Opening fronts, doorway and bay window.

Each door should be hinged with three good butts, and the platforms should be raised about  $\frac{1}{8}$  in. from the base. The base of the house may be framed up of  $\frac{1}{2}$  in. or  $\frac{3}{4}$  in. material, halved at the corners. The front stile will be 6 in. wide: the back stile and rails may be 2 in. A stiffening centre rail 2 in. wide should be added.

#### How to Make the Roof.

A scale plan of the roof is given at Fig. 5, and at Fig. 7 a simple method of its construction. First make a frame of  $\frac{1}{2}$  in. material, 32 in. by 15 in., to overhang 1 in. at front and sides, but flush at the back, halved at the corners, with four holes bored to enter dowels fixed in the top. From Fig. 7 it will be seen that two gable pediments and a back piece (all of  $\frac{3}{8}$  in. material) are nailed to the frame. Over these the 3-ply roof may be laid.

The shapes of the three inner slopes should be cut in stiff paper to secure the correct angles. The flat back portion of roof is approximately 18 in. by 6 in., and will take a balcony rail. The front gables may be overlaid with  $\frac{1}{8}$  in. fretwood cut to a width of  $\frac{1}{2}$  in. The arrangement of the strips is shown at J, Fig. 7.

The doorway has two steps,  $\frac{3}{8}$  in. or  $\frac{1}{2}$  in., the lower one cut back close on the left-hand hinged front (Figs. 2 and 8). The door pilasters, (K, Fig. 9), of  $\frac{1}{4}$  in. fretwood, 10  $\frac{3}{4}$  in. long by  $\frac{3}{4}$  in. wide, are surmounted by a ledge supported by two shaped brackets. The ledge may have an ornamental rail as shown in Fig. 1. The door may be 8 in. by 4 in. with  $\frac{1}{16}$  in. veneer

mounted on to form panels. The fanlight above will be treated as a window. The arch shown above the doorway should be of  $\frac{1}{4}$  in. or  $\frac{3}{8}$  in., set back about  $\frac{1}{4}$  in. from face of the house front. As the arch opens with the right-hand house front, it must be made rigid at the left-hand side by glueing in a small piece of wood to secure it in the recess. If preferred, the lower step may be out flush with the upper one, so that the left-hand door may be made to open before the right-hand one.

Fig. 10 shows the bay windows, of  $\frac{1}{4}$  in. material with three-ply roofs, the plinth (M) and moulds (N) being glued on. The upper windows are made up of  $\frac{3}{16}$  in. fretwood glued on in strips. Narrow moulds are planted on above and below. All windows should be glazed, the glass being beaded in. To secure the effect of sashes, strips of narrow veneer may be glued to the glass as at O, Fig. 10. The construction of the little dormer window, shown at Fig. 7, calls for no comment. The chimney stack (Fig. 7) is a block of whitewood 5 in. wide, 3  $\frac{1}{2}$  in. high and 1  $\frac{1}{4}$  in. thick. Above is a flat piece of  $\frac{1}{4}$  in. fretwood, and three short lengths of 1 in. dowel rod will serve as chimney pots. For the top balustrade the posts may be  $\frac{3}{8}$  in. square by 1  $\frac{1}{2}$  in. high. Between these, on the roof floor, are glued strips of fretwood  $\frac{3}{8}$  in. wide, whilst the rail itself may be  $\frac{1}{4}$  in. beech dowel rod with little turned balls on the post tops.

A special feature should always be made of the outside and interior decoration of a doll's house, for it is this touch of reality that appeals to the child. The exposed woodwork may be painted a soft cream, the stand green, and the chimney pots red. The outside walls should be covered with doll's house redbrick paper, and the roof with blue tile paper. For the inside a great variety of miniature patterns is available.

**The Furniture.** If the floors have been smoothly planed, they can be stained, but if rough, it is better to carpet them all over, cutting the carpets from any odd pieces. The floor of kitchen and bathroom can be covered with linoleum, and little rugs can be made of tiny pieces of carpet in contrasting colours. Long side curtains of cretonne or casement cloth surmounted by a little frill in the same material across the top of the windows look well. Little net or muslin half curtains can be placed across the lowest sashes.

Charming little beds can be made out of notepaper boxes, chocolate boxes, etc., arranged so that the lid of the box forms the head of the bed, and trimmed with a frill of muslin to form valances and curtain. Mattresses and pillows stuffed with cotton, wool, and calico sheets, are added. The bed curtains in the different rooms can be tied with different coloured ribbons and the coverlets made of ribbon to match. An eiderdown can be made by stitching up about 12 in. of 5 or 6 in. wide satin ribbon to form a bag, stuffed with a layer of wadding. The bag is then sewn up, and the rows of stitching added by machine, which produce a facsimile of an eiderdown quilt.

The kitchen equipment should include a stove, pots

and pans, wash-tub, mangle, irons, and all the usual outfit. Tiny brooms can be made by tying a few wisps of fibre to a thin skewer or a few little feathers to a matchstick. A set of kitchen towels, dusters, etc., can be made, and, of course, the usual complement of cups, saucers, plates, etc., obtained. Sets made of aluminium are quite inexpensive, and minute cutlery, spoons, forks, etc., are obtainable in tin.

*Doll's Furniture. Fig. 1. Complete set of kitchen furniture. Fig. 3-6 Diagrams showing how to make the various pieces.*

#### Furniture Designed for the House.

Doll's furniture may roughly be divided into two classes. There is the miniature furniture that a child can use with her dolls on the nursery floor—chairs, tables, beds, etc., made on a scale proportionable to the size of an average doll. Then there is the toy furniture used to decorate the doll's house, and it is to this latter type that the accompanying illustrated suggestions chiefly apply. Almost all the designs shown, however, have been so prepared that they can be made to any size—in miniature form for the doll's house, or to toy items for the kitchen. Constructional details are shown in conjunction with a tub. The peg dolly consists of a vertical rod forming the handle; the lower end carries a disk on which are mounted a number of wooden pegs. The clothes are washed by using the dolly to propel the clothes, employing an undulating and rotary movement for this purpose. at Figs. 2—6.

Miniature dining room and bedroom furniture is shown in Figs. 7-13. Hints for other items may be

gathered from our furniture articles on other pages of this work. For the smaller toy furniture odd scraps of fretwood ( $\frac{1}{4}$  in.,  $\frac{3}{16}$  in. and  $\frac{1}{8}$  in.) will be serviceable. larger scale for floor amusement. At Fig. 1 is a group of

*Fig. 12. Wardrobe.*

*Fig. 13. Bedstead.*

*Dolly. Left, peg; and right, chump. (Courtesy of T. Bradford & Co., Ltd)*

**DOLLY.** A dolly is employed for washing clothes in conjunction with a tub. The peg dolly consists of a vertical rod forming the handle; the lower end carries a disk on which are mounted a number of wooden pegs. The clothes are washed by using the dolly to propel the clothes, employing an undulating and rotary movement for this purpose.

The chump dolly has the pegs formed by shaping them from the

solid, and are considered stronger, as there are no separate parts to work loose. Many of the hand and power driven domestic washing machines consist essentially of the washing tub and a dolly that is mechanically actuated, as by turning a handle or pushing a lever. *See Laundry.*

**DOMETT.** A cotton imitation flannel, unbleached or white, twill-woven and with a fleecy nap on both face and back, domett corresponds closely to flannel-ette (q.v.) and serves the same purposes.

**DOMICILE.** A man's domicile is the place where he actually lives with the intention of making it his home. It is quite different from his nationality. The intention is very important, because many people live in a country for a very long time without any intention of making it their home. Thus British members of the Indian Civil Service do not lose their English or Scottish or North-Irish domicile by any number of years residence in India, because it is presumed that on the expiration of their service they intend to come back to the country they always call home.

But mere intention without the fact of residence will not do. Thus if I, who was born and have always lived in England, make up my mind to go and live in Scotland, but do not go—postponing my departure from time to time—my intention does not make me a domiciled Scot.

Until attaining 21, a person's domicile is that of his father. The domicile of origin is retained until another is acquired, either by the person when over 21 going to live in another country with the intention of making it his home, or, in the case of a female, by marriage with a man of another domicile.

Domicile regulates a person's matrimonial status and the disposition of his personal property, wherever situate, on his death. Thus, personal property in England of a person domiciled in Scotland must be disposed of by Scots law. A will should be made according to the law of the testator's domicile, and if it be good according to that law it will be recognized by British courts.

Any person seeking divorce must apply to the courts of the country of his domicile, and if he obtains a divorce elsewhere the British courts will not recognize it, and will send him to prison for bigamy if he marries again. In England and Scotland a marriage contracted according to the law of either country is legal; but British girls marrying foreigners should be very careful to ascertain that the marriage will be lawful according to the law of the husband's own country. *See Naturalization.*

**DOMINO.** A domino is a kind of loose cloak with wide sleeves and a hood, worn at masquerades by men and women who are not personating a character. A small mask, generally covering the upper part of the face only, is worn with a domino. Dominoes are made in a variety of colours and in any suitable material. Taffeta, satin, Italian cloth or sateen are the materials

most frequently used. *See Fancy Dress.*

**DOMINO CAKES.** Cut some Genoese pastry into small rectangles, split them lengthways, and spread the insides with raspberry jam. Coat the little sandwiches with royal icing, and when set decorate them to resemble dominoes. This may be done with the aid of a forcing pipe and a little chocolate icing. Almost any kind of cake, preferably white, can be used for making these sweet cakes. *See Genoese Pastry; Icing.*

*Domino Cakes, consisting of raspberry sandwich decorated with royal icing and chocolate pips.*

**DOMINOES:** How to Play. There are many variants of this popular game. It is played with 28 oblong pieces, usually made of ivory or bone, as far as the fronts are concerned, and of ebony or a substitute for the back. They are made sometimes in wood or in cardboard. The face of each domino is divided into two equal squares by a black line, and each square, save a few that are blank, is marked with black pips, varying in number from one to six. A set consists of pieces marked as follows:

0.0	3.1	4.4	6.0
1.0	3.2	5.0	6.1
1.1	3.3	5.1	6.2
2.0	4.0	5.2	6.3
2.1	4.1	5.3	6.4
2.2	4.2	5.4	6.5
3.0	4.3	5.5	6.6

There are in existence many sets of 55 pieces which are numbered up to 9.9, and others of 91 pieces go up to 12.12, but an ordinary set does not go beyond 6.6.

The block game, which is one of the commonest domino games, is played as follows, usually by two persons, although more can play. Shuffle the dominoes face downwards and then let the players draw for the lead, unless, as is frequently done, the one holding double six or the highest piece in play takes it. This decided, the leader takes the number of dominoes agreed upon, and his opponent follows his example. They look at these dominoes themselves, but must keep from the view of the other player.

The leader then places a domino on the table, and the other player must fit to one of its ends one having the same number of pips as are at that end, e.g. 3 must be fitted to 3. If the player plays double 3 or any other doublet, which is placed crosswise, he is allowed another turn, while if he cannot fit a domino he loses

his turn. Conditions are the same if three or four people play.

A variant of the game is to leave a certain number of dominoes, generally 14, in the pool or centre of the table. These are drawn upon by a player who cannot fit one from his own hand. As he draws when they are face downwards, if he draws one that is unsuitable he increases his holding and thus suffers a disadvantage. The pool is not drawn upon after only two dominoes remain in it. A game is usually for 100 points, these being made by the winner of each round counting the pips that remain in his opponent's hand or hands.

**Matador.** Another popular domino game is called matador. In this, instead of fitting the dominoes with ends like to like, e.g. 4 to 4, each player in turn must fit one to make up a total of 7. Thus, if the line of dominoes on the table have 2 and 4 at the ends, he can play one having 5 or one having 3, or he can play a matador, as four of the dominoes are called. These are double blank, and three that total seven, 6.1, 5.2 and 4.3. If he cannot play he must draw from the pool, losing his turn if he cannot find one suitable. If a domino having one end blank is played, no dominoes can be fitted to it, except one of the four matadors. When no further play is possible the winner, i.e. the player who has the fewest pips on his remaining dominoes, scores the number held by his opponent or opponents.

**Other Games.** Two other games are known as All Fives and All Threes. In the former two, three or four players can take part. Each takes an equal number of dominoes, provided that at least two remain untaken and that no one has more than seven. They are shuffled and distributed with the faces downwards. The object of the players is to make the two end pieces five or a multiple of five when the pips are added together. All double dominoes must be placed transversely.

All Threes is a variant of All Fives, the essential point being that three and its multiples score instead of five and its multiples. The scoring numbers are therefore three, six, nine, 12, 15, and 18, which score respectively one, two, three, four, five and six. The game is usually played for 61 points.

Another game is known as fortress. Four players take part, each having seven dominoes. The one holding double six leads and the others must play to it, as in the ordinary game, until they can go on no longer. The game owes its name to the fact that the players have the right of placing the dominoes at right angles to those already down, as well as in line with them, thus forming them into a fortress-like plan.

**DONKEY.** For people of modest means or for teaching children the rudiments of horsemanship the donkey is very useful. Costing not more than a few pounds to buy, his yearly keep is equally inexpensive, especially if there is a paddock in which he can run. He is hardy, docile, sure-footed, and seldom is ailing. He measures generally well under 12 hands. If one is

bought young, treated in a kindly manner, and given a little corn and hay, he should be able to trot well, and grow up free from the stubbornness so characteristic of the race. Ladies living in the country find an animal of this description most useful for conveying luggage, etc., to and from the station. A light village cart is the most suitable and brown harness looks the best.

In choosing an animal select one of the dark-coloured sort with fine, clean legs. They are said to be preferable to the lighter. If kept out at grass all the year round they cannot be expected to do as much work, or trot as quickly, as if they are fed more like a horse. Children may begin to ride a donkey in panniers as soon as they can sit up, later on coming to a saddle. When old enough they should be encouraged to ride bare-backed.

*Donkey. Useful animal for teaching the elements of horsemanship to young children.*

## DOORS: MAKING NEW & IMPROVING OLD ONES

### Styles and Methods of Work Explained and Illustrated

Among the many headings in this work that contain information on doors are Adam Style; Architecture; Cottage; House. See also Amateur Carpentry; Architrave; Bolt; Bracing; Burglar Alarm.

After the solidly plain doors surmounted by the beautiful arch of Tudor times, Jacobean doors were elaborately panelled, but towards the end of the 17th century panelling became simpler, doors often showing only two panels each. In the 18th century, however, there were usually six panels or more, but the mouldings retained simplicity. At the end of the century Robert Adam fully appreciated the decorative importance of beautiful doors and designed doors and architraves enriched with fine mouldings and carvings to suit the style of his buildings. Unfortunately a great many ugly doors were constructed during the 19th century.

While the doors of the modern house are usually designed by the architect to suit the character of the building, whether modern or influenced by Tudor, Jacobean, Queen Anne or Adam style, much may be done to improve the appearance of existing doors when reconstructing or redecorating the house. Front doors should never look shabby. This is not likely to happen when the door is of mahogany or matured oak and only needs the ordinary care given to such woodwork and the regular cleaning of the door furniture. It does, however, happen in the case of painted hall doors which have been allowed to remain dusty, dirty, splashed or blistered owing to neglect, wet weather or lack of a sun curtain.

Though bright colours for doors in a town street or

terrace are attractive, it is well to remember that they will not continue to be so unless paint with a very hard, glossy surface to withstand the weather is used. Black or dark blue gives a door a dignified appearance, but any dark colour is apt to show dust collected in the panels unless carefully kept. Green is an excellent front door colour, the colder greens such as malachite or jade being good with wrought-iron door furniture for a terrace door, while the warm leaf greens form a pleasant contrast to a red brick house and harmonize with any surrounding trees.

*Door. Iron door with hammered enrichments suitable for the inner hall door of a large house. (Courtesy of Bayliss, Jones & Bayliss. Ltd.)*

This illustration shows a good design for the inner hall door of a large house. It is of hammered iron, panelled with glass.

#### Improving Ugly Doors.

Inside many houses badly made and badly proportioned doors have to be endured or camouflaged. Such a door may be rendered unobtrusive by painting it the same colour as the walls and placing a draught screen so that it is partially hidden, but apart from this expedient there are small improvements which can be made without much expense or trouble. Where panels are shallow, strips of narrow picture moulding, sold by the foot, can be applied all round inside the panels. The strips are held in place by tiny pins, and may be painted before applying if the door has already been repainted. A good idea is to use a different colour for the moulding, contrasting with the door and matching the frame, or the mouldings may be painted in gold or silver metallic paint, the panels in a deeper shade of the door colour and the metallic paint used to outline the frame. Such details necessarily depend on the decorative scheme of the particular room.

An insignificant door in a room of fair height can be remedied, as shown above on the right, by the use of a plywood pediment and pilasters made of thin boards. This treatment would be particularly suitable for a room with decoration and furniture based on an 18th century style. Applied mouldings are used to border the pediment and to ornament the pilasters, picked out with a contrasting colour.

Another improvement which can be carried out is also illustrated. The door is cased in plywood and is thus made panelless and flush. This treatment is suitable when a brilliant enamelled surface is given to the plywood and a rich colour is used, the architrave of the door being in a paler shade which matches the skirting and cornice of the room. Coloured glass or painted china door furniture to tone make such a door

highly decorative.

*Door. Left, door improved by being encased in plywood, the resulting panelless surface being highly enamelled.*

*Right, the addition of pediment and pilasters*

*transforms an insignificant door.*

**Defects and Remedies.** The practical test of a good door is that it opens and shuts easily; inferior doors tend to drop and drag, being susceptible to damp. Unsatisfactory working of a door is nearly always the result of swelling, warping or other such change in the wood. A common trouble is sticking when shut. Passing a piece of paper all along the crack between the top of the closed door and the lintel, and between the edge of the door and the jamb, working from inside the room, will reveal the region of contact by the fact that the paper cannot be passed along the crack there. The door can be kept open by a wedge inserted under the bottom, while the high place is planed down. To plane the bottom the door must be taken down and then rehung.

Sticking can be cured without planing if there is a good wide crack between the door and the jamb on the hinge side when the door is shut. If the sticking region is located between the door and the jamb towards the top, or if it is between the bottom of the door and the floor or carpet, the door should be taken down, the recess in the jamb which receives the top hinge should be cut deeper with a chisel, and the door replaced. If the tight place is over the top of the door, or if it is between the door and the jamb towards the bottom, the same procedure is to be followed, except that in this case it is the bottom hinge, not the top one, that is to be sunk further into the jamb.

A door that will not stay shut or that has to be forced to make it latch or that cannot be locked, can usually be cured by moving the perforated plate which is provided on the jamb to receive the latch and bolt. If the latch works correctly when the door is forced home in shutting it, then the plate should be moved a little outwards towards the room. If latching is facilitated by lifting on the door handle, the plate requires lowering, while if pressing down on the handle makes the latch work, then the plate must be raised. In bad cases all three tests will fail, and it is necessary to resort to measurement. The door should be nearly shut so that the height at which the latch meets the plate can be marked. Then on opening the door the worker will be

able to see at a glance whether the plate needs raising or lowering.

If the height proves correct, then what is required is to move the plate out towards the room, the exact amount being found by shutting the door and measuring the position of the latch by inserting a knife-blade in the crack, this measurement being compared with the position of the holes in the plate on opening the door. The plate is moved as required by unscrewing and removing it and then cutting an extension of the recess it has occupied in the jamb. The deep holes in the jamb which admit the latch and bolt will probably require extending, an operation which demands care, and the old screw holes must have plugs of wood hammered in and cut off flush before the new screw holes are made.

The latch trouble may be due to an entirely different cause from the above, i.e. a broken spring or excessive friction in the lock; the test is to see if the latch springs out freely when the handle is turned and released with the door open. If this test shows that the mechanical action is at fault, the lock should be taken off the door by removing first the screw securing the handle to its square bar, then the handle, then the bar, then the screws which hold the lock in place in or on the door, and finally the lock itself.

When a door yields at the joints, take it down, drill out any dowels, and take the door to pieces. Then refit all the joints, glue and wedge it up as if it were a new door, using new wedges in place of the old ones. If a proper clamp is not available the door can be assembled and glued up, all wedges driven in tight and flush, and the door placed in the frame. The door is fixed in the frame first of all without the hinges. Thin wedges are then driven in between the door and the frame and the whole left to set hard. The joints can be repinned while in this position to ensure a permanent tight fit.

When setting out a door, it should be made to fit tightly to the inside of the casing to allow for any necessary truing and cleaning up. It will be noticed that the casing is rebated, as in Fig. 13, so that the sizes will be taken from the rebate.

If a door is to be made for use in an old building, it is always advisable to ascertain if the existing casing is square, and to make any necessary allowance in size if it is not. Clearance must also be carefully allowed for the carpet.

The height, width, and thickness depend upon the casing, but the measurements of the various parts may be taken from the illustrations as a guide and varied to suit any particular design, provided that strength and durability are always evident.

**Ledged and Braced Door.** Fig. 1 is sometimes handy for a cellar door or for temporary use. The battens, of such a width that together they make up the exact size required are 1 in. thick, tongued and grooved together. The tongue of the one outside batten and the groove of the other batten will both be removed.

First cut off all the battens slightly longer than the finished length, select one for the outside and mark the

position of the ledges, which should be in section as in Fig. 2. Nail these on firmly at right angles and place the remaining boards in position and cramp them together. Next turn the door right over and drive the nails of the remaining battens through into the ledges, the outside battens being screwed to prevent them from curling off. The braces, which are the same width and thickness as the ledges, are fixed as in Fig. 1, the ledges being cut away to take them. The lower ends of the braces are at the hinging edge of the door. Fig. 3 shows an alternative section for the ledges. Cross-garnet hinges should be used for this style of door. An ordinary latch or rim lock will be quite sufficient for fastening purposes in the ordinary way.

*Door. Figs. 1-3. Diagrams showing construction of a simple ledged and braced door suitable for a cellar or shed.*

Fig. 2

Fig. 3

Fig. 4 is a plain, panelled door, suitable for a kitchen. The stiles are first prepared from 1½ in. deal about 2 in. longer than required, and the position of the mortises marked out on both edges, extra allowance being made on the outside edges for the wedges. The mortises will not occupy the full width of the rails, but only commence in a line with the panel groove, the usual depth for which is 7/16 in. (Fig. 6).

All the rails are then marked out, also the centre upright or muntin, the shoulders for which are marked from the stiles. When cutting the tenons of the top and bottom rails, allow haunches at the outside edges to fit into the panel groove (Fig. 6).

All the rails are then marked out, also the centre upright or muntin, the shoulders for which are marked from the stiles. When cutting the tenons of the top and bottom rails, allow haunches at the outside edges to fit into the panel groove (Fig. 6).

Having cut all mortises and tenons, the panel groove may be ploughed. For the panels use ½ in. deal, cutting them ½ in. short in length and breadth for clearance (Fig. 5). All the joints should now be fitted and the door assembled, commencing with the centre upright and the top and lock rails. Place the two top panels in position and fit all the rails into one stile and fit the

bottom panel, finally knocking on the other side. Now carefully test to see that the door does not wind. When glueing the job together, knock the stiles partly off, glue the tenons and knock together again and cramp up, knocking the wedges in lastly.

Avoid getting any glue on the panels, as they must be quite free in the grooves. When dry, level off the joints and smooth with glass-paper. This particular door is hinged with 3 in. or 3 ½ in. iron butts let in in the usual way, and a rim lock fitted as shown in Fig. 4.

constructional details.

**A Jacobean Door.** A fine oak door in the Jacobean style is shown in Fig. 7. The mouldings should be in the solid, i.e. worked on the edges of the stiles and rail as Fig. 8. When preparing the materials remember that the stiles and rails, etc., include the moulding in their width; also, when marking out the tenons, the shoulders reach to the inmost member of the moulding, which is cut away and mitred as in Fig. 9. The materials are first marked out and the mortises and tenons cut; next plough the panel grooves, working the mouldings last.

The mitres of the mouldings should be cut separately at each joint to ensure perfect fitting, and it should be noticed that the wedges at the top and bottom rails occur at the outside only, thus driving the mitre together. The top panel, of 1 in. stuff, is bevelled away at the edges to give a raised effect. A mortise lock is

used with brass or beaten iron drop handles.

Fig. 7. Fine  
oak door in  
Jacobean  
style.

Figs. 8 and 9. Details of the mouldings, which should be in the solid.

**A Tudor Door.** Interest is given to an ordinary ledged door by treatment as in Fig. 10. The door is made as in Fig. 1, minus the braces, except that instead of ordinary cut nails, rose-headed nails placed at equal distances are used. The Tudor arch effect is gained by adding a facing portion all round. As the door casing is rebated it will be necessary for this facing to stand in from the edge to clear, as in Fig. 11. To get this true the door should be hinged in position and a pencil line drawn right round the door at the rebate. To this line the facing is fixed. This is ¾ in. thick. The uprights or stiles run right through at the top and are stop-chamfered as shown, a small rounded notch being cut away near the top to take the shape of the arch. The cross-piece is cut to shape, and the arched portion chamfered. The small corner is put in separately, as shown in Fig. 12 by the dotted line indicated.

It is intended that the corner decoration above the arch should take the form of a sunk panel, but this may be omitted if desired. The whole facing is nailed on and the nails punched in and the holes filled in. A rim lock and cross garnet hinges are used, and a beaten iron handle is in keeping with the style.

*Door. Figs. 10-12. Lugged door in Tudor style, with detail for shaping the stiles. Figs. 13-14. Diagrams showing method of hinging.*

It is necessary to allow a small clearance all round when fitting a door, except at the top corner opposite the hinged side, which will be found gradually to drop in time. When ordinary butts are used, a fairly big clearance is allowed at the bottom for the carpet. If a particularly thick centre carpet is laid leaving a plain surround it is customary to use skew hinges. These take the form of a spiral working on a centre pin, so that as the door opens it is lifted from the floor, thus clearing the carpet, and standing near to the floor when closed. The door also closes automatically by its own weight. These hinges are let in in the usual way, except that the knuckle should stand forward about 1/16 in. from the face. The butts are screwed to the door first, and then to the casing. It really requires two persons to hinge a door; a good plan is to put a thin wedge under the door when screwing, in order to bring it to the required distance off the floor.

Large doors for a garage or stable often take the

form of a lugged and braced door of the type shown in Fig. 1. Still larger doors, especially intended to divide a room into two, are known as folding doors. Various systems are in common use.

In making or repairing doors it is essential to see that the timber is properly seasoned, otherwise warping and swelling are inevitable. The same applies to purchased doors, which can now be bought quite cheaply either in the natural wood, for finishing at home, or ready painted, stained, varnished, or polished.

**The Door Frame.** This is the structure, usually of wood, that surrounds the door and to which it is hung. Most are composed of posts 3 in. or more in thickness. Thinner frames are generally known as door linings. For most outside work the door frame should be at least 4 in. wide and 3 in. thick, and rebated to form a recess for the door.

A door frame can be made and fitted by the following method, assuming the door to be an outer one, with a wooden threshold or tread. The sides or door posts are cut to length and rebated for the door. A similar piece is prepared for the head, allowing this to project on either side of the door post for building into brickwork, or cut off flush if it has to be set into existing brickwork or concrete which it is not desired to disturb. The threshold or step is then prepared and rebated or not as required. The side posts are mortised and tenoned into the head and secured by wooden pegs properly driven through to make a secure joint by draw-boring (q v.).

The bottoms of the side posts are mortised into the threshold or tread and two stout galvanized iron dowel pegs driven into them, leaving about 2 in. projecting; their purpose is to hold the bottom of the frame secure.

They are embedded in cement mortar and set in holes cut in the brickwork. If the frame has to be set up in new work, it is braced by diagonal struts of rough wood about 3 in. by 1 in., placed as shown in the illustration to prevent the door frame from racking or getting out of the square.

*Door. Fig. 15. Door frame placed ready to build in.*

The iron dowels are fitted to the brickwork and the frame bedded down on cement mortar, set up plumb and square and held in that position with a temporary strut to the ground, such as the light scaffold-pole seen in the illustration. The brickwork is then built up to the framework.

Finally, the joint between frame and brickwork is made good on the outside by a cement fillet, and by a wood or plaster lining on the inside. In cases where a new frame has to be fitted to an existing opening, the frame is set up plumb and square and secured by wooden wedges driven in hard, over the top of the door

## Modern Flush Doors

Handsome, simple and modern, these plywood doors (type A), are usually made of straight-grained British Columbian pine, kiln-dried. They are so built that they cannot warp or "bow" outwards, drop or develop a "wavy" surface. Another type (B) is made of solid blockboard. It can be hung either way up, opening right or left, and the mortise lock is concealed within. Alder is best for painting, birch for staining. These doors can be made to measure at a slightly increased price.

## FLUSH DOORS

Sizes and Approximate Prices

	ft. in.	ft. in.	Type A £ s. d.	Type B £ s. d.
Alder	6	0 x 2 0	1 3 0	2 7 9

*Venesta, Ltd.*

posts and at the ends of the head. The joint is then made good with a cement fillet and an inner lining as before.

It is frequently found in old buildings that the door frame has perished at the bottom, and when the expense of a new frame is not desired an excellent repair is possible by splicing or scarfing on new feet. Remove the frame and take it to the bench if possible, but where this is not practicable strut the posts to the ground or the floor while the joints are being cut.

Before fixing a new frame, or refixing an old one, it should be treated with wood preservative if it is to be finished with stain, or with two coats of red lead priming if with paintwork.

### DOORS: THEIR FURNISHINGS AND FITTINGS Choosing and Fixing Knockers, Handles, Knobs and Springs.

This article, together with the preceding one on Door gives the householder much useful information on a subject of interest to every home.

Furniture for doors includes knockers, letter plates, handles, knobs, finger plates and key plates. Front doors usually have a knocker, a letter plate and a handle or knob. The last is generally for ornament rather than use on a town house door. Sets for interior doors are commonly made in three pieces, namely, a finger plate, knob and key plate, but sometimes there is a second finger plate fixed below the key plate. It must always be borne in mind that the style of the door furniture should accord with that of the door, and choice of metal or of the material and colour used for fancy sets are points of decorative importance.

Fancy sets, suitable for the less formal type of bedroom and sitting room doors, are made in white or coloured glass. There are also pretty sets obtainable in painted china with wreaths and bunches of old-fashioned flowers. For bedroom doors coloured sets in milk composition are suitable and are made in numerous shades. These materials are an improvement on the brass furniture which requires cleaning with metal polish. Such cleaning leaves marks on the surrounding paint and eventually may rub it off. When in doubt with regard to a handle or set for a painted door it is advisable to choose plain glass, which is always in good taste. Sets in raised Chinese lacquer work or in painted glass are handsome in a suitably furnished room.

**Door Knockers.** The appearance of a front door can be greatly enhanced by the knocker. On massive wooden doors such a design as the lion's head, shown in Fig. 1, would be suitable in wrought iron. Equally striking would be the brass knocker in Queen Anne style (Fig. 2) on a panelled mahogany door or on one painted in dark colour. Another beautiful design is the snake knocker, Fig. 3, which is an excellent choice in hand wrought iron for the brightly coloured town house door. The Adam style of Fig. 4 is graceful in brass and suitable for a flat door. The door of a Georgian style house would be completed perfectly by

a brass knocker like that shown in Fig. 5, while for the country cottage or bungalow, either Fig. 6 or 7 would strike a pleasing note. Painted metal door knockers are obtainable which are suitable for small front doors. They are made in many designs, from sailing ships to dogs, and Punch and Judy figures. In smaller sizes such knockers are used for bedrooms in some houses. Combination door knocker, handle, and letter plate sets are known as postal handles. The letter flap of such combination sets is either horizontal or vertical.

**Door Handles.** Among various classes of door handles the first consists of the type in which the handle forms part of, or is attached to, a spindle for actuating a lock or catch. The simplest is the plain brass knob, fitted to the spindle by a screw thread and set screw, which sometimes gets slack and fails to turn the lock.

The remedy is to screw up the handle, or to remove it and pack the spindle with a wedge shaped piece of metal, refixing the set screw into a new recess drilled in the spindle, as in Fig. 1. Better qualities of such handles are made with a door plate, machined to form a bearing for the handle, and adapted to retain it in position without need for a set screw again using a square shaft. On the inner side of the door a handle would be secured in the ordinary way with a stud or set screw. The lever handle gives ease of control, the door being unfastened by pressing the lever downwards.

The second class of handle comprises those used in conjunction with a latch, or forming an integral part of the fastening device as the Norfolk latch (Fig. 7). More ornate patterns in wrought iron are sometimes used on entrance doors. Gate latches are sometimes fitted to doors of country cottages, especially the type known as a Gothic gate latch (Fig. 8). Another example is the cupboard door latch (Fig. 9), where the handle has a screwed or squared shank to which is attached a small lever or turn. Latches and locks are dealt with in their respective articles.

The door handle in its simplest form, unconnected with lock or catch, forms a third class. It is used for cabinet work, and on doors fitted on swing hinges and not intended to be latched.

**Door Knobs.** The cheapest types of door knob screw simply into the door. A hole is bored with a bradawl or gimlet, the knob screwed in as far as possible with the fingers and tightened by means of gas pliers, a piece of cloth being wrapped round the handle to prevent damage by the pliers. Frequently this type of knob is longer in the screw than the thickness of the door. The method of treatment then, shown at Fig. 2, consists in reinforcing the door by screwing or nailing behind it a piece of wood into which the screw can bite.

**Door Springs.** The term door spring covers all kinds of resilient controls adapted to the closing of a door. The simplest device comprises a coiled spring

*(Continued in page 680)*

## DOOR

Examples of knockers. Beautiful specimens in both wrought iron and brass, from which choices can be made for doors of varying size and period. See text.

Handles and knobs. Sections of various types and methods of fixing.

having a metal plate at each end, one attached to the door, the other to the frame. The spring is set at a slight angle upwards across the door; it is tensioned by turning one end of the spring with a tommy bar, the other end being fast to the plate fixed to the door frame. The number of turns given to the spring determines the pressure that it can exert, and therefore the speed at which the door will shut without slamming.

The method of securing the spring varies, but a common form comprises a steel pin inserted through a hole in the fixed part of the spring plate, and engaging with a groove in the movable end piece of the spring. Other holes are provided to take the tommy bar, which in emergency may be a stout nail.

Another neat device is a pair of double hung spring hinges.

**DORKING FOWL.** This fine old English breed is without a rival as a table fowl, having more flesh in proportion to the size of its frame than any other, while in colour, quality and flavour it leaves nothing to be desired. It is a moderate layer, and excels as a sitter and mother. There are five varieties, viz. dark, silver grey, white, cuckoo and red, the first two ranking as best. The Dorking is not adapted to confinement, but is an ideal fowl for the farmyard. *See Poultry.*

*Dorking Fowl. Cock of the old English breed of table fowl.*

**DOSAGE.** The estimate of the amount of a drug or of X-rays, etc., to be given in particular circumstances is known as dosage. In the British Pharmacopoeia and similar publications an exact amount is not usually advised,

but an upper and lower limit are given, e.g. tincture of opium, 5 to 15 minims, the lower amount being what is necessary to produce any useful effect at all, and the higher the limit of safety. These doses are meant for an adult, i.e. a person of 21 or over.

A rough rule for finding the dose of medicine suitable for a young child is to give a fraction of the adult dose calculated by taking the child's age as the numerator and the age plus 12 as the denominator. Thus the fraction of an adult dose of 20 minims for a child of 8 would be  $\frac{8}{8+12}$  or  $\frac{2}{5}$  of 20, that is 8

minims.

People for whom the average dose is far too much are said to show intolerance for the drug, and a person who has discovered intolerance for particular drugs should mention the circumstances to any doctor who may be called in to treat him.

The dose of a drug injected under the skin is about half of the dose by the mouth.

**DOUCHE.** As used medicinally a douche is a stream of water or air directed against a particular

part of the body, and is used to cleanse or apply fluid medicaments. Astringent douches are employed to allay the discharge resulting from catarrhal inflammation of a mucous surface, and antiseptic douches are valuable for destroying germs.

A douche may also be used for washing out the nose in chronic catarrhal conditions, and a convenient form of apparatus is the glass nasal douche.

*Douche. Nasal douche of glass employed for catarrhal troubles.*

**DOUGH.** By this term is understood a mass of flour moistened and kneaded, but not baked. Sour dough (leaven) can be, if necessary, used instead of yeast to raise flour for bread-making purposes. *See Baking Powder; Bread; Yeast.*

**DOUGH CAKE.** Before mixing the fruit and other ingredients for dough cakes, grease 2 or 3 cake-tins and line each of them with 2 layers of greased paper, which should reach 5 or 6 in. above the tops of the tins. Then clean and stalk  $\frac{1}{2}$  lb. each of currants and sultanas. In a large basin rub  $\frac{1}{4}$  lb. butter into 2 lb. flour, using the tips of the fingers. Afterwards mix in the fruit,  $\frac{1}{2}$  lb. moist sugar and  $\frac{1}{4}$  oz. of allspice.

Put 1 oz. compressed yeast in a small basin with 1 teaspoonful of castor sugar, mix them together vigorously with a wooden spoon, and, when they are creamy, add 1 pint tepid milk. Pour this liquid into the flour, etc., mix to a light dough, knead it well, and put it into the prepared tins. Put these in a warm place for 1 hour or more, until the dough has risen to twice its original size, then bake in a hot oven for about 2 hours.

**DOUGHNUT.** With 1 lb. flour must be used 1 oz. yeast, 2 eggs & pint milk and  $\frac{1}{2}$  lb. each of sugar and margarine. Spices, such as cinnamon and grated nutmeg, can be added, and raspberry jam is usually placed in the middle of the doughnut.

*Doughnut. Four stages in the cooking of doughnuts. The dough ready formed on the board, and being dipped in boiling fat; and the finished cakes, draining on paper, and ready for serving. (Courtesy of Our Homes and Gardens)*

The yeast should be dissolved in the milk, previously slightly warmed, and the sugar and about  $\frac{1}{2}$  lb. flour stirred in. This mixture is then covered over and put

aside in a warm place. When it has well risen and fallen again it is ready for the addition of the eggs and the margarine. The eggs should be beaten and the margarine melted before they are added, and a pinch of salt sprinkled in.

The dough having been well mixed, another  $\frac{1}{2}$  lb. flour is stirred in, and the dough is again put aside in a warm place. After about 10 min. it is laid on a floured board and kneaded into balls, with a small spoonful of jam placed in the centre of each. The balls should be dropped into a deep pan containing boiling lard and cooked for 10 to 15 min. When done they require to be well drained on kitchen paper and rolled while hot in castor sugar.

Doughnuts can also be made successfully with baking-powder instead of with yeast. Beat 4 oz butter, or butter and lard, to a cream, then add 4 oz. white sugar, a beaten egg, and a pinch of salt and of allspice. Mix well together, and add 1 lb. self-raising flour, or household flour, with which a level teaspoonful of baking-powder has been mixed. If the paste is not damp enough, add milk. Turn it on to a floured board and roll to a thickness of about  $\frac{1}{2}$  in. Cut into rounds and push a thumb through the centre of each to make rings. Alternatively in the centre of half the rounds, put a dab of jam, and cover with the plain rounds. These will lose their resemblance to sandwiches when cooked as described above.

**DOULTON WARE.** In its more limited sense, Doulton ware, produced by the Doulton potteries at Lambeth, and elsewhere, consists of salt-glazed stoneware produced with a single firing, decorated with applied mouldings or scratched patterns, called sgraffito, filled in with neutral colours. A special form, called carrara ware, has a crystalline enamel, sometimes finished with gold and colour.

Various forms of twice-fired earthenware are also produced. Doulton faience has a terra-cotta or biscuit body, decorated with scenic or floral paintings and fired under a dull glaze. One of its forms, called impasto, has thin layers of coloured clays, applied to the smooth surface. *See Faience; Pottery.*

**DOVE.** There are three kinds of dove most usually kept as pets, viz. the ring dove, turtle dove, and stock dove. The first-named, commonly known as the great wood pigeon, is a native of Great Britain; the other two are migrants. The ring dove is a very handsome bird, and its crescent-shaped mark of white, which nearly encircles the neck, stands out in striking relief against its dark, ashen-grey plumage.

**Making a Dovecot.** In Fig. 1 is shown a hanging dove or pigeon cot which provides accommodation for five pairs of birds, three on the lower storey and two above. The front of the cot is made to open for cleaning purposes, and when in position it is secured with two turn-buttons.

Almost any wood 1 in. thick may be used. Fig. 4 shows a general view of the construction. Required are

two sides (A), 1 ft. 9 in. long by 1 ft. 5 in. wide, strengthened with 2 in. battens fixed as shown at Figs. 2, 3 and 4. The bottom of the lower nests (B) is 3 ft. 1 in long by 1 ft. 5 in. wide, and it rests upon battens fixed to the bottom of the sides, to which it is nailed. The bottom of the upper nests (C) is 3 ft. 1 in. long by 11 in. wide, fixed to the upper battens on the inside of the sides.

There are two divisions (D) dividing the lower nests, which are 11 in. wide and simply nailed in position. The centre division (E) of the upper nests is 11 in. wide by 11 in. high, and fitted above is a ridge-piece (F), 1 ft. 5 in. long by 2 in. deep, nailed to the division. The end divisions (G) are 11 in wide by  $7\frac{1}{2}$  in. high. It will be necessary to bevel the top edges of the sides, divisions and ridge to suit the slope of the roof. The back boards should be fitted horizontally, and nailed to the edges of the sides, bottom and divisions. The roof overhangs about 3 in. at the ends, and to make it quite weather-proof it could be covered with canvas or felt, tacked around the edges.

*Dovecot. Figs. 1-7. Small dovetail for attaching to a wall, with diagrams showing method of construction.*

The front may be made up of boards battened together, as shown at Fig. 5. The entrance holes should be cut as shown, and it will be necessary to cut a small slot at the top for fitting over the ridge piece. The alighting boards for the upper holes (Fig. 6) are nailed to the front, and supported by small bracket pieces (Fig. 7). The turn-buttons for fixing the front to the body of the cot may be of wood fitted to the front with screws. Fit small fillets on the bottom (B), behind the front, to prevent water finding its way into the interior. The inside should be lime-washed and the outside painted. *See Pigeon.*

**DOVER'S POWDER.** The compound powder made up of ipecacuanha, opium, and potassium sulphate is commonly known as Dover's powder. The

dose is from 5 to 15 grains. It acts as a mild diaphoretic and as a sedative. Five grains taken at bedtime, and followed by hot lemonade or hot whisky and lemon, is a favourite old-fashioned treatment for arresting an oncoming cold. See Opium.

**DOVETAIL JOINT.** One of the most useful joints in woodwork, the dovetail has great strength, and the ability to resist strains in different directions. The parts are united by so shaping that the outer end is wider than the inner and cannot be pulled apart in the direction of its length. The simplest of the many types is the half-lap dovetail, used for simple framing, and shown in Fig. 1.

*Dovetail. Fig. 1. Simple half-lap dovetail joint.*

There one member is shown at right angles to the other, but the same joint can be made at any angle, and in the following manner. The joint is first marked

out, and the timber sawn from the one part to form a groove, half the thickness of the wood in depth, and wider at one end than the other. The shoulders, or sides, of the groove are out with the saw, and the wood chiselled away to form the groove. The other part is sawn to the same taper, and half the thickness of the wood sawn away, the joint being finished off by chisel work until a perfect fit is obtained.

The common dovetail. Fig. 2, is much used on drawers and similar cabinet work. Suppose, the dovetail is wanted on a drawer side, about 9 in. deep, first plane the ends of the wood true and straight; then, with the marking gauge, scribe a line on all faces of each piece, and at a distance from the edge equal to the thickness of the wood; this is known as the shoulder line. The number and shape of the dovetails have now to be set out on the wood, making use of a scribe and the dividers.

*Figs. 2-9. How to mark out and make a common dovetail joint.*

First settle the thickness of the pins at their narrowest part, say  $\frac{1}{2}$  in., for example. Set off one half this thickness from each end of the shoulder-line, on the outer face of the wood, as the dovetail has to resist outward pressure. Then divide the distance between these points into any number of parts, say five, and from these points mark on each side the half thickness of the pin. Square off with a try-square, and mark off from these points to the end of the wood, as shown in Fig. 3.

Set the bevel square to an angle of about  $15^\circ$ , and mark on the end grain the shape of the dovetail (Fig. 4); then square off from these points with the try-square to the shoulder-line on the opposite side of the wood. Set the job upright in the vice, and cut just inside the lines with a fine-tooth tenon saw, then cut away the waste wood between the saw cuts, either with a bow saw (Fig. 5) or by chiselling; in any case, finish and fit with the chisel.

#### How to Mark Out the Sockets

Now mark out the sockets on the other piece. This may be done in the way described above or with a scribe, marking direct from the pins of the corresponding piece. In the latter method the position and shape of the pins is scribed on the wood (Fig. 6), keeping the scribe on the inside, so that the point will not tend to wander from contact with the sides of the pins. Square off on to the end of the wood (Fig. 7), set it up in the vice and saw to the inside of the lines (Fig. 8). Cut away the waste as before, and all that remains is to fit the parts accurately together, doing this with a chisel, and watching the progress of each set.

When much work of the kind has to be done, it is a convenience to use a metal template shaped to the correct angle for marking out the dovetails (Fig. 9). This tool is obtainable from the shops, or is easily made from a piece of thin sheet metal.

When two pieces relatively thick have to be dovetailed, as for the framing of a staircase opening, a single dovetail suffices, as illustrated in Fig. 10. When a dovetail is not to show on the face of the work, as for the front of a drawer, it is known as a lap dovetail. It is set out by scribing a line on the end grain at a distance from the face of the front piece corresponding to the thickness of wood required for the lap or solid part. The pins are then set out in the same manner as before and the waste wood removed by saw kerfing, and careful horizontal and vertical paring. The sockets may be marked out as before and shaped with the saw, and

by paring with the chisel.

A development of the same idea is the secret lap dovetail, in which no dovetail is visible on any face of the work (Fig. 11). This is accomplished by leaving a lap on each part instead of only the face piece; the work of construction is similar to the previous example, but calls for more skill. When the two lapping parts are mitred instead of being lapped, the joint is known as a mitred secret dovetail (Fig. 12). The construction of the mitred secret dovetail is similar to the lapped secret dovetail, except that the mitre is first set out and roughly shaped, the pins and sockets are formed, and the whole is then very carefully fitted together. *See Joint.*

*Dovetail. Figs. 10-12. Examples showing various forms of the joint commonly used in cabinet making and joinery.*

**DOWELLING.** This is the term given to the method of jointing timber and other materials by wooden or metal pegs called dowels.

Iron dowels are used to secure the uprights of door frames to the stone step, and dowels made from iron nails are occasionally used for packing-case making.

*Dowelling. Fig. 1. Grooved dowel. Figs. 2-3. Marking out*

*and fixing dowels to joint two boards. Fig. 4. Mitre*

*joint. Fig. 6. Table leg and framing.*

*Fig. 5. Leaf of table.*

For cabinet making and similar work straight-grained beech wood dowels may be bought in lengths of about 36 in., and of any desired diameter. Fig. 1 shows a

dowel with a small groove running along its entire length. The object of this groove is to allow the air and superfluous glue to escape and thus avoid splitting the work on hand; the groove also secretes a certain amount of glue, which increases its hold on the timber.

Fig. 2 illustrates the method of marking out and gauging two boards for dowelling. The edges of the boards are first shot to a true joint; then the face sides are placed together and the lines for the dowels are marked across the edges. The boards are then gauged from the face side, thus giving the points indicated in the sketch. A safe rule for the spacing of dowels when jointing sideboard tops, dressing table and wardrobe ends, etc., is to place the dowels 9 in. to 10 in. apart, and place two dowels at each end, as shown at Figs. 2 and 3. The length of the dowels should be about  $\frac{7}{8}$  in.

Fig. 3 shows the two boards prepared ready for glueing. The one on the left is bored to receive the dowels, and the one on the right shows the dowels glued in position. It is customary to warm the edges of the boards before spreading the glue. Cramps, to squeeze the joint tight, should be left on the jointed board from one to four hours.

Fig. 4 shows the sketch of a mitred and dowelled frame. One corner only is shown. The dowels should be at right angles to the line of joint, and consequently the dowel at the outside edge of the frame will have to be shorter than the others. Fig. 5 is a leaf for the telescopic screw type of dining table. Circular dowels are shown at one end, and rectangular wooden pegs at the other; both methods are good, and, of course, the dowels are only glued into the leaf. The object of these dowels is to guide the shelf into its proper position when the leaf engages with the table proper, and to make the table and leaf register correctly.

Fig. 6 is a dining table leg and portion of the framing, showing the method of dowelling the frame to the leg. Chairs, couch frames, etc., are made in a similar manner. *See Cabinet Making; Joint.*

**DOWER.** In English law this was the life interest which a widow formerly had in one-third of her husband's landed property. This right has been abolished in the case of persons dying after 1925. In Scotland a widow has a right called 'terce,' equivalent to dower, which entitles her to a life interest in one third of her husband's property in land. This right still survives. *See Marriage.*

**DOWN.** The word down is applied to the soft hair found under the feathers of fowls; it also describes

kapok, a vegetable down obtained from such plants as the thistle, etc.

For ordinary purposes, a mixture of down and fine feathers gives excellent results, provided that the mattress, cushion or pillow is given frequent and thorough shakings to prevent lumps from forming. Vegetable down or kapok, which is much cheaper than real down, needs to be separated carefully with the fingers before use to ensure freedom from lumps. The best kind of down is that obtained from the neck of the eider-duck; less expensive varieties include cygnet, duck, and goose-down. *See* Cushion; Eiderdown; Pillow; Quilt; Swansdown.

**DRABA.** Sometimes called whitlow grass, this is a low growing hardy, evergreen alpine plant which must be planted in very gritty soil in a sunny position in the rock garden. During winter it is wise to provide protection by placing pieces of glass over them to keep off excessive rain; the glass should be raised a few inches above the soil by wires. *Aizoides*, yellow; *aizoon*, yellow; *bruniaefolia*, yellow; and *pyrenaica*, lilac-rose, are some of the chief kinds. Propagation is by seeds sown in gritty soil in the rock garden in spring or by division in September.

**Drachm.** Apothecaries' weight equalling 3 scruples or 60 grams. It is distinct from the avoirdupois dram, which contains  $27 \frac{1}{3}$  grains.

**DRAINAGE: Of the Soil.** Surface drainage is important to the householder, as waterlogged soil is a menace to health. Systems of land drainage include grading or sloping the surface of the earth, the provision of ditches and trenches, laying agricultural drain pipes, digging a trench and placing brushwood or rubble in the bottom of it, and then closing in the top with soil.

There must be adequate means for disposal of the surface water at the termination of the pipe lines or trenches. These can generally deliver into a brook or pond; failing that, a soak-away drain must be constructed.

This takes the form of a cavity filled with gravel, rough stone, rubble or any porous material, the water collecting in the cavity and ultimately soaking away into the earth. The site for a new house or bungalow should drain naturally; if it does not, a system of surface drainage must be provided. At the same time some pipes must be introduced through the foundations to dispose of any water that may accumulate beneath the building and cause damp walls or dry rot.

**Garden Drainage.** Water lying stagnant in a garden instead of passing away fairly quickly is proof that the natural drainage is insufficient. In draining a garden first ascertain by levelling what fall the land has and in which direction it runs. Then take out a narrow trench a foot or so deep at the top end, letting it slope evenly and gradually till it reaches the lowest

point in the garden (Fig. 4). If one main drain is not sufficient, secondary drains, herring-bone fashion, must be added, as in Fig. 7. In this diagram the main drain is shown running from A towards C, while the secondary drains are labelled B.

*Drainage. Figs. 1-8. Diagrams illustrating the principles of garden drainage here described.*

*(By special arrangement with Amateur Gardening)*

There are three styles of drainage, plain pipe, rubble, and pipe-rubble, illustrated in Figs. 1-3. Secondary drains must be packed with broken tiles where they join the main drain (Fig. 6).

Joints between pipes should be covered with a turf (Fig. 5). The pipes used should have a bore of not less than 2 or 3 in. When rubble is the medium, layers of 6 in. will be found satisfactory. Generally one drain running obliquely, as shown in Fig 8, will be sufficient in the average small garden, or one main drain and secondary drains.

Where there is not opportunity to take the outfall into a ditch or road drain, let it empty into a tank sunk in the soil. Water will not be carried off readily if drainage is laid on the level. In clay garden lands drains should not be farther apart than 15 ft. *See* Drains; Sanitation.

**DRAINING BOARD.** A draining board is a wooden structure erected at the side of the sink in a kitchen or scullery to facilitate washing up, the dishes as they are washed being laid on it to drain. The draining board should be made from hardwood such as beech or sycamore at least 1 in. thick; its width should equal that of the sink, and the length can be about 3 ft or more according to the space available.

The upper surface must have semicircular grooves formed in it, and spaced about 3 in. apart. The underside of the board is strengthened by ledges 3 in. wide and 1 in. thick. A hardwood skirting board  $\frac{3}{4}$  in. thick and 3 in. wide should be screwed to the board with brass screws to protect the walls from wet. A similar skirting at the front, but only projecting 1 in. above the surface, is a safeguard for crockery.

A draining board should have a fall towards the sink of about 1 in. in every foot of length; moreover, for sanitary reasons, the board should terminate flush with

the walls of the sink and avoid any crevices where dirt or dust could accumulate. Draining boards can frequently be fixed on deal bearers, secured to adjacent walls, otherwise the best plan is to construct a pair of gallows brackets from sound deal 2 in. wide and 1 in. thick, as shown in the illustration. These brackets comprise three elements, (a) a vertical strip to attach to the wall, (b) a horizontal bearer to support the board, and (c) a diagonal strut or brace. The joints can be screwed together, or preferably mortised and tenoned and securely wedged.

Draining boards are kept clean by scrubbing with white sand or using one of the many brands of cleaning powder which are now on the market. See Kitchen.

*Draining Board supported by a gallows bracket; right, detail of joint between board and edge of sink.*

#### DRAINS: THE DOMESTIC SYSTEM EXPLAINED Points of Importance to both Landlord and Tenant

See further the articles on the various types of house, e.g., Bungalow; Cottage; House; also Cesspool; Disinfectant; Refuse; Sanitation; Septic Tank; Water

Essentials in any house drainage system include disconnexion of drains from the sewer by means of traps; disconnexion of rain, bath, and other water waste pipes, by discharging them into the open air above a trapped gulley; adequate ventilation and self-cleansing apparatus.

The following notes illustrate the general requirements of a small house in the matter of drainage. A typical installation comprises the provision of drains for a bath, lavatory basin and sink, a water closet, and means for disposal of rain water. The latter may or may not be a part of the house drainage system, but at least some of the rain water from the roof should be admitted to the drains to ensure periodical cleansing and flushing. In general the whole of the rain water is disposed of by the house drainage system, except where a rain-water storage tank is provided, into which the rain-water pipes would discharge.

The apparatus required is shown in Fig. 2, from which it will be seen that the bath and lavatory basin wastes deliver into a separate waste pipe which should be carried up as a ventilating pipe, the open end being above all window openings; usually it is taken just above the eaves.

In modern patterns the bath, lavatory basin and sink have special overflows moulded in the stoneware, and these discharge above the seal of the trap underneath

the fitting. Where these overflows are separate they are treated in the same way as the flushing cistern overflow, that is, the pipe is run through the outer wall for about six inches and cut off in a sloping direction. Should the ball valve of the cistern go wrong, or the taps to any fitting be left running, warning is given by reason of the water pouring out of this pipe.

*Drains. Fig. 1. Exterior of house showing drainage pipes corresponding to those depicted in Fig. 2.*

The waste from the water closet passes down the soil pipe, through the manhole and thence to the disconnecting trap. The bath and lavatory basin discharge through the waste pipe under the grid of the trapped gulley. The sink waste discharges in a similar way, and both gullies deliver into the manhole and thence to the disconnecting trap.

The bath, sink, and basin are all fitted with a trap or interceptor, which acts as a water seal; the closet pan incorporates a similar device; hence adequate protection is provided against the entry of foul gas.

A pipe is connected from the manhole to the disconnecting trap, which is situated in a second manhole, marking the termination of the drainage system and the commencement of the sewer. A typical arrangement is shown in Fig. 3, and comprises a disconnecting trap with cleaning eye, a connecting channel, an air inlet or ventilation pipe, and manhole cover. This completes the drainage system.

It is absolutely essential in any system of drainage that sewer gas should be prevented from working back from the sewer (Fig. 3) into the drains. From this arises the importance of the disconnecting trap—a bent or U-shaped pipe, so arranged that water lying in the hollow effectually seals or stops up the channel, the water being impervious to sewer gas. Every time the drains are flushed this water seal is renewed. An inspection or cleaning eye enables the connexion between the trap and sewer to be used for drain rods should that portion become blocked; the eye is closed by means of an air and gas proof plug.

The manhole is built in brickwork and well rendered with cement to guard against leakage. The cover is generally made of cast iron, embedded in cement mortar and sealed with cart grease and sand. The air inlet or vent pipe has a flap or non-return valve at the top; this pipe should be some 2 or 3 ft. above ground level. The purpose is to admit fresh air to the drains; the air ultimately escapes through the air vent pipe which forms the upper termination of the soil pipe, and thus provides a constant current of air through the whole system. The manhole enables any obstructions to be cleared away in case of a stoppage.

**Drains.** Fig. 2. Diagrams illustrating in section and plan a typical drainage system for a small house such as that shown in the previous column.

The pipe line between the disconnecting trap and the house manhole must be straight and continuous, with a regular fall of at least 3 inches in 10 ft., and nowhere less than 12 in. below the surface of solid earth. The house manhole serves a similar purpose to the disconnecter, with the additional duty of collecting together three separate delivery pipes.

The pipes from the bath and sink waste are brought to the trapped gully, which terminates at about the level of the surrounding ground, and is bedded in concrete and provided with a brick and cement rendered curb. The waste pipes from bath and sink terminate in shoes which discharge over or under the grid of the trapped gully. This acts in the same way as the disconnecter, having a similar water seal. A removable cast iron grating is fitted.

The soil pipe is taken by a pipe sloping upwards slightly from the manhole to a bend and thence perpendicularly to a junction branch, the arm of which

connects to the water closet which incorporates the water seal or trap. The soil pipe continues upward and terminates at least 3 ft. above the roof level, and is provided with a globular wire cap. Fig. 1 shows the use of a swan neck to avoid leading the pipe past the bathroom window. The provision of traps or water seals, Fig. 4, at bath and sink outlets in conjunction with those already described entirely closes every possible inlet for poisonous gases.

Sewage drains must comply with the by-laws and requirements of the sanitary authorities. No alteration must be made without due notice being given, and the work has to be approved by the local authority's inspector.

**Drains.** Fig. 3. Sectional diagram through disconnecting trap and manhole.

**Fig. 4. Water seal or trap for bath or sink waste.**

**Stoppages.** The task of rectifying stoppages is one that brooks of no delay, and the practical man can set about it himself in most cases. If it is the sink or lavatory basin that is choked, as exhibited by water remaining there instead of running away, the stoppage will probably be found in the waste trap. This should have a screw plug at the bottom, and what is required is to place a bucket or receptacle beneath it, remove the plug with a spanner, and with a flexible cane or soft wire endeavour to remove the obstruction. Take care that the receptacle is sufficiently large, as the trap itself holds a fair amount of water, and if much remains in the sink or basin a small bucket might fill to overflowing.

Should the stoppage be below the trap, it can be removed by plunging with a force cup, first replacing the plug. Sometimes the palm of the hand cupped and pressed down over the outlet will force water down the pipe and get rid of the obstruction, if a little water is first run into the basin.

When a water-closet is choked up, the obstruction is almost always in the trap at the bottom and back of the

pan. This can sometimes be cleared with a flexible cane, by using the force cup, or plunging.

When there is a stoppage in any of the drain pipes, take off the manhole cover and ascertain where the stoppage occurs. This is tested by pouring water down the pipes and noting which one is choked, either by the absence of water or by the fact that it only trickles out slowly. It can then be cleared by pushing a drain rod through and at the same time pouring in liberal quantities of water at the highest available point of the system. When this fails, a screw end can be attached to the rods and worked in, and the obstruction cleared by drawing it backwards. When handling these rods it has to be remembered that they are screwed together, consequently they must be twisted to the right or the joints may unscrew and a length of rod be left in the drain. Rods having patent locking joints are, as a general rule, free from this defect.

A drain that is only partially obstructed can sometimes be cleared by plugging the outlet into the manhole with sacking and then allowing the pipes to fill with water. On suddenly removing the sacking, the rush of water will often dislodge the obstruction. When a complete stoppage occurs, a plunger of leather can be affixed to the end of the drain rod and the obstruction forced out, using the rods as a plunger or force pump.

Should there be any suspicion that a drain is leaking, as evidenced by an unpleasant smell, the drains should be tested by a competent person, the seat of the trouble ascertained, and the cause remedied. This in dry weather may be nothing more serious than evaporation of the water in a trapped gully. In this case the remedy is to fill the gully with clean water.

**The Legal Position.** A tenant, when he or she takes possession of a house, may or may not receive from the owner a verbal or written guarantee that the drains are in proper order. He may, however, have the drains tested, and, in certain cases under the Rent Acts may refuse to pay increases of rent made on the ground that the landlord is liable for repairs if a sanitary inspector certifies that the house is not reasonably fit for habitation.

If a drain gets out of order by stoppage or foul smell, the tenant should at once inform the landlord, after first endeavouring to remedy the nuisance, e.g. by flushing with hot water and soda, or by using a rod and plunger. If the landlord fails to make the drain right and the householder feels that his family's health is being imperilled, he can call in the local sanitary authority.

Where the drain is condemned as faulty the owner has no alternative but to take it up and substitute an entirely new one.

A tenant who takes a house for a term of years is bound in the absence of anything to the contrary in his tenancy agreement to keep the existing drains in repair, but is not liable for repairs, due to bad construction of the drains. If a tenant or his family become ill owing to faulty drains through no fault of the tenant, a claim may lie against the owner of the house. Anyone building his own house must have the sewage drain

pipes passed by the local authority before filling in.

**DRAUGHT: How to Avoid.** A draught is frequently due to faulty ventilation, as for example in a small room, when the doors and windows are closed and a fire is burning. Under such circumstances air must be admitted to the room, and unless the doors and windows are absolutely airtight, the heated air will ascend up the chimney and a strong suction be exerted upon any cracks and crevices, with a draught as the result.

The most effective cure for a draught is to give attention to the adequate ventilation of the room, as by opening a window at the top, by the provision of air bricks, or any means that admit sufficient fresh air at a low velocity. When the air is admitted slowly an objectionable draught is not created. It is the large quantity of air entering at high speed through a small hole that gives the trouble. Adequate treatment on these lines is more in the nature of building construction and should have attention when the house is being built.

Conditions are somewhat different in boisterous weather, as a strong wind will force air through a crevice that would otherwise be draughtproof. Doors and windows are the chief offenders, and the trouble is generally due to defective workmanship and material. The remedy is, however, simple and effective. India-rubber draught tube with a canvas flange can be glued or nailed round the window frame so that it seals the joints or covers the cracks. Felt or cloth strips are more durable, as they never crack; rubber is prone to dry up and split in hot weather.

Sash windows are effectively protected by cloth-covered sandbags made in the form of long rolls.

*Draught Excluder. Figs. 1-3. Devices for closing the gap between door and floor.*

*Fig. 4. Weatherboard fitted to an outside door.*

**Draught Excluder.** Fittings of various kinds are obtainable to close the gap between door and floor. Fig. 1 shows a device consisting of a cloth or plush-covered roller loosely mounted in brass brackets screwed to the door. This rolls over the floor when the door is opened or closed, but when at rest the roller lies upon the

ground and checks the draught. One type of automatic device is shown in Figs. 2 and 3, and comprises a moulded strip attached near the bottom of the door. The end of a sliding member projects and is pushed back by the door frame, thus forcing the movable strip down on to the floor. A tight joint is ensured by means of a flexible rubber strip at the extremity of the slide. A concealed spring lifts the strip clear of the floor as the door is opened. Owing to the method of cutting the diagonal slots, this type of excluder may be readily reversed to suit the hand of the door.

When considering the application of draught-excluding devices it is best to inspect the door-frames and to make sure the door shuts up tight against the door-stop. If it does not, the stopping can be removed and replaced so that it abuts against the door, and this will stop the draught. The door-latch may be slack, allowing the door to rattle. This can be remedied by overhauling the lock or by resetting the socket or staple.

Outside doors are often improved by the addition of a weatherboard (Fig. 4), but this must be throated or grooved as shown, or the rain-water will work its way in under the door. A narrow metal slip projecting slightly above the surface of the threshold will often be a boon in checking a draught.

**DRAUGHTS.** This game, in America called checkers, is played between two opponents on half of the squares of the chessboard, either on the 32 white squares or on the 32 black squares. For convenience it is here assumed that the white squares are used, in which case the board is set with a black square to the right hand of each player. Each side has 12 pieces, all of the same shape, which are placed at the start in the position shown in Fig. 1. In the notation which enables games to be recorded the squares are numbered as in Fig. 2.

*Draughts. Fig. 1 (left). The pieces set out ready for the game to begin. Fig. 2. Notation of the board.*

A draughtsman moves one square forward diagonally. If a man of the opposite colour stands in the way, with a vacant square immediately behind him on the same diagonal, that man can be captured by jumping over him on to the vacant square, and removing him from the board. Thus, if in the initial position black (who invariably has the first move in draughts) plays from 11 to 15 and white replies by moving from 22 to 18, black jumps from 15 to 22 and removes the hostile man from 18. Further, not merely

one man can be captured at a time, but a succession of men, all in the same move. Suppose a black man to stand on 1 and three white men on 6, 15 and 23. Black can jump in succession to 10, 19 and 26, removing the hostile pieces.

The object in draughts is to capture all the opponent's pieces or to reduce them to such a position that they cannot move at all, in either of which cases the game is won. When a capture is possible it must be made. If by error it is not made, there is a penalty called huffing, which consists in removing the piece which could have made the capture off the board, this huffing not counting as a move. It is a player's option either to huff his opponent, to insist upon his making the capture, or simply to let the wrong move stand.

When a man reaches the farther side of the board (the 8th rank away from the player) he becomes a king, with the power of moving and capturing backwards as well as forwards. A king is shown by crowning, i.e. putting a spare piece upon him. The reaching of the 8th rank completes a move. Suppose a black man to stand on 21 and two white men on 25 and 26. Black can play to 30, capturing the man on 25 and making his own man a king; but he cannot in the same move capture the man on 26.

**Draughtsmanship.** See Drawings.

**DRAW-BORING.** This method is employed for pegging the components of a mortise and tenon joint so that the joint faces are drawn tightly together. The method consists in drilling a hole through and at right angles to the mortise. Next put the tenon into the mortise, and drive it home; then mark on the tenon the position of the hole in the mortise, by scribing a circle on the tenon, using the hole in the mortise as a guide.

*Draw-boring. Various stages in this method of making tight-fitting mortise joints.*

Remove the tenon, and, supporting it on a block of waste wood, drill a hole, the same size as that in the

mortise, but nearer the shoulder of the tenon, the usual amount being slightly less than the half diameter. Prepare a tapered hardwood pin of a size to suit the hole, put the joint together after removing any ragged edges around the holes, and drive the pin home with a hammer or mallet. The peg then acts as a wedge and draws the shoulders of the tenon very tightly against the mortise, and to a certain extent obviates the need for a cramp. If the joint is to be permanent it can be secured with glue and the peg glued in as well. When the glue is dry the projecting ends are cleaned off smooth and flush. If it is considered desirable to be able at a subsequent time to take the joint apart, the thin end of the peg should be left projecting so that it can be knocked out when desired.

The peg hole should be nearer the edge of the wood against which the shoulder fits. A common practice is to drill the hole so that its centre is  $1\frac{1}{2}$  times the diameter from the edge of the wood. The various stages in making this joint are illustrated.

**DRAWER: How to Make.** For drawer construction dovetails are the ideal joints to use, since by their formation they exert resistance in the direction of the chief strain to which a drawer is exposed, i.e. the forward pull. The ordinary hand-cut drawer dovetail does not vary much in form, except, of course, when the particular construction or formation of the job requires different treatment. Fig. 1 is typical of the average drawer. When making one of medium size, it is usual to use 1 in. or  $\frac{3}{4}$  in. stuff for the front, and  $\frac{1}{2}$  in. or  $\frac{3}{8}$  in. for the sides and back. At the front the dovetails do not run right through, a small lap being left on the front. This is necessary to hide the ends of the dovetails, which would otherwise disfigure the front. To make a drawer such as Fig. 1, all the stuff is first planed up and thickened, and marked in the relative positions which they are to occupy. The front is then planed to fit exactly between the rails. A good plan when fitting this is to cant the edges very slightly inwards, so that the front wedges in between the rails. The sides are also planed to fit just hand-tight, and both ends squared off.

The back is now squared up at both ends to coincide with the job, but it does not occupy the full width of the drawer. At the top it stands down about  $\frac{1}{4}$  in., and stands on the drawer bottom (Fig. 1), so that the position of the bottom must be decided upon;  $\frac{1}{4}$  in. is usually sufficient for this to stand up, so that the distance, added to the thickness of the bottom, will give the bottom position for the back.

When marking out the dovetails, note that the groove for the bottom is contained within the lower front dovetail, as the groove would otherwise show a gap in the pins. At the back the square lower edge of the bottom runs right through along the pin, so that when the side is marked out this is cut square (Fig. 2). When all the joints are cut, the front is grooved for the bottom and the top edge of the back rounded over; the drawer is then glued up.

Figs. 3 and 4 show how the bottom is held at the

sides, grooved slips being glued to the sides. The object of using these instead of grooving the sides is partly to present a greater width underneath, thus giving greater wear resistance to the runners, and partly to avoid weakening the sides. The bottom is either nailed or screwed to the back, and is made sufficiently wide to stand out from the back about  $\frac{3}{8}$  in., so that in the event of it shrinking the screws can be taken out and the bottom pushed forward.

*Drawer. Figs. 1-6. Diagrams showing the component parts and details of construction of an ordinary drawer.*

#### Centre Support for a Long Drawer

In the event of the drawer exceeding 18 in. or so in length, a centre support for the bottom should be fixed. This is about 2 in. wideband is grooved in the same way as the slips. A stub tenon is cut at the front to fit into the groove in the drawer front, and the support is held at the back with screws, the upper lipping being cut away to bring the groove against the back. The drawer is then fitted and the top back corners bevelled off (Fig. 2). The running of the drawer is facilitated if the sides are slightly bevelled off at the back along the dovetails.

Ordinary candle-grease is a good lubricant to use to ensure smooth running.

In cases where it is required to place the bottom flush underneath, as, for instance, in the trinket drawers of a dressing table, a rebate is run round the front and sides, as in Fig. 6, and the bottom dropped in this. It is also necessary to arrange the dovetails as illustrated in Fig. 5 to prevent any gaps showing at the sides. See *Birds' Egg Cabinet; Bureau; Chest; Chest of Drawers; Desk; Dressing Table; Wardrobe*, etc.

## DRAWINGS: THEIR PREPARATIONS AND USE

### Some Practical Hints for the Amateur Craftsman

The facts given in this contribution, together with the illustrations, are intended to help those who wish to make any of the constructional articles described in this work.

The ability to produce an intelligible drawing is of great value to all amateur constructors. The tools and materials required need not be expensive, but it is well to buy reliable instruments. A minimum outfit comprises a drawing-board, tee square, set squares with angles of  $45^\circ$ ,  $60^\circ$ , and  $30^\circ$ , one or two ruling pens and a 6 in. half set of drawing instruments (the latter comprising compasses with ink and pencil points, an extension bar, and a pair of dividers); drawing paper and pencils, some Indian ink, a piece of indiarubber and a few drawing pins. It will be well to add a pair of small spring bow compasses with ink and pencil points, as these are handy for drawing small circles.

For all-round use the imperial-size drawing board is the most convenient. This measures 32 in. by 23 in. and it may be of the cheap, clamped variety or, preferably, with battens on the underside. For mechanical drawing it should be truly square on the left-hand side, the left edge being used to guide the stock of the tee square. The ordinary cheap clamped board made of sound, dry pine, will last for many years, and has the advantage that both sides are available. The best quality boards are made with battens on the underside, and are grooved to allow the wood to expand and contract. For the same reason the battens are secured to the board with slotted plates and screws. They usually have an ebony or hardwood slip inserted in the left-hand edge for the tee square to work upon.

Essential qualities in the tee square are straightness of the ruling edge. This can be tested by ruling a line, turning the square upside down, and ruling another line on top of the first one; if the edge of the tee square is true the two lines will coincide and appear as one. The preferable form of tee square is made in mahogany with ebony edge.

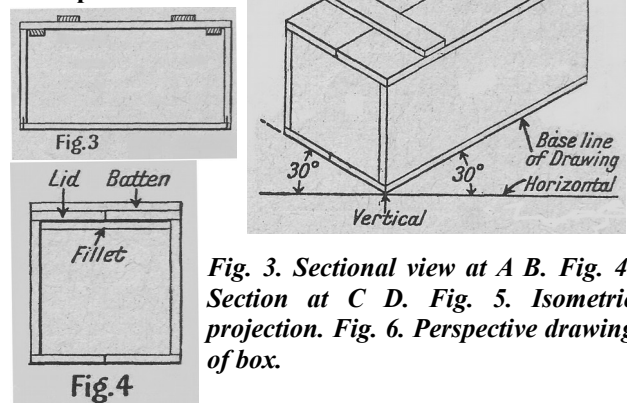

In choosing set squares, those made of celluloid or a transparent material are to be preferred, and should have one edge bevelled, as this minimises risk of the ink running under while using the ruling-pen. Compasses should have fine sharp points, preferably those with a needle held in a clamp; should have firm joints and

exhibit no shake or play on any of the joints. The various types and qualities are discussed at length under the heading *Compasses* (q.v.). The same remarks apply to dividers.

*Drawing. Figs. 1 and 2. Elevations and plan of a simple wooden box.*

The ruling pen comprises a fixed and a movable steel blade, the ink being inserted between them by means of a small brush or an ordinary pen. It is essential that the exterior of the blades be free from ink, otherwise it will be liable to cause a blot when ruling a line. The pencils are preferably of the hexagonal type, as these do not roll off the board so easily as the round one. For fine work a hard pencil, such as an H.H., is to be preferred; but where much rubbing out has to be done, a softer pencil, such as an H.B. or B. is more convenient, as it is more readily erased. Pencils should be sharpened to a chisel point.

*Fig. 3. Sectional view at A B. Fig. 4. Section at C D. Fig. 5. Isometric projection. Fig. 6. Perspective drawing of box.*

For ordinary working drawings cartridge paper will be found quite suitable, but for more highly finished drawings in ink, a smooth-surface paper should be used, such as a Whatman H.P., or hot pressed paper. The only inks that are of any practical use for mechanical drawings are those generally known as Indian inks.

In using compasses or dividers, place the metal point exactly on the line or centre from which measurements are to be taken. If equal on both sides of a centre line,

mark them by rotating the dividers or compasses while the needle point rests exactly upon the centre line; as far as possible take all dimensions from a few centre lines. When using ruling pens or the pen points in the compasses, charge them with ink from a brush or pen, wipe the points of the blades clean with a piece of rag wrapped round the finger, and before ruling long lines see that the blades have sufficient ink between them, as it is difficult to join up the two parts of a straight line. The pen should travel at an even speed over the paper, be held nearly upright, and always at the same angle to the paper. Before laying the pens aside, wipe off the ink with a piece of rag or blotting paper. The points of all drawing pens should be kept sharp but perfectly smooth by setting them occasionally on a piece of fine oil stone. Other instruments used in mechanical drawing comprise proportional compasses, French curves, parallel rulers, scales, and other special appliances.

**Methods of Projection.** There are several ways in which an object may be depicted. Simple projection assumes that every part of the object visible in, say, a vertical plane is projected upon an imaginary flat surface, although, in fact, the object may be curved or of any other shape. It is usual in mechanical drawing to show a plan of the object, that is, the appearance as seen from above, and a front elevation or view of the object as seen from the front and projected upon a plane at right angles to that of the plan; an end view is also drawn upon a plane at right angles to that of the plan, and also at right angles to that of the front elevation.

Where the object is differently shaped on both sides and both ends, elevations are given of all these four sides. Suppose now the object were hollow and that the cavity could not be seen from the exterior, this would be depicted by means of a section, this being neither more nor less than projections on a vertical or horizontal plane imagined as passing through the object, and it thus shows its shape as if it were parted asunder with a saw.

Isometric projection is a method of showing three surfaces of an object simultaneously, whereas plain projection shows only one face on any one elevation. In drawing an object in isometric projection, all horizontal lines are measured from one centre point along lines inclined at  $30^\circ$  to the horizontal. Vertical dimensions are taken at any necessary place along these inclined base lines.

In Figs. 1 and 2 a simple wooden box with the planes marked on the drawing shows the various elevations. The sections through the box are shown in Figs. 3 and 4. The same box has been drawn to the same scale by isometric projection in Fig. 5, and in Fig. 6 again in mechanical perspective.

Comparison of the three processes and their relative advantages can therefore be made. By the first system the actual shape and size of the object is depicted either full size or to any convenient scale. The isometric projection gives a better impression of the appearance of the finished object, and dimensions can be scaled off

from it. In the third illustration the appearance of the article is extremely good, but it is not practicable conveniently to take any dimensions from the drawing. Hence for a working or mechanical drawing, the first system is the best for amateur purposes, The second system is very good, as it indicates something of the external appearance of the object and provides the necessary means of measurement. The third system is of value to the architect or constructor who wishes to show the correct appearance of the article when it is finished.

*Drawing. Fig. 7. How to set out the working drawing of a chair back.*

*Fig. 8. The curves shown in Fig. 7 transferred to the wood.*

No special instructions are required for the preparation of drawings of objects that are made from flat material with straight or angular surfaces and edges. It is in drawing curved surfaces that greater difficulty is met with, and as an example Fig. 7 shows one method of drawing part of a chair back, and clearly indicates what has to be done in preparing a drawing for such a piece of furniture. To transfer the curves to the work it is desirable to draw lines at right angles to one or more of the edges of the piece of wood from which the chair back is to be made; and to set off the distances along these lines and transfer them to similar lines drawn upon the wood itself, drawing the curve through the points thus found. The method is illustrated in Fig. 8.

**Scale Drawings.** The amateur cabinet maker

should try his hand at a scale drawing of the article he is about to construct, practising until he is able to draw mouldings or other details full size from a scale sketch. There is nothing really difficult in this; it is a matter of knowing how to use the T-square and rule, and rarely involves freehand drawing. The great advantage of a scale drawing is that it shows at once whether the proportions are good. Error may be avoided if the elevation of the piece of furniture is set out to scale.

It is equally desirable to know how to set out the complete vertical and horizontal sections of a cabinet or other article full size. We know exactly then what we are doing, and every dimension—length, width and thickness—may be taken from our set-out. It is not only that the work itself is rendered easier, but again and again we are saved the mortification which results in the discovery that, through some trifling miscalculation, we have cut a costly bit of fine wood the wrong size. Careful setting-out, indeed, is the first step towards the attainment of good results in all cabinet work.

In making a full sized drawing of some detail, e.g. a chair back, squares may be ruled on the small sketch and the drawing transferred square by square to paper similarly ruled on the enlarged scale. By numbering the squares vertically and horizontally the chance of error may be eliminated. Where necessary in our constructional articles a squared detail sketch is given, the scale being indicated.

Certain conventional treatments are generally followed in draughtsmanship to indicate sections, different materials, screw threads, and the internal shape of an object, examples of all of which are given in Fig. 9.

Drawing. Fig. 9.

Conventional methods of treating various materials in mechanical drawing.

**The Finishing Touches.** Drawings are usually finished after completion in pencil by going over all essential lines with Indian ink, using the ruling pens, and ink points on the compasses, after which the dimensions are given and the points from which they are taken indicated by dotted lines, the latter conveniently drawn in a different coloured ink. If a drawing is to look well it should be neatly lettered; simple sloping letters are easier to draw than those which are upright. Various simple letterings and methods of ruling for them are illustrated in Fig. 10.

Fig. 10. Examples of the ruling necessary for good lettering

When a drawing has to be copied, it is as well to make the finished drawing on tracing paper or linen. This is pinned over the pencil drawings, and wiped over with French chalk to clean the surface. Subsequent work is performed as if

on paper, the pencil lines showing through the tracing cloth and acting as a guide. When completed, blue prints or black line prints on white paper can be obtained by sending the tracings to a firm of photo-engravers, or the amateur can make his own sun prints in favourable weather.

## DRAWING ROOMS IN SEVERAL STYLES

### Suggestions for Furnishing and Suitable Colour Schemes

For related information see Chair; Colour; Decoration; Furniture, and for details about accessories Curtain; Cushion; Mirror, etc. See also Carpet and the entries on various styles, e.g. Adam; Chippendale; Queen Anne, etc.

There is a certain formality which distinguishes a drawing room from the ordinary living room and from the lounge. At the same time, except in a big house where there are four or five recreation or sitting rooms of different types, a drawing room should have a lived-in aspect and express to some extent the personality and taste of its owner, so that it does not look merely a room set apart to entertain visitors.

Perhaps one of the best things noticeable in many modern drawing rooms is the tendency to do away with overcrowding, not only of furniture, but also of superfluous ornaments, pictures and cushions. Things have a meaning and a definite place in the scheme. Small tables instead of being dotted about the room are

produced as required from a "nest" of four; the larger occasional table is often a useful book table. Comfort is still ensured by the inclusion in the furniture of a good settee or Chesterfield, and one or two lounge chairs, supplemented by several newer types of chairs designed to take up little space and yet for ease. If a piano, music stool, bureau or writing-table and bookcase are added the essential furniture is collected. Niches with shelves for china are always delightful features in a drawing room, while a recess provided with shelves is an excellent place for a gramophone. The records are kept in neat compartments on the under shelves and the gramophone on the top one about three feet from the floor. It is thus both easily got at and out of the way should the room be required for dancing. A light fitting should be placed conveniently for seeing the records. In small rooms the piano sometimes has to be omitted.

Whatever the furniture already possessed may be, it can usually be improved by good choice of furnishing fabrics. When starting to redecorate, renovate or furnish a drawing room take a view of the whole of its possibilities and determine the essential things to be done or bought, and the styles and colours needed to enhance it. This method precludes buying a carpet merely because it is a good bargain, a piece of furniture that is not in accord with others in the room, or picking up cushions at a sale merely because in themselves they are pretty. Such haphazard methods have spoilt many rooms that could have been charming with far less money spent on them than was lavished to produce an unsatisfactory medley.

**Country House Drawing Rooms.** A drawing room in the country is often simpler in treatment than the one in a town house. Freshness and the happy nature of the colour scheme will make up for a mixture of styles in pieces of furniture. Loose covers rightly play an important part in the scheme of such a room. If they are to be of a patterned cretonne, it is useful to remember that the larger the room the bolder can be the nature of the design on the fabric, but that such a design requires a plain setting. An attractive idea is to have the curtains of the gaily printed material and the covers in plain linen. This looks particularly well in a room where the windows are a feature.

A charming scheme for a sunny drawing room, which boasted no beautiful architectural features except a well-proportioned group of outward swinging casement windows, was evolved from a colourful cretonne used for the short curtains and box-pleated valance. The ground of the cretonne was dark smoke grey with large bunches of old-fashioned flowers multi-coloured, but with pink and red rose shades and the green of the leaves predominating. A grey wallpaper was chosen with a faintly suggested brocade pattern in an oyster shade. The paintwork was carried out in the latter colour except for the architrave of the door and its panel mouldings which were the deep grey of the cretonne ground. The settee was upholstered in dark grey velvet, but for the chairs, loose covers with box pleated frills were made in leaf green linen, which also

lined the curtains. A panel of embroidery, glazed and framed in a narrow grey moulding, was substituted for an ugly overmantel, the only ornaments on the chimney shelf being a pair of Sheffield plate candlesticks and one piece of old ruby and white glass. The owner of the room had housed any china ornaments in a big corner cabinet where they made a pleasant piece of decoration and were out of the dust. Cushions and shades discreetly repeated the colours in the cretonne, and the scheme was further bound together by a modern grey pile carpet into the border of which lighter grey, dull rose and leaf green were pleasantly introduced.

Another charming scheme is illustrated in Fig. 1. The Persian pattern carpet and the parquet surround would harmonize delightfully with beige walls, the satin curtains in a golden tone and lined with the shade of chestnut brown chosen to emphasise the frieze and cornice mouldings. The furniture is in Queen Anne and Chippendale styles. Loose covers should be made without frills to show the graceful cabriole legs of the armchairs. A glazed floral chintz with a deep cream ground would be a good choice for such covers. A few pieces of old brass lend their charm to this warm colour scheme which could be further enhanced by peach-coloured shades.

*Drawing room. Fig. 1. Scheme for the drawing room of a country house, the prevailing tones being beige, gold and brown. The two long windows and the glass door into the garden, let in plenty of light and sun. (Courtesy of Our Homes & Gardens)*

**Town Drawing Rooms.** The small drawing room in a flat can be treated delightfully in formal fashion. Quite often—except in modern buildings—there is a tendency towards Adam style in designs of doors and chimney pieces, more or less suitably adapted to unpretentious rooms. As a rule this has to be made the best of, as structural alterations are impossible during a three-year tenancy. A successful method is to paint the walls a suitable pale colour and simulate panels with applied mouldings. Such a scheme forms a good background for most furniture whether of modern, antique, lacquer, painted or reproduction varieties. A ceiling paper of silver is a highly decorative finish if the

furnishing of the room permits it.

*Fig. 2. Corner of a town drawing room. The furnishing and decoration are based on a dignified yet simple Queen Anne style enhanced by flower paintings. (Courtesy of Hampton & Sons, Ltd.)*

#### A Pleasing Colour Scheme

Another scheme which is pleasantly noncommittal is to distemper walls and ceiling a clear pale yellow or in flesh pink, paint the woodwork in a cold sea green picked out with silver, have a settee upholstered in a deeper shade of the same green in damask or heavy moiré; repeat this colour also for the curtains, the pelmet for which is trimmed with silver braid and fringe. Loose covers for the chairs would be in a cretonne with a pale green ground patterned in a small conventional design introducing pink and yellow. A carpet of modern pattern in which the predominating colour is green might be used or one of plain green pile. Tiles which are not harmonious in colour can be toned to suit the woodwork. Waxed walnut furniture with one lacquered or painted piece and a floor standard lamp in the sea green colour would look particularly well in such a room, but the scheme is not one that necessitates any particular style in furniture.

For a town house drawing room the simple Queen Anne style, illustrated in Fig. 2, could be carried out without great expense. The curtain treatment would be beautiful in plum-coloured silk with dull gold trimming. The carpet could be an oriental one introducing plum colour and old rose shades, the upholstery a modern silk tapestry in which the colours of the carpet are blended with a gold thread running through the design, and the walls are painted a soft apple green, while the ceiling is a pale gold colour. The panelled flower painting over the fireplace and the gold net glass curtains brighten the room.

A contrast to this room would be one in which the scheme was based on a biscuit, fawn and pink wallpaper of classical design. This could be completed by a light brown pile carpet unobtrusively patterned in fawn, taffeta curtains shot with pink, fawn and gold, and loose covers made of a shadow tissue in which these colours blended with a soft blue. Either oak, mahogany or walnut furniture would be at home in such a room.

**DRAW KNIFE.** This is a tool used by carpenters for roughing out along the grain. It consists of a heavy blade to which two wooden handles are fitted and riveted to prevent them being pulled off in use, the blade being ground to a chisel edge. When using a draw knife the operator stands astride of the wood to be cut and, holding the knife by the two handles, draws it towards him along the wood, while keeping the blade at an angle to the wood. The result is to draw off massive shavings slowly and steadily. The action should be one of drawing, not chopping, though chopping has to be resorted to when cutting through knots in the timber.

*Draw Knife used in roughing out timber.*

**DRAWN THREAD WORK.** This work is mostly executed on linen of an open weave, which allows the threads to be easily drawn, and is suitable for afternoon teacloths, table centres, and all kinds of house linen. The soft canvases used for duchesse sets and sideboard runners, and also crêpe-de-Chine, georgette and satin dress materials can be decorated with drawn thread work.

Modern drawn thread has many additions in the way of fancy lace stitches, from which have evolved the beautiful designs seen on the corners of tablecloths. In its initial stages it began with punto tirato, threads drawn one way of the material, then punto tagliato, threads drawn both ways so that they cross, and these were followed by opum tiratum, the fancy stitches worked on the loose threads.

The outlay in materials is small, as, apart from the material, working thread, crewel needles and a sharp pair of embroidery scissors are the only other things necessary. The thread should be about the same thickness as the ravellings of the ground material, and it can be either embroidery cotton or flax thread sold in small skeins for the purpose. Very elaborate work is best done on a special frame, but for small corners an ordinary round embroidery frame is sufficient, while the long rows can be worked over the left fingers.

The first stitch in this work is simple hemstitch. The hem itself will vary in width according to the article, and this must be measured off exactly before drawing

the threads, which come immediately under the folded hem (Fig. 1). If a single thread is drawn exactly where the hem is to turn at the top and about  $\frac{1}{4}$  in. from the edge for the little turn up, a perfectly straight and flat hem will result. Join the thread just under the hem and bring it through to the right side. Pass the needle from right to left under three or four threads, according to thickness, and draw the thread through. Insert the needle in the same place and bring it up again through the hem just above the place where it was brought out before. Insert the needle under the next three threads and repeat, Fig. 1. Fig. 2 shows the hemstitch used as an insertion.

Fig. 3 gives the pattern of a single crossing evolved from Fig. 2 after hemstitching both edges. The clusters of threads are crossed thus. Put the point of the needle from left to right under the second cluster, then let the point travel from right to left under the first cluster, still keeping the second cluster under the needle, and bring the needle up to the left of the first cluster. Repeat along the line, turning every second cluster over the preceding one, and this will give a running thread through all the clusters, Fig. 3 shows the needle in position for beginning this stitch. Fig. 4 depicts trellis hemstitch. Hemstitch one edge as at Fig. 1, but when doing the opposite edge take half the strands from one cluster and half from the next.

*Drawn Thread. Figs. 1-5. Simple and more involved forms of hemstitching.*

**The Faggot-Stitch.** Fig. 5 introduces faggot-stitch and the punto tirato knot. The latter is used largely in the most beautiful drawn-thread designs. Prepare the hemstitch insertion as in Fig. 2, then three or four clusters are bound together with the knot, when they resemble faggots of wood. The thread should be joined at the end of the work, or where there is not a hem it can be tied to the first three clusters to make the first faggot.

The knot resembles chain-stitch in embroidery with a slightly different placing of the needle. Take sufficient length of thread to do the whole length of insertion.

Now, working down the line of insertion, turn the

cotton towards the left and hold it down with the left thumb; bring the point of the needle over to the left of the cotton held down and insert it down the upper part of the space between the faggot just tied and the next faggot. Pass it behind the three clusters that will form the next faggot and bring the point up over the cotton that is held down by the thumb. Draw the needle through with sufficient tightness to bind the faggot and let the thread lie in a straight line between the faggots. Fig. 5 shows the accurate position of the needle and thread, which is very important.

Fig. 6 shows how to finish a corner so that the threads are not drawn right to the hem. Buttonhole the two outside edges of a square along exactly the number of threads that will be drawn on each side, then cut the threads under the pearl edge of the buttonhole stitches and draw out the threads on both sides, when a square hole will appear, as in Fig. 6. This can be filled with a fancy pattern as in Fig. 7, or with the spider web. Fig. 7 shows a corner where two insertions of faggots cross each other. The working thread crosses the square hole from both sides, then two other threads are laid obliquely across these from corner to corner and secured firmly on the linen. Now join a new working thread in the very centre of the star of threads and work point de reprise under two threads, a corner one and a side one. This stitch is like simple darning-stitch and goes over one thread and under the other until the spokes are nearly covered.

*Figs. 6-7. Stages in working the drawn thread work corner shown in Fig. 8.*

Point de reprise forms the groundwork of the most beautiful drawn-thread designs, where a large number of spokes are laid and the stitch darned in and out all the threads according to formation of design. A spider's web can be worked on the spokes by weaving round and round the threads, taking care to keep them flat against each other so that they do not overlap. Fig. 8 shows a completed centre with two rows of faggot insertion and point de reprise fillings at the corners. In this case the threads are drawn right to the hem of the cloth. *See Embroidery; Linen; Tablecloth, etc.*

**DRAW STRING.** A draw string of tape or ribbon may be slotted through a casing or hem, and attached in the middle to prevent its being accidentally pulled through the slot too far. A double draw string is often used where fullness is only required for a few inches, or in drawing up bags, etc. Two lengths of ribbon tape or cord are used, one being attached at one end only, the other at the opposite end, and threaded through the slot; the two loose ends drawing up easily and evenly.

**DRESDEN CHINA.** The best period of Dresden china, which is porcelain made at Meissen in Saxony, extended from 1720 to 1775, and the mark is the famous crossed swords in blue under the glaze. To this period belong the breakfast services and other useful wares, with moulded decorations, painted on mauve, yellow, green or marone grounds, with tiny landscapes or flowers. Of the figures and groups, the best are in white, but those with painted decorations are much favoured. There were also clockcases, mirror-frames, cabinet-panels, tables, candelabra, and other furniture accessories.

*Dresden China. Coffee-pot painted with Watteau subjects, c. 1760.*

During the 30 years preceding 1814, called the Marcolini period, marked with a star beneath the crossed swords, the pieces show a somewhat classical taste. After that time the old moulds and marks were frequently copied, but never equalled. Many pieces were sold in the biscuit state, this being indicated by a nick across the swords; so that any painted decoration upon them, when so marked, must have been done elsewhere. The present factory, whose fabric is in a different clay and glaze, still possesses many of the original moulds, and uses the original mark. Painted with flowers, tea, coffee and dessert services are among the best examples of modern Dresden.

Thousands of counterfeit pieces have been produced. About 1880 a Dresden firm adopted a mark comprising a cross-tipped crown and the word Dresden. This so-called Crown Dresden has no historic value, such as that which pertains to Crown Derby. See China.

#### DRESSERS FOR DINING ROOM AND KITCHEN The Welsh Dresser and other Kinds Described and Illustrated

See further Dining Room; Dining Table; Kitchen, and the articles on the woodworking processes involved in making one of these articles of furniture, e.g. Amateur Carpentry.

The dresser developed from the buffet, and took its present form soon after 1600. Oak was used for most of the early ones, but afterwards mahogany became popular and fine specimens were inlaid with box and other woods. The piece of furniture known as the Welsh dresser is made of oak and mahogany combined.

The plain kitchen dresser of deal, with its drawers and cupboards and unbacked superstructure of shelves, is a fixture, whereas the dresser which is sometimes substituted for the sideboard is a movable piece, and the shelves of its upper part are backed with plain wood or panels, and very often enclosed in order to keep the dust off the china that may be stored there. Some attractive modern dressers or built-in sideboards are made with glazed doors at the top, arranged either to swing or slide, as well as the cupboards and drawers in the lower portion. The unenclosed super-structure is most common; but there is always scope for the architectural treatment of the dresser, and both parts of it may be elaborated up to a certain point without diminishing its usefulness. The chief difference between old and new is in the material. Mahogany is now too expensive a wood for most people. Weathered oak has largely taken its place, and the cheaper woods, stripped and wax polished or stained, often give good results.

Where a dresser is intended for the display of good china, the shelves should be lightly grooved for the plates and saucers. A few good pieces carefully arranged will show themselves and the dresser to the best advantage.

The real Welsh dresser is easily distinguishable from the many faked ones on the market. The wood is oak, frequently with a simple inlay of mahogany, dark polished, with severe rectangular mouldings, and there should be plain brass droppers for the drawers.

One is constantly seeing examples, alleged to have been restored, with dark oak stain on the wood, curved Queen Anne legs, curved mouldings, or Sheraton shell ornament on the panels, and other contrivances designed to bring them into line with the popular conception of the period. In a good many cases the restored Welsh dresser is simply built up on an English foundation, with top back panels supplied from Victorian church pews. A useful test, though not, obviously, an infallible one, of genuineness is the condition of the brass furniture. The brass in a genuine antique will have become browned by the passage of time. Drawer handles looking like new should, therefore, be suspected. Many good furniture makers construct reproductions of period dressers, copying detail with artistic precision, or modern types are designed in limed oak.

**Making a Deal Dresser.** The particulars of a dresser given here will apply to any length up to 6 ft., and any reasonable height up to 7 ft. 6 in., in which case an extra shelf might be fitted.

For present purposes the dimensions are put at 3 ft. 6 in. wide. Depth back to front can be between 1 ft.

*(Continued in page 699)*

### DRESDEN CHINA: SELECTED EXAMPLES FOR THE COLLECTOR

1. Pluto and Cerberus (1740). 2. Monkey musician (1750). 3. Cupid and Psyche (1760). 4. Girl's figure (1745). 5. Scaramuccia and Colombia (1760). 6. Cockatoo (1750). 7. Teapot in Chinese style (1730). 8. Vase (1750). 9. Barbara Utmann (1750-60). 10. Musician (1750). 11. Vase (1750-60). 12. Figure of Europe (1750). 13. Centre-piece (c. 1745). 14. Satirical group (1765). 15. Child's head (1770). 16. Bird on nest (1750). Vase (1750). 18. Court Fool of Saxony (1741). 19. Elephant. 20. Circassian (1740-50.) 21. Vase (1735). See pp. 434 and 696.

6 in. and 2 ft. Common deal will answer all purposes.

*Dresser: two antique examples of this piece of furniture. Above, enclosed dresser of Sussex make, with drawers and cupboards. Right, old Welsh dresser, with panelled back, cupboards and drawers (Courtesy of Waring & Gillow, Ltd.)*

The legs, from 3 in. by 3 in. material, are 3 ft. long. The top side rails or ends are double mortised into the legs and are 10 in. wide, finishing flush with the bottom of front bearer rail. The end may be cut to extend from top to bottom by those who desire entirely to enclose the lower part of the dresser.

The top front rail is dovetailed into legs as at C, Fig. 3, and finishes from 3 in. by 1 in. stuff. The bearer rail enters the legs with a couple of tenons each end, and is of similar width and thickness. The top back rail (D) is of equal width and thickness with the ends, dovetailed into back of legs and screwed, with a matched back of  $\frac{3}{4}$  in. stuff fitted to the lower part, as shown by dotted line at Fig. 2.

The division rail (G) between drawers is cut with two tenons right through the top front rail, and one through the bearer rail, and is 3 in. by 1 in. by 10 in. long. Between the front bearer rail and the back rail a 3 in. by 1 in. piece (E) is tongued and dovetailed respectively (Fig. 3). Upon this piece the drawers run backward and forward, the division rail being extended by glueing and nailing on a 1 in. by  $1\frac{1}{2}$  in. slip to form a guide (F, Figs. 2 and 3), so that all slides in line. A similar runner with guide is needed at each end. In assembling, dovetail and screw into under edge of

back first, then the tongue on E should enter bearer and the dovetails on back enter legs simultaneously. Below, the legs are stiffened by stout rails tenoned in as H. These rails can be 3 in. wide, and upon them the pot-board, notched to fit round legs, will get a level bearing.

For the doors, stiles and rails,  $2\frac{3}{4}$  in. by 1 in., mortised and tenoned together and grooved or rebated for  $\frac{5}{8}$  in. panels, should be got out. The opening for panels is indicated at Fig. 1 as with a  $\frac{5}{8}$  in. mould dropped in on face as a finish. The drawers should have 1 in. fronts,  $\frac{3}{8}$  in. sides and backs, and  $\frac{1}{4}$  in. bottoms. The dimensions are given in the cutting list. The construction of drawers is clearly explained in the article Drawer (q.v.). Either wood knobs or cup handles in iron or brass can be fitted.

The upper ends or sides of the dresser, from 6 in. to 7 in. wide at top and shaped as Fig. 1, are cut back  $\frac{3}{4}$  in. below each shelf to 4 in. wide at bottom, where they drop into grooves in the top. In marking the heights of the two or three shelves, first measure the plates and dishes, or any other items that have to be mounted. Usually the lower shelf is at least a foot above the table top, the others graduated in space as necessary. The stop for plates on edge is formed by lengths of  $\frac{1}{4}$  in. bead cut to butt between the ends and panel-pinned to the shelves, so that they ensure a safe angle when the plates are tilted. These shelves are fitted into corresponding grooves in the ends, each groove being stopped back  $\frac{1}{2}$  in. from the front edge and the shelf corners notched to agree.

	Long ft. in.	Wide in.	Thick in.
1 top .. .. .	3 6	20	$1\frac{1}{4}$

Face rail .. .. .	3 6	4	$\frac{3}{4}$
Back, matching .. .. .	3 6	42	$\frac{3}{4}$

A face piece (J) is cut into the front edges of ends at top, and upon this the cornice mould will bed as at K, Fig. 3. The mould, a 3 in. by 1 in. section, is mitred to

return round ends. The face piece can be cut  $5\frac{1}{2}$  in. wide, and shaped as Fig. 1 to ease the line. A back of  $\frac{3}{4}$  in. matching is best. A length of  $\frac{3}{4}$  in. mould, cut to butt between the bottom parts of ends, makes a good finish. Brass dresser hooks of suitable size for the safe hanging of jugs are obtainable. A cutting list for the 3 ft. 6 in. size is given. Lengths and widths allow for joints and paring, but thicknesses are net.

Fig. 3

**Dresser for a Recess.** Fig. 4 depicts a dresser fitted to a recess 5 ft. by 18 in. The main face of the lower part, i.e. the legs and drawers, etc., stands forward 1 in., and is fitted with a set of drawers at the back. Fig. 7 shows the ends made flush with the inside faces of the legs, so that irregularity in the

sides of the recess will not make a difference to the fitment. A batten nailed to the wall (A, Fig. 6) gives ample support. The top rests on the batten and is nailed to it. The legs, cut from 2 in. squares, are mortised for the front rails and the ends. These latter are rebated for the back (Fig. 7). The front rails are cut from 1 in. stuff, except the bottom which is  $1\frac{1}{2}$  in.; this is also rebated, as in Fig. 7 to take the pot-board, and bevelled at the front.

Glue the ends up first, then clean the inner surfaces and glue the front, lastly fitting in the back, which is glued and nailed. Now fit the job in position; it will be necessary to scribe the legs over the skirting. Having fixed the carcass to the batten (previously secured), the top is cut out and nailed down. This projects at the front round the walls. The potboard is best made from matchboarding, and is held at the back by a batten

(Fig. 7).

**Dresser.** Fig. 4. Useful dresser made to fit into a recess. Figs. 5 and 6. Front and side elevations. Fig. 7. Diagrams showing details of drawer runners and bottom.

Fig. 6

Fig. 4

Fig. 5

Fig. 7

Drawer runners and kickers are fixed as in Fig. 7, and the drawers made. The set of small drawers at the back of the top are made separately and screwed to the

top. The carcass for these takes the form of a box rebated together, with drawer divisions grooved in. The shelves above, grooved or provided with stops to take the plates, are supported by bearers nailed to the wall. They should be nailed down on to the bearers.

**DRESSING: What to Wear.** Being well dressed is largely a matter of personality—it does not necessarily call for a great deal of expenditure. A woman requires what is usually termed "good taste." In other words, she must have great discernment in order to observe the general trend of fashion and adapt or modify the changes in line, colours, etc., to suit herself. No woman should attempt to follow a fashion slavishly, regardless of whether it suits her or not. Nor, if she is naturally quiet and retiring, should she wear loud and ultra-smart clothes, for in these she will only feel obvious and uncomfortable, thus completely swamping her personality, whereas she should aim rather at expressing it. But in order to know how to adapt fashions to best suit herself, a woman must first know her limitations.

This means that she must criticize herself thoroughly before a mirror, and, after admitting all her good points, proceed to take stock of her bad ones—every trifling fault in figure, face, hair and skin. This is essential, for only by playing up to and emphasising her good points can a woman detract attention from the bad points, while at the same time minimizing the latter as much as possible. This taking stock of herself will enable her to determine her type, and dress accordingly. For instance, if she is of lean, rather angular build with severe features, she will be best advised to avoid all fussy clothes, frills, flowers and ribbon trimmings and choose instead clothes of a tailored style. Even her afternoon and evening dresses should be utterly simple in style, relying on the richness of the fabric and colours to express her character and dignity.

**Men's Wear.** The hard and fast rules which govern men's attire make for a standard level in their dressing. With the exception of some of the younger men who take a real interest in their clothes, and of a few who actually make suggestions to their tailors, every man's desire is to look exactly like his well-dressed fellow. Colour harmony of shirt, tie, handkerchief and socks is not to be despised. A morning coat and dark-striped trousers have a slimming effect, and so have all dark-coloured, smooth-surfaced materials, particularly those which are narrowly striped, for lounge suits.

Men can be suitably equipped for all ordinary evening occasions by the possession of one suit of evening clothes, a couple of white waistcoats, and a dinner jacket suit, white bow ties to wear with the first, a black bow for the last and, in addition, correct evening shirts.

**Dressing to Help the Figure.** There are certain well-established rules in dress with regard to the too tall and thin, or the too short and stout. The former can

detract from their height by wearing materials with a horizontal pattern or stripe. By breaking the long line of a dress with a wide belt at the waist, a jabot at the neck, and fullish sleeves instead of tight ones. They can wear shoulder capes with great success, also large-patterned prints, boleros, and tunic dresses when these are in fashion. To them wide-brimmed "cartwheel" hats are most becoming, as also are loose, unbelted coats of the swagger type, from finger-tip to full length. If instead of wearing suits in one colour they have the jacket and skirt in two different colours, or even two definite shades of one colour, they will find that this appears to diminish their height appreciably.

With the too short and stout, it is, of course, the reverse. Although they should avoid too loosely cut or sloppy clothes, at the same time they should not have their things unduly tight, as this emphasizes the line of the figure. They should not have anything horizontal about the line or pattern of their dress. For them stripes and seams should run lengthwise, and printed patterns should be of the small, unobtrusive type, nothing flamboyant. The narrow V-necked or cross-over style of bodice suits them best, with long fitting sleeves unbroken by gathers or noticeably fussy cuffs. A line of buttons down the centre of the bodice or a narrow inset panel in a contrasting colour—these give height, as also does the princess style of dress or coat, unbroken by a waistline. As to colours, it is well-known that dark shades make for slimness. Black, navy blue, dark brown, plum-colour, dark grey—all these are good relieved by small touches of white, oyster, beige or a very pale shade of the basic colour itself, according to the wearer's taste and skin colouring.

#### Correct Clothes for the Occasion.

Having a thorough knowledge of the type of clothes that suit her best, a woman's next care should be to always wear the correct clothes for the occasion. This is perhaps the essence of good dressing. For day wear in town, light simple tweeds and woollens are, generally speaking, most suitable for cool weather, with medium heeled shoes and practical accessories. Heels can be higher and accessories more ornamental in the afternoon and evening, according to the material and style of the gown. For the country, for race-meetings (apart from the very fashionable ones), for golf, and motoring, rough tweeds are usually worn, and with them low or medium heeled shoes are considered good style, with simple accessories in tweed, felt, leather or suede, or any fabric that happens to be fashionable and appropriate.

**Care of the Clothes.** One of the most important factors in good dressing is the care of clothes. No matter how old a suit or dress is, provided it is cleaned and pressed regularly, it will always look stylish, and fresh accessories or lingerie touches will give it a new lease of life. White collars, cuffs, frilling, etc., should always be spotless, and for this reason it is wise to have these easily removable for laundering.

There are one or two other things that affect the look

of clothes in general. Posture, primarily. No matter how much money is spent on clothes, or however tastefully a person is dressed, the effect is marred considerably if the wearer walks with a round-shouldered slouch, or sits or stands badly. Also, the line of a perfect gown can be completely ruined by badly fitting undergarments.

A woman should call attention to whatever she considers to be her good points. First, she should express her personality by dressing to her type. Then, if she has particularly lovely hair, the colour of her clothes should subtly complement it. If her eyes are good, again she should play up to their colour. Similarly, if her hands are her best feature, she should always keep them exquisitely groomed, and wear only the very best gloves.

**DRESSING:** In Surgery. The term dressing is used in surgery for any material applied to a wound to cover and protect it and further its healing. A simple aseptic dressing, that is, one which itself is germ free, can be prepared by baking ordinary absorbent cotton in an oven until it is slightly scorched.

Whatever the material applied to a wound, a burn or other breach of the surface, it must be clean and it must absorb discharges. To provide for absorption of discharges it is usual to cover the wound, etc., with lint or gauze, and over this put a thick layer of absorbent cotton-wool or wood-wool. The dressings are then fixed by a bandage.

In the case of a clean wound it is desirable that the dressing should be dry, because moisture favours the growth of microbes; but where there is a considerable raw surface and it is desired to keep the dressings moist to prevent them from sticking into the wound, the lint or gauze is wrung out of an antiseptic lotion and covered with oiled silk or gutta-percha tissue, the latter being cut smaller than the area of lint to be covered.

The smooth side of lint should be applied to the wound, as the fluff of the other side tends to stick in the sore. Two useful kinds of lint are ordinary surgeon's lint and boracic lint. Useful gauzes are plain gauze, cyanide gauze, and iodoform gauze.

Among lotions which may be applied for moistening dressings are the following:

Carbolic solution	1 in 40
Lysol	1 in 200
Perchloride of mercury	1 in 2,000
Boric acid	1 in 30

See Bandage; First Aid, etc.

**DRESSING CASE.** Dressing cases for men and women are intended to hold the various toilet accessories and requisites arranged compactly so that they can be taken about easily when travelling. The case itself is usually made of leather of various qualities, and should be cared for as other leather articles. The sizes and contents vary. A typical case for a man measures 24 in. by 16 in. by 8 in.; that for a

woman is somewhat smaller. The fittings are usually of silver but may be of ivory, enamel, tortoiseshell and gold or silver, or even of gold.

**DRESSING ROOM.** In small flats, the bathroom is sometimes arranged as a bath-dressing room. Furniture must be of suitable material to withstand damp, and clothes may be kept in the bedroom provided there is sufficient wardrobe accommodation. Failing this, room may possibly be found for a small wardrobe in the passage. Convenient wardrobes are devised containing space for hanging clothes, shelves, and a set of narrow drawers with glass doors, so that a man can see which drawer contains ties, which handkerchiefs, and so on. In the case of the dressing room proper a dressing chest or table must also be provided, but it is not usually necessary to have a wash-stand, as the modern house gives good accommodation in the bathroom. A small bed or a practical divan is often also included in dressing room furniture.

### DRESSING TABLES: PRACTICAL AND DECORATIVE

The Choice and Construction of this Bedroom Piece Other articles upon allied subjects include Bedstead; Chest of Drawers; Wardrobe. See also Bedroom; Bed-Sitting Room; Furniture; Table; and for the accessories Toilet Mirror; Toilet Set, etc.

In origin the dressing table was a table or chest of drawers used for toilet purposes, a mirror being placed upon it for assistance while dressing. As a distinct piece of furniture, it dates from the end of the 17th century. In the time of William and Mary and of Anne beautiful dressing tables were made in walnut and other fine woods. These were often fitted with drawers, and on them a loose swing mirror was placed. This style has been revived in the 20th century.

In the elegant styles for which the 18th century was notable, dressing tables are remarkable for grace of design and beauty of ornament. On them are found the various decorative features that distinguish 18th century furniture—the cabriole leg, for instance—while marquetry and inlay are frequently seen. These pieces are of rosewood, satinwood, and other rich woods, and they were designed by Chippendale and other great cabinet makers of the time, who made them also in mahogany. In some the mirror, either swing or triple in form, remained separate from the table, but more often it was fitted into the back.

Fig. 1 in the next page shows a finely decorated piece of the late 18th century classical period. It is of satinwood, with a bow-shaped front in which is a drawer. It is supported on slender legs connected by carved rods, at the junction of which is a box. Above the table proper are five drawers, and above these are two pedestal cupboards, between which a toilet glass shaped like a shield is swung. The beautiful design is enhanced by the graceful decoration of medallions painted on the cupboard doors and garlands of flowers

round the mirror. painted on the cupboard doors and garlands of flowers round the mirror.

*Dressing Table. Fig. 1. Late 18th century example of the piece in satinwood. Fig. 2. Reproduction of a William and Mary dressing table, with triple mirror, in walnut.*

*(1, Victoria & Albert Museum, S. Kensington; 2, courtesy of Gill & Reigate)*

Fig. 2 shows an older example, being of the time of William and Mary.

It stands on twisted legs, strengthened by a stretcher. The mirror and the drawer handles should be noticed. Such triple mirrors are largely reproduced to-day, both framed and frameless.

In the 18th century Sheraton, Hepplewhite, and other designers made dressing tables of the type that close up by means of folding doors on the top. The various partitions into which the well under the lid is divided were intended for combs, powders, patches, and other accessories demanded by the toilet of fashion. The glass, which is fitted into the well, rises on hinges in front and is supported by a foot fixed in the back. These articles were made in mahogany, but the cheaper woods also were employed.

In the 19th century the dressing table became an essential piece of furniture, but many of the tables manufactured in the latter half of the century are of poor design, especially those made to form pieces in bedroom suites of heavy so-called Victorian style.

**Modern Dressing Tables.** At the beginning of the present century the dressing table was nearly

always bought in a suite of bedroom furniture, and was of the duchesse variety with mirror attached to supports rising from small drawers on either side. These were manufactured in designs based on Jacobean, Chippendale, Sheraton and other styles. While there are still many suites made in both modern and antique styles in walnut, mahogany, oak and other woods, and also in painted and lacquered furniture, separate pieces are often again preferred, knee-hole and drop-end tables are utilized with separate toilet mirrors, or the dressing table takes form as a corner or wall fixture. Extremes are seen in Figs. 3 and 4 of modern dressing table treatment, showing the severely plain and the daintily trimmed.

*Dressing Table: two modern examples. Fig. 3. Space-saving suggestion for a small bedroom: it combines plenty of drawers with ample shelf room. Note use of cellulose and chromium handles. Fig. 4. Revival of a Victorian fashion in painted wood and taffeta. Any table of*

*suitable size can thus be brought into a decorative scheme. (3, photo, Margaret Currant)*

Note the utilization of all possible shelf and drawer space by an undershelf at right-angles to the main structure. It would be an excellent arrangement

for dressing table accommodation in a small dressing room or in a study bedroom. The other treatment (Fig. 4) is an example of a fashion revived from Victorian days. This particular dressing table is of painted wood. The curtain is made of art-silk taffeta to match the bedspread in the room, and trimmed with silver braid. The top of the table has a separate cover of the taffeta under plate glass. These petticoats for tables can be carried out in a variety of materials suitable for elaborate or simple furnishing schemes. With transparent fabrics, such as spotted and organdie muslins or voile, a separate lining of sateen is required. In country bedrooms chintz or cretonne dressing table petticoats may match the curtains. Such washable materials can be made up as complete covers with tops to fit the corners of the tables and the petticoats gathered on at a depth of about 6 in., or separate tops may be made edged with a 6 in. frill, the petticoat being attached to the table underneath the frill. Sometimes the petticoats have tiers of scallops, or three tiers of contrasting colours; as, for instance, three shades of rose pink voile on a pink sateen foundation.

One of the most attractive of recent designs which combine "period" characteristics with up-to-date ideas is the frilled and glass-topped design shown in Fig. 6. This includes the present tendency towards "kidney shapes" in mirrors, also curves, and a mahogany stool which goes well with furniture of various kinds.

**Construction of a Dressing Table.** A dressing table of the more usual type has two or more drawers with mirrors above. The general construction may be gathered from the article on Chest of Drawers (p. 394), which also describes a man's dressing chest with shaving mirror. When making a dressing table with framed three-fold mirror it is important that the stiles or uprights of all three mirrors should be marked out together, to ensure uniformity in size. The method of framing and fixing the glass is indicated in the article just mentioned. The centre mirror is hung with special brass movements made for the purpose, and the side mirrors are hinged with ordinary brass butts let into the mirror framing.

*Dressing Table. Fig. 5. Modern design in figured oak with a frameless triple mirror (Courtesy of Williamson & Cole, Ltd.)*

Frameless bevelled mirrors, as shown in Fig. 5 on the next page, lend a nice appearance to a dressing table, and are attached to  $\frac{5}{8}$  in. backboards by means of neat brass or plated clips screwed to the backboards themselves. The clips and other necessary fittings, with the movements for the centre mirror, may be obtained

from a furnishing ironmonger.

**Pedestal Dressing Table.** Fig. 6 shows a dressing table set composed of two pedestals and a stool. A tall mirror is fixed to the wall, and two useful bracket shelves complete the set. The pedestals have plate glass tops, and each contains two drawers. The mirror is illuminated by a tubular lamp fixed above it.

*Dressing Table. Fig. 6. For a corner: this modern glass-topped table wears an old-fashioned frilled valance. Such tables are available with swivel hinges, swinging aside to reveal a washstand. (Photo, Margaret Currant Studio)*

The construction of the pedestals is explained in Figs. 7 to 11, and the worker will find

further information about joints and methods in such articles as Chest of Drawers: Drawer; Joint Mortise, etc. Fig. 9 shows the base, which stands in a trifle under the pedestal, the latter being held in position by blocks or stout dowels.

*Dressing Table. Figs. 7-13. Diagrams showing construction of the pedestal dressing table set.*

The stool (Fig. 12) comprises a stand and the seat proper. The latter is an inverted box fitting on to a saddle between the uprights of the stand. The seat must drop down low enough to be quite firm and stable. It is secured by screws from the under side of the saddle into a cross piece (not shown) fastened inside the seat box at the correct height, and resting on the upper side of the saddle. Allowance must be made for the thickness of the covering material, so that the seat fits tightly between the uprights of the stand.

The pedestals are 28 in. high by 20 in. wide and 24 in. deep. The base is 21 in. by 17 in. by 3 in. high. A suitable size for the seat of the dressing stool is 20 in. long by 15 in. wide by 12 in. high. The ends of the stool are 11 in. wide, leaving 2 in. of the upholstered seat showing at each side. The seat stands up about 4 in. above the stool ends. The pedestals might be made of 1 in. whitewood, the boards being glue jointed to the requisite width. The ends are dovetailed to the top and bottom, or in a simpler form of construction these parts might be tongued together. The drawer rail and runners are grooved to take a dustboard, the rail being tenoned to the end, as shown in Fig. 10. The runner is housed to the end, and enters the groove of the rail with a stub tenon. The back of the pedestal (Fig. 8) is of plywood.

The two drawers may be made up as described in the articles Chest of Drawers and Drawer, the relative depths being adjusted to taste. The handles are shown in Fig. 10. The mirror is 6 ft. by 2 ft. or so, and may be framed up in the manner described in the article on Cheval Glass. The method of securing the glass is shown in Fig. 13. The tubular electric light fitting may be obtained from any electrical dealer, a switch being fitted inconspicuously under one of the bracket shelves. A white or cream-coloured switch would be suitable. Of course, one of the existing lights might be converted, when the switch in its usual position near the door of the room would control the mirror light. The mirror is attached to the wall with plated brackets and screws, utilizing rawlplugs.

The woodwork of the pedestals, stool, mirror frame and bracket shelves should be cleaned off nicely and prepared for painting. One of the cellulose enamels would be eminently suitable for this job, the edges and details being finished in coral pink or delft blue, say, and grey for the ground. One or more coats of cellulose undercoating should be applied to the wood before the colour coat, and on an open grained wood a cellulose paste wood filler might first be employed with advantage.

A rubber-set brush must be used, as the solvent in the enamel will loosen the hairs of the ordinary sort of brush. The brush should be used in one direction only in applying the enamel, and on vertical surfaces the strokes should be from top to bottom, as far as possible.

**DRESSMAKING.** This requires a knowledge of the correct methods of cutting out and sewing together the various parts that make a garment, though the same main principles govern the making of all clothes.

With regard to cutting out the garment, which is

often done with the aid of a paper pattern, it is necessary to know how to set each part of the pattern correctly on the material, so as to get the right hang to the garment.

Fitting and pressing are very important complements to sewing and making. For fitting purposes the garment is roughly put together in the first instance with temporary stitches, known as tacking, and, after the arrangement of other minor details, the garment is tried on the wearer for the fitting. The seams, at this stage, are adjusted to fit the wearer more correctly, and the exact length estimated.

After fitting the seams are fixed permanently, durable stitching replacing the tackings, while the pressing, finishing, and trimming are also done. Pressing in itself is a highly important factor, and can easily make or mar a garment. Various stitches are used in the sewing together of the dress. Simplest of all are the temporary stitches used at the first stage, these not only including tacking as just described, but also basting. The permanent stitching which replaces the tacking may comprise machine-stitching, running, hemming, gathering, over-sewing, catch-stitching, herring-boning, etc.

With regard to machine-stitching, it is very important that the dressmaker should have a thorough knowledge of the working of a sewing machine, as some models can be adjusted to do all kinds of stitchery, such as hemming, also decorative or trimming stitches; for example, tucking, embroidery, openwork-hemstitching, etc. The sewing machine, in fact, is one of the most important tools of the dressmaker. Others include scissors in two or three sizes, sewing needles in mixed sizes, pins, white and coloured tacking cottons, and ordinary sewing and machine cottons and silks, thimbles, buttonhole twist, an inch tape, pieces of tailors' chalk, flat irons, and an ironing-blanket; also a sleeve-board on which to press sleeves, and a skirt-board for skirts. Hooks and eyes, fasteners, etc., can be bought as required. A dress stand should be included.

**How to Learn.** As a business, dressmaking offers possibilities of a good livelihood, if a thorough knowledge of all its branches is acquired. In order to obtain this, the would-be dressmaker can enter a dressmaking firm as an apprentice, and afterwards pass through various stages, until she becomes a full hand, capable of working without supervision.

Another way of learning dressmaking is in trade schools. There are several of these in large industrial centres, such as the trade schools of the L.C.C. in London, into which a girl may pass directly she leaves school. In these she is taught every branch of the business, the course, when completed, enabling her to take a place in any house of business. Dressmaking classes are also held at various technical institutes throughout the country for those who cannot afford to give the time for an apprenticeship.

Anyone with an intelligent acquaintance with ordinary needlework will find it possible to make her own clothes at home, with the aid of the various fashion journals now on the market. These journals supply paper patterns of various garments, together with diagrams and instructions showing how to cut out in material and make up, while they often include in addition practical articles on various aspects of dressmaking. *See Cutting-Out.*

**DRESS STAND.** A dress stand is a frame of light wood, or wire, partly covered with canvas or drill made to the measurement of the figure, upon which a dressmaker drapes and fits a gown. Dress stands are to be bought in all sizes or made to order; those made in wire are sometimes partly collapsible and adjustable.

A stand padded to about 9 in. below the waistline is the most useful type for fitting on and moulding a bodice or coat.

**DRESS SUIT.** This term is given to the suit of clothes worn by men at dances, dinner parties, and in the evening. Except for the waistcoat, which may be white, a dress suit is invariably of black cloth. *See Dressing.*

**DRIED FRUIT.** These fruits especially currants, sultanas, and raisins, constitute important ingredients in many kinds of puddings, cakes and fancy breads. Among the varieties dried are apples, apricots, figs, peaches, pears and prunes. Before use, these should be washed thoroughly and soaked for 24 hours in cold water. When they are ready to be cooked stew them slowly until tender in the water in which they have been soaked adding sugar to taste.

Fruit drying may be done at home without the aid of any special equipment, but if the result is to be successful the fruit must be perfectly sound. Apples should be peeled, cored and cut into rings, and if they are not to be dried immediately, immersed in 2 quarts cold water to which 1 oz. salt has been added, to prevent discoloration.

Pears, peeled and cut into halves, should be left in the same solution for 15 min., while, except for stalking, cherries, plums and damsons need no preparation, though the two last-named are better if pricked before being placed in the oven. The oven itself should be cool, and the drained fruit placed in it on an ordinary wire tray. In order that the fruity may not scorch, the temperature must be kept low and the fire not allowed to burn fiercely. The time of drying will depend upon the kind of fruit used, apple rings requiring about 5 hours and halved pears a whole day. The smaller fruits will not take so long. *See Compote; Currant; Fig; Prune; Raisin.*

**Dried Fruit Pudding.** When fresh fruit is difficult to obtain, this pudding is specially welcome. Make it by washing 2 oz. each of dried apple rings, dried pears and dried peaches, and 3 oz. of raisins, cutting each of the peaches and pears into 3 or 4 pieces. Put all the

fruit into a basin, cover it well with cold water, and leave it to soak for 24 hours. Then put it into a saucepan with the water in which it has been soaking. Add 3 oz. Demerara sugar, and cook the fruit until it is quite soft. Then put the fruit into a pie-dish, and continue to boil the syrup for a few minutes until it thickens. When cold, pour it over the fruit.

*Dried Fruit Pudding. An attractive and useful sweet which can be prepared when fresh fruit is difficult to obtain.*

Put a quart of milk into a saucepan over the fire, sprinkle in 4 oz. semolina, add the grated rind of a small lemon and 2 dessertspoonfuls granulated sugar, and cook all together until the mixture is soft and creamy, stirring it frequently to prevent it from burning. Leave it to cool slightly, then pour it over the fruit, but do not mix them together. Whisk together to a stiff froth 2 whites of eggs and 1 gill cream, fold into the mixture about 1 teaspoonful castor sugar, and then shake it on top of the semolina etc. finally decorating it with strips of angelica. If a plainer pudding is required, the cream and white of egg may be omitted.

**DRIERS.** Driers is the name given to a group of preparations used to ensure the proper drying of the fatty oils in paints and varnishes. Litharge (oxide of lead), minium (red lead), and white lead are those usually employed in commercial preparations. Care should be taken not to use them to excess. A safe proportion is 10 per cent of the total bulk.

Driers are sold by the colourman in two forms, liquid and patent driers. Liquid driers, known as terebine, have as a basis oils in which metallic salts have been boiled, and may be purchased ready mixed or prepared for use as required. Patent driers are sold ready ground in oil, and when purchasing it is as well to see that no brittle skin is formed on the top of the colourman's keg. This is an indication that the drying agent is too active, and the paint in which such driers are used will be spoiled. *See Paint; Varnish, etc.*

## DRILLS AND DRILLING METHODS

### Boring Tools for Use on Metal

This contribution is one of the group that includes Bent Iron Work; Metal Work. *See also Bit; Boring; Brace; Chuck; Lathe; Rivet.*

A drill is a small, sharp-pointed instrument with cutting edges, fixed in a stock which is revolved to pierce a hole in metal.

Drills are made in two chief grades, carbon steel and high speed steel, the latter removing metal faster. For

practically all ordinary amateur purposes the carbon is quite satisfactory, and costs considerably less.

For all-round use there is the twist drill, so named from the shape of the double helical fluting, made from 1/16 in. to 1 in. or more in diameter. For drilling holes in thin sheet metal and any holes in brass or copper, the straight fluted drill is preferable. The flat, arrow head, and diamond point drills are useful, especially in the larger sizes, for drilling holes with a ratchet brace, and are equally effective on iron, steel, or brass. They are also convenient for use in a lathe, especially those made from flat strip metal.

Expansion drills comprise a short twist drill fixed in a shank, and an adjustable cutter, for drilling large diameter holes in sheet metal, as when making holes in hot-water tanks, cisterns, and other household appliances. Centring drills are used to start the hole when intending to drill one of large diameter, and also to form a properly sloped centre on the end of a bar to be mounted and turned between the centres of a lathe. Pin drills have a central pin or pilot, which guides the drill while it counter-bores or enlarges a hole already drilled. The general form is shown at Fig. 5.

Drill. Fig. 5. Diamond point drill. Fig. 6. Pin drill. Fig. 7. Morse taper shank twist drill. Fig. 8. Flat arrowhead drill with ratchet brace shank.

Drill. Fig. 9. Diagram of drill made from iron gas barrel, for brickwork.

Fig. 10. Paper drill in section.

The limit of size that can be operated effectively with a hand drill is seldom over 3/16 in. to 1/4 in. diameter. A breast drill will tackle holes up to 5/16 in. to 3/8 in. diameter; a small hand-power bench drilling machine

will handle drills up to 1/2 in. diameter, and a powerful hand-power drill of the blacksmith's type will tackle work up to 3/4 in. in diameter. A treadle drill will take up to this size, but for larger sizes a power-driven machine is required. Drills are purchasable in millimetre sizes, in letter sizes corresponding to the gauge sizes of wire, and in ordinary fractions of an inch, the latter being the best for general purposes. Very small drills are made for watch and clock work and similar delicate apparatus.

Fig. 11. Method of drilling through glass.

Drill: various types. L-R. Fig. 1. Reciprocating drill on the Archimedean principle; it drives the drill on both upward and downward strokes. Fig. 2. Straight shank twist drill with double helical fluting, the best for all-round use. Fig. 3. Hand drill in use. Fig. 4. Powerful bench two-speed drill.

There are a number of different types of stock, but the amateur may well do with a hand drill as illustrated at Fig. 3, effective up to 1/8 or 3/16 in. diameter holes. An example of a powerful wall or bench drilling machine is shown at Fig. 4. A reciprocating drill on the Archimedean principle (Fig. 1) drives the drill both on the upward and downward stroke, by having right and left hand threads formed

upon the spindle.

Having selected the right drill for the size hole, place it in the chuck and screw it up tightly. Next make a centre punch mark exactly on the centre for the desired hole. Then, using a hand drill, hold this so that the drill is perpendicular and in an axial line with the position of the hole (Fig. 3). Rotate the drill by turning the crank handle with the right hand, while keeping the drill and the stock in position with the left hand. Exert sufficient pressure with the left hand to make the drill cut properly; this will be evident from the turnings, which should curl up and away from the drill if working in steel or iron, or in the form of chips or powder from brass or cast iron.

It is necessary to hold the drill stock steadily, and to rotate the drill at the correct speed, which varies with the size of drill and the nature of the material. Using a  $\frac{1}{4}$  in. diameter drill on steel, the speed would be about 300 revolutions per min.; on cast iron, about 200 revolutions; and on brass, about 550. Smaller sizes of drills should be rotated faster, and larger sizes more slowly. If the drill turns off nice clean chips or shavings, all is well; if not, try a different speed, with greater or less pressure on the drill. Drills should be lubricated with light machine oil while working, except on cast iron, which drills dry.

**The Breast Drill.** Breast drills are used in the same way, but pressure is brought to bear by leaning the weight of the body on the pad at the top of the stock, and holding the guide handle with the left hand. The work must always be held securely, as if the work moves the drill will almost certainly be broken. Drills should not be used to enlarge a hole that is only a little smaller than the drill, as the hole is then apt to jam or tear, or smash the drill. A reamer is the proper tool to use for this purpose. If a large hole has to be made, drill a small pilot hole first.

The correct shape of the cutting edges can only be maintained by accurate grinding. Essentials are that the angles of both cutting edges are alike, that their length is uniform, and that both faces slope back at the same angle. The use of a drilling gauge to test these angles is recommended, as well as an ordinary drill or wire gauge plate for testing the size of drills.

Paper is drilled with a tubular drill shaped as shown in Fig. 10. A serviceable drill for making holes in brickwork is made from iron gas barrel, shaped as in Fig. 9. Marble can be drilled with a twist drill.

Glass is drilled in several ways. A simple method is to take a piece of brass tube of the desired diameter and equal to that of the hole. Revolve the tube slowly, and use carborundum powder moistened with oil, applying the drill tube to the abrasive, which should be spread out evenly and thinly on a piece of wood, and not put on the glass. The glass must be supported on a felt or rubber pad only a little larger than the size of the hole. When possible, drill from one side halfway through, and then reverse the glass and drill from the opposite side. China and crockery are drilled with a steel point and diamond dust or carborundum as a cutting medium, or a diamond-tipped drill is employed for the

purpose.

Drilling in a lathe is accomplished by holding the drill in a chuck on the mandrel, or by revolving the work and holding the drill in a chuck on the tail-stock. Flat drills are generally used in a special holder held in the slide-rest.

**DRILL: In Gardening.** The drill is a straight furrow, made in the soil, in which seeds are sown. It varies in depth from half an inch to 2 in., according to the size of the seeds. A wide, flat drill is usually made for large seeds, e.g. peas and beans, and a double row is sown. The distance between the drills depends on the height of the plants.

**DRILL: Linen and Cotton.** White linen drill, so much used for men's suits and riding-breeches in the tropics, owes its popularity to its coolness in use and a great durability which enables it to withstand frequent washing. Too substantial for dresses, it is excellent for hot-weather tailor-made costumes, and for boys' sailor suits. Blue drill is also obtainable.

Drill is more largely made in cotton than linen, and khaki cotton drill used for the troops in India and extensively for civilian wear in the Colonies, is serviceable also for summer wear in England. Solid and compact, drills are woven with twilled or sateen faces, and wear well, because of the strength and number of threads forming the surface. The closeness and solidity of their structure make them somewhat difficult to sew. Either cotton or linen drills make excellent pocketings, and remnants should be saved to that end. Certain lighter cotton drills, called drilletes, are made for this purpose.

**DRILL: HEALTHY EXERCISES FOR CHILDREN**  
**How to Secure Balance and a Good Carriage**  
 Other information on the important subject of physical fitness will be found under the headings Breathing; Exercise. See also Child; Diet; Food.

Suitable exercises keep every muscle in good condition, strengthening weak ones and making supple those which are tight. Girls especially suffer from weak abdominal muscles and very often those across the shoulders and the back of the thighs are too tight. Exercises also help to attain a perfect balance which is the secret of good deportment.

No child should be allowed to overdo these exercises, and they are best performed for five or ten minutes before breakfast. Those illustrated have been chosen because they give the maximum result with the minimum amount of expended energy. Hence their advantage over skipping exercises, for example, in which an enormous amount of energy is spent in lifting the body off the ground so frequently, much extra work is placed on the heart, while comparatively little benefit accrues to the muscles.

At school, exercises are usually performed to a rhythmic time, a piano being used, with the beats well

marked. But at home, it is quite enough to clap the hands while the child is getting into the rhythm, and afterwards it can be dispensed with, the youngster doing the counting. Naturally, this rhythmic time is not absolutely essential, but it will be found that it not only prevents the exercises from being rushed through, but gives a certain amount of grace to them as well. Also, a child enjoys doing a thing to rhythmic measure more than without this aid.

*Drill. Figs.*

*1-9. Exercises for children designed to keep the muscles in good condition and to ensure good balance and carriage of the body.*

Fig. 1 shows an exercise for developing balance. This is most valuable, not only for deportment but for exercising the muscles as well. When the child has become more efficient at balancing, the exercises can be performed with a book resting on the head. If this stays in position it is a proof that the balance is being strictly kept. Count two for each movement.

First, hands on hips and lift the left leg, pointing the toe; raise the leg and place the hands on the shoulders. Keep the leg raised and stretch the hands sideways. Lastly, lower the leg and hands, then feet together all in the one count. Repeat with the right leg. When balance has become more assured, while the leg is raised, the hands can be stretched forwards as well as outwards, making it a longer time on the one leg.

The last exercise can be followed up by the simple one of raising and lowering the heels (Fig. 2). This is especially good for the arch of the foot and for the foot muscles, and is also a corrective for flat feet. Count two for raising the heels and two for lowering, and repeat several times. Another exercise for the same purpose consists simply of "feet apart and feet together." Count two for each movement and repeat several times as in the last exercise.

Fig. 3 illustrates an exercise for strengthening the back and abdominal muscles. Such exercises, as has already been noted, are particularly important for girls, whose abdominal muscles are often weak. The first movement is feet apart with a jump, then with a swinging movement raise the two hands and lower them, taking hold of the ankle with both hands, as in the illustration. Next body upright with hands outstretched; then repeat the swinging movement, taking hold of the other ankle. Body upright again with hands outstretched, then bend, taking hold of each ankle with either hand. Lastly, straighten up, hands outstretched then down, jumping feet together.

The next exercise (Fig. 4) is for the neck muscles and for developing a good carriage for the head. The first movement is done in a sitting position with the legs tucked underneath, as in the photograph. Stretch out the first hand and look towards it, giving the head a smart turn and hold it erect. With the next count of two, place both hands on knees, now repeat the first movement with the other hand, taking care of the position of the head. Place hands on knees for the next count of two; now bend the head right down between the knees (as in Fig. 5), counting two; then up again, counting two. Repeat this three times, for this is the most important part of the exercise. Now stretch out the legs and stand.

If the child should tire at all during the exercises or after, she should lie flat on the ground with the knees bent and the legs as near to the body as possible, as in Fig. 6. It is an excellent position of complete resting, and should be used for a tired child even if it is not connected with drill.

The trunk muscles are most important and should be given a chance to be in good condition together with the other muscles. The exercise shown in Fig. 7 is quite simple, but it must be done smartly, with head erect

and back straight. This does not mean quickly; the count of "one," "two," is to be used in this, as in the others. First, jump the feet apart and place the hands on hips. Now stretch out the hand straight and turn it with the trunk backwards as in Fig. 7. Hands at sides and eyes front. Now repeat with the other hands, doing it to time, yet smartly. Hands at sides and jump the feet together. Repeat this three times.

Another exercise for abdominal muscles is the one illustrated in Figs. 8 and 9. This is rather more strenuous and should not be performed more than twice at a time. First lie flat on the back with the legs outstretched and the hands underneath the head, or at the sides, as shown. Now begin the counting "one," "two," raising the left leg upwards and pointing the toe. Lower leg to the count of two, then begin with the other leg, pointing toe upwards, then lower. Next raise the two legs together and lower. The last part of the exercise is to draw the legs up, placing hands in front, as in Fig. 9, then on the ground to raise the body. It must be remembered that some of these movements, such as the last one, are to aid the counting or the rhythmic effect. They are not really essential in the sense that they are conditioning the muscles. Each exercise has its share of both, the one helping the other.

With regard to drill costume, most schools have their regulation dress, which consists of a gymnasium tunic and blouse, such as is worn by the child in the illustrations. This can, of course, be varied, the yoke being slightly different, or a blouse with a kilt may be worn. For exercises at home any dress and knickers will do providing they allow free movement.

**DRINKING.** All the tissues of the body contain a certain amount of water, and in addition to this there is a large quantity of free fluid in the form of lymph, cerebro-spinal fluid, and blood. If the body is deprived of water, the tissues become dry and shrunken, the blood is thick, and the circulation sluggish. The body thus requires to contain a certain amount of water to maintain health and life.

The natural beverage for mankind is water, and its place can only be taken to a limited extent by other beverages. Milk can replace it largely when the solid diet is restricted, but is usually only drunk in such quantity when it is a matter of duty to one's health, while tea, coffee, and alcoholic drinks in large quantity are injurious. It is a matter of importance to health that a sufficient supply of water should be taken into the body daily. Water enters into the composition of the tissues and provides for the circulating fluids; it forms more than two-thirds of the body weight. On an average about 3½ pints are necessary each day, and a certain amount of this is taken in solid food. But the bulk of the day's supply should take the form of beverages.

Tea and coffee are consumed by most people and are beneficial, apart from their affording water to the body, and harmless if they are taken properly prepared and in moderate amount. Cold weak tea is a good thirst quencher, and this or oatmeal water proves very grateful to those who are engaged at hot, laborious

occupations which cause free perspiration. Milk alone or with soda water should be taken freely by those whose nutrition is poor.

Alcoholic liquor, if taken as spirits, should be freely diluted, as neat spirit drinking is a fruitful source of gastric catarrh; the same is true of taking large amounts of alcoholic liquors in any form, especially when they are taken apart from food. Beer or light wines are agreeable beverages and tend to increase the appetite and aid digestion, but the heavier brands should be taken sparingly. As summer drinks lime juice or lemon juice in water or soda water are very wholesome. Cider makes another wholesome drink and appears to benefit some people who suffer from rheumatism. The natural table waters may be taken alone or as diluents of other liquids.

Only a moderate amount of liquid should be taken at meals, and then only when there is no food in the mouth. A liberal allowance of fresh, wholesome water may be taken with great benefit in between meals. It is a mistake to take liquids very hot, as they may easily check the flow of gastric juice; an immoderate use of acid liquids, e.g. lime juice, lemonade, etc., in hot weather is a bountiful source of dyspepsia.

**Drinking Water.** Not only must drinking water be free from the gross contamination which sets up diseases like typhoid and alimentary disorders, but it must not contain too much mineral matter. Gross contamination may gain access to the water not only at its source but also when inside the house.

The source from which the water is drawn should first of all be considered, and the following classification is useful:

Wholesome	{Spring water.
	{Deep well water.
	{Upland surface water.
Suspicious	{Badly stored rain water.
	{Surface water from cultivated land.
Dangerous	{Unfiltered river water.
	{Shallow well water.

In the home, drinking water should be stored in vessels or cisterns placed in a light and well-ventilated position and kept scrupulously clean. Where there is a main supply, drinking water should never be drawn from the cistern but always from a tap on the rising main. In districts where rain water, collected from the roof, is used for domestic purposes, it should be stored in a covered concrete tank. It should not be allowed to stand in contact, with metallic lead, as soft waters are often able to dissolve lead, which may cause poisoning.

Where the source is dangerous or there is suspicion that the water is polluted, as happens in times of epidemic, it may be purified at home. This is done most conveniently by bringing the water to the boil. Heating it in this way will destroy all germs likely to produce

disease, and has the added advantage of rendering hard water softer than it was before. Some people object to the flat, vapid taste of boiled water, but this may be counteracted by pouring it backwards and forwards several times from one jug to another. This causes the air to circulate once more through the water, lack of oxygen being responsible for its lifeless taste. *See* Alcohol; Beer; Cider; Coffee; Diet; Filter; Milk; Tea; Water; Wine; etc.,.

**DRIPPING:** How to Prepare. The dripping from beef is less hard when cold and devoid of the tallowy and sometimes even rank flavour of that from mutton. Spread on bread or toast, beef dripping is a nourishing food often given to children. In cookery, for frying, etc., it is invaluable, and is sometimes used for mixing with the flour for making cakes and pastry.

There are two methods of preparing beef dripping. The first is as follows. After a joint of beef is roasted, pour all the melted fat from the baking-tin into a jar or basin. Pour about a gill of hot water on to it, stir it well, and leave it until it is set and hard. Then raise the cake of fat, scrape off any soft or dark part from under it, and use as required. The water under the fat will often contain a little of the gravy from the meat, and should be saved for stock. If the fat is left on the water for long, it will absorb some of it and go sour. The second method consists of putting all the dripping from the joint in a saucepan with about  $\frac{1}{2}$  pint water. Boil it with the lid off the pan, until the bubbling ceases; then take the pan off the fire and cool it a little. Pour off the fat, from which, by means of the boiling, and its resultant evaporation, all water has been extracted, into a clean basin and it is then ready for use. Mutton and pork dripping are prepared in the same way. *See* Clarifying.

**DRIVING.** In driving a single horse the reins should be taken in the left hand, the left or near side rein being held between the forefinger and thumb, and the offside or right hand one between the second and third fingers, the palm of the hand being uppermost. The reins should pass out under the remaining fingers, which should close tightly over them. The arm should be held at almost a right angle across the body with the hand about 6 in. in front of the bottom button of the waistcoat. This will enable the right hand to be used easily when it is necessary to employ both hands, while it can also be used when the whip is required. In driving, the whip should always be used from, the wrist, not from the arm.

The seat should be above or at least on a level with the horse's head. It should be placed so that the driver can, if necessary, use his legs and feet to nullify the pull of the horse. The reins should never be allowed to hang loosely, although it is a mistake to grip them at all tightly. The driver should always feel the horse's mouth. The term hands used in connexion with driving and riding refers to the exact weight and pressure put upon the horse's mouth in guiding him and the give and take of the driver's hands.

In driving a pair the reins are held in the same manner, but as there are two horses to control instead of one, the task is more difficult, because they may not pull equally.

In Great Britain the rule of the road for driving is to keep to the left. If another vehicle is overtaken, the one that overtakes it must leave it on his left, himself taking the right. *See* Bit; Horse; Motor Car; Reins, etc.

*Driving. Correct method of holding a pair of reins and whip.*

**DROPSY.** An accumulation of fluid, derived from the blood vessels, in the tissues and in the cavities of the body constitutes dropsy. This takes place when the pressure in the veins becomes high, when the vessels' walls are damaged and made more permeable, and when the blood becomes thin. The first condition occurs when the veins are obstructed or when the heart is feeble and cannot drive the blood efficiently through the veins. The second condition exists when the circulation is poor or the blood thin and when poisons are present in the blood stream; and the third in anaemic and debilitated states.

When it affects the tissues it is called oedema, and if superficial causes visible swelling. If firm pressure is made on the swelling, particularly over bone, a depression is made in the skin by the displacement of the fluid, and the skin shows pitting. Oedema of the leg may be caused by a garter being too tight, and it also occurs in varicose veins. Oedema may occur in both legs in people who have been on their feet all day, particularly if they are somewhat anaemic. If there is definite anaemia and debility, it may appear even when the patient is in bed. The same thing applies to the dropsy of heart disease, which, eventually, may appear all over the body. Dropsy also occurs in Blight's disease.

Treatment of dropsy depends on the cause, but includes rest, and in some cases measures directed to increasing the discharge of fluid from the body by diuretics (q.v.).

**Drop wort.** *See* Spiraea.

**DROUGHT.** The effects are more apparent on heavy land than upon that of lighter texture, but the harm to crops during hot, dry weather is in both cases shown in starved and stunted vegetation. During days of drought the value of deep cultivation becomes apparent, for it is then that the hoe may be put to work to stir the surface earth to some depth, and thus prevent undue evaporation.

A thorough and frequent pulverization of the soil a few inches down is one of the best aids possible to counteract in measure the effects of drought, and there is no implement more suitable for the purpose than a three or five-pronged cultivator. A thin covering of some non-absorbent retentive substance is also of assistance, and one of the handiest materials for this purpose is short grass mowings from the lawn.

Watering should be done in the cool periods of evening or early morning. Effectual watering of the soil, overhead sprinkling, or spraying, to freshen leaves through their pores and wash dust from the foliage, followed by surface stirring and mulching, yield success in droughty seasons. *See Soil.*

**DROWNING: The Treatment.** In all cases of death from immersion in a fluid, what oftenest happens is that the fluid is drawn into the air tubes and produces suffocation. It will also be found that there is a large amount of fluid in the stomach. In some cases death is not caused by asphyxia, but by shock, due to cold or fright, or exhaustion from prolonged efforts to keep afloat.

The first thing to do in the treatment of the apparently drowned is to lay the patient on his back, turn his head to the side, examine, and, if necessary, clear the mouth and throat of mucus or anything else found there. Then, without delay whatever, carry out artificial respiration. No matter though the patient gives no sign of life, and has been immersed in the water for a long time, a persevering effort should be made to resuscitate him.

When he commences to breathe of himself, the rescuer's efforts should be turned to encouraging the circulation and bringing back a natural warmth. The patient's wet clothes should be got off, the limbs should be chafed, the direction of the rubbing being towards the heart, and he should be well wrapped in hot blankets, while hot-water bottles, adequately protected against burning, should be placed in the armpits and at the feet. A few teaspoonfuls of hot water may be given, and thereafter a cup of very hot black coffee, or a ½ oz. of whisky or brandy, diluted.

The patient should be kept in bed for at least 24 hours, to allow the heart to recover from the results of the strain thrown upon it. *See Artificial Respiration.*

**DRUG.** The continuous taking of certain drugs is apt to produce an irresistible craving for them, despite their injurious effect upon both mind and body. The commonest instances are addiction to alcohol, and smoking. The less frequent drug habits, such as the taking of opium or cocaine, may originate in taking the

drug in the first instance under medical orders.

To check the serious growth of the drug habit, an Act of Parliament was passed in 1925 which aimed at the suppression of illicit traffic in cocaine and other dangerous drugs. Moreover, certain drugs can only be obtained by the general public on presentation of a doctor's prescription, which is afterwards retained by the dispensing chemist. The habitual drugtaker can be certified like an habitual drunkard.

When a drug habit has been formed, the only satisfactory method of treatment is to get the patient into an institution where it will be impossible to obtain the drug. Tonic medicinal treatment may form part of the cure, but moral treatment is what is really valuable, in the form of helpful advice and encouragement. Little or nothing can be expected from nostrums. *See Alcohol; Cocaine; Opium; Poison; Tobacco, etc.*

**DRUGGET.** This is a common felt or coarse woollen fabric, frequently printed with a pattern on one surface only, either used as a protection or substitute for a carpet. A lighter glazed linen drugget is sometimes laid to protect stair carpets and is used for table covering.

**DRUNKENNESS.** Over indulgence in alcohol causes loss of control over the movements of the body and over the speech, which becomes thick and indistinct. The same loss of control affects the mind, and the mood may become bellicose or maudlin and silly. In some cases a condition resembling somnambulism results. Frequently nausea and sickness ensue. Drowsiness manifests itself sooner or later, and may deepen into coma. This state is very like that of various other conditions, e.g. apoplexy, uraemic or diabetic coma, poisoning by other narcotic drugs like opium, chloral, etc.

It is often a matter of difficulty even for doctors to distinguish between these conditions and drunkenness, and obviously the greatest care should be exercised in dealing with such persons. It should not be hastily assumed that because a person smells of drink he is simply drunk, for he may be both drunk and ill. It is necessary to emphasise this point, as serious mistakes have been made and people suffering from apoplexy have been left to die because they were supposed to be simply drunk. A doctor should be summoned at once and in the meantime the person should be kept warm if necessary.

In the treatment of acute drunkenness the patient should be made to vomit and wash out his stomach with large draughts of tepid water. Strong coffee or sal volatile in teaspoonful doses in water may also be useful. Chronic drunkenness is very difficult to treat and will fail unless the victim can be induced, by beginning his cure in an institution, to give up alcohol altogether. Some of the graver results of chronic drunkenness are sterility, multiple neuritis, a tendency to apoplexy, delirium tremens and insanity, and the likelihood of epilepsy in the drunkard's offspring.

**The Legal Aspect.** In law drunkenness is a punishable offence in the following circumstances: being drunk in a highway or public place; being found drunk on licensed premises; being drunk and disorderly or riotous in a highway or public place; being drunk and in possession of loaded firearms; and being drunk, when in charge, on any highway or public place, of a carriage, horse, cattle, or steam-engine. It is also an offence to be in charge of a motor vehicle while under the influence of drink to such an extent as to be incapable of having proper control of the vehicle. A driver may be convicted of this offence although he is not drunk.

Where husband or wife is an habitual drunkard, the other spouse has the right to apply to a magistrate's court for a separation order. An habitual drunkard is a person who not legally a lunatic is yet, by reason of habitual drinking, at times dangerous to himself, or herself, or to others, or incapable of managing himself or herself, or his or her own affairs. A person who, in intervals of sobriety, is quite harmless and capable of business, may yet be an habitual drunkard. *See Alcohol; Cirrhosis; Delirium Tremens; Dipsomania; Separation Order.*

**DRY CELL.** The term dry cell is applied to the unit of all forms of primary electric battery in which the electrolyte is in a paste or semi-solid form, as distinct from the liquids used in wet batteries and accumulators. *See Battery.*

**DRY CLEANING.** Soiled garments of a delicate texture which cannot be subjected to the ordinary laundering processes may be sent to a professional cleaner, or the work can be done at home, special care being taken when using petrol or other highly inflammable cleaning agents.

Light coloured cloth garments are simply treated by the application of kitchen salt on a pad made from a large piece of white linen or nainsook. Lay the garment on a table, and scatter salt over it with a liberal hand, spreading it gently with the finger-tips until a thin powdering of salt is evenly distributed over the entire surface. Next take the pad and rub the salt into the cloth with long downward sweeps, not round and round, since this tends to roughen the surface and destroy the sheen of the material. Finally brush out all the salt, and the cloth will be found quite clean. If there are any badly soiled parts, such as on the hem of a skirt or the cuffs and collar of a coat, repeat the process two or three times.

Silk and satin garments are thoroughly cleaned by the following method, which should on no account be used except in the open air. Spread a clean sheet on a table placed out of doors, and have ready two large wash-hand basins, a tin of petrol, and a soft-bristled nail brush. Half fill one of the basins with petrol, dip the garment into it, giving it a gentle squeezing, then spread it out on the sheet, and brush it all over with long downward sweeps, going the right way of the material, from top to bottom. Rinse and squeeze it in

the petrol again, and rub it vigorously with a folded pad made of white cloth. Pour some clean petrol into the second basin, rinse the garment thoroughly in this, squeeze it well, and hang it up to dry in the open air. Pull the garment carefully into shape before hanging it up. When quite dry and free from the smell of petrol, it may be brought indoors and ironed.

**Cleaning Furs.** Most furs, when really dirty, can be cleaned with hot bran, but this should rarely be necessary if they are wiped with a damp towel immediately after wearing. Children's white furry caps, coats, and capes can be cleaned with cornflour, which is scattered thickly over the fur, rubbed with the tips of the fingers, and then brushed out with a soft, white-bristled brush. This process creates a great deal of white dust, so that it is wise to tie a large handkerchief round the hair and to conduct the operations in the bathroom, where the powder can be easily wiped away with a damp cloth.

It is easier to clean things the first time than the second or third. Surfaces roughen with use, and dust and smoke fasten more quickly to a rough material than to a smooth one, and are also much more difficult to remove. For this reason the rubbing of the finger-tips on garments during dry cleaning operations should be done as gently as possible, and a hard brush should never be used.

**Removing Grease Spots.** Almost all kinds of grease spots will yield to treatment with a hot iron and a sheet of blotting-paper, while fuller's earth, dry pipeclay, magnesia, and French chalk are also effective if spread over the affected parts, left for a while, and then shaken off. Two applications are usually sufficient.

Another method of removing grease consists of putting a pad of clean cloth under the material, and sponging it on the wrong side with benzol, gasoline or tetrachloride. Use such cleansing agents at an open window and away from any naked light. To prevent the grease spreading as the spirit begins to dissolve it, surround the spot with a ring of French chalk, which acts as an absorbent. French chalk may be used with safety on any light coloured and delicate fabric. The article to be treated is placed on a clean towel, and rubbed all over with the chalk, extra attention being paid to those places where there are definite marks to remove. The garment should then be rolled up in the towel, laid aside for three or four days, and afterwards brushed lightly to remove all traces of chalk. *See Clothes.*

**DRYING: Of Clothes.** The ideal method of drying clothes is to hang them in the fresh air on a breezy day. Fresh air, and especially bright sunshine, have a bleaching action, and will remove stains and any yellow tinge caused by the soap and soda used in the washing process. More important is the fact that fresh air is a powerful disinfectant, therefore woollen and silk garments which cannot be disinfected by boiling can be

rendered free from infection if exposed to fresh air.

In the country the washing may be hung in a meadow or small orchard, which removes from the house windows a view of the necessary posts and line, somewhat unsightly in small gardens. Strong tall posts, preferably of oak, are required if there are no trees or other supports, such as a brick wall, to which the lines can be attached.

Galvanized iron wire and hemp rope are the usual kinds of lines used. Rope lines must not be left out of doors longer than necessary, as rain, with particles of dust and soot, soon causes them to become discoloured and rots the fibres. A soiled line is often responsible for dirty marks on clean linen. After use the line should be coiled up and put away with the clothes pegs, in a linen bag in preference to a basket.

Whoever is hanging clothes out to dry should stand with her back to the wind and peg with the garment facing her, this arrangement allowing the wind to blow well into the garment. Avoid placing the pegs in any very conspicuous part, e.g. peg blouses by the waist and not by the collar. Pillow-cases should be hung with the open end uppermost. Before pegging out, all garments should be turned if they are not already on the wrong side, in case the damp clothes inadvertently touch trees or bushes.

The ordinary clothes horse placed around the kitchen stove is a very general way of indoor drying. Woollen garments are the most difficult to dry indoors. Place these on a ceiling dryer or on lines hung across the kitchen. Drying in front of the fire often causes woollen and flannel garments to shrink. When indoor drying is a necessity, open the windows and doors to allow a current of fresh air to pass through. This is the best alternative to drying in the open air.

There are fitted cupboards heated by gas, electricity, or oil specially made for drying clothes which are designed so that a current of fresh warm air constantly passes through the cabinet, and arranged that the heavy and moist air is extracted from the bottom. These are specially useful for flats and houses where there is no hot cupboard for airing clothes. They answer the double purpose of dryer and airer. *See Airer; Clothes Horse; Clothes Line; Laundry.*

**DRY MEASURE.** Dry measure is used for potatoes and vegetables generally, also for grain of various kinds. Analogous in some respects to liquid measures, it is as follows:

4 gills =1 pint	4 pecks =1 bushel
2 pints =1 quart	8 bushels=1 quarter
4 quarts =1 gallon	36 bushels=1 chaldron
2 gallons =1 peck	

A peck or stone of flour weighs 14 lb.; a bushel or 4 pecks of flour 56 lb., and five bushels or a sack of flour 280 lb. A quartern (or quarter-peck) of flour weighs 3 lb. 8 oz. There are a number of local bushels. A bushel of English wheat is 60 lb., of foreign wheat 62 lb., of English barley 50 lb., of oats 39 lb.

**DRY MOUNTING.** This is a process for mounting photographs and prints of any kind perfectly flat on any kind of support. Between the print to be mounted and the card or other support a thin sheet of tissue paper impregnated with shellac is placed. This tissue can be obtained from photographic dealers. Heat and pressure are applied, under which the shellac melts and firmly cements the print to its mount. No moisture of any kind is required.

The amateur can obtain good results with the ordinary flat iron. A special electric iron is also available. To mount a photographic print by this method, take a sheet of dry mounting tissue of exactly the same size as the print to be mounted and lay it flat upon the back of the print. Touch the tissue lightly at the two upper corners with the point of a fairly hot iron; this causes the tissue to adhere where it is touched. If the print requires trimming it should be done at this stage so that print and tissues are trimmed together.

Lay print and tissue down on the mounting card in its right position, lift the print and touch the tissue at the bottom corners with the hot iron, so that it adheres to the mounting card. The print is now ironed all over with an iron heated to such a temperature that water applied to it sizzles slightly, i.e. it should be just above the temperature of boiling water. If the temperature is not right it will be impossible to carry out the mounting process successfully.

The print should be covered with a sheet of thin tin or a piece of brown paper which has previously been well ironed on both sides, and the heated iron then applied with considerable pressure for about 15 or 20 sec., moving it about so that each part of the print obtains heat and pressure. If the print is a large one the ironing will have to be done in portions. If the print adheres to the tissue but the tissue does not adhere to the card, the iron was not hot enough. If the tissue adheres to the card but not to the print, the iron was too hot. *See Mounting; Printing.*

**DRY ROT.** The most prolific cause of dry rot is the use of timber in a wet condition, such as might be seen on new buildings when the timber is on the site but lies uncovered perhaps for months before it is used. If such timber is then placed in position, certain parts being built in the walls, often covered with mortar, there is no chance of it ever getting dry in a natural way.

Combined with the above cause the ground on which the building is taking place is often made up; that is, it has been used as a public tip, whereon any and everything imaginable has been deposited to fill it up to the required level for building.

The house is kept down to as low a level as possible to save expense, and perhaps no earth is carted away from under the floors. The consequence is that the wet wood and the foul earth encourage fungus to start.

**Preventive Measures.** To prevent dry rot the timber should be kept as dry as possible, and if it

cannot be kept under cover it should be so piled that the water will run off instead of soaking in. When timber is built into walls, allow it to lie on the bricks; any bricks which are built up to it or which lie on it should have no mortar intervening. Not only does mortar encourage the growth of fungus, but if the bricks come to the wood they will fit sufficiently slack to allow a certain air-space between. The mortar does not do this. Avoid the use of wood bricks. Even if put in dry they are unsatisfactory, but when cut out of the odds and ends on the job, usually soaking wet, and bedded in mortar like ordinary bricks, they are a fruitful source of trouble. It is better to plug the walls after; the risk will be practically nil.

Dry rot cannot be cured, but where the fungus has already got a hold it may be destroyed. Take out every piece of wood which shows the least sign of being affected. The disease runs further on the inside of the wood than it does on the surface, and unless every trace is cut away it will certainly start again. Next clear out the fungus from the adjoining brickwork, from openings in the walls, and from the bedding of all bonds, etc. The fungus and the affected wood should all be swept up and burnt to prevent the new wood from being attacked.

Before any old wood is replaced with new, the surrounding walls, the old wood left in, and all the new wood should be coated with an antiseptic solution, such as corrosive sublimate mixed fairly strong. This can be obtained from any chemist and must be used carefully, being a deadly poison. *See Wood.*

**DUBBIN.** Dubbin is a greasy preparation for dressing leather and rendering it waterproof, and is used especially for fishermen's boots or for boots worn in wet weather. The dressing, which is not glossy, may be made by melting together tallow, 2 oz.; paraffin wax, 1 oz.; and heavy mineral oil, 5 oz.; and perfuming with a few drops of mirbane oil. Another recipe is to melt together Russian tallow, 8 oz.; paraffin wax, 1 oz.; cod liver oil, 16 oz., and add sufficient mirbane oil to cover the odour of the fish oil. Dubbin is freely rubbed into the leather after washing off the mud and drying the boots.

**DUCHESS COVER.** This type of toilet cover came into fashion when dressing tables were first made with the looking-glass attached to supports rising from trinket drawers on either side. It is usually a straight strip of white or coloured linen embroidered and hem-stitched or inset with motifs of the lace which forms the border, and is sold in two or three lengths and widths to suit the average size of tables. Duchesse sets may be purchased, with three extra mats to match the cover.

Large squares or oblong motifs in real or imitation filet lace of good design can be used joined together and bordered with narrow filet insertion. Fine crochet, let into linen or worked to form handsome corner pieces with narrow edging to match, wears better than anything for this purpose. Embroidery or drawn-thread work can be used in combination with crochet

or as separate trimming. On coloured linen of rather coarse weave wool embroidery is effective. *See Crochet; Drawn Thread Work; Dressing Table.*

#### DUCKS: THE BREEDS, THEIR CARE & COOKING Methods of Breeding and Feeding with Preparation for the Table.

Related information will be found under the headings Apple Sauce; Aspic; Boning; Casserole; Forcemeat; Pastry; Salad. *See also Chicken; Egg; Incubator.*

Duck keeping in Great Britain is practised mainly for the purpose of producing ducklings for the table, but ducks of a good laying breed and strain may be kept profitably for egg production a season longer than hens. The duty on imported ducks has stimulated home production. Refer to the Ministry of Agriculture's Bulletin No. 70 for detailed information.

**Types of Duck.** The fawn and white Indian runner, the white Indian runner, the khaki-Campbell and the buff Orpington breeds can all be recommended for egg production. Both the Orpington and the khaki-Campbell produce good marketable ducklings of moderate size for the table, although they are not equal in size or quality to Aylesburys.

As a table duck the Aylesbury is unequalled, owing to the superior quality of its flesh, to its size, and to the rapid growth of the young ducklings; but it is not as a rule a good layer. Ducklings can be produced weighing from 4 to 5 lb. apiece at about eight weeks old—a result impossible of achievement with any other duck. Adult drakes occasionally turn the scale at 9 or 10 lb. The plumage is pure white, the bill flesh coloured, and the eggs a bright orange. The body should be massive with good girth, deep and straight keel, a full breast carried low, the crop almost touching the ground.

The Indian runner is characterized by an almost upright carriage. As a utility breed it is in the front rank and, although not a large bird, its flesh is of fine quality. As a layer it excels all other varieties, its eggs being large and white-shelled. It is an excellent bird for the smallholder, as it need not necessarily have water for swimming.

The Pekin and Rouen ducks have the merit of size, and the former, besides being rapid in growth, is superior to the Aylesbury as a layer. Taking the average, a dozen Pekin eggs will weigh 2 ½ lb., and this is not excelled by any other duck. As a table bird it does not equal the Aylesbury, but its breast is wide and carries a lot of flesh of a particularly nice flavour and of fine quality.

An adult Pekin drake should weigh 9 lb. to 10 lb., and a duck 8 lb. to 9 lb. From stock birds of such weight can be bred ducklings which weigh 4 lb. to 5 lb. at 8 weeks, 7 lb. at 10 weeks, and 8 lb. at 12 weeks.

Pekins are a canary colour, the bill is bright orange, and slightly convex in shape; the legs and feet are orange, whilst the eye is a dull leaden blue colour.

The Rouen drake has a greenish-yellow bill, dark green head and neck, claret breast, green-black back;

the thighs are silvery grey, pencilled with a darker shade. A glossy blue band, bordered by a narrow black outer clear white bar, runs across the wing; the legs and feet are brick red. The duck is brown, the feathers being laced with bright black lacing; the wing bar is like the drake's. Stock Rouens in breeding condition weigh—drakes, 10 lb. to 11 lb., ducks 9 lb. to 10 lb. When fattened they weigh 2 lb. more. They are not so white in skin as the Aylesbury and Pekin, and for this reason are not quite so popular as table ducks; the flesh, however, is extremely rich and luscious. They are a hardy and very profitable breed.

*Duck: some profitable breeds. 1. Rouen drake and duck, excellent both for table and for egg production.*

**2. Drake of the Aylesbury breed, unequalled as a table bird.**

**3. Buff Orpington, a good laying breed.**

**Duck Breeding.** The breeding of ducks upon a small space is not advisable, and although the smaller laying varieties will breed without access to water for swimming, better results are secured in the case of the larger table breeds

when the birds are able to obtain swimming exercise. The cost of feeding an adult duck upon a limited space exceeds that of a hen, without, as a rule, yielding a proportionate return.

Ducks are not sufficiently mature for mating

purposes until they are about eight months old, and drakes should preferably be a month or two older. For the best results, young drakes should be mated with ducks from eighteen months to two and a half years old. With the large breeds four or five ducks may be mated with one young drake, while with the smaller breeds one drake may be sufficient for from five to eight ducks. The stock should be kept in active condition by only giving sufficient food to supplement foraging, but when a large number of eggs for consumption is required diet on a more generous scale may be given.

As regards the duck house, one can either be purchased or a disused shed adapted to the purpose. It need not be more than 5 ft. high, but the more air space the better. Ducks and ducklings must have dry bedding.

The use of incubators for the hatching of duck eggs is less commonly practised than in the case of hen eggs. The temperature for incubation should be run at 102° if a hot-air machine, or 103° if of the hot-water type. Preference should be given to the use of broody hens. It is seldom worth while permitting a duck to hatch her own eggs.

When hatched, the ducklings of the larger-table breeds are stronger and more easily reared than chickens, and if mothered by a hen it is seldom necessary to leave them with her for more than 3 weeks, and from 10 to 14 days or even less will prove sufficient in warm weather. If reared with artificial

**5. Indian runner duck. (Courtesy of The Agricultural Gazette)**

heat, the temperature of the foster-mother should be kept lower than for chickens. Plenty of air is required in the heated compartments, and the ducklings should be accustomed to do without heat as quickly as possible. The ducklings of the smaller laying breeds are rather delicate for the first few weeks, and should be well protected from rain and damp. No food should be placed before the ducklings until about 36 hours after hatching, and then some damp earth may be supplied in a saucer in which the birds can find particles of fine sand or grit. For the first feed, bread and milk or fine biscuit meal scalded and dried off with middlings or ground oats, or coarse steeped oatmeal with a little maize meal, are among the most suitable.

**4. Pekin, kept for both table and laying.**

**Feeding Ducklings.** This food, and in fact all the meals, should be given in a moist crumbly condition. At about a week old, boiled rice can be given for variety, and a little finely chopped cooked meat with this is beneficial. Fresh cooked meat can be given daily in small quantities, or fish meal can be used, or meat meal, provided this be free from bone, fur and hair—frequent causes of impaction of the crop. Both these meals are better if scalded before mixing with other meals, and a proportion of five per cent of fish or meat meal in the whole mash is sufficient at first.

From a month old barley meal may be substituted for ground oats. The fish meal can be increased to 15 per cent after the first month and boiled rice may be included in the diet several times weekly. Feeding should take place at 2 to 3 hour intervals during the first month, and the ducklings will benefit by frequent feeds in small quantity, but this must depend upon the amount of natural food which they can obtain for themselves by foraging.

If the ducklings are intended for table, they should not be allowed swimming water, and should have their range restricted at the age of five weeks. While fattening they should be given as much food as they will consume three times a day. The fattening food should consist largely of barley meal and good quality middlings. A small proportion of maize meal can be added, and ground or crushed oats used as an alternative to barley meal. Boiled rice can be continued, mixed with middlings, and it is an advantage to boil the rice in water in which nettles have previously been well boiled. Fish meal should be omitted when fattening and cooked meat offal supplied in its place. Ducklings for the table should be killed when about 10 weeks old, and in any case before they begin, to show the adult feathers. Ducklings intended for stock purposes thrive better upon free range and with only sufficient food given to supplement their needs after foraging. Similar food as for table birds may be used, except that fish meal may be continued and barley meal replaced with middlings in larger proportion.

Adult ducks upon free range only require one feed daily for about eight months of the year. This should be given in the evening, and should be a moist mash consisting of simple ingredients such as middlings, bran and maize or oat meals, with about 10 per cent fish meal. A moderate feed of steeped grain or of meals should be given in the morning during hard weather, or if natural food cannot be obtained by foraging. A set hour for feeding should be observed.

**Treatment of Roup.** Ducks and ducklings are subject to fewer diseases than fowls and chickens. Like fowls, they suffer from roup, but of a far less virulent type. There is no discharge from the nostrils, but there is from the eyes, which water copiously and damp the feathers all round. Foam and dry matter collect, giving the duck a very peculiar appearance. The eyes should be bathed and wiped, and if the eyelids look sore a little vaseline should be rubbed round, and the birds should also be given roup powder

or suitable pills. When the sun's rays are powerful, ducklings should never be let out in the middle of the day, or some are sure to be affected by sunstroke, as the covering of the skull is very thin. They will be found lying on their backs kicking feebly, and seldom if ever recover. Adult ducks are not affected in this way, as their feathers afford protection from the sun's rays.

**Plucking the Birds.** All birds should be starved for a full 24 hours before killing, in order that the crop and intestines may be emptied of food. The best method of killing is to dislocate the neck just where it joins the head. This method, when properly performed, results in the breaking of the jugular vein, and the blood drains from the body veins into the neck. Some persons like the fowls to be bled by a knife passed through the slot in the roof of the mouth.

Birds should always be plucked while the body is still warm, as the feathers then come out more easily and there is less danger of tearing the skin. If this is not possible the operation should be postponed until 24 hours after killing. In plucking, fowls should be held by the legs, with the head hanging downwards. The feathers should be drawn by a firm yet gentle pull towards the head. The plucking should begin at the tail and be continued in the following order: back, neck, wings, sides, legs, and breast. The breast bone should not be broken. The wings and half the neck must be left unplucked. The legs and feet should be quite clean.

When plucking has been completed, the birds should be singed and packed tightly, breast downwards, in a shaping trough with their heads hanging over the front board. They are left in position for the flesh to set and cool. A long, narrow board should then be placed along their backs and the board weighted, a common method being to use a 9 lb. brick to every two birds. In placing the birds in the trough, the stern is pushed hard up against the back board, thus giving the birds a shortened appearance.

**How to Cook.** Ducks require a shorter time for cooking than either fowls or turkeys, since their flesh is much firmer and closer. When buying ducks, it is well to remember, that they are at their best under a year old. Their bills and feet should be yellow and pliable. If they are red and feel hard, it is an indication that the bird is old.

When roasting a duck after trussing spread plenty of beef dripping over it. Put the giblets into a pan with a pint of stock and six peppercorns and stew these to make the gravy. Put plenty of dripping into the baking tin for basting and allow about 1 hour for cooking. The oven must be hot when the bird is put into it. After 10 min. lower the heat slightly and continue cooking in the same temperature until the duck is done. A quarter of an hour to each pound of meat and a quarter of an hour over is a good average time to allow for cooking. Frequent basting with the dripping is necessary, and must be done quickly, as heat is lost in opening the oven door.

When cooked, remove the bird from the oven and untruss it. Place on a hot dish and mix the dripping with a little flour before browning it over the fire. Stir in any brown particles clinging to the sides of the tin, then add a little giblet stock and also  $\frac{1}{2}$  pint brown sauce or water and a seasoning of salt and pepper. Boil up and cook for 5 min., then strain the gravy into a hot tureen. Garnish the dish daintily with watercress.

The duck should be served very hot with apple sauce, green peas, roast potatoes, celery or other seasonable vegetables, and a little of the gravy should be poured round the dish.

**Braised Duck.** Duck is excellent braised in a casserole. Wash 1 lb. turnips, 2 carrots and a stick of celery, and peel an onion, cut all into large pieces and then put them into the casserole. On these lay 2 slices of ham, then 1 good-sized duck, trussed for roasting, and lastly another 2 slices of ham. Put in a bunch of parsley and herbs tied together,  $\frac{3}{4}$  pint brown stock, a little salt, and a dust of nutmeg. Lay a piece of buttered paper over the bird, put the lid on the casserole, and let its contents cook gently for about 1 hour or until the duck is tender. When the duck is ready, remove the skewers and string, replace in the casserole, and serve.

**Savoury Recipes.** Salmi of duck is prepared from a roast bird. Put the giblets into a saucepan containing a little stock, 3 finely shredded shallots, and a little cayenne pepper and salt, and stew them gently for 25 min. Then cut the roasted bird into neat pieces, add it to the gravy, and let it simmer until it is thoroughly heated. When this is done, arrange the pieces of duck on a hot dish, boil up the gravy and add the juice of a bitter orange. Strain this gravy over the duck and serve the whole very hot accompanied by an orange salad.

A rich dish known as terrine of duckling is prepared by first making a forcemeat with ducks' livers as the chief ingredient. Season 5 or 6 of these with pepper and salt, and sprinkle over them a little powdered bay leaf and thyme and half a small chopped onion. Have ready heated in a frying pan 3 oz. butter and the same quantity of chopped fat bacon, and in these put the livers over a fierce fire to heat, but not to cook thoroughly. Leave them to cool, and then put them through a sieve.

Bone and stuff a duckling with the forcemeat, tie it into a more or less natural shape, and put it into a terrine. Sprinkle over it a wineglassful of brandy and lay on it a slice of fat bacon; then cover the terrine, and place it in a bain-marie in the oven and cook the bird for about  $\frac{3}{4}$  hour. Make a savoury jelly with the bones of the bird and some good veal stock, and use it for covering the duck. Before dishing the bird, make certain that all grease has been removed; coat it with the jelly, and serve it cold in the terrine on an oval dish.

**Duck Pie.** Duck pie is a baked pie and makes a welcome change from the more usual methods of cooking duck. Prepare it by cutting an average-sized bird into

neat joints, and frying these in a pan containing 2 or 3 oz. dripping. When the pieces are of a delicate brown tint, lift them out of the pan, drain them thoroughly and mix them with a little sage and onion stuffing. Simmer any trimmings left over in a saucepan containing just enough water to cover them, and add half a chopped onion and a pinch of salt.

Parboil a few large potatoes, then cut them into slices and arrange them, with the joints of duck and stuffing, in alternate layers in a pie-dish. Moisten the whole with a little water before covering it with puff pastry and bake it in a fairly hot oven for about  $1\frac{1}{4}$ - $1\frac{1}{2}$  hours. Before serving the pie, pour a little of the stock from the trimmings through the hole in the pastry.

**The Eggs.** Slightly larger than hens' eggs ducks' eggs are either light green or white in colour and contain a greater proportion of oil. They are, too, more strongly flavoured, and because of their richness are not suitable for invalids.

The eggs may be boiled, poached, or cooked in any other way as directed for hens' eggs. The time required for cooking them is approximately the same as that required for other eggs. In the preparation of puddings, cakes, pastry, etc., where the use of eggs is recommended, ducks' eggs may be used with excellent results. Employed in this way, they are most economical, one duck's egg being equal to two small hens' eggs.

**DUCK: Linen and Cotton.** Serving in its heavier form for tent cloth, duck in its lighter makes is used for sailors' white uniforms and for men's suits in the tropics. There are both linen and cotton ducks, and the former are the more expensive and last longer. The cloth is not twilled, but plain, and is often made in hopsack pattern for suitings. It is stiff and wears well.

Uppers of gymnastic shoes are often made in white cotton duck. Awnings, sunblinds, stretchers for deck chairs, hammocks, boat sails, motor car covers, kit-bags, are other uses for heavy duck.

**DUCK BOARD.** The name is applied to a form of slatted framework used to place on muddy or soft ground to act as a temporary footpath. Such boards can readily be constructed from odd material; convenient sizes are 6 ft. long and 18 to 24 in. wide.

The term is also applied to a board used by plumbers and tilers when building or repairing a roof; it is used to preserve the roofing material from damage by the workers' boots.

**DUFFEL CLOTH.** Taking their name from a Flemish town, duffel cloths are winter overcoatings. Warm without being too heavy, they are a useful alternative to nap cloths, and have generally a plain surface with a short fluff of fibre, soft and spongy.

**DUMB BELLS.** Dumb bells are grasped one in each hand, and it is claimed that their use brings every muscle in the body into play. Iron ones, weighing from

4 to 6 lb. each, are the most general, but wooden ones are also used. The weight depends upon the age and strength of the user. It is a mistake to use bells that are too heavy, as they cause undue exertion, while those that are too light are almost useless.

The best times for using the bells are in the morning, just after a bath, or before retiring to bed. Most persons will find 4 or 5 min. quite sufficient for this exercise, although usually men training will give much more time to it. There are a number of useful exercises which may be repeated for 20, 30 or 40 times. One is to raise the arms horizontally and rigidly till they meet over the head, and then to lower them in the same way. Another is to hold the bells at full length in front of the body, then raise the arms vertically and lower them in the same way. A more elaborate exercise is to place the bells on the ground, then, bending from the hips with the legs quite stiff, take them in the hands and raise them with rigid arms over the head. This exercise is an excellent means of improving and strengthening the muscles.

*Dumb Bells. Above, plain wooden type; below, sectional diagram of grip-testing pattern. (Courtesy of Standard Health Appliance Co., Ltd.)*

The dumb bells illustrated are constructed in the form of the hands, so as to give a better grip than is given by the ordinary bells. By turning the ring A in the direction of the arrow the pressure resistance is increased; by turning it in the opposite direction the resistance is decreased. The pointer B indicates in pounds on the scale the pressure exerted to close the dumb bells. Whilst exercising, the user should keep the two halves firmly closed, and to enable him to do this a bell C will ring when compression is complete. To begin, the spring should be set at a minimum resistance and gradually increased. *See Exercise.*

**DUMB CRAMBO.** This is a variant of charades and may be played under similar conditions. Sides are picked, and one side goes out of the room while the other selects two words which rhyme with each other, e.g. nose and rose. They decide that the other party shall act rose, and accordingly tell them that the word rhymes with nose. The outside party proceeds to act in

dumb show any word which rhymes with nose, until they guess the right one.

The spelling of the word is unimportant providing that the sound is the same. In the case given they might act the word as if it were spelt rows. The best results are obtained when the guide word is one which has many rhymes to it, and if the most unusual of these is chosen in order to tax the ingenuity of the acting party. *See Charades; Crambo.*

**DUMBNESS.** The condition of dumbness arises from inability to produce articulate speech and its most frequent cause is deafness (q.v.).

**DUMPIE FOWL.** This is a Scottish breed characterised by remarkably short legs giving it a curiously squat appearance. It is a very fine layer, a good table bird, and an excellent sitter and brooder. It is bred in several colours the most popular of them being cuckoo or barred like the Scotch Grey. *See Fowl; Poultry.*

**DUMPLING.** Dumplings are made from the same ingredients as a plain suet pudding, and cooked, tied in a floured cloth, in boiling water. They can be served plain, in soups, stews and hashes, or made savoury and served with gravy.

To make dumplings,  $\frac{1}{2}$  lb. suet should be allowed to 1 lb. flour and 1 teaspoonful baking powder. These ingredients are stirred together with a pinch of salt and mixed with cold water into a soft paste. This is divided into balls, and these are tied up in the corners of a floured pudding cloth which has been wrung out in hot water, and are then boiled for about 1  $\frac{1}{2}$  hours.

Savoury dumplings are made by adding to the above ingredients 2 tablespoonfuls of chopped parsley and 1 tablespoonful of mixed herbs, pepper and salt. They should be dropped into the stewpan an hour before dishing up the stew. *See Apple Dumpling.*

**DUNDEE CAKE.** This fruit cake is very simply made. Cream together 5 oz. granulated sugar and 7 oz. margarine, afterwards beating in 3 eggs, one by one. When these are mixed stir in 1  $\frac{1}{2}$  oz. ground almonds,  $\frac{3}{4}$  lb. flour, 6 oz. sultanas, and  $\frac{1}{2}$  lb. currants.

*Dundee Cake, a rich fruit cake the top of which is covered with blanched almonds.*

Beat all these ingredients for a few minutes, and put the mixture in a greased cake tin lined with greased

paper reaching 2 inches above the top of the tin. Cover the top of the cake with halves of blanched almonds and bake it in a moderately hot oven for about 2 to 2 ½ hours, lessening the heat after the first 20 minutes, and covering the top with paper when lightly browned.

**DUNGAREE.** For making overalls dungaree is extensively used. It is a cotton fabric, usually blue or brown, a strong twill, often rough to the touch, not easily torn and made from hard-twisted yarn. *See Overall.*

**DUNNING.** Although appetising when thus treated, cod loses much of its nutriment in dunning. The fish is opened, well cleaned, and the non-edible parts removed, then washed and scaled. It should be rubbed inside and out with common salt and left to hang in a cool place for 24 hours. A mixture is made of 1 oz. brown sugar and 1 oz. saltpetre to 2 oz. bay salt, and this is rubbed into the fish. The fish is sprinkled with common salt and allowed to stand for 24 hours more. It is then drained, well dried, and kept in a cool, dry place until needed. *See Cod.*

**DURHAM CUTLET.** Prepare these cutlets by putting 1 oz. butter and the same quantity of flour into a saucepan, and mixing them over the fire. Add ¼ pint stock or water, and let it boil, stirring all the time, then put in a pinch of salt, pepper and cayenne and 1 dessertspoonful of bottle sauce. Then pour the liquid into a bowl, add 3 or 4 tablespoonfuls of breadcrumbs, and ½ lb. of any minced meat, mix them well, and spread the mixture on to a plate.

Lay it aside to get cold and firm, then cut into triangular shapes with a floured knife, starting from the centre. Sprinkle the hands with flour, and shape each piece into a neat cutlet, putting an inch of macaroni into the narrow end of each to represent a bone. Egg and crumb the cutlets, fry them in hot fat, and arrange them in a circle round a hot dish. Mashed potatoes, spinach or green peas might be heaped up in the centre of the dish.

**DURHAM PUDDING.** Put a tablespoonful of Demerara sugar and ½ gill water into a saucepan and boil them for 5 min. to produce a syrup. Stalk and wash ½ lb. red currants, add them to the syrup in the pan, and cook them slowly until they are tender, which should take about 20 min. Dissolve the contents of one packet of red currant jelly in a pint of hot water.

Line a pie-dish with sponge cake, splitting the cakes in halves, and placing the top halves to the bottom and sides of the dish. Mix the stewed fruit with the jelly, and pour the mixture over the sponge cakes until the dish is full. Then place the remaining halves of the sponge cakes on the top of the dish, with the cut side inside. Press these well down so that the fruit and jelly soak into them, and cover the top with a dish, pressing it down with a heavy weight, and leaving the whole until it is cold and set. Turn it out to serve. Any kind of stewed fruit can be used for Durham pudding.

**DUST: A Menace to Health.** In large towns the air is laden with particles from fires and furnaces, and dwellers in those places show the effects in pigmentation of their lungs. In coal and other mines, and in certain classes of workshop and factory, e.g. potteries, steel grinding shops, etc., unless the ventilation is attended to and spraying adopted, workers who do not wear masks are liable to suffer ill-effects from the irritation of the lungs by dust. In occupations involving the deposition of dust on the skin, inflammation of the skin or dermatitis is likely to result, unless strict cleanliness is practised. (*See Spring Cleaning.*)

The air passages have natural protective powers against dust, but when a large quantity is inhaled the defensive mechanism is overpowered, and some of the dust remains and produces discoloration of the lungs. The lungs of an infant are pink, but after years of residence in a town or elsewhere, if there is much dust in the air, they become grey, apparently without any bad effect on the lungs or the general health. But if the accumulation goes beyond a certain point, or if the particles inhaled are irritating, a reaction is produced in the lung tissues, and catarrh of the bronchial tubes is set up. The general health suffers, the patient is anaemic, and later consumption may occur.

The risk to life involved in the chest diseases due to dust varies even among dusty occupations, but the tin miner certainly stands the poorest chance. The terms grinders' rot and potters' asthma convey the menace to health in other occupations; the list is a long one, including workers in cotton and grit mills, tobacco factories, sawmills, brickworks, etc. Preventive measures are carried out in most factories and mines by improved ventilation, keeping the air damp, etc., with immense benefit to all concerned. Workers in dusty trades should always wear respirators, however troublesome they find these to be in the course of their employment.

**DUSTBIN.** The metal sanitary dustbin is secure against insects, and also against prowling animals, provided the lid is always kept on, as it should be. The lid also keeps the contents of the bin from getting wet or being blown about when there is a wind.

The dustbin should be kept clean, both inside and out, by means of hot water and some disinfectant, such as permanganate of potash. It should be placed outside the house on a firm, dry foundation in a spot readily accessible for the dustman. The contents should be emptied at least once a week. Dustbins should be used, as far as possible, for dry refuse; all damp refuse should be burnt. *See Refuse; Sanitation.*

**DUSTER.** Bought dusters, unless extremely low priced, are satisfactory, but it is economical to make dusters at home from material which would otherwise be thrown away. Ordinary cotton materials are unsuitable, as they are non-absorbent, but wincey,

flannelette, and old sheets all cut up into serviceable dusters when hemmed. A slightly damp (not wet) duster collects dust more readily if a room is really dirty. To wash out the grime and grease from soiled dusters, the best medium is a soapy lather to which a little soda has been added.

A soft piece of chamois leather soaked in cold water and wrung out tightly makes an excellent duster. It can be used on the finest furniture without fear of scratching, and will remove the most obstinate fingermarks. An additional advantage is that chamois leather leaves no threads or fluff behind it. When polishing any kind of furniture, a great saving in labour can be effected by using a hot duster. It is a good plan to keep a couple of dusters in a cool oven and use them alternately while they are warm. A high polish will then be easily secured. Care must be taken to see that the dusters are not scorched.

**DUSTING.** A house should be dusted throughout every day. In the living-rooms the fireplaces should be done first and the room swept, and no dusting ought to be attempted until the dust caused by the sweeping has had time to settle.

All dusting should be done from the top to the bottom—that is to say, mantelpieces and the higher pieces of furniture are done before fenders, etc., as the dust dislodged from them will sink on to the lower places, and be finally removed from them. Every ornament must be moved: it is not enough merely to go round them, as that will leave an ugly ridge of dust.

Among things which are frequently neglected, yet which provide harbourage for dust, may be mentioned picture frames, bars of chairs, and electric-light shades or gas-lamps, for which a light dusting brush may be used. Last of all, the surround of the floor should be dusted. For this purpose a slightly damped duster may be used or a long-handled mop.

**Dust Sheet.** Made usually of coarse sheeting, dust sheets can be cut from any spare length of material. They are especially useful when spring-cleaning, white-washing, or distempering is being done, or when the occupants of a house are leaving for holidays. If they are not bought ready-made, the sheets should be hemmed down on all four sides.

The amount of material required depends upon the size of the article to be covered, but for an armchair about 2½-3 yards of wide material should be sufficient. *See Brush.*

**DUSTPAN.** The tin scoop with a handle into which dust is swept by means of a small brush is chiefly used for collecting the dust on stairs. The dustpan and brush have been largely replaced by the use of vacuum cleaners and carpet sweepers. *See Carpet Sweeper. Vacuum Cleaner.*

**DUTCH AUCTION.** This method of selling goods is the exact reverse of the one in ordinary use. A high price is first named for the article or property

offered, and this is reduced by stages until a bidder is found. *See Auction.*

**DUTCH CHEESE.** A true skim-milk cheese, the Dutch product is mild in flavour and has many good points, although it is less nourishing than the whole-milk cheese, and is frequently a little salt. This class of cheese is best for keeping purposes, as it dries and hardens, whereas the rich, fatty varieties of cheese are prone to decomposition. Its shape and colour vary, some being round, others oval and either coloured a brilliant red or left yellow on the outside. *See Cheese.*

**DUTCH GARDEN.** With its trim and formal beds and borders, carefully trained yews and clipped dwarf box edgings, the Dutch garden has a charm of its own, and though no longer so fashionable as it was in the 18th century, many fine examples are still to be found in England, the result of generations of careful treatment. Directions and plans for laying out a Dutch garden are given in this article.

A Dutch garden should be enclosed by a clipped hedge of yew or box, and if possible laid in a position where it can be looked on from above. Planning the formation of beds and borders is a simple matter, with such a diversity of geometrical shapes available, among which, squares, circles, hexagons, and rectangular forms, such as those shown in the diagram, will be found most suitable. In the centre of the garden may be placed an ornament to which the beds converge, and this may take the form of a trained tree, a stone figure, a weeping or pillar rose, a sundial, a fountain, or a fine stone vase to be kept filled with seasonable bedding and bulbous plants. Crazy paths of York stone, having wide crevices between, planted with tufts of lowly plants, are very old-world in appearance. Well-rolled gravel will also serve.

In planning the beds all angles and circles should be carefully pegged out with wooden stakes, and, as far as practicable, boards should be nailed against these to outline the shapes desired. Gravel should then be laid for the paths, and after this has been rolled thoroughly hard, the boards may be removed, and the beds filled to a proper level.

Box edging may afterwards be inserted, but it is advisable to use a garden line when planting to ensure regularity of outline. Although construction may be carried out at any time, autumn or spring is the best, as the dwarf box required for edging is then in suitable condition for planting. Clipping or training of the box is best performed during May, and after planting due attention must be given to watering until the roots have taken hold of the soil.

The Dutch garden is usually planted with low-growing plants which do not obscure the lay-out. A modern variation, now more popular, is the Formal Garden in which free-growing plants are set in beds and borders of formal design.

**Plans for the Gardens.** The accompanying plans suggest four arrangements for typical Dutch formal

gardens. The first example would result in a charming old-world garden.

*Dutch Garden. Figs. 1-4. Plans of examples of formal gardens, the laying out and planting of which are described in the text.*

FIG. 1

Corner beds, A, B, C, D, cabbage, Provence, damask, and China roses.

Centre bed, E.—A sundial surrounded with clumps of southern-wood, thyme, or marjoram, with viola Maggie Mott planted between.

Outer beds.—F, white flowers; G, red flowers; H, yellow flowers; J, blue flowers; K, white flowers; L, red flowers; M, yellow flowers; N, blue flowers.

O.—Seats or arbours of clipped yew.

FIG. 3

Outer border A.—Mixed snapdragons.

B to E.—Beds of mixed perennials and annuals.

Inner beds.—Roses carpeted with violas.

Centre.—Weeping or pillar rose, sundial, or clipped tree.

F.—Seat or arbour.

FIG. 4

A paved or red-tiled garden of angles.

AA.—Mixed border of hollyhocks, sunflowers, paeonies, larkspurs, lupins, and other tall-growing or bushy plants.

BB.—Mixed beds of annuals and perennials, with a rose, paeony, or shaped tree planted at about the centre of each angle.

C.—Pillar rose with carnations and violas.

In this plan an edging of Mrs. Sinkins pink is suggested in place of the border of dwarf box.

Fig. 2. displays a somewhat elaborate and not uncommon type of bed. The darkest portions show the inner and outer edgings of dwarf box, the tinted parts signifying gravel and the white spaces where flowers are to be planted around dwarfed shaped trees. Such beds entail hard work and great attention if they are to be successful; but the result is well worth the trouble that has been taken. *See Crazy Paving; Garden; Path; Tile.*

**DUTCHMAN'S PIPE.** Popular name of a very

vigorous hardy climbing plant valued chiefly for its large leaves, *Aristolochia siphon*. The curious shape of the small brownish flowers has given rise to the popular name. Some of the hot-house kinds of *aristolochia* have evil-smelling flowers of extraordinary appearance.

**DUTCH METAL.** This is a copper zinc alloy with a high proportion of copper; it is so ductile that it can be worked down to a thickness comparable to that of gold leaf. This fact, coupled with its yellow colour, leads to its use as a cheap substitute for genuine gold leaf in gilding work; it is also sometimes used in powder form for so-called gilding.

**DUTCH OVEN.** Formed like a miniature roasting screen, the Dutch oven is made to fasten on to the bars of an open grate or range. It is fitted with two or three meat hooks at the top, under the hood, and contains a dripping pan below, which is supported on iron rests. The oven is designed to enable a small joint or fowl to be cooked in front of the fire when other means of roasting are not available.

*Dutch Oven. Useful roasting contrivance in metal, provided with four meat hooks and dripping pan.*

The fire should be clear and the suspended meat must be turned and basted precisely as if cooked on a spit. This method, if properly carried out, gives the joint the same flavour as if roasted in the old-fashioned way. It is really a form of toasting or grilling. A Dutch oven may also be used for cooking chops, steaks, bacon, or fish, and it is adapted for browning the top of macaroni cheese, scallops or other savouries. For this purpose the dishes should be rested on the dripping pan.

For those persons without a kitchen range or gas cooking stove the Dutch oven presents a solution of the difficulty of roasting, but it must be kept scrupulously clean. It should be scoured in the same way as tinware. *See Roasting.*

**DUVETYN.** The cloth known as duvetyn derives its name from the French word for down, duvet, and

it emulates the downy softness of peach skin or the skin of young animals. Silk duvetyns are the best known, and their surface approaches that of hatter's plush. Ornamented with stencilling or embroidery this cloth is suitable for such articles as blotters and floor cushions.

**DWARF BEAN.** The French or dwarf bean is one of the best summer vegetables. The pods, which should be gathered while the seeds are immature, are of more delicate flavour than those of the runner bean. Deeply dug and manured soil is necessary to ensure good crops.

Seeds may be sown out of doors at fortnightly intervals from early May until the middle of June to provide a succession of produce in late summer and early autumn. The seeds should be set about 3 inches apart and 1-2 inches deep. The seedlings must be thinned out so that they are 9 inches or so from each other. The rows ought to be 20-24 inches apart. Canadian Wonder is a good variety, though most seedsmen sell their own special sorts.

Early crops of dwarf beans under glass are obtained by sowing the seeds at intervals in August and September in 8 inch pots filled with loamy soil, keeping them in a frame until October and then placing them under glass in a temperature of 55 to 60 degrees.

The climbing French bean, which needs the same treatment as the dwarf kind, provides pods of excellent flavour throughout many weeks. It is less vigorous than the runner bean. Tender and True is one of the best varieties.

The waxpod or butter beans are grown for the sake of their pale yellow pods, which are cooked without being sliced; both dwarf and climbing types are available and they need the same treatment as advised for French beans. Mont d'Or, climbing, and Golden Waxpod dwarf, are favourite varieties.

The ordinary runner bean can be grown without sticks if the ends of the shoots are pinched off frequently; the plants thus remain dwarf and become well branched. They cover a good deal of ground, and it is necessary to support them with short sticks to keep the pods off the soil. *See Bean.*

**DWARF TREES.** The miniature Japanese trees of larch, orange, maple and various evergreen conifers have become popular in Great Britain and are imported in considerable numbers. Some of those exhibited are said to be over 100 years old, yet so restricted are the roots that they remain dwarf and the stunted branches give them a very picturesque appearance.

The trees may be grown in a room window or unheated greenhouse, but they need careful treatment to preserve them in a healthy condition. Incorrect watering is likely to affect them adversely. The soil should be watered only when it is moderately dry, but sufficient water ought then to be given to moisten the soil thoroughly. If the soil is kept in a sodden state or if

it is allowed to dry out, the trees are certain to suffer. They must be placed in a light position though not in strong sunshine. Gas-heated or gas-lit rooms do not suit them. Every year it is advisable to take off some of the surface soil without damaging the roots and to replace it with fresh compost of loam and a little sand.

During mild weather in spring and summer the trees benefit by being placed out of doors, for they are hardy trees. Branches which tend to spoil the symmetry of the trees should be shortened whenever necessary. If a tree shows signs of ill-health it should be turned out of its pot, the latter being scrubbed clean and provided with adequate drainage. The tree should then be repotted in loamy soil containing sand and a little crushed charcoal.

Miniature trees can be grown at home by setting seeds of various trees in pots, repotting them seldom, and pruning the branches to force the trees to grow in the shape desired.

*Dwarf Trees: two specimens. 1. Thuya obtusa, 70 years old, 30 inches in height. 2. Miniature orange, 15 years old, 6 inches high.*

## DYEING FABRICS AT HOME

### Hints on an Economical Form of Domestic Renovation

By following the instructions given in this article clothes and furnishings can be tinted not only in one but in two colours. Consult also the entry Colour Schemes, etc.

The many varieties of dyes on the market prove the popularity of home dyeing. Articles, both of dress and household hangings, may become faded and shabby a considerable time before they are worn out. With the expenditure of a little money, time, and trouble they can be renovated by tinting to match their original colour, or the colour may be entirely changed. One immersion in a dye bath completely recolours articles of plain material. Patterned fabrics may require two immersions or even three before the pattern is quite hidden by the new colour.

The usual forms in which dyes are sold are cakes, flakes, powders and, tubes of paste. Some are soap dyes, the dye being intimately mixed with soap, others are merely colouring matter put up in convenient forms for use.

Cold water dyes are chiefly used for giving pale and

delicate colours to fabrics of fine textures such as silk, muslin, etc. Some dyes are prepared for woollen and silk fabrics, some for cotton and linen, the reason being that animal fibres take dyes differently to those made from vegetable fibres. If a cotton and wool mixture fabric is to be dyed, choose a cotton dye, because wool will take a cotton dye, but cotton will not take a wool dye. Buy plenty of dye. It is far better to buy one packet too many than not enough.

**Initial Preparation.** Before commencing, remove all buttons, buckles, bead or other trimmings, which obviously could not be expected to dye satisfactorily. Any stitched-down parts, such as turned-back cuffs, collars, hems, revers or pleats should be unpicked. This allows free access of the dye solution to all parts of the garment. Thoroughly wash every article before attempting to dye. This particularly applies to new materials; any starch remaining in the fabric will prevent the dye taking evenly. Grease and dirt act in the same way. Although the directions on a few soap dyes distinctly state that previous washing is unnecessary, good results must not be expected if the washing is neglected. It is a well known fact that a really dirty garment is not thoroughly cleaned by simply immersing it in hot soapy water. Rubbing or friction of some kind is essential. Further, any dirt coming from a soiled article when mixed with the dye solution will naturally prevent the dye giving such a clear or brilliant colour.

Weigh the articles carefully before making the dye solution; this avoids waste, and ensures sufficient solution being ready. The directions supplied with some makes do not state any definite weight that can be dyed, but only how much solution can be made from the packet. In these circumstances individual judgement must be used, remembering that a small thick article, especially of wool, will often require much more liquid than a large one of fine texture.

**Method of Dyeing.** For the dye bath choose a basin or washing tub large enough to take the article to be dyed conveniently. The utensil selected, if required for cotton goods, must be capable of being heated over the fire. White enamelled iron ware is the most suitable. Ordinary china basins can be used for all dyeing that does not actually require to be boiled.

Make sufficient dye solution not only to cover the fabric easily, but to allow room for stirring and moving the article about. All dyes, whether soap dyes or not, should be completely dissolved in boiling water. If the packet is hard it requires to be shredded or crushed. Should the dye not dissolve easily, place it in a small enamelled jug or basin and boil for a few minutes. When quite dissolved strain the concentrated dye through muslin into the dye bath (Fig. 1), and dilute with water. Before adding the material, test for colour by dipping a small piece of the same material into it. If this is not possible, take a small piece of fabric resembling the article in colour, and texture. Rinse well and dry; if the result is satisfactory, it is safe to proceed. If a deeper or paler tone is required, more dye

or water must be added.

Should the test not give the exact colour, try judicious mixing of one or more colours until the desired shade is obtained. Most makers prepare dyes for sale in about 20 different shades, but by mixing these a much greater number of colours can be produced. Details about the particular dye are printed on the package and directions should be carefully read. When the dye bath is ready, open out the article, which has been previously washed and rinsed, but not dried, and place it in the solution. Use two smooth wooden sticks or spoons (Fig. 2) to move the fabric about. On no account should the dye bath be left, as it needs constant stirring whilst being heated. Unevenness of shade may result from carelessness at this stage.

*Dyeing. Fig. 1. Straining the dye through fine muslin.*  
*Fig. 2. Two wooden spoons are used for stirring the dye bath.*

Most makers advocate the use of salt, some also of vinegar. Salt is particularly useful when dyeing cotton goods, as it enhances the depth and brightness of the colour. The average time required to dye is from 10 to 40 min., according to the tone required, deep shades requiring longer than pale ones. Navy blue, for instance, would require 40 min., while a pale blue would be dyed in 10 min.

The dyeing completed, the colour must be fixed by thorough rinsing in several changes of cold water, until no colour comes from the newly dyed article. A certain amount of unabsorbed colour is always lost in rinsing, and this must be taken into account when preparing the dye bath. Wring the article lightly and hang it out to dry, taking care to put the pegs in some inconspicuous part. When nearly dry take the article from the line and roll it up ready for ironing.

Delicate fabrics such as georgette or chiffon do not require to be hung up; any surplus moisture can be removed by rolling the garment in a clean cloth. Such materials and certain crêpes are apt to shrink after immersion in hot dye. They should be pulled into shape during the ironing process while the fabric is still damp. When ironing newly dyed material protect the ironing sheet from stain by placing a piece of muslin or thin cotton between the sheet and article being ironed. If much dyeing is being done, it is advisable to wear a rubber apron. Rubber gloves are useful when rinsing

after dyeing dark colours, such as black or dark brown, as there is sometimes sufficient dye in the first rinse waters to stain the hands. Lemon juice will usually remove such stains, or an application of peroxide of hydrogen.

Skilled treatment is required for such articles as suède, kid, or buckskin shoes or gloves, furs, carpets, rugs, waterproofs, overcoats, woollen costumes, or any heavy garments having interlinings and paddings, and the dyeing of these should not be attempted at home.

**Knot Dyeing.** Certain articles such as straight scarves, unlined curtains and cushion squares, made of thin fabrics, can be decoratively treated in two harmonious colours by means of knotting after having first been dyed in the ordinary way. The article should be rinsed and then knotted tightly in the middle with smaller knots at each corner, or—as in the case of curtains—at each lower corner. The knotted fabric is then dyed in a second deeper colour in the same manner as before, rinsed and unknotted. The two colours will blend into each other with a pretty shaded effect without hard lines of division between the tints.

Should it be wished merely to give a contrasting border effect—to a scarf, for instance—the article may be tightly bandaged with cotton rags, after the first dyeing and rinsing have been accomplished, leaving exposed for the second immersion only the ends. The scarf is then simmered as before, rinsed, and the bandaging removed before drying and ironing. This method of dyeing gives a charming effect to short curtains made of natural shantung silk.

**DYNAMO: Working Principles.** The dynamo is a machine employed for converting mechanical energy into electrical energy, and consists essentially of an armature rotated in a magnetic field.

The general arrangement of a dynamo is shown in the diagram. The magnetic field is produced by a cast iron frame or yoke into which are fixed an equal number of iron poles, each pair being diametrically opposite. Upon each pole is mounted a magnetizing coil, the coils being so connected as to influence each alternate pole as a N. pole, and each intervening pole as a S. pole. The yoke is necessary to provide a path for the magnetic lines of force outside the armature, while the magnetic circuit is completed across the air gaps between pole tips and armature. The armature takes the form of a cylindrical iron structure mounted between bearings. Electrical conductors are carried by this structure, each cutting the magnetic lines of force as the armature rotates, with the result that a relatively small electric current is set up in each conductor. Upon the number of conductors, the number of magnetic lines of force produced by the field coils, and the speed of rotation depend the value of the electric current generated by the dynamo. The current is collected by the brushes from the commutator, a rotating contact device.

Any convenient mechanical power, such as a gas, steam, or oil engine, may be employed to rotate the armature, the important point being to have sufficient

power at the speed necessary to enable the dynamo to deliver the voltage for which it is wound.

**Types of Dynamo.** Certain types of dynamo have been evolved for specific duties. Thus, the dynamo on a motor car has a duty different from that of the apparatus which is used for lighting a private house, while a dynamo for charging accumulators would not be suitable for lighting purposes. A charging dynamo delivers a heavy amperage at a low voltage, whereas a house lighting dynamo gives a lower amperage at a higher voltage.

*Dynamo. General view of small dynamo showing commutator, armature, brushes, field magnets, and driving pulley.*

Typical windings are the series, shunt, and compound respectively. In the series winding the armature conductors and the field coils form one continuous circuit, it being characteristic of this winding that the voltage varies as the load fluctuates. For this reason the series dynamo is not suitable either for charging or lighting. In the shunt winding the armature conductors and the field coils form two separate circuits, and a hand-operated regulating resistance is introduced into the field circuit. The purpose of the latter is to control the voltage generated in relation to the load fluctuations plus the voltage drop due to the heating of the coils. Within well defined limits a shunt wound dynamo can be considered a constant voltage machine. The compound method of winding combines both series and shunt. Its utility lies in the fact that it accommodates itself to load fluctuations by virtue of the series winding, which increases the magnetic field as the load increases. Such a machine is excellent where the current demand varies within fairly wide limits. Details of the windings and the speed of the dynamo should be found on the maker's plate fixed to the machine.

A dynamo to give the best results must be properly installed upon a sliding base fixed to a firm foundation. The sliding base enables the machine to be properly lined up with the engine, and allows the driving belt or chain to be adjusted to a nicety. A dynamo bolted direct to an engine shaft through a coupling is said to

be direct driven, and when once lined up needs no further adjustment.

It is important to house a dynamo in a dry place, as damp has a detrimental effect upon the insulation and may cause "earthing" troubles. Dust also should be kept away from the machine. If fixed on a wooden floor, a thick bed of incombustible material, such as asbestos, should be placed beneath the dynamo to insulate it. All wires and connexions must be properly protected, as, for example, by enclosing them in steel tubes, or in any manner that will ensure them being out of the way of gas-pipes, a hot flue, or heat or acids that might tend to destroy the insulation.

Regular attention has to be paid to replenishing the oil boxes. The used oil should be drawn off and replaced with a fresh supply. No oil must get on any part of the insulation, as oil is a solvent of rubber, and if it be allowed to get on the rubbered wires the rubber will perish, and ultimately cause a failure.

**Commutator and Brushes.** The commutator and brushes give the most trouble, and should be regularly inspected. When in good order there should be no sparking at the points of contact. The contact face of the brush should be of the same curvature as that of the commutator, and this can be ensured by placing a piece of glasspaper between the brush and the commutator and then rocking the latter so as to rub the paper on the brush and thus shape it to the desired curve. This applies to the usual carbon type of brush; those made of copper gauze are shaped with a very fine file and emery paper. In either case see that there are no loose ends to cause sparking.

The pressure of the brush on the commutator should be adjusted if requisite, by altering the tension of the springs. The rocker arms should be properly spaced, two being diametrically opposite, and four spaced at 90° apart. A slight movement of the rockers will often correct sparking and ensure perfect running, but this can only be determined by trial. The commutator should not be lubricated. When all is in good order it should be a dark coppery colour; if blackish it indicates that the brushes are too soft. A bright and scraped appearance indicates either that the brushes are too hard or the pressure is too great.

**DYSENTERY.** Under this name are included several forms of intestinal inflammation. In hot countries cases are constantly cropping up. In Great Britain epidemics are not infrequent in asylums and other institutions.

The disease is spread by germs in the excreta of a patient suffering from the disease finding their way either into food or drinking water. This may happen in several ways. Flies may feed on infected excreta and then defile food, beverages, or food utensils. Infected excreta may be drained into shallow wells or washed into surface water. This water may be drunk or used for washing raw food, e.g. salad or food utensils. Raw food may be infected by polluted soil, and not washed clean. Persons found to be carriers of the disease frequently have been amongst those handling food, e.g.

cooks, waiters, nurses, etc.

There are two main forms of the disease: bacillary and amoebic. For one or two days an attack may resemble ordinary acute diarrhoea, and then the stools are found to contain mucus (slime) streaked with blood. Soon the motion may consist of mucus and blood only. There may be severe straining and griping pains. The patient may die from weakness or from perforation of the bowel, or may become the subject of chronic dysentery.

The patient should be put to bed at once between hot blankets and have a hot-water bottle at his feet. The abdominal pain will be relieved by hot fomentations. He may have whey or albumen water at 4-hour intervals. Arrowroot may be useful. In the bacillary form 1 dram doses of sodium sulphate should be given every hour till the straining is relieved, and then at less frequent intervals. The doctor will treat bacillary dysentery by injections of anti-dysenteric serum and amoebic dysentery with emetine.

**Preventive Methods.** The stools of the patient should be mixed with a disinfectant before being disposed of, preferably by burning. Efforts should be made to diminish the number of flies. No food or beverage should be left without a cover if flies are about. All water for drinking or washing food or food utensils should be boiled or otherwise sterilized, unless it comes from an unimpeachable source. The hands should be washed thoroughly before partaking of food. Salads should be avoided, and care should be taken to prevent chills and to correct constipation and diarrhoea (q.v.).

**DYSMENORRHOEA.** Pain occurring at the menstrual periods in women and girls, and felt in the lower part of the abdomen. It is always more or less disabling, and may be very severe. The causes are numerous, but always include some abnormality in the sexual organs.

The patient's general health is important. Iron in some form will be necessary in anaemia. Constipation must be corrected. If the pain is severe the patient should remain in bed, and the abdomen and feet should be kept warm. Much relief may be obtained from hot mustard hip baths or foot baths. Aspirin, grains 10, or phenacetin, grains 7, with citrate of caffeine, grain 1, may be given to a woman, and will frequently lessen the suffering. Alcohol in any form should never be given.

**Dyspepsia.** *See* Indigestion.

**EAR: Anatomy and Diseases.** The human ear is divided into three parts—the external, the middle, and the internal ear. The first consists of the auricle or pinna, the ear in the popular sense, and the external auditory meatus or passage which runs 1 ¼ in. inwards from the earhole and ends at the tympanic

*(Continued in page 728)*

**EGG MOULD.** To make Egg Mould, dissolve  $\frac{1}{2}$  oz. gelatine in  $\frac{1}{2}$  gill water, then mix with 2 gills white sauce and 1 gill unsweetened condensed milk. When thoroughly mixed, stir in 4 chopped hard-boiled eggs, 4 oz. boiled rice, 1 teaspoonful chopped parsley, salt and a few grains cayenne. Decorate bottom of plain china-mould with shapes of beetroot and some green peas, and pour in egg mixture. When set, turn out and serve with green salad round base of mould.

**EGG FRICASSÉE.** For Egg Fricassée, melt 3 oz. butter and add 3 or 4 slices cucumber, 3 shallots cut small, and 4 or 5 small pieces celery. Cook for 10 min.; then add 1 dessertspoonful flour, 1 table-spoonful prepared proteid food, and stir. Pour in 1 pt. milk and simmer for 15 min., stirring continuously. Strain, add a little ground mace, pepper, salt and 1 table-spoonful cream. Cut 6 shelled, hard-boiled eggs into slices, drop these into the sauce and serve with mashed potatoes.

**FISH TOAST.** Break 6-8 oz. cooked white fish into small flakes, season with salt, pepper and a little chopped parsley, and add lemon-juice to taste. Melt 2 oz. butter in a pan over the fire, put in fish and a small teaspoonful of curry or fish sauce, and heat through. Serve the mixture on hot buttered toast cut in long finger-shaped pieces. Garnish with chopped parsley.

**FRUIT CASTLE.** To make Fruit Castles, stamp some slices of stale cake into rounds about 2 in. thick. Then with smaller cutter stamp out the centres, but not right through. Put rounds on plate and pour over a little wine or fruit syrup. Fill insides with stewed, fresh or bottled fruit. Whip some cream, sweeten, flavour, and heap on top.

**'E' AND 'F' RECIPES: A SELECTION SHOWN IN ACTUAL COLOUR**

**Easter Cakes.** Beat 5 oz. butter to a cream, mixing in same quantity of sugar, beaten yolks of 3 eggs and a little brandy. Stir in 1 lb. flour, moistening mixture with a little milk if too dry, and add 3 oz. currants. Leave paste in cool place for an hour, roll out thinly, and cut into rounds. Bake in warm oven. A few minutes before ready, brush over with beaten white of egg and sprinkle with castor sugar. **Fish Salad.** See p. 1100 for different varieties. **Floating Island.** Cut a round sponge cake into slices, spread these with apricot jam and soak in a little liqueur. Put them together again in a large glass dish, cover with whipped cream, sweetened and flavoured. Decorate with chopped almonds and pistachio nuts and pour custard round base of cake. Sherry may be used if preferred to liqueur.

**'D'-RECIPES: A SELECTION SHOWN IN ACTUAL COLOUR**

**Dresden Creams.** Whip  $\frac{1}{2}$  pt. cream and divide into 3 portions. To one add strawberry jam rubbed through sieve, 1 oz. castor sugar and juice of  $\frac{1}{2}$  a lemon, also 1 or 2 drops of cochineal. Portions 2 and 3 are flavoured with coffee essence and vanilla respectively, and sweetened with castor sugar. Put layers of the 3 flavours on broken macaroons arranged in soufflé cases. **Deception Cakes:** Cut some puff pastry into rounds, cover half of them with currants; sprinkle over sugar and a little grated nutmeg, and add a few drops of brandy. Cover with remaining rounds. Brush with white of egg and sprinkle with sugar. Bake in oven. **Damson Cream Ice:** Made as strawberry ice with damsons substituted for strawberries.

# **DAHLIA: COLOUR AND FORM IN SEVERAL STANDARD VARIETIES**

or drum membrane stretched across the passage. Sound waves entering the passage strike against the membrane and cause it to vibrate.

The middle ear lies inside the membrane. Its chief contents are the ossicles, three tiny bones which connect the drum with the actual hearing apparatus, or internal ear. In the posterior wall of the middle ear there is the opening into a small passage leading to the mastoid antrum, a hollow space in the mass of bone to be felt immediately behind the ear. In suppuration of the middle ear infection may thus pass through and cause mastoid disease. In the anterior wall there is the opening of the Eustachian tube, which leads directly to the back of the throat. The importance of this tube is that through it air can find its way into the middle ear, so that the air pressure on the two sides of the drum is always kept the same. The deafness so commonly noted in chronic catarrh of the nose and throat is generally due to the catarrh spreading up the Eustachian tube and closing it.

*Ear. Diagram showing anatomy of the outer, middle and inner parts of the ear.*

The internal ear or labyrinth is divided into three parts: the cochlea, the true organ of hearing, in front; the semicircular canals, which control balance, and the vestibule, between these others.

Sound vibrations can reach the inner ear otherwise than through the air. Thus if a tuning-fork is sounded and the end of the handle placed on the bone behind the ear or elsewhere on the skull, the note will be clearly heard if the internal ear is healthy. If it is not heard we imply that the patient suffers from nerve deafness due to disease of the internal ear or the nerve connecting it with the hearing centre in the brain. The tuning-fork will be heard distinctly, however, where the deafness is due to blocking of the external passage, as by wax, or to disease in the middle ear causing stiffness or destruction of the membranes and the conducting bones.

Discharge from the ear is most commonly due to inflammation of the middle ear, with the formation of matter which escapes through a perforation in the drum-membrane. This condition is a frequent complication of the convalescence of measles or scarlet fever in children, or it may result from simple cold in the ear. The treatment of discharge coming from the middle ear must be supervised by a doctor.

Perforation of the drum membrane may be caused

by some sharp instrument poked into the ear, or by the impact of water in diving, etc., but most commonly it is the result of middle ear inflammation. The ears should be protected in high diving by plugs or otherwise. It is a dangerous practice to box children's ears, as this is a frequent cause of perforation of the drum membrane.

A foreign body in the ear may be a living insect or something which has been pushed in. It is safer to have it syringed out by the doctor, and the sooner the better. If it is a pea or a bean, no one should be allowed in the meantime to put water in the ear, as this causes these to swell and renders their removal more difficult.

*On no account should attempts be made to remove a foreign body with a hairpin or other instrument.*

Mastoid disease is most usually due to infection from the middle ear through the opening above mentioned. The symptoms are sudden fever, pain behind the ear, shooting over the head and down the neck, swelling, redness and tenderness on pressure on the bone behind the ear, and usually a profuse discharge. Suppuration occurs in the spaces within the mastoid process, and as the pus cannot readily escape through the narrow opening into the ear or through the hard bone on the surface of the mastoid, it tends to turn inwards, and may produce meningitis or abscess of the brain. Early surgical treatment is imperative.

Noises in the ear may be the result of a large number of causes, e.g. chronic inflammation of the middle ear causing partial deafness, certain drugs, such as quinine, sodium salicylate, etc., catarrh of the nose and throat, etc. Treatment will depend on the cause. Wax in the ears may be removed by gentle syringing as described under the heading Deafness.

**Earache.** This pain in the ear may be due to a number of causes. Among these are neuralgia, a boil in the meatus, impacted wax, the presence of a foreign body, or inflammation of the middle ear. Teething in children is another cause.

To relieve the pain, heat should be applied. A hot-water bottle may be covered with flannel or a shawl and laid against the ear, or a flannel bag may be made and filled with common salt which has been roasted on a shovel. This should be applied as hot as it can be borne. If, however, the pain is continuous, a doctor should be consulted.

**Ear Cap.** The purpose of ear caps is to correct prominent ears in children. Made of mercerised cotton or of silk, they are worn round the head at night, being held in position by straps firmly but not too tightly tied. They can be obtained in most sizes from chemists, surgical instrument makers, and drapers.

**EARLY CLOSING.** In Great Britain, since the passing of the Shops Act of 1912, it has been compulsory for shops to close for one half-day a week. Earlier evening closing is governed by the Acts of 1922 and 1928. The hours per week for persons under 18 are

also limited and with certain exceptions, shops must be closed on Sundays.

The day chosen varies from place to place, being fixed by local authorities after consultation with the shopkeepers; but a shopper should acquaint herself with it in her own locality so as to avoid disappointment. In central London the early closing day is Saturday, but in other places it is more usually a day about the middle of the week, Wednesday and Thursday being the days that are most frequently selected.

**EARRINGS: Choice and Care.** While never quite out of fashion as ornaments, styles for earrings change frequently, especially during periods when women are wearing much fancy jewelry and new designs are evolved in keeping with various dress fashions. When long earrings are being worn, good examples may be purchased at shops which specialise in antique jewelry. Many such earrings are made in two parts, a top or stud and a long drop, or an intricately designed lower part, which hooks on to the upper part. These ornaments possess an advantage for those who do not care for elaborate earrings in the mornings as the studs can be used alone, the lower parts being added for formal wear.

*Earring. Types of fastenings for both pierced and unpierced ears.*

The two main types of fastening for earrings are illustrated, the first being suitable for pierced ears and the second for unpierced. The latter type are attached by means of screws to the lobes of the ears. They should be light in weight or they are liable to drag the lobes and either to hurt or to be lost.

**Fastening Methods.** The fastening of valuable earrings should never be of the type which screws on the lobe of the ear. It causes unbearable discomfort if the fastening device is screwed so tightly to the ear as to prevent the possibility of the ornaments falling off. Those who possess diamond or other valuable earrings should have the lobes of their ears pierced. This can always be done by a practical jeweller without any risk and with very little pain.

Before purchasing earrings inquiries should be made as to whether the wires or fastenings are of silver or gold. The less expensive varieties may have metal fittings which might possibly poison the ear, though the extra cost of silver is infinitesimal. For safety when wearing earrings the style of fitting that is most reliable is what is known as the Brissure fastening. This is an old French style, consisting of a wire which, when passed through the ear, is covered by means of a

grooved loop of gold or silver affixed to the ornament by means of a spring hinge. Withdrawal of the wire from the lobe of the ear is thus rendered impossible without the hinged loop being first opened so as to uncover the ear wire at the back of the ear.

**EARTH: In Electrical Work.** Any part of an electrical circuit which is connected to the ground or earth is said to be at earth or zero potential.

A good earth system is very necessary in wireless reception, although many modern sets dispense with the traditional type of external earth wire. It is immaterial whether the earth wire is bare or covered, but it should be of a substantial cross section; copper aerial wire, 7/22 gauge, is suitable. A main water pipe makes a satisfactory earth, provided the earth wire can be attached close by the point where the pipe enters the ground. If, for example, the set is to be used in a room at the back of the house, the earth wire can be joined near the tap in the kitchen or scullery. The lead pipe should be scraped clean and bright for a distance of about one inch, and an earthing clip attached. The earth wire from the set is then connected to the terminal which is provided on the clip.

Gas pipes make unsatisfactory earths, owing to the fact that high resistance joints are employed. Moreover, considerations of safety make it undesirable to utilise a gas pipe for this purpose.

If the receiver is not conveniently placed in relation to the main water supply, a buried earth may be employed. The earth wire is soldered at several points to a large sheet of zinc or copper, which is buried edgewise in damp soil to a depth of about three feet. After cleaning off any excess flux with methylated spirit or petrol, it is advisable to protect the joint with a coating of paint in order to prevent corrosion.

An alternative to the metal earth plate is an earthing tube, which is driven into the ground and has a terminal at the top to which the earth wire is attached. Besides this connexion it is as well to lead the bare wire down through the tube, and out through one of the holes near the bottom, where it may be soldered or otherwise attached to the tube. Earth tubes are usually perforated, and should be filled with water at regular intervals during dry weather to ensure satisfactory electrical connexion with the surrounding soil.

*Earth. Copper earthing tube for connexion to a wireless set. In use it is driven into the ground.*

A counterpoise earth is sometimes used for short-wave reception, and may comprise, one or more wires, running beneath the aerial and a few feet above the ground. The wires have to be insulated in exactly the same way as the aerial, and may be passed through an ebonite lead-in tube to the earth terminal of the set. If a decrease in volume or flatness of tuning is observed, it is as well to inspect the earthing system, making sure

that any terminals or other joints have not become dirty or otherwise defective. A faulty earth may also produce high frequency and low frequency instability. *See Aerial.*

**Earth Switch.** This is a device for disconnecting the receiver and joining an outdoor aerial direct to earth, so that atmospheric discharges (e.g. lightning) flow straight to earth instead of passing through the aerial circuit of the set. A stoutly constructed single pole change-over switch having a porcelain base is suitable, and should preferably be mounted outside the house, near the aerial lead-in insulator. It is advisable to provide a cowl or other covering to prevent leakage of the aerial currents to earth over the surface of the switch in wet weather.

*Earth. Aerial-earth switch, single pole change-over type. In this switch a simple form of lightning-arrester gap is incorporated.*

The connexions are as follows: The aerial lead-in is joined to the centre terminal or arm of the switch. One side of the switch is then connected via the lead-in insulator to the aerial terminal of the set, and the remaining side is joined to earth. Thus in one position of the switch arm the aerial is connected to the receiver, while in the other position the aerial is joined direct to earth. The aerial should always be earthed when the set is not in use.

**EARTH CLOSET.** In country districts where no public sanitary arrangements exist, an earth or chemical closet, located in an outbuilding, takes the place of the town water closet. A simple form consists of a movable receptacle or pail beneath the seat. Dry loamy earth may be provided in a receptacle above the seat, feeding through a hopper to a shoot terminating

above the pail at the back. A flap can be fitted to regulate the flow of dried earth, as shown in the figure above.

*Earth Closet. Sectional diagram showing method of construction and hopper for earth supply.*

The outbuilding for an earth closet can advantageously be built of brickwork and should be frequently lime-washed. A weather-boarded erection is cheaper, but the numerous crevices harbour a great number of insects. The floor should be of concrete raised three inches above the level of the ground, with a fall to the entrance door. The cheapness of the best earth closet system is a great recommendation, and if constructed to embody the foregoing features it will prove entirely satisfactory in country districts for a small-sized house.

It should be noted that dry loamy earth is the best material, as its deodorant properties are greater than those of ashes, etc. In fact, unless earth be used, the closet may be treated by local by-laws as a privy, with the result that more frequent cleansing is insisted upon. This applies particularly when a fixed receptacle is used. *See Cesspool; Refuse; Sanitation; Water Closet.*

**EARTHENWARE.** This term is used for household and other articles made of clay and similar substances. Glazed and unglazed earthenware of fireproof quality is largely used as a substitute for iron, tin, aluminium, etc., in the manufacture of saucepans and other kitchen utensils. It is easily kept clean and does not rust, besides which, as in the case of casseroles, the dish itself may be brought to the table. Earthenware utensils require no scrubbing or polishing, but should be washed in warm soapy water immediately after use. In case of stains, soak the pans in hot water to which a little soda has been added, or apply some fine sand; then rinse and dry thoroughly. *See China; Crockery; Delft; Fireproof.*

**EARTHWORM.** The ordinary earthworm is the friend rather than the enemy of flower gardeners, because of the work that it does in mixing and lightening soils.

Few people would object to worms in lawns but for the fact that at certain periods of the year there is a heavy crop of casts which entirely spoil the appearance of the grass. The application of worm killer (a preparation sold by seedsmen) which must be thoroughly watered in, will destroy the worms.

**EARWIG.** This pest damages the petals of dahlias, chrysanthemums, carnations and other flowers. Most damage is done while the gardener is sleeping. At dawn the earwig creeps into a place of refuge, such as a dahlia petal, into the openings of a sponge, a wisp of hay in a flowerpot or a hollow stem such as that of a dead sunflower. The gardener should, therefore, place one or other of the articles mentioned among his plants to serve as traps. In the case of sponge or hay, he immerses it in boiling water in order to kill the insects; if they are in hollow stems, he must either shake or blow the pests out into boiling water. The traps should be set in the plants in the evening and examined in the morning.

**EASTER.** This Christian festival falls in March or April. In England it has come to be a general holiday which includes Good Friday and Easter Monday, and often extends from Thursday evening until Tuesday or even Wednesday morning. It is celebrated by the giving of Easter eggs, and sometimes by presents of other kinds, but is more popular as the first holiday season of the year.

For some years business men and others have carried on an agitation to make Easter a fixed date. A measure to this effect was passed into law in 1928, but it will not become operative until the Home Secretary makes an order to that effect. The Act fixes Easter Sunday as the Sunday immediately after the second Saturday in April.

The dates on which Easter Sunday falls during the ten years 1939-1948 are as follows:

1939	April 9	1944	April 9
1940	March 24	1945	April 1
1941	April 13	1946	April 21
1942	April 5	1947	April 6
1943	April 25	1948	March 28

**EASTER EGG.** Among the less costly varieties of Easter egg are the small chocolate ones, either filled with cream and marzipan, to imitate the yolk and white, or hollow, and sometimes containing chocolate drops or other sweets. There are also fancy nests filled with eggs; the nests are usually made in cardboard or light basket work, and the eggs may be of almost any kind of sweetstuff.

For more costly gifts there are the large egg cases, made of painted cardboard, silk, satin, or some decorative material. These can be filled with a piece of

jewelry, or with chocolates or perfume.

**An Egg Hunt.** An Easter egg hunt is an inexpensive way of entertaining children, the eggs being hidden in the garden. Small chocolate eggs about the size of a bantam's egg, and done up in silver paper, are most suitable, two or three eggs apiece being allowed. The hiding of the eggs in the garden should not be done too carefully, and a note should be kept of each place chosen, in order that any not discovered may be retrieved at the end and each child have a fair share. Clumps of rock plants or low growing shrubs offer excellent hiding-places. Two or three eggs may sometimes be hidden in the same place to look like a nest. The children should all start seeking at the same time, and the hunt should not last too long; in most cases half an hour should be sufficient. Should the weather be unfavourable the hunt may be equally well arranged indoors, where many ingenious hiding places are available.

**EASTON'S SYRUP.** Syrup of iron phosphate with quinine and strychnia, known as Easton's syrup, is an excellent tonic for convalescents in slight anaemia, loss of appetite, general debility, etc. A dose for an adult is  $\frac{1}{2}$  to 1 fluid dram in a little water. It can be obtained in tablet form in  $\frac{1}{2}$  dram and dram strength.

**EASY CHAIR: How to Make.** For making the framework for an easy chair such as Fig. 1, either beech or birch is a suitable wood, and the joints are the mortise and tenon in preference to dowelling. Fig. 2 is a perspective view of the framework, and the dimensions are indicated in the working drawings at Figs. 3-6. Set the job out to full size, as this will then show clearly the various angles at which the shoulders are cut. Fig. 6 shows how the back is marked out. The leg is tapered away at the bottom on the inner edge to the height of the stuffing rail, 6  $\frac{1}{2}$  in., a piece being glued on at the back to take the shape.

Fig. 1

Fig. 2

*Easy Chair. Fig. 1. Padded chair, which can be easily made by the amateur. Fig. 2. Framework.*

Economy may be exercised in cutting out the front legs. Two pieces of stuff are glued together, and the shape cut out afterwards. The scrolls at the top are obtained in a similar way. Having cut out all the stuff, the joints are marked out and cut, all the various lengths and sizes being obtained directly from the

setting out. Glue the front and back up separately, and allow them to set before glueing the side rails. The joints may be further strengthened by pinning them with  $\frac{1}{4}$  in. dowels. When the whole is glued up, all sharp edges must be removed with a rasp, and the bun feet fitted, with  $\frac{3}{4}$  in. or 1 in. dowels. It is advisable carefully to stain and polish them before fixing.

*Easy Chair. Figs. 3-6. Working drawings giving details and measurements of the framework of the chair shown in this and next page.*

The fitting of the castors is important, as in the event of these becoming loose and sagging, strain is thrown on the joints of the framing. Full instructions for the springing and covering of this type of chair will be found in the article

Upholstery. See Armchair; Chair; Chair Bed.

**EATING.** The mastication of food is necessary for its thorough subdivision into small enough portions to make digestion easy. The operation should not be hurried, as it too often is, the ill-masticated food being swallowed by the assistance of draughts of liquids. This can be avoided by refraining from the use of liquids throughout meals. See Diet; Digestion; Drinking; Fish; Food; Fruit; Indigestion, etc.

**EAU-DE-COLOGNE.** There are excellent English makes on the market, or this perfume can be prepared at home if preferred. Care must be taken to procure the best rectified alcohol. The following

ingredients are placed in an ordinary glass bottle.

Rectified alcohol	1½ pints
Essence of lemon	1½ drams
„ bergamot	1½ „
„ cedrat	1½ „
„ lavender	1½ „
„ rosemary	½ „
„ thyme	¼ „

The mixture must be well shaken until the essences dissolve in the alcohol. The liquid is then strained through a filter paper, which can be obtained from any chemist, and put into bottles with close-fitting stoppers.

The toilet uses of eau-de-Cologne are many. Rubbed into the palms of the hands after washing and drying them, it keeps them free from perspiration in hot weather. It is a good facial astringent for use about once a week. A pad of cotton wool should be squeezed out of cold water and then further moistened with eau-de-Cologne. The face should be briskly patted with this pad and then sponged with cold water. Skin food may be applied afterwards at night. Eau-de-Cologne is refreshing on a railway journey and, in addition, does much to alleviate a headache.

**EAVES: Of a Building.** Eaves constitute the lower portion of a sloping roof which projects beyond the wall of a house, making, with the aid of an eaves channel or gutter, an overhanging drip for rain water. A projection of 18 in., and in some cases from 2 to 3 ft. will not be too much. The advantage of wide eaves is that besides protecting the walls and upper windows from the weather, they give good shadows and thus remove the bleak appearance of a too rigid roof line.

In designing the eaves the questions of the indispensable gutters on the fringe and the down pipes must be studied. If the eaves are continuous along the front or side of a house—not broken, that is, by gables or other interruptions—the question of down pipes is greatly simplified. As regards gutters, the half-round variety is better than those with mouldings.

A simple form of eaves in course of construction is illustrated in Fig. 1. which shows very clearly the arrangement of the fascia board, as the vertical board is called, and the position of the soffit board, which is fixed in a horizontal manner to the feet of the roof rafters. This arrangement is very effective on cottage property. A convenient and economical scheme is to use a 4 in. fascia board, 1 in. thick, and a 6 in. soffit board,  $\frac{3}{4}$  in. thick. These boards are fitted to the feet of the rafters by cutting the latter to shape, getting them all in line by stretching a cord between the end rafters and cutting all the rafter feet accordingly. The boards are then nailed securely to every rafter. The gutter, if of the O.G. type and, say, 4 in. wide, is then screwed directly to the front of the fascia, thus saving the expense of the usual gutter brackets.

A more elaborate arrangement is that shown in Fig. 2, where an eaves course of brickwork has been

introduced for the purpose of effecting a better appearance. The soffit is enclosed by a board supported on brackets. *See Architecture; Bungalow; Cottage; House; Roof.*

*Eaves. Fig. 1. Showing how and where the fascia and soffit boards are fixed. This arrangement is particularly suitable for cottage property.*

*Eaves. Fig. 2. Section showing construction of a simple type with an eaves course of brickwork.*

**EBONITE.** Ebonite is a hard usually black material made by incorporating rubber with other ingredients. It is amenable to a high finish, and has many domestic applications, examples being gramophone records, fountain pens, electrical apparatus, for which last named purpose it possesses good insulating properties. It is procurable in the form

of rods, sheet or tubing from ironmongers and dealers in electrical apparatus.

Ebonite can be cut with a hack saw in the ordinary way. When drilling holes in it, the drill is apt to clog, and should be backed out frequently; soft soap can be used as a lubricant. Filing is best accomplished with very coarse or rough files.

**EBONY: The Wood.** There are several kinds of ebony, which is a hard, dense, and heavy wood, often quite black in colour. Generally the heartwood is black, or nearly so, and the sapwood yellowish grey or brown, or nearly white. The wood too is often streaked with shades of lighter or darker colour. Ebony is valued chiefly for its colour; it is used for veneer, for inlaying, for small turned articles, and for small cabinet work; being a scarce wood, it is often imitated. The artificial sort, sometimes known as German ebony, is mostly stained sycamore, pear, or boxwood, and is used for the backs of certain brushes of the cheaper sort.

Ebony furniture which has become dull and shabby looking may be restored by the application of olive oil. If it has lost its polish, it is best treated with a preparation consisting of vinegar 3 oz., linseed oil 6 oz., methylated spirit 3 oz., and butter of antimony  $\frac{1}{2}$  oz. *See Wood.*

**ÉCARTÉ.** This is a card game for two persons which is played with a piquet pack of cards. The rank of the cards is king (high), queen, jack, ace, ten, nine, eight, seven (low), the ace coming between the jack and the ten.

The cards are cut for deal, highest dealing, and five cards are dealt either three at a time and then two at a time, or vice versa. The 11th card is turned up as the trump; if it happens to be a king the dealer scores one point. After the trump has been turned up, the two players look at their hands. If the dealer's opponent is willing to play his cards as they stand he says, "I play." If, however, he is dissatisfied with them and wishes to strengthen his hand by discarding and drawing, allowing the dealer the same privilege, he says, "I propose." The dealer may refuse, and say, "Play," or may accept, in which case he deals his opponent as many fresh cards as he discards. The dealer himself then may discard and refill his hand, and the players may repeat this procedure until one or the other declares his willingness to play.

Discarded cards are placed face downwards on the table, and are not looked at by the opposite player. If a player does examine such cards he may be called upon to play with his cards exposed, face upwards on the table. If a player asks for more cards than there are left in the pack he must take back into his hand enough cards from his last discard to fill his hand. Players may discard any number of cards up to five, and have their cards replaced by an equal number. If the dealer's opponent proposes and the dealer accepts them, the dealer's opponent must discard at least one of his cards.

Before leading a card, the dealer's opponent says, 'I

play," and thereafter the winner of each trick leads for the next trick. If a player holds a king and wishes to score it, he must announce it before any card is led, but he is not bound to announce or score it if he does not wish. Players must follow suit, and take the trick if possible. If a player cannot follow suit or take the trick with a trump, he discards. If he fails to follow suit or win a trick when he could have done, or trump when he could have followed suit, it is a "renounce," and the cards are taken up and the hand played again.

**Scoring.** Should a player thus renouncing take less than five tricks on the replay, he cannot score. If he takes five tricks he scores one point. Tricks are turned down as taken, and must not be examined afterwards during play. If a player throws down his hand as not being worth a point he cannot score, even though he would have won if he had played. If he puts down his hand and claims one or two points he may score them if his hand substantiates his claim.

The king of trumps turned up counts one point to dealer; held in the hand one point to holder if declared as already explained. Dealer's opponent who stands or dealer who refuses counts one point for taking three tricks and two points for five tricks, called vole. If a player stands or refuses and fails to take three or more tricks his opponent scores two points. The first player to make five points wins the game.

**ÉCLAIR.** The small finger-shaped cakes known as éclairs are prepared from choux pastry, the mixture used for making cream buns, etc. The top may be iced either with chocolate, coffee, or other icing, and the inside filled with confectioner's custard or whipped and sweetened cream. *See* Banana; Chocolate Éclair; Cream Bun; Custard, etc.

**ÉCRU.** Silk before it has been boiled and cotton and linen before being bleached are écreu, which in French signifies the natural colour. Lace and curtain nets can be bought either in white or écreu, implying in this case a slightly brownish shade.

**ECZEMA: Its Treatment.** The commonest of skin diseases, eczema is characterized by reddening of the skin, by little hard pimples called papules, and watery blisters or vesicles containing matter known as pustules. When the skin is raw there is a sticky discharge.

In the causation of eczema two factors that must always be looked for are external irritation and increased susceptibility of the skin. The external irritant may be something employed in one's occupation or hobbies, e.g. sugar in baker's eczema. It may be cold or heat, friction of clothing, or otherwise. Strong soap, cosmetics, tooth pastes, may produce eczema about the lips; decomposing sweat is another cause. Irritants may be brought to the skin by the blood.

Every effort should be made, by better personal hygiene in respect of exercise, sleep, fresh air, and diet,

to increase bodily and mental tone. Alcohol in all forms must be given up. Sugar must be reduced. Tea and coffee should "be discontinued in acute eczema, and may have to be watched subsequently. Salted meats, pickles, chutney, and highly seasoned dishes must be avoided. It may be found best to restrict the patient to milk diet. Woollen underwear may have to give place to silk or cotton. Mild or super-fatted soaps should be used, and none at all in acute eczema.

For erythematous eczema or reddening, lotions or powders are applied, such as calamine lotion, or the following dabbed on and allowed to dry.

Zinc oxide powder	3 drams
Solution of lead subacetate	1 dram
Glycerin	1 „
Camphor water to make	6 oz.

A useful powder is made up as follows, and is dusted on to burning red areas occasionally:

Zinc oxide powder	2 drams
Talcum powder	2 „
Starch	4 „

Papules are usually found on the arms or legs. Burning is not so pronounced, but the itching is often intolerable. The lotions given above may be used, or the following ointment applied locally twice a day:

Carbolic acid	15 grains
Calomel	20 „
Zinc oxide ointment	2 oz.

When vesicles occur, the skin of the face, particularly in children, is the commonest site of this variety of eczema. The lotions mentioned above may be used, and when the discharge lessens, Lassar's paste, which is composed of zinc oxide powder and powdered talc, 2 drams each; vaseline, ½ oz.; salicylic acid powder, 10 grains. Pieces of lint or old linen are used, the paste being spread evenly all over. The dressing is changed when it becomes moist. For children, equal parts of zinc ointment and lanoline could also be applied in this way.

**Making a Starch Poultice.** To clean the parts and remove the crusts, gently sop off with a little cotton wool wet with olive oil. If the crusting is thick a starch poultice or diachylon ointment may be used. The poultice is made by making a paste with a heaped teaspoonful of fine starch, and then making up to a pint with boiling water. Allow to cool and apply on six or eight layers of butter muslin. Anoint with cold cream before applying the poultice.

For reducing the inflammation the parts may be sopped every hour with a saturated solution of boracic acid, and then treated as for the vesicular stage. In the terminal stage, characterised by redness, thickening of the skin and scaling, this ointment may be used: Liquor carbonis detergens, ½ dram; white precipitate ointment, 1 dram; lanoline and vaseline, equal parts,

to 1 oz. This will also be found useful in most cases of sub-acute and chronic eczema.

**EDAM CHEESE.** Of the two varieties of Dutch cheese, Edam is round in shape and Gouda is flat. The Edam cheese is made of milk deprived largely of its cream, so that although highly nutritious, it cooks badly, the reason being that it is deficient in fat. *See Cheese.*

**EDELWEISS.** This favourite Swiss mountain flower (*Leontopodium alpinum*) can be grown without difficulty in rock gardens in Great Britain. It needs a sunny place and should be planted in loamy soil with which stones have been mixed. The plant grows about six inches high and has grey leaves; the small yellow flowers are surrounded by greyish-white woolly bracts, which are more curious than beautiful. It is propagated by seeds sown in pots of soil in a frame in spring; growth is slow for the first year.

*Edelweiss, a popular Swiss mountain flower which can be grown in British rock gardens.*

**EDGING:** In the Garden. There are two kinds of garden edging, known respectively as "live" and "dead." The former consists of plants, the latter of various materials, e.g. wood, tiles, bricks, concrete, or rockery stone. A rockery edging is very attractive: if the spaces between the stones are filled with sandy loamy soil many pretty low-growing rock plants will thrive there. Strips of wood fastened at intervals to short stakes driven into the ground provide a cheap and convenient edging to flower beds and borders, but tiles or a narrow edging of concrete are more lasting. Bricks set in various ways are often used, and if hard bricks are chosen they last indefinitely. Soft bricks are soon damaged by frost. A concrete or cement edging is made by setting up a narrow trough of boards and filling this with home-made concrete or cement. When it has set the boards are removed.

Live edgings, that is those composed of plants, are more attractive and generally to be preferred. There are suitable kinds among both perennials and annuals; the former ought to be used if a permanent edging is required. Edging plants in a border which runs alongside a lawn are apt to spread on the grass and ruin it: this can be prevented by having a narrow paved path alongside the border. Not only does this prevent the grass being damaged, but it provides a dry footing when the lawn is sodden, and the plants look very charming when trailing over it. The best perennial

edging plants are thrift (*armeria*), mossy saxifrage, pink, London pride (*Saxifraga umbrosa*), *Campanula muralis*, stonecrop, *Veronica rupestris*, aubrietia, yellow alyssum, arabis and viola. Pink, aubrietia, alyssum, arabis, mossy saxifrage, London pride and viola should be cut well back after flowering to keep them compact.

Some of the low-growing annuals make charming edging plants: seeds are sown out of doors in March-April to produce plants that will bloom from June onwards; they perish after the flowers are over. Some of the best are Virginian stock, dwarf white alyssum (best of all), leptosiphon, *limnanthes*, candytuft, *nemophila* and *nemesia*. The last named is sown under glass early in March. Golden feather (*Pyrethrum aureum*) and half hardy plants such as *mesembryanthemum*, *echeveria*, and *lobelia* are often used as edgings to formal summer flower beds. The edgings can be kept trim by the use of the tool called the edging iron. *See Border; Flower Garden; Path, etc.*

**EEL: How to Cook.** Eels are at their best during the autumn and winter months, and are usually stewed. After being skinned and cleaned, the fish is cut into small pieces, 2-3 in. in length. These are placed in a jar with a sliced onion, a tablespoonful of chopped parsley, 1 oz. of margarine, pepper, salt, and a squeeze of lemon juice. A clove or a teaspoonful of anchovy sauce may be added. The jar is then covered and placed in a saucepan of cold water, being allowed to simmer until the eel is tender, which takes about two hours.

To serve eels fried they should be cut into short pieces, dipped in seasoned flour, and coated with egg and breadcrumbs or batter, and fried until crisp and brown. They should be well drained before the dish is served, and garnished with fried parsley. The smaller fish are best cooked in boiling salted water to which a little vinegar has been added, and served with butter and parsley.

Baked eels can be prepared by cutting the skinned and cleaned fish into short lengths, and standing these in an upright position in a shallow baking-tin. Pour in a little water, add salt and pepper to taste, a little minced parsley, chopped shallots, and some sweet herbs, and bake the whole in the oven. When the fish is ready, take it out of the tin, and thicken the gravy with a small lump of butter rolled in flour. A little white wine may be used for flavouring.

Collared eel is prepared by cutting off the head and tail of a fairly large fish and then skinning it and slitting it down the centre, removing the backbone. Lay the eel flat on a table and spread over it a seasoning made from two finely chopped sage leaves, 2 cloves and 2 blades of mace, a small bunch of herbs (chopped), and pinches of allspice, salt and pepper to taste.

Roll up the fish and tie it securely with a piece of tape. Put the head, tail, and backbone into a pan of well-seasoned water. Boil down these trimmings, then add the fish to the stock, and stew it for 35-40 min., or until it is tender.

To pickle eels, skin the fish, slit them down the centre, and, after removing the bones, rub the flesh over with salt. Lay the eels aside for 3 days, turning them daily; then wash and dry them thoroughly. Season them with a little nutmeg, cloves, mace, and bay leaf, then roll up and tie them in a cloth. Boil them until tender in equal quantities of white wine and vinegar, take them out of the pan to cool, and put them, with the liquor, into clean jars.

**Eel Broth.** A nourishing broth for invalids is made by simmering  $\frac{3}{4}$  lb. of small eels in a pan containing 2 quarts of water, a few sprigs of parsley, 2 or 3 thin slices of onion, and a few peppercorns. Continue simmering until the fish is broken, then season the broth sparingly and strain it off.

**Eel Pie.** To make eel pie the eels should be washed, skinned, cut into short pieces, and placed in a pie-dish on a foundation of forcemeat. Lemon juice, chopped parsley, and seasoning should be sprinkled over them, and the pie covered with a crust of short or puff paste. The pie should be baked from  $\frac{3}{4}$  to 1 hour in a moderate oven, and a white sauce can be served with it.

**Eel Spitchcock.** This dish is prepared by cleaning an eel, rubbing it over with salt, and then slitting it up the middle and removing the bone. After washing and drying it, cut it into pieces 2 or 3 in. long, dredge these with flour to dry them and then shake it off. Make a thick egg batter, to which a little seasoning, minced parsley, sage and shallot, have been added. Dip the pieces of fish in this, and then roll them in fine breadcrumbs. Repeat the process, and then broil them over a clear fire until they are pale brown in colour. *See Batter; Conger Eel; Pastry.*

**EELWORM.** This is a minute garden pest which attacks cucumbers, tomatoes, daffodils and other plants.

The first symptom of attack is a drooping and yellowing of the foliage, followed by the stem becoming limp, and the collapse of the entire plant. The finer branches of the root are more or less studded with swollen portions or knots, varying in size up to  $\frac{1}{4}$  in. across; knots of larger size are also often present on the thicker branches of the root. To destroy these eelworms the soil must be thoroughly saturated three times, at intervals of a fortnight, with a solution of one part cresylic, or liquid carbolic acid, in 40 parts of water. The plants that are ruined by the eelworms should be burnt.

## EGGS AND EGG DISHES

The Best Ways of Preparing a Staple Article of Food  
See also the entries Batter; Curry; Custard; Omelette; Savoury; Souffle, etc. The articles Diet and Food may be consulted, as may those on Chicken; Duck; Poultry.

Like milk, an egg is a perfect food, as it contains all the

requisites of a diet—proteids, fat, carbohydrate, salts, and water. The yolk is rich in fat and in lecithin, a substance which is important in the nutrition of the nervous system and in growth. A duck's egg contains more fat than that of a hen. The digestibility of an egg is impaired by keeping, hence the value of fresh eggs. Digestibility is also affected by cooking; raw, lightly boiled, or poached eggs being much more easily digested than hard-boiled. Hens' eggs are those most commonly eaten; ducks' eggs are larger, and stronger in flavour. Turkeys' eggs are considered to be delicately flavoured, and the small, spotted egg of the plover is regarded as a delicacy.

**Beaten Eggs.** The binding properties of a beaten egg are utilized in the mixing of dry ingredients, such as dried fruits, sugar, and flour, for puddings and cakes; minced meats and fish, for the making of rissoles, cutlets, etc. Savoury mixtures are most successfully fried if dipped in beaten egg, as the egg cooks round the outside and makes a coating that prevents the frying fat from reaching the food. Eggs, boiled or poached, are much used as an addition to simple dishes; the boiled whites and yolks, chopped finely, are a favourite garnish for cold service meat dishes. Hard-boiled eggs are a feature of most salads.

Eggs are beaten into batter to give lightness and substance to the coating mixture. When boiled or steamed puddings are mixed with them, the ingredients adhere more closely together; the mixture is lighter, colouring and flavouring richer, and the whole more nourishing. Eggs bind the ingredients of a cake, and help to make it lighter, especially when the yolks and whites are beaten separately.

The yolks add colour and richness to savoury dishes, and make soups for invalids more strengthening. Pastry is given a deep brown gloss if it is brushed over before baking with a little egg. Yolks of eggs are the foundation of mayonnaise sauce, and also of almond paste for cakes.

Whisked white of egg with the broken shell is used for clarifying clear soups. Added to jellies when they are almost set, and whisked into them, it makes the jellies light and foamy. A jelly will turn out whole if the mould has been smeared with white of egg, and circles of kitchen paper brushed over with white of egg make excellent jampot covers.

White of egg is particularly useful in cooking for invalids, as it is rich in albumen, and more easily digested than the yolk. The beaten whites of two eggs added to a tumbler of boiled water that has been left until tepid, with a pinch of salt added, make a nourishing drink for an invalid who can retain no other food.

**Boiling and Poaching Eggs.** To boil an egg, it should be lightly placed in a pan and covered with boiling water, then drawn to the side of the fire where it will simmer, but not boil. In ten minutes the egg will be cooked with a firm white and soft yolk. To boil an

egg hard 15 min. boiling over the fire or gas ring should be allowed, and if required for use cold, the egg should immediately be plunged into cold water to prevent the yolk becoming discoloured, and to make the shell leave the white. When boiling cracked eggs, wrap them lightly in tissue paper.

To poach an egg, if a poaching vessel is not available, a shallow pan should be half filled with boiling water, to which a pinch of salt and a teaspoonful of vinegar are added. The egg should be broken into a cup, gently slipped into the pan, and drawn to the side of the fire. As soon as the white has set, the egg is cooked. Poached eggs are served on toast, and garnished with parsley, or are served over a dish of mince. To fry an egg, use the frying-pan containing the fat from fried bacon, or heat a small piece of fat. Break the egg into a cup and slip into the boiling fat. The pan should be placed over gentle heat, and the egg is ready as soon as the white has set. If preferred the egg can be turned with a thin egg slice and fried on the other side before serving.

*Egg. Poached eggs on toast, an appetising breakfast dish.*

An egg poacher is an appliance which comprises essentially an outer pan or water vessel with an inner plate whereon are located the egg divisions. These may be any convenient number, but four is a useful size for the average household.

**Scrambled Eggs.** Scrambled eggs served on rounds of toast make a good breakfast dish. Prepare them by breaking 2 eggs into a basin, whisk them and mix in 2 tablespoonfuls milk, and a little salt and pepper. Melt 2 oz. butter in a saucepan and, when hot, pour in mixture. Stir with a fork over a gentle heat until the mixture sets, and then turn it on to pieces of toast.

What are sometimes known as Scotch eggs are made by shelling 2 hard-boiled eggs and rolling them in a little flour to dry. Skin 2 raw sausages, season the meat and wrap it round the eggs. Coat the latter with beaten egg, and then roll them in breadcrumbs. Put them into a deep frying-pan containing smoking hot fat and fry them slowly, to make certain that the sausage-meat is thoroughly cooked. When fried, cut each egg in half, place each half on a hot croûton, and garnish it with fried parsley. Tomato sauce makes a good accompaniment to this dish.

**Egg-and-tomato cutlets** is a dish that does not take much time to cook. Melt 1 oz. of fat in a small saucepan, and in it fry 2 tomatoes. When cooked remove them and rub them through a sieve. Add to the fat 2 hard-boiled eggs, chopped into small pieces. Put the tomato pulp back into the pan and add 1 tea-

spoonful of chopped parsley and seasoning, and 1 gill of thick brown sauce. Then beat up the yolk of an egg, pour it into the pan, and stir the whole over a gentle heat until the mixture binds. Turn it on to a plate to cool, shape the mixture into cutlets, brush them over with the slightly whipped white of an egg, and coat them with breadcrumbs; then fry them in smoking hot fat. If the mixture is too soft to shape into cutlets, add some breadcrumbs to it. When the cutlets are ready for dishing, drain them and arrange them on a paper doily on a hot dish.

*Egg and tomato cutlets, which are easily and quickly prepared in an emergency.*

**Eggs au Gratin.** Eggs treated in this way form the basis of a tasty supper dish. Put 2 oz. of sliced cheese in a casserole or baking-dish, well greased with butter or dripping. Sprinkle with pepper and salt, a little chopped parsley, and a piece of butter or margarine. Pour over it  $\frac{1}{2}$  gill white sauce, and break on the top sufficient eggs to cover, or allow one egg to each person. The yolks should not be broken.

Sprinkle the eggs with breadcrumbs and grated cheese and place a few pieces of butter on top. Bake in a hot oven for about 10 min. The remains of any savoury white sauce can be used to pour over the cheese in place of the milk and flour. A few drops of anchovy essence added to a plain white sauce mixture give a piquant flavour.

**Egg Jelly.** A jelly that is made from eggs is much used in sickroom cookery. To make it, dissolve  $\frac{1}{2}$  oz. of gelatine in 1 gill of cold water. Add 4 oz. of castor sugar and the juice and rinds of an orange and a lemon. Stir over gentle heat, on no account allowing the liquid to boil. Remove the lemon and orange rinds and beat separately the white and yolk of one or two eggs.

Add to the yolks a wineglassful of sherry or brandy and stir in the gelatine liquid. Stir in lightly the stiffly beaten whites of the eggs and pour the jelly into a wetted mould.

**Egg Mayonnaise.** This favourite hot-weather dish is one made from 6 hard-boiled eggs, the same number of tomatoes,  $\frac{1}{2}$  pint of thick mayonnaise sauce, and a little pepper and salt. Shell the eggs, and cut them into halves lengthways. Then cut the tomatoes into halves, put them on a baking-tin, and bake them in the oven until they are just tender, but not broken.

Let these get cold, and then arrange them in two straight lines down a pretty dish, dusting a little salt and pepper over each. Lay the halves of eggs on the top, with the cut side downwards. Flavour the mayonnaise sauce with tarragon vinegar, and then pour it gently over the eggs until they are smoothly coated. Garnish this dish with pickled chillies cut into small diamond shapes. (*See Mayonnaise.*)

Eggs sur le plat are prepared by melting a small piece of butter in a fireproof dish and then breaking 2 eggs into it. Season to taste with salt, pepper, and chopped parsley, and then pour over them 2 tablespoonfuls of cream and put one or two little lumps of butter on the top. Bake the eggs in a slow oven until they set, and then serve them in the same dish.

Poached eggs, served on squares of toast with a little green sauce poured over them make an appetising dish. Poach 6 eggs as already described, and prepare the sauce by washing 2 oz. of leaves of tarragon, chervil, parsley, chives, and watercress mixed. Pound these together in a mortar, mixing with them a few drops of anchovy essence, and pass the mixture through a wire sieve. Add to it  $\frac{1}{2}$  pint of white sauce, and stir the whole in a pan over the fire until all the ingredients are well blended.

Poached eggs may also be served on spinach. Rub  $\frac{3}{4}$  lb. of cooked spinach through a wire sieve, or chop it finely, melt 1 oz. of butter in a saucepan, and put in the spinach with a little seasoning. When quite heated through place the spinach on a hot dish, and arrange 2 or 3 poached eggs on top.

A tasty and economical dish is given the name of vegetarian egg. To prepare it boil 4 eggs hard, put them into cold water, then remove the shells. Boil 4 oz. of lentils until tender. Melt in a saucepan 1 oz. of butter or margarine, stir in 1 oz. of flour and a tablespoonful of milk, or water in which the lentils were boiled, and cook until the mixture leaves the sides of the pan. Add the lentils, a teaspoonful of mixed herbs, and pepper and salt. Mix all together and turn on to a floured plate. When the mixture has cooled and become stiff, divide it into small pieces and cover the eggs with it. Dip them into beaten egg, then roll them in breadcrumbs. Fry in hot fat, cut each in half, and serve hot, garnished with fried parsley.

**Egg Drinks.** Egg flip is a drink prepared from beaten eggs, sugar, and brandy, though the last-named ingredient is sometimes replaced by sherry or port.

Egg nog is prepared by beating up an egg, straining it into a tumbler, and adding to it 2 teaspoonfuls of brandy and half that quantity of castor sugar. Fill up the glass with  $\frac{1}{2}$  pint of scalded milk.

**Substitutes for Eggs.** The various substitutes on the market include egg powders, custard powders and dried eggs, but it must be remembered that although these may give to any dish an identical appearance, they cannot supply the food values of the real article.

In a simple cake mixture eggs can be omitted and a level teaspoonful of baking powder used to each cupful

of flour. A dessertspoonful of vinegar in which half a teaspoonful of bicarbonate of soda has been dissolved can be used in place of 2 eggs in a cake containing fruit or ginger. The vinegar should be the last ingredient to be added. Milk must be used to bind the dry ingredients. When using eggs for cakes or puddings, one egg can serve for two if yolks and whites are beaten up separately. Instead of an egg with a milk pudding, a teaspoonful of grated suet can be used. In making custard, instead of 2 eggs to a pint of milk, one egg and a tablespoonful of cornflour can be substituted. The cornflour should be blended with a little cold milk and added to the milk just before it boils, and brought to the boil in the pan. Stir in the egg after the milk has been removed from the stove.

**Testing Eggs.** There are various ways of testing the freshness of eggs. The shell of a fresh egg is dull and frequently has almost a bloom, while that of a stale egg is glassy and smooth. An egg with a stained shell has probably been preserved in lime, and if a musty smell clings to the shell it has probably been preserved in bran. One of the surest tests for the freshness of eggs is to place them in a bowl of water. A fresh egg will sink to the bottom of the vessel and lie in a level position, and a bad egg will float on the surface.

Another test is to hold the egg up to the light, in front of artificial light if possible. A fresh egg has an almost transparent shell; the yolk is discernible and the white unclouded. A black speck inside the egg or a thick and clouded appearance is a sign that the egg is not fresh. A stale egg appears to be more transparent at the end than the middle, whereas a fresh egg gives a reverse effect.

**Preserving Eggs.** Waterglass is one of the most widely sold preparations for preserving eggs; the process really is preservation in lime. The freshness is so successfully retained that the eggs treated in this fashion can be used for all the purposes of fresh eggs.

To make the lime preservation at home, pour 6 quarts of boiling water on to 3 lb. of lime. Add 1 oz. of cream of tartar and  $\frac{1}{2}$  lb. of salt. When the preparation is cold, plunge the eggs in. They will swim in the liquid, and should be kept in the tub or vessel in a cool room, or on the shelf of the larder, and taken out as required. It is important that they should be kept at a low temperature, so that the air and fluids which are in the shell do not decompose. Clarified butter and gum arabic can be used as outside preservatives. The eggs are dipped several times in clarified butter and hung in nets, small end downwards, in a room that is kept at an even temperature of about 33° F. If gum arabic is used, paint over the eggs with a brush dipped in the gum, and afterwards pack them in dry charcoal.

New laid eggs may be stored in racks, that is, on wooden shelves containing holes for the insertion of the eggs, with the small ends downwards. They can be kept fresh for months provided they are preserved straight from the nest and are perfectly dry and kept at a low temperature in the summer, but secured from freezing

in the winter. It is unsafe to keep them in a refrigerator, as a fungus forms inside the egg.

Eggs can be preserved by pickling in the following manner. They are first boiled for 10 min., then placed in cold water. The shells are taken off, and when the eggs are quite cold they are put in jars and covered with spiced vinegar. The jars should then be covered with airtight covers, and the eggs can be kept until they change colour.

**Cups and Spoons.** Eggcups are generally made of china or pottery, but are also to be had in aluminium, nickel, or silver, and in wood. China eggcups should match the breakfast service in colour and pattern. Some are provided with saucers to match, or four or six eggcups are made to fit into a single stand when they are brought to the table. For the nursery, sets are made with appropriate designs. Individual eggcups are also made to order, with each child's name painted on his own cup.

The eggspoon is a variant of the ordinary small spoon, and is used for eating a boiled egg. It is somewhat smaller than the typical teaspoon and somewhat shallower in the bowl. Four or six of these are often made to go with an eggstand, and sometimes the bowls are lined with gilt. (*See Spoon.*)

**Uses for Eggshells.** Eggshells are used both for cooking and cleaning purposes, and constitute a valuable ingredient in food for poultry. For whitening enamel-lined pans, the shells should be finely crushed and, in the case of stains, mixed with ordinary salt. Crushed eggshells are effective for removing discoloration from glass water-bottles and decanters. The shells should be put into the bottle with warm water and a little shredded soap, allowed to stand, and shaken occasionally. Eggshells are pounded and mixed with other foods for chickens, or with hard-boiled eggs in the case of small chicks. In cookery eggshells are sometimes used in order to clarify clear soups and broths.

#### EGG - AND - TONGUE ORNAMENT.

This is a form of carved ornament used on furniture and for panel mouldings. It is also a favourite style of moulding for picture frames and is frequently found on chimney pieces in Georgian style. It is also known as egg-and -dart ornament, as the character of the decoration is made by egg-shaped forms alternating with tongues or arrows. It was used by both Adam and Chippendale.

*Egg-and-Tongue Ornament, used in furniture and mural decoration.*

**EGG BOILER.** An article that served this purpose existed in the 18th century. It is usually an ovoid or flat vessel in two parts, with a ring for 3 or

more eggs. The body is supported in a frame with legs, and under it is a small spirit lamp. An antique egg boiler in silver is illustrated below. It is made to hold 8 eggs, and on the handle is a sand glass. The lid is divided and opens outwards on hinges at either side to disclose the egg ring which is attached to the handle and is removable from the vessel.

The egg warmer was made to serve a slightly different purpose, i.e. to keep the eggs warm, not to boil them. It had no lamp, but was provided with a liner or hot water jacket and a light tray by which the eggs could be let down or raised from the bowl.

*Egg Boiler. Antique specimen with hinged lid. It has a spirit lamp beneath and sand-glass above. (Courtesy of Chapple & Mantell, Ltd.)*

**EGG COSY.** Egg cosies are designed to keep boiled eggs hot when they are put in their eggcups. They are usually included in breakfast tray sets, with tray cloth, napkins and tea cosy to match. Tiny detachable linen or lawn covers are worked in coloured cross-stitch to match the china used. The padded cosy is made like a miniature tea cosy. Egg cosies can also be made from white blanket cloth stitched in colour. Two semicircular pieces are needed. When sewn together they should be large enough to cover the egg and egg cup. *See Cross-stitch; Tea Cosy.*

**Egg Plant.** This is an alternative name for the aubergine, a plant of the natural order Solanaceae. *See Aubergine.*

**EGG SHAMPOO.** The beaten yolk of an egg either used alone or mixed with hot water makes a good shampoo for a greasy scalp.

The yolk of an egg is beaten up in a gill of tepid water. This is rubbed thoroughly into the scalp and

hair, and then the head is douched repeatedly with warm water till the hair is clean. The shampoo is effective, and does not have the hardening effect on the hair of soap, ammonia, or spirit. If liked, a few drops of oil of lavender may be added. *See* Hair; Shampoo.

**EGG STAND.** Stands made to hold a number of eggcups for use on the table can be had in a variety of materials and styles. Some are of china and others of earthenware or metal. The eggcups are placed in holes in an article which is shaped not unlike a basket, from which they can be removed when required. Silver or electro-plated stands usually have pegs on to which the cups fit, and a device for holding spoons. A handle, often in the shape of a ring, is provided for lifting the stand. The screws or other fastenings of these articles need inspecting occasionally.

Egg frames, as they are called, existed in the 18th century, when they were made in silver and Sheffield plate. They are sometimes found in combination with a toast-rack or salt-cellar. One fine example stands on ball feet and is decorated with shells and the gadroon. It is fitted with cut-glass eggcups.

**EGG WHISK.** Various kinds of patent egg whisks can be obtained from the ironmongery stores. One of the most satisfactory types is manipulated by means of a small wheel with a handle attached. This wheel, when set in motion, causes the wires to rotate rapidly so that the egg is whisked to the required stiffness in the minimum amount of time.

**Eglantine.** This is a name sometimes given to the fragrant sweet briar (q.v.).

**EGYPTIAN STYLE:** In Furnishing. Sometimes if it is wished to give a special character to a sitting room, or to make an appropriate setting for ornamental Egyptian possessions, this style is suggested in the decoration and in the furnishing fabrics. The latter may be woven or printed in the conventional stripes or in the figure and animal designs of ancient Egypt, while views of pyramids, the Sphinx, and fallen pillars half buried in desert sand appear on lampshades and are embroidered on cushions, or are painted on screens or wall panels.

Browns, from sand colour to the darkest shade are used with Nile green and scarab blue to show the Egyptian inspiration, which also appears in trimmings and beaded tassels, arabesque designs on rugs or carpets and carved wooden screens. Such a furnishing scheme must be kept as simple as possible or the owner of the room will quickly tire of it.

**EIDERDOWN.** Owing to its extreme lightness and the large quantity of air and down it encloses, an eiderdown gives extra warmth with only a negligible increase in weight, air and down being non-conductors of heat. Ventilation is provided by small circular holes, which are strongly buttonholed to prevent fraying and any escape of down.

Down quilts, as well as providing extra warmth, are decorative when covered in silks and sateens of beautiful colour and design. The most important matter is to get a perfectly down-proof material that is light in weight and soft to the touch. Down-proof printed sateen, cotton-back satin, fancy shantung, Jap silk, and artificial silk taffeta are the materials chiefly employed. The last two possess the disadvantage of easily slipping off the bed unless sateen is used for the under side. *See* Down; Quilt.

**ELASTIC.** The elastic used for garters, suspenders, braces, belts, corsets, surgical stockings and many other purposes owes its stretching quality to rubber. The more strips of rubber there are in a given width the better the elastic.

If overheated the rubber loses its virtue. Moist heat is less detrimental to it than dry, so that an elastic article that may stand washing will suffer from artificial drying; rubber is ruined by hot ironing or by overstraining. Oil is detrimental. After a certain time any rubber perishes and must be renewed.

**Elastic Stocking.** A stocking made of a woven elastic fabric is used to exercise equable pressure on the leg from the foot upwards, and so assist in the return of the blood from these parts when the veins are dilated and varicose. It should always be properly fitted. A woven elastic bandage has the advantage that it can be freshly applied each morning and the pressure properly adjusted. *See* Varicose Veins.

**ELBOW.** The region at the elbow or bend of the arm possesses two joints, the elbow joint and the joint between the upper ends of the radius and ulna, the bones of the forearm. The elbow joint is of the hinge variety.

Dislocation may take place at these joints, a common one being a backward displacement of the upper end of the ulna, stiffening the joint and forming a prominence on the back of the elbow. The treatment of dislocations is to support the arm in a sling and apply cold to the joint while awaiting the doctor. Fracture of the lower end of the humerus near the joint is liable to be followed by stiffness for a long time.

Sprains of the elbow are treated by the application of cold water and supporting the limb with a greater arm sling. Tennis elbow is a painful affection of the arm; it does not interfere with the coarse movements of the limb, e.g. lifting weights, but it renders very difficult movements calling for a finer adjustment of the muscles, e.g. handling a teacup. It has been suggested that it is caused by using a racquet with too big a handle for a comfortable grasp. *See* Bandage; Dislocation; First Aid; Fracture.

**ELDER.** The common elder (*Sambucus nigra*) is a hardy shrub distinguished by its soft stems, lobed leaves, the odour of its white flowers and its clusters of black fruits. It will flourish in shady places and is

useful as a shelter shrub in seaside and other windy gardens. There are several varieties with coloured leaves, e.g. aureo-marginata; the variety laciniata has deeply cut ornamental leaves. The golden leaved variety of the red-berried elder (*Sambucus racemosa aurea*) is a handsome shrub of considerable garden value. The branches should be hard pruned each spring, for the leaves are most highly coloured on the fresh shoots. Propagation is by cuttings set out of doors in autumn.

**ELDERBERRY WINE.** For elderberry wine, take 5 gallons of water, boil for half an hour, and then stand till just cool to the hand. Add this water to a tub in which have been placed 20 lb. of Malaga raisins, chopped with a knife or shredded and the stalks removed. A wooden tub is best for this purpose, but a glazed stoneware vessel will serve.

Stand the tub for 10 days in a moderately warm room, stirring at least three times a day in order to keep the raisins submerged. At the end of this time press the juice out of 10 lb. of fully ripe elderberries, and to this juice, which should be about 5 pints in amount, add 2 ½ lb. of sugar, boil for half an hour, cool, and add to the raisin liquor. Stir the mixture thoroughly, and strain it off into a 4 ½ gallon cask.

Slight fermentation may go on for some days, and the cask should be bunged lightly to let the gas escape; better still, bore a hole in the bung and fill it loosely with cotton wool. Keep the cask full, and do not allow it to get chilled. The wine should be ready to bottle in a couple of months. If the raisin liquor should show no sign of fermentation after 5 or 6 days, 2 or 3 oz. of brewer's yeast may be added; but this should be unnecessary if it has not been allowed to get too cold.

**ELDER FLOWER WATER.** To make this water, take 8 oz. of elder flower blossom and 1 pint of raw alcohol. The flower blossoms are steeped in the alcohol for 10 days, and the liquid is strained through filter or blotting-paper. A few drops of simple tincture of benzoin is then added. The mixture is placed in small bottles with airtight stoppers. Elder flower water is soothing and whitening when applied to the skin. It can be added to the washing water.

**ELECAMPANE:** In Medicine. The drug is obtained from the root of *Inula helenium*, a bog plant, and is used for many medicinal purposes. It is found useful in dropsy; it acts as a tonic and stimulant, and it may also be used as an expectorant and as an emmenagogue. Externally it has been found helpful in scaly skin diseases. The dose is 20 grains to 1 dram.

**ELECTOR.** An elector is one, whether man or woman, who is entitled to vote at elections for members of Parliament and for town councils, county councils and other local authorities. To become an elector one's name must be placed upon the electoral roll, which is drawn up every year. The ordinary qualifications are residence or the occupation of business premises for

three months, and the attainment of 21 years. Those who are in doubt about their position should apply to the town clerk if they live in a borough, or, if not, to the clerk of the county council. *See* Vote.

**ELECTRICITY:** In Medicine. Treatment by electricity may be employed in various kinds of disease. The best-known forms used are those of galvanism and faradism. The former is constant current electricity; the latter is an induced current of an alternating nature. A high frequency current is one which reverses the direction of its flow so rapidly that there may be as many as two million alternations per second. Diathermy, which is a heat-producing agent, is carried out by an intense current of this description.

The galvanic current is used in ionisation for treating neurasthenia and other constitutional diseases; to stimulate paralysed muscles; for nerve and muscle testing; in electrolysis for the removal of birthmarks and superfluous hairs. The faradic current is of value in the regeneration of wasted muscles; in obesity, this form of electricity being used in the Bergonié method; and in certain gynaecological conditions.

High frequency is especially valuable in conditions of pain and congestion, and in treating skin lesions such as boils and ulcers. Diathermy is used to destroy piles and various kinds of tumours; to increase metabolism: to relieve neuritis; in pneumonia, and for other purposes. Diathermy is much superior to poultices and similar hot applications, because the heat is produced in the tissues themselves.

The application of electricity to the diagnosis and treatment of disease can only be carried out properly by a doctor or under his immediate supervision; much of the work is done by specialists.

Indirectly, electricity is used in medicine to operate the electro-magnet, used for removing metallic foreign bodies from the eye; burrs, used in operations on bone and on the teeth; and vibratory machines for massage. Instruments on the principle of the telephone are used as aids to the deaf. Electric lamps are used for radiant heat baths, and electric currents, with suitable apparatus, are necessary for the production of artificial sunlight and of X-rays. *See* Electrolysis.

## **ELECTRICITY IN THE MODERN HOME**

### **Devices which Lighten Labour and Increase Comfort**

This article describes the wiring and fittings desirable for an up-to-date house, and explains how to make the best use of electrical equipment. *See* also Bells; Cooker; Fire; Fuse; Kitchen, etc.

In a house that is connected to a public electric supply main the possible applications of electricity for lighting, heating, cooking and the driving of small machines are almost endless. If the wiring of a house is carried out in accordance with the recognized rules (and it is the business of the supply undertaking to see that this has been done before the installation is connected to its system), the chance of any accident is

negligible. A wire cannot cause a fire unless its temperature has been raised to a red heat or more; but while heat is developed in any conductor through which a current of electricity passes, wires such as are used in the electrical installations of houses do not become appreciably heated unless the current passed through them is a great deal larger than that which they are intended to carry.

**Safeguards Against Fire.** The circuits are always provided with fuses, which are in effect weak places that, in the event of the current becoming excessive through some accident, give way at points so arranged that no harm can be done. These fuses consist of short lengths of metal which melt at comparatively low temperatures, so that if the current in the circuit becomes too great, they are heated and melt before the rest of the circuit becomes unduly hot. In so doing they break the circuit and cut off the current, which cannot be restored until a new fuse is put in.

A small supply of proper fuse wire should always be on hand for emergencies. This can be purchased from most electricians, and should be of the same thickness as before. For any ordinary house lighting circuit it should not be larger than that known as 5-amp. wire. The use of too large fuse wire may be an infringement of the wiring rules approved by the fire insurance company. Full directions for replacing a burnt out fuse are given in the article Fuse. If after replacement the new fuse should melt also, then some definite reason should be looked for and the fault removed. This is a job for a practical electrician. It may be that the lights and small appliances on the circuit take a total of more than 5 amperes, when, in emergency, the fuse might be strengthened to two strands of wire—not more. The main double pole switch should be open while any such repair is in progress, so that no current can pass.

**Mains and Meter.** In the case of a public supply, the main wire, or service cable as it is properly called, will be brought into the house, and terminate in the basement or other convenient location on the ground floor. The company will also fix two safety devices known as fuse-boxes, and, when the installation is complete, will test the whole system. If all is correct, they will fit the fuse wires and close and seal the fuse-boxes. Both the meter and the fuses remain the property of the company and must not be interfered with.

From these fuse-boxes the current is taken to a meter, to indicate the amount of current consumed, and from this point to a double pole switch, so that the current can be entirely disconnected from the house at will. The current is taken to various fittings known as distribution boards, and thence by thinner cables to the various lamp points and other fittings. This system is known as the wiring system, and it is the part of the work carried out by the electrician or contractor employed by the house owner.

The source of supply settles the nature of the electric current (i.e. direct current or alternating), and the voltage of the system. The voltage for lamps and

fittings must correspond with that of the system. Thus a lamp that is made for a 220-volt circuit can only be used on that voltage; if the voltage is less, the lamp will only glow dull red, and if a higher voltage is used the filament will burn out and the lamp be destroyed. The quantity of current depends on the number and type of lamps used in the house, and this determines the size of the wires and the nature of the safety devices or fuses.

**Measurement of Electricity.** The pressure of the electricity is called voltage, measured in volts; the quantity is the current, measured in amperes (amps.); and the power is measured in watts, this being ascertained by multiplying the volts and the amps. Thus a pressure of 200 volts and a quantity of 5 amps, is known as 1,000 watts. 1,000 watts equal 1 kilowatt (kw.). The basis of payment is the Board of Trade "unit" or kilowatt hour (kw.h.), which is equal to the power taken in kw. multiplied by the time of use. Thus a 1-kw. fire used for one hour or a 2-kw. fire used for half an hour consumes one unit.

*Electricity. The dial of an electricity meter showing positions of the dial hands. The correct reading should be 9475.*

In reading the dials of an electricity meter, start with the right-hand side, putting down the figures in order of units, tens, hundreds, thousands. The dial hand should always be read as indicating the figure it has last passed and not the one to which it may be nearest. Thus, if a dial hand is very close to a figure, whether it has passed that figure or not must be determined from the preceding or lower dial. If the dial hand of the lower dial has just completed a revolution, the dial hand of the higher dial has passed the figure, but if the dial hand of the lower dial has not completed a revolution the dial hand of the higher dial has not reached the figure, even though it may appear to have done so. When one dial hand is on 9, especial care must be taken that the dial hand of the next higher dial is not read too high, as it will appear to have reached the next number, but it will not have really done so until the dial hand at 9 has come to 0. The dial hands on adjacent dials revolve in opposite directions; therefore, a reading should always be checked after being written down, as it is easy to mistake the direction of rotation of the hands.

The small size dial, marked 1/10 kw.h., and sometimes coloured red, is usually for convenience in

testing the meters, and in reading the meter consumers need not regard anything below the dial divided into units or kw.h.

**Wiring Specification.** The following specification of wiring suitable for medium size rooms is issued by the Electrical Development Association, 2, Savoy Hill, London, W.C.2.

**FRONT ENTRANCE.**—One lighting point at front entrance; switch in suitable position in hall.

**HALL.**—One ceiling lighting point. In large or long halls, additional ceiling or wall points as required. Two two-way switches fixed in convenient positions. One large plug and switch in a convenient position for fire and vacuum cleaner.

**DINING ROOM.**—One ceiling lighting point over centre of table; one switch in room near entrance. Wall points as required. Additional switches to be installed to control wall lights. One small plug fixed near sideboard for toaster, warming plate, percolator, etc. One large plug and switch at side of fireplace.

**DRAWING ROOM OR LOUNGE.**—One ceiling lighting point in centre of room; switch near entrance. Two small plugs fixed near window or fireplace or in other convenient position. One large plug and switch

on skirting at side of fireplace or window.

**KITCHEN AND SCULLERY.**—One ceiling lighting point. Additional ceiling or wall points may be installed in ceiling or on wall over cooker, or sink. One switch to control ceiling light. One small earthing plug fixed between 3 ft. and 4 ft. from floor in suitable position for use of iron, etc.; two large earthing plugs and switches for fire, water heater or wash boiler. Special wiring with cooker and kettle control board if not provided by supply authority.

**LARDER, BACKDOOR, AND OUTHouses.**—Lights to be installed as required. One switch to be fixed in most convenient position for each light.

**GARAGE.**—One ceiling lighting point; one outside light over garage door if desired. One switch inside door to control inside light; one waterproof earthed switch to control outside light to be fixed outside. One small earthing plug for convenient connexion of hand-lamp, engine heater, etc.

**NOTE.**—In the kitchen, scullery, larder, garage and wherever there is a concrete, stone, tiled or composition floor, lampholders are to be made of insulating material and switches are to be earthed or made of insulating material.

**LANDING.**—One ceiling lighting point to be fixed so as to illuminate landing and top of stairs. Two two-way switches to be fixed, one on the landing and the other near the hall light switch on ground floor. One small plug for convenient connexion of vacuum cleaner.

**BEDROOMS.**—One ceiling lighting point. Wall points for bracket lights to be installed if desired. Two two-way switches to control ceiling light, one fixed at the door and the other near the bed. An additional switch to be installed to control wall bracket points. One small plug to be fixed preferably 3 ft. from the floor near the bed for table lamp, kettle, etc. One large plug and switch to be fixed on skirting in a convenient position for fire.

**BATHROOM.**—One ceiling lighting point preferably over basin; wall bracket over shaving mirror. One switch to control ceiling light. Lampholders to be made of insulating material. Switches to be earthed or made of insulating material. All appliances such as towel rail, water heater and fire, to be permanently fixed and all exposed metal connected with earth. Portable electric appliances, such as a fire, should not be taken into the bathroom.

**WATER CLOSETS, ATTICS, LOFT, CUPBOARDS.**—Ceiling or wall lighting points as required. One switch for each light. It is recommended that lights should be installed in all places such as cupboards under stairs, etc., which are not properly illuminated by general lighting.

The above specification is based on the assumption that electricity will be available under a "Two-part" or "All-in" tariff at the same price for lighting as for heating. If this tariff is adopted the wiring is much simplified. In arranging for an installation it should be specified that the work and materials should

be in accordance with the rules and regulations of the supply company concerned, the fire insurance companies, and the Institution of Electrical Engineers. This is specially important when a house is being erected under a contract.

**Wall Plugs and Sockets.** One of the great advantages of electricity in the house is its cleanliness, and another is its flexibility. With a few yards of flexible wire a portable electric lamp can be placed exactly where it is most comfortable to read by, and similarly small electric appliances, such as irons and toasters, can be used in the position that is most convenient. The flex has attached to one end a bayonet catch adapter which can be inserted in the lampholder of any fixed electric lamp. The bulb, however, must previously have been removed, and this means that the fixed lamp and the portable lamp or appliance cannot be used simultaneously. This difficulty can be got over by using a special form of adapter, one end of which is inserted in the fixed lamp holder, while the other has two branches, one to take a lamp and the other to take the adapter attached to the flex of the appliance.

*Electricity. Above, switch plug; right, interlocking switch-controlled connecting plug.*

A better plan, however, is to have sockets and plugs placed on the walls of the rooms. The adapter at the end of the flex then takes a somewhat different form, consisting of a plug with two prongs or pins which go into two holes in the socket and establish the circuit. Preferably, the wall sockets should each be provided with a switch, so that the current can be switched off when the appliance is finished with and before the plug is withdrawn from the socket. A good type of switch plug incorporates an interlocking device, so that the plug cannot be withdrawn from the socket unless the current is first switched off.

The merits of the various types of electric light fittings are discussed in a subsequent article, and the larger cooking appliances are dealt with under the heading Cooker. Apart from these and the various heating appliances, described later, there are the many accessories for the home which add to comfort or lighten labour.

Most electric appliances, such as a toaster, coffee percolator, table warming plate, or flat iron can be safely connected to the ordinary lighting circuit. This applies also to the vacuum cleaner or the motor

for working a sewing machine, but not to the larger appliances. The lighting circuit is not usually designed to carry the heavy currents that are required by large appliances, and if it is asked to do so the result will be blowing of the fuses. If electrical heating, or cooking appliances are to be used on any considerable scale, it is essential to have a separate circuit. This need not involve an extra meter, as most supply undertakings have a system by which a fixed standing charge is made, and all units consumed are charged for at a flat rate, whether used for lighting, heating, or for small mechanical appliances. In the electric fires used for warming rooms, and also in such appliances as toasters and grills, the heating elements are exposed to view. In electric kettles and saucepans the heating elements are concealed in the walls or in a double bottom, and are liable to be burnt out and destroyed if the current is turned on when the vessel does not contain any liquid. Similarly in an electric boiling plate they are arranged inside so as to heat the iron plate, which in turn heats a utensil placed upon it. Electric ovens are made on much the same plan. Immersion heaters are another form of electric heater which can be used for liquids, and are small portable heating elements which are placed in the liquid to be heated. The advantages of electricity as an illuminant are many and well known. For warming rooms it is rapidly coming more into use, and the all-electric house, where the essential services of lighting, heating, cooking, etc., are performed by the aid of electricity, is a feature of some modern housing schemes.

*Electric Heating. Fig. 1. Period heater in Adam style, finished in black, copper or bronze. (Courtesy of Belling & Co.)*

*Fig. 2. Standard element or firebar used in the electric heater shown above and in similar apparatus.*

The power that is required for lighting a moderate-sized house can be estimated roughly by taking the number of bedrooms and reception-rooms, multiplying it by three to get the approximate number of lights in the whole house, and then allowing an average of 30 watts per light. It is assumed that in all cases gas-filled lamps are used and the walls are light in colour and the ceiling white.

**Electric Heating.** By far the majority of electric heaters used to-day are of the open wire element type. The element which provides the heat consists of some

variety of porcelain, fireclay, asbestos or mica bar, on which open coils of resistance wire are wound. These coils end in terminals which are wired up to the switches of the heater, and when the current is turned on the coils glow to incandescence and thus project heat out into the room.

Fig 1 shows a period stove, designed to heat a room 18 ft. by 16 ft. It takes 3, 2 or 1 unit per hour, according to the switching. A smaller size to heat a room about 16 ft. by 14 ft. by 9 ft. high, consumes at the maximum 2 units per hour, but can be reduced by the switch to half power, when it will take 1 unit per hour. It is generally arranged, in fires of this type, to leave one of the elements permanently connected across the main supply. Thus the plug must be removed from the wall socket, or the wall plug switched off, entirely to switch off the fire, preventing any possibility of a live flexible lead being left lying about the floor, where it might be a source of danger.

Fig. 2 shows the standard element or firebar employed in this make of stove. The face of the bar consists of a number of wells of parabolic shape, in which the heat generating wire is seated in correct focus. The heat rays projected on to the bar from the glowing wire at its focus are thrown out in parallel horizontal beams, and thus the maximum amount of radiant heat is projected. Fig. 3 shows a back view of a fire with the cover removed. The switch used on this type is designed to be operated by means of the foot.

*Electric Heating. Fig. 3. Back view of electric fire of the type illustrated above, showing the heating elements, wire connexions and foot switch. (Courtesy of Belling & Co.)*

With electric fires there is freedom from draughts. An existing coal grate need not be displaced, as a portable electric fire may be stood on the hearth in front of it. Fig. 4 shows a fireplace specially designed for electric heating. The fire is shown in process of fixing. This type may be placed flat against a wall. Fig. 5 illustrates an imitation coal fire, in this case one of the Efesca type. In the "Tri-city" fire, shown at Fig. 6,

there is a series of metal reflectors.

*Electric Heating. Fig. 4. Bell self-contained fireplace, showing how fire is fixed.*

*Fig. 6. Tricity sunray radiator.*

*Left. Fig. 5. Efesca electric fireplace.*

A figure that is given to decide upon the size of electric fire required to heat a given room is 1,000 watts, or 1 unit per hour per 1,000 cubic ft of space to be heated. Thus in an ordinary room, say, 10 ft. high by 14 ft. by 14 ft. (i.e. cubic capacity 1,960 cubic ft.), a 2,000 watt (2 kw.) fire, consuming at maximum 2 units per hour would be a suitable size.

*Electric Heating. Fig. 7. Horizontal air warmer for a small room. (Courtesy of Belling & Co.)*

*Fig. 8. Electric convection heater controlled by a thermostat. (Courtesy of Belling & Co.)*

Other methods of warming by electricity include various forms of convection heaters (popularly termed "radiators") and also systems where the heat is mainly dissipated by actual radiation from the surface of the element, which is non-luminous. An example of the convection heater is the air warmer shown in Fig. 7. It is designed to heat rooms 12 ft. by 10 ft. by 9 ft. high, and con-

sumes 1 unit per hour. The dimensions are 8 in. by 18 in. by 4 in. high. Other convection heaters have a three-heat switch and a thermostat can be fitted if required. In the hall it will prevent draughts and circulate warm air upstairs (Fig. 8). There are also hot water radiators, in which the water is warmed by an electric immersion heater fitted in the lower part of the casing. The convection heaters described are especially useful for warming halls or passages.

A system well worthy of attention is that known as "Unity" tubular electric heating. It works by low temperature radiation, the whole surface of the tube being active. The heating coil is laced on a mica frame and encased in a steel tube 2 in. in diameter. The tube is supported on brackets, the number and length of the units being proportioned to the size of the room to be warmed. There is a rapid rise of temperature when the current is switched on, and full heat is available in a few minutes. The temperature may be automatically controlled by a thermostat. This system is illustrated at Fig. 9.

Fig. 9. "Unity" Tubular System installed in a nursery school. Heating tubes are attached by brackets to the skirting boards and the system operates by low temperature radiation.

(Courtesy of Young, Osmond & Young, Ltd.)

In a system known as Dulrae panel warming self-contained electric heating elements are disposed in the ceilings of the room, and the apartment is warmed by direct radiation from the heated ceiling areas. This system can be readily installed when a house is in course of erection, and may also be applied to existing buildings. An automatic device regulates the heat, and this may be set to just the temperature needed to keep the room and its contents well aired (e.g. when the house is left unoccupied).

**Safety Precautions.** Always turn off all switches, where provided, on the device first, then switch off at the wall socket. To disconnect, take hold of the plug; do not pull the flexible cord or get it into a tangle. Frayed, knotted, or otherwise damaged flexible cords, broken connectors, plugs and switches, should not be used until properly repaired or renewed. Appliances, of a loading exceeding 700 watts should not be used from lampholders.

#### ELECTRIC LIGHT: FITTINGS FOR THE HOME

##### Suggestions to Suit the Several Styles of Room

The reader is referred to the preceding article on Electricity; and also to Candleshade; Lamphshade;

Standard Lamp. Bedroom; Hall; Staircase may be further consulted.

The effective possibilities of room lighting have assumed an important place in schemes for interior decoration since electricity has been within the reach of so many people and is likely to become still more accessible. Even where any public supply of current is unavailable it is not a matter of great expense or difficulty for a house in the remotest country district to have electric lighting by means of its own generating plant, as for this sole purpose a much smaller plant is sufficient than would be required for heating.

Electric Light. Fig. 1. Strip lights in tubes. Fig. 2. Shade of translucent glass. Fig. 3. Stalactite corner lighting. Fig. 4. Central fitting in opaque glass.

Fig. 5. Combined lamp standard and heater, well guarded

When planning the lighting for a room the practical side will, of course, not be overlooked for the sake of the decorative. The two necessary considerations on the first side are the adequate placing and strength of lights for their requisite purposes in the

particular room and the economy achieved by choice of the correct type of fittings. It is a much better scheme, for instance, to have wall plugs conveniently placed for extra lamps than to depend on one central fitting for all purposes, which must either be too dazzling for the eyes or quite ineffectual for concentrated light on reading or work. It is not economy to strain the eyesight or to produce irritation by a glare when it is unnecessary.

Several new forms of gas filled lamps have been introduced which overcome the tendency to a glaring light when used with the type of pendant or wall bracket which discloses the bulb. At the same time these do not in any way interfere with lighting efficiency. The most commonly known are the 'opal' and 'pearl.' The bulb of the former has an inner clear glass and an outer one of thin opalescent glass, while the latter bulb is frosted on the inside.

**Modern Ideas on Lighting.** The modern lighting expert not only brings out the good features of a room, but also creates fresh beauty by his artistic methods and designs. Wall niches covered with gold or silver leaf or metallic paint and a framing of mirror glass, metal or contrasted moulding, are rendered even more effective by night than by day with a concealed light placed above and below to show off the china or other ornament in the niche. Other niches or small wall cupboards have glass panes in the doors, which are in themselves fine pieces of decoration, being tinted, engraved, semi-transparent with sand-blasted designs, or beautiful with metal work in wrought iron or bronze. The light, white or coloured, shines through these glazed doors with a glowing effect. Other decorative ideas for corner lighting are glass statuettes and flower bowls placed on stands which are lit from inside, the light shining through a top of frosted glass which illuminates the glass object on the stand. Moulded glass panels are also set into walls to give diffused lighting when lit from behind.

Strip lighting is effective for recesses, or cupboards, but is apt to be too expensive for the concealed lighting of a whole room, although it has recently become much cheaper. Strip lights set in tubes of frosted glass are, however, a feature of modern lighting and are very practical either as wall fixtures arranged vertically with metal plates and bands as shown in Fig. 1, or set in a single tube horizontally for illuminating mirrors. An illustration of a fitting of this kind can be found in the article on dressing table attached above the mirror in the design for constructing a pedestal table.

While modern wall and ceiling fixtures tend to severity of style, beautiful effects are obtained by means of good outline and by the faint stripings and diffused lighting which glows from the translucent or opaque glass used by the designers. Such fittings as those illustrated in Figs. 2, 3, 4 are obviously suited to the modern type of room and would look out of place in a room furnished in a period style. Fig. 2 would be a charmingly decorative wall fixture for a drawing room, while Fig. 3 would be equally appropriate for a dining room, hall, staircase, or lounge fitting and would

decorate a corner in the practical fashion of to-day when things beautiful are also required to be useful. Other charming wall brackets for sitting rooms have oxidised silver or gilt mountings with either rimped or tinted glass.

For a sitting room there is still a general liking for a central fitting using two or three 60-watt lamps, especially where a room is of good size. This fitting is usually supplemented by table and floor standard lamps and by wall fixtures where these are necessary. Fig. 4 illustrates a plain ceiling fitting of effective and beautiful outline for dining room or living-room with appropriately severe style of furnishing. Pendants are also made of imitation vellum in squared or oblong tiered designs with coloured tassels of woollen beads and silk on the corners of the lowest tier. These pendants have a somewhat Chinese character, which renders them particularly suitable for a room with pieces of lacquer furniture. A modern lantern form of ceiling fitting for a hall is designed for tubular lamps with an outer framework of oxidised metal alternating with strips lacquered in a brilliant red or green.

**Colour in Lighting.** Colour is of importance in lighting as it is often possible to improve the aspect of a room by this means. Warm tints should be chosen, whether for the colour of lamps behind translucent glass or for shades. Bleak lighting, white or bluish, for general effects should be avoided, though for local lights or for reading and working lamps, it may be essential. The suitable colours for shades are pink, and tones from cream to orange, because these are related to the actual colour of the light itself. They are not only becoming, but also impart a cosy look to the sitting room, an inviting one to the entrance hall, and an appetising one to the food in the dining room—all important points in the well-run home.

**Lighting the Kitchen.** Kitchen lighting is of still greater importance from the practical point of view. A good kitchen central light is a 100-watt lamp enclosed in a bowl of opal glass fixed close to the ceiling. A light should also be placed over the stove, while one in the larder and in the kitchen cupboard saves much time and trouble.

Bathroom lighting also is satisfactory with a diffusing central opal globe enclosing a 60-watt lamp. A small fixture is useful over the bathroom mirror with a 25-watt lamp. Should the mirror be used to shave by, the light may be fixed underneath so that it shines upward on the chin.

**Period Fittings.** While it is obviously absurd to talk of Tudor or Queen Anne electric fittings, the lighting fixtures have to be brought into decorative harmony with such period styles in furnishing, as expensive forms of concealed lighting are impracticable for most people. In a bedroom the most important lighting fixture, besides that for the dressing table, is a good reading lamp or bed-head light. For a country

bedroom wooden wall brackets in oak are designed to hold candle lamps which are in keeping with old-world furniture.

*Electric Light. Fig. 6. Wall brackets and central fitting for a lofty room. (Courtesy of Waring & Gillow)*

*Fig. 7. Lantern fitting in wrought iron suitable for a hall or staircase. (Courtesy of General Electric Co.)*

The simple central fitting in tinted glass illustrated in Fig. 5 is suitable for a dining room or sitting room, and is pleasing whether used with modern or 18th century style of

furnishing. In a dining room such a fitting can be hung rather low over the table. The lofty and good sized panelled room of Georgian style is suitably lighted by gracefully shaped wall brackets and a ceiling fitting as shown in Fig. 6. For a lower room the central fitting is often dispensed with, the wall lighting being supplemented by standard lamps in equally harmonious designs.

Lantern fittings in wrought iron look particularly well for panelled halls and staircases or for rooms with oak-beamed ceilings. The one illustrated in Fig. 7 is a good example, and such lanterns may be either suspended on chains or hung from wall brackets made of the same metal. The latter plan is suitable for rooms or staircases with low ceilings.

In a hall a bracket light is convenient over the mirror; a 60-watt lamp will suffice for the ceiling fixture, and a 40-watt for the bracket, and also for a landing or staircase wall light in a small house.

## ELECTRIC MOTOR: ITS CARE AND USE

### With Instructions on Building a Model Motor

In the first part of this article we give hints on the care of fractional horse-power motors. The second describes a model motor which the amateur can build. See Boat

Small motors—fractional horse-power motors, as they are termed—are used for many domestic appliances, and the handicraftsman can employ a suitable type to run his lathe or other small machinery.

As a rule, the household appliances—vacuum cleaner, washing machine, refrigerator, etc.—are covered by the maker's guarantee, and the motor or machinery should not be interfered with. It may be an

advantage, however, for the handy man to know how to deal with minor defects on other small motors.

The electric motor working under industrial conditions is a prime mover giving the greatest service with the minimum of attention. The essentials are to keep the oil reservoirs for the bearings properly cleaned and filled with good oil; to see that the lubricating rings are travelling or carrying oil to the shaft; to keep the brush gear, commutator and windings free from dust, dirt and oil; to make sure that the commutator is clean, and that the brushes are properly bedded to the curvature of its circumference.

To clean an oil lubricated bearing, first remove the drain plug, where this is provided, or the overflow pipe when it is not, and draw off the old oil. Replace the plug and fill the reservoir with paraffin until it reaches the top of the overflow pipe. After a while this can be drained away again. After refitting the plug fill the reservoir with fresh oil, and replace all oil-hole caps.

A motor fitted with ball bearings need not usually be disturbed more often than once every twelve months. The wisest plan is to get an electrical engineer to repack the ball race with grease, since the bearings require properly fitting and adjusting.

Oil must be wiped away from brush gear, commutator and windings, and all dust and dirt either blown out with a bellows or otherwise removed. Oil, unless removed, may penetrate the insulation of electrical machinery and prepare it to receive the dust and dirt which so often leads to a breakdown.

A careful inspection of the commutator should be made before this part is touched. If it is of a coppery colour its condition is healthy, and no more should be done than just wipe it with a clean rag. Otherwise, the surface can be polished with fine carborundum cloth wrapped round a piece of wood and held against it while the armature is revolved. Care must be exercised with a commutator that is ventilated or has undercut micas, to ensure that copper dust does not fall between the segments and set up short circuits. A commutator of the latter type should have periodical attention by an electrical engineer.

To bed carbon brushes properly to the commutator surface a strip of carborundum cloth should be inserted between the brush and the commutator (with the cutting face towards the brush) and carefully drawn backwards and forwards until the whole of the carbon face has been shaped.

**Electric Motor for Toys.** The small electric motors that are nowadays used on toys usually work on both alternating and direct current. Some small motors are constructed with a permanent magnet instead of a field winding, as, for example, the smaller boat motor shown in page 196. These will only work from dry batteries, such as the Ever Ready No. 126, or a special light-weight accumulator.

The construction of a small motor suitable for driving a toy boat or for any other small-power purpose is not difficult, as all the parts can be pur-

chased in the rough. Figs. 1-6 show a practical type of motor with horizontal field magnets; the winding is at the back, and the whole is low and compact, and adapted for almost any kind of mechanical toy. Castings may be obtained from Whitney's, 129, City Road, London, E.C.I.

Electric Motor for Toys. Figs. 1-6. Plan and diagrams of a small electric motor suitable for driving a model boat

*Electric Motor for Toys. Figs. 1-6. Plan and diagrams of a small electric motor suitable for driving a model boat.*

The field magnet tunnel should be bored in a lathe, but if this cannot be done it must be carefully cleaned up to shape with a half-round file. Then the various holes are drilled and tapped as shown on the drawings, and the

field windings put on. Each layer must have just the same number of turns of No. 22 D.C.C. wire, and is

insulated with a thin slip of waxed paper, and the wire coiled evenly. For the motor in question 36 feet of wire will be needed. Before winding, the cone and side cheeks should receive a covering of several thicknesses of waxed paper. The armature casting is drilled and fitted to the shaft, and the arma-ture poles trimmed up if required so that they just clear the poles of the field magnets. The casting is secured to the shaft by a grub screw, a hole being drilled for this through one section.

The armature windings are No. 24 D.C.C. Each slot holds two layers with six turns each, and 13 ft. of wire will be needed. The wire should be given a coat of shellac varnish. All turns of the wires are made around the armature cores in the same direction. Each winding starts on one side of the cores and terminates on the other. The starting end of the first coil is attached to the commutator segment two places away from the pole piece, and the finishing end, twisted up with the starting end of the second coil, goes to the next adjacent segment of the commutator, and so on. The finish of the last coil is joined to the same segment as the beginning of the first coil. The slots in the commutator are set exactly opposite the centre of the pole pieces. The latter should be insulated with cotton tape.

The back bearing (Fig. 4) is attached to the main casting underneath by two screws. Fix it temporarily and mark the position of the hole for the armature shaft. The hole for the shaft should not go right through. A small oil hole is made on top and countersunk a little way with a larger drill. Two holes are drilled in the frame and tapped for the screws. The bearing should be positioned so as to bring the armature in line with the field magnet poles, and the armature must of course turn quite easily and just clear the poles.

The brushes (Fig. 6) are made from narrow strips of copper gauze rolled up to fit inside the brush holders, and are held against the commutator by coil springs made from steel wire. A hole is drilled through the top of the frame and tapped to take a brass screw which retains the brush holder in place and allows it to be adjusted. A hole for each brush holder is drilled through the face of the frame, large enough to take a fibre insulating bush, through which the holder passes. The brush holders may be made from brass tube, a nut being soldered on to the outer edge for the terminal.

The front bearing of the armature shaft is a boss on the bridge piece (Fig. 5), the latter being attached by two screws as shown. The boss is drilled through and an oil hole formed on top. Holes are needed also for the two terminals. The latter require each a fibre bush. A hole is drilled through each of the fixing lugs, to fasten the motor to its bed.

The Commutator. The commutator has six segments. It is formed from brass tubing, driven on to a piece of fibre rod. The position of the segments being marked out, pins are driven into the fibre through holes drilled in each segment, and the segments are

parted by making slots with a hacksaw. Take the slots clean through the brass ferrule and well into the fibre. The pins prevent the segments from coming away from the fibre. A hole is drilled through the axis of the fibre, and the commutator is driven on to the armature shaft, to which it must fit tightly. The armature will find its own running position in relation to the field, and the shaft is then positioned correctly in the bearings by slipping a short piece of brass tube on the shaft between commutator and front bearing. This forms a washer, and its length must be such as to afford sufficient play between front and back bearing. The latter forms a stop for the back end of the shaft.

The wires from the field coil go one to the lower brush shown in Fig. 2, and the other to the lower (nearest) terminal. The other brush and terminal are connected together by a short piece of wire. The accumulator positive is joined up to the upper terminal and the accumulator negative to the lower terminal. The appearance of the finished motor may be seen from the illustration in the article on Boat, where also a suitable propeller, coupling, and shaft are shown. A 4- to 6-volt accumulator will energise the motor, and if it is desired to use it in a model boat a special lightweight low built type of accumulator can be employed. Should this or any similar motor not work, the whole of the connexions should be examined; if they are in order the windings should be tested for continuity, and it should be ascertained if there is a leak to the frame of the motor. The commutator segments should be examined, as it is possible that a short circuit is occurring between one segment and another. If the motor still refuses to work, then the adjustment of the brushes will have to be tried.

**ELECTRIC SHOCK.** A severe electric shock causes a person to cry out, and he may fall to the ground and stop breathing. If he remains in contact with a live wire the current should be turned off. If this cannot be done at once, his connexion with the wire should be broken; but proper precautions must be taken in doing so. The rescuer should stand on a pile of dry clothing, if a dry rubber mat is not available, and his hands should be covered with rubber gloves, tobacco pouches or dry woollen clothing. A dry stick, if at hand, may be used to push the wire off the body. It will be noted that emphasis is laid on everything used in connexion with the rescue being dry, as moisture conducts electricity readily.

If the patient has stopped breathing, artificial respiration (q.v.) should be carried out. Smelling salts may be held to the nose, or if the patient can swallow he may be given diluted spirits of sal-volatile. He should be kept as warm as possible.

**ELECTRODE.** In a primary cell electrodes are the plates or elements. The electrode most vigorously attacked by the electrolyte is known as the anode, and the other plate as the cathode. The poles or terminals of an electric battery are known as electrodes also. *See* Battery.

**ELECTROLYSIS.** The operation of breaking up chemical compounds by passing an electric current through them is termed electrolysis, and when skilfully performed it is effective in removing superfluous hairs, birthmarks, moles, and for other purposes. Living tissues are killed by electrolysis, the area of destruction varying with the strength of the current and the length of time for which it is used. A caustic effect is produced, but there should be no scar if electrolysis is performed by a skilled operator. As this method for destroying superfluous hair requires so much time and patience it has to some extent been superseded by diathermy. Electrolysis is applicable to scattered hairs; comparatively few can be removed at one sitting, while by diathermy as many as 200 can be depilated by a skilled operator. When used to destroy naevi (birthmarks) a general anaesthetic is usually necessary, especially in the case of children undergoing the operation. Electrolysis is sometimes effective for the cure of aneurism and hydatid cysts. *See* Depilatory; Hair.

**ELECTRO-MAGNET.** The combination of a coil of wire and an iron core is known as an electro-magnet, the wire as conductor carrying an electric current round the iron bar in the centre. It has a common application in the electric bell. *See* Bell; Relay.

**ELECTRO-PLATE.** The wisest thing when purchasing electro-plated table forks and spoons is to go to one of the leading firms of silversmiths or general stores and to pay the price for a quality that can be recommended by the retail dealer. Even if the best qualities which are marked A.I., E.P.N.S., are not within the reach of the purse of the prospective purchaser, there are other qualities, known in the trade as B and C. which are reliable, provided they have the recommendation and guarantee of an old-established retailer. The patterns of table forks and spoons that are most popular are those which are simplest in design, such as the old English and fiddle patterns.

It is best to wash plated ware in hot water to which a few drops of ammonia have been added with enough shredded soap or soap powder to make a good lather. The electro-ware should be thoroughly washed in this water, a soft mop or piece of flannel being used. It should then be rinsed in very hot, clear water, and immediately dried in a dry, soft towel. After drying, rub with chamois-leather.

#### **ELECTRO-PLATING FOR THE AMATEUR** **How to Coat Small Articles with Silver or Nickel**

This article describes the process of electro-deposition and explains how to make solutions for copper, nickel and silver plating. The work also contains entries on a number of articles to which the process can be applied, e.g. Bowl; Crumb Scoop.

The process of electrically depositing one metal upon

another is known as electro-plating. The home-worker can do a great deal with an inexpensive outfit, provided only small articles have to be plated, and the first thing is to clean them.

The amateur is counselled to treat all articles of brass or copper as follows. First clean and polish with fine emery-paper, or on a buff in the usual way, then attach a fine wire to the object and immerse it in a solution of potash. The solution is composed of 2 oz. of caustic potash to 1½ pints of water. This must be brought to boiling point, and the articles immersed until perfectly clean. Rinse them in clear hot water, and then place them in a potassium cyanide solution, composed of 4 oz. potassium cyanide to 6 pints water.

*The cyanide is an extremely poisonous substance, and the greatest care should be taken in using it. The hands and arms must be kept well away from these solutions, and the fumes must not be inhaled. The articles must be wired so that they need not be touched with the hands.*

The process of electro-deposition is briefly as follows. When an electric current is allowed to flow from one immersed terminal to another through a metallic solution (the electrolyte), and the anode, or terminal at which the current enters the solution, is of the same kind of metal as that in the solution, the metal will be conducted from the anode and deposited on the cathode. This ultimately results in the cathode becoming heavily coated with the metal and the anode being either reduced in size or entirely dispersed. If metal articles to be plated are arranged and connected so as to form the cathode, they will therefore become coated with metal (*see illus.*)

**Batteries and Bath.** Assuming that only small articles are to be dealt with, the following outfit may be suggested. The source of electric current can be a 4-volt accumulator of 40 ampere-hour capacity; or a Bunsen battery or Daniell cells may be used. The bath can be a glazed earthenware jar, deep glass bowl, or a wood vat. Some stout brass or copper rods ⅛ to 3/16 in. diameter, and long enough to span across the mouth of the jar, are needed on which to hang the articles to be plated. These rods are most conveniently provided with binding screws or terminal nuts at one end for easy attachment of the electric conductor or wire. Copper wire of 24 and 16 gauge is needed, the fine wire for wiring small articles and the stout 16 gauge for the larger ones.

The next requirements are the metals and solutions. Iron and steel articles are first coated with copper, and a solution for plating is composed of 4 oz. of copper sulphate dissolved in 12 oz. of distilled water. Add a strong solution of ammonia until no more green crystals are precipitated: add more ammonia solution, until the green crystals are re-dissolved, resulting in an intense blue-coloured solution. Then add slowly a strong solution of potassium cyanide until the solution is clear. Add ¼ as much again of the same potassium solution, and water to make 2 quarts. The anode may

be a perfectly clean piece of copper plate or bar.

**Silver Plating.** For silver the solution may be prepared by dissolving ¾ oz. of silver nitrate in 8 oz. of water, and adding slowly a strong solution of potassium cyanide. Pour off the liquid and wash the white precipitate carefully by putting it in a corked bottle, partly filled with water. Shake it well, stand it aside and allow the precipitate to settle. Pour away the water, refill, shake up and allow to settle as before. This should be done until the precipitate is clean.

After this washing, add a solution of potassium cyanide until the precipitate is entirely dissolved. Then add about ¼ as much again of the same potassium cyanide solution, and make up to 1 quart with water. This kind of plating requires from 2 to 4 volts, and a pure silver anode must be used. Iron, steel, zinc, lead, and pewter should be copper-plated immediately before the silver plating is effected.

A "quicking" solution of 1 oz. of potassium-mercury-cyanide, 1 oz. of potassium cyanide, and 1 quart of water should be prepared. Articles that have been copper plated are first cleaned and pickled, immersed directly into the quicking solution, and left there until the surface is uniformly covered with mercury, when they are rinsed in clean water and placed in the silver-plating bath.

First coating with mercury in this way gives better results than direct deposition on the copper, as the silver adheres much better. Iron and steel articles should be kept moving while being plated. The silver will be deposited in from 20 to 30 min., and if all is correct the article will appear dull or lifeless and nearly white, and must be polished with scratch brushes, rouge, and buffs. A small polishing head is very handy for this work. Gold can be deposited in the same way, using a gold anode and a solution of the double cyanide of gold and potassium in distilled water.

**Nickel Plating.** Nickel plating is similar to copper plating, and a suitable solution for it is composed of nickel ammonium sulphate, 1½ oz.; ammonium sulphate, 1½ oz.; water 1 quart. Hot water will fasten the dissolution of the crystals. An electric current of 2 volts, and density of 5½ amperes per sq. ft. of area of the article to be plated, is required for this solution. Pure nickel is used for the anode.

Electrical connexions are completed directly the objects are placed in the bath of solution; the anode is connected to the carbon of a battery, or the + sign of an accumulator, and the cathode is connected to the zinc of the battery, or to the — sign on an accumulator. Do not allow any article being plated to touch the anode or the sides of the vat, or a short circuit will result. Place the objects into the vat and see they are all clear of each other before switching on the current.

Plate as many objects as possible at one time. Prepare the objects by cleaning, etc., immediately before plating; do not leave them hanging about, or they will get dirty and the result will be failure. See

that all connexions are securely made. Judge the correctness of the work by watching results.

**ELM: The Wood.** The elm is a hardwood with rather limited uses, though excellent for some purposes. The English variety is a dark brown colour with curly and plaited grain, which does not split easily.

Elm is not used for building and very little for furniture, not being durable enough for the first, while its appearance is against it for the second; besides which, it is liable to warp. The bodies of barrows are often of elm, and it is largely used for wheelwright and agricultural purposes. *See Wood.*

**EMBEZZLEMENT.** This is a form of theft by a servant or clerk from his employer. It differs from larceny in this: a servant commits larceny when he takes money or property of his master out of the master's possession with the felonious intent of depriving the master of his property. He commits embezzlement when, having money paid to him for his master, he appropriates it for himself with the intention of not accounting for it as he ought to do.

The punishment for embezzlement is imprisonment up to 2 years with or without hard labour, or penal servitude for not less than 3 and not more than 7 years. The court has also power to deal with a first offence under the First Offenders Act. Besides by clerks and servants, embezzlement may be committed by partners as against their co-partners, and also by one joint owner against another, and by public officers who may not be strictly clerks or servants.

**EMBOLISM.** When some solid body is carried along by the blood stream until the narrowing walls of a blood vessel prevent it from going farther, the result is embolism or stoppage of the blood vessel. If an artery of the heart is blocked death will ensue, and the result will be serious if an important artery of the brain is affected. Pending the doctor's arrival the patient must be kept at rest.

**EMBROCATION or Liniment.** The liquid preparation known as an embrocation or liniment usually contains oil or spirit, to be rubbed in or applied outwardly to the skin in sprains, chronic rheumatism, chronic lumbago, etc. Examples are camphor and ammonia liniment, soap liniment, belladonna liniment, etc. Liniments act mainly as counter-irritants (q.v.). A useful liniment for relieving pain is the following:

Chloral hydrate	1 part
Menthol	1 "
Thymol	1 "
Camphor	3 parts

The following is a stimulating liniment for sprains, chronic stiff joints, etc.:

Oil of turpentine	12 oz.
-------------------	--------

Soft soap	1 ½,,
Camphor	5 "
Water	5 "

For chest complaints in young children camphorated oil is a favourite liniment, but care should be taken lest undue irritation of the skin is set up by too vigorous rubbing.

## EMBROIDERY FOR HOME AND DRESS

### Decorated Needlework Described in Detail

For related information see Applique; Canvas; Gross Stitch; Darning; Drawn Thread; Lace; Tapestry; Woolwork. See also Cushion; Table Cloth; Tea Cosy, etc.

The embroidery of today can be described under two headings. There is first the work which consists of the use of simple decorative stitches combined in modern designs, realistic, imaginative or formal. This work is comparatively easy to do, and some charming and gay effects can be quickly achieved with very little trouble. Then there is the more elaborate work of the fine needlewoman, and all intricate traditional embroidery, which will never lose its popularity.

1. *Butterfly worked in Broderie Anglaise and, below, three stages in making an eyelet.*

**Simple Modern Needlework.** The first class of work makes it more possible for the average woman with little experience and little spare time to produce quickly achieved and attractive work. Some of the simplest stitches are the most charming in effect, and simple designs consisting of straight lines or curves can be most attractive if carefully planned combinations of stitches are used. Some stitches, used in a way that is not obvious, add greatly to the attractiveness of the design. Chevron stitches, for example, massed together to fill in a design, give the delightfully crisp effect of smocking. If a transparent material such as organdie is

used, double backstitch worked on the wrong side, so that the crossed stitches show through, give an exquisite shadowy effect. Rows of buttonhole stitches, each row being worked into the last one, make a very attractive modern filling stitch, and rows of fly stitch making a design of lozenge shapes has also an unusual and pleasing appearance.

After a little practice it becomes easy to discern which stitches should be used for each kind of design, and which stitches should not be used together. The more unusual filling stitches, such as those mentioned above, should not be used, for instance, for formal flower designs. For these, satin stitch, long and short stitches massed together, and other smooth stitches are more suitable, with occasional French knots and lazy daisy stitches where necessary. For the flower group the main stitches used are satin stitches for smaller leaves and petals, and long and short stitches for the larger ones. The round design with the four figures is much more gay and sprightly, and here the main stitch used is double back stitch, worked in rows, giving a very modern crisp effect which would be completely out of place in the more formal flower designs.

Transfers of widely varied embroidery designs are easily obtainable, and the actual stitches and colours to be used in working out the design are usually left to the imagination. Simplicity should be the main rule in choosing these. Too many different styles of stitch make the general effect as unpleasing as a badly conceived colour scheme, but the appeal of the design is usually strong and direct if worked in a few well-chosen stitches and colours.

Simple designs for the corners of table mats and napkins, tray cloths and tea cloths can be easily invented when the possibilities of the various stitches have been grasped. There are many variations and elaborations of these, and some of them can be attractively combined for borders and patterns. Chain stitch, for example, is very easy to elaborate, and a very pretty border can be produced by working French knots, in a second colour, in the angles of a zig-zag chain. Double chain stitch is also very attractive, and is worked by making open triangular chain stitches first to the right and then to the left.

Interlaced buttonhole stitch makes a very firm fancy border, and two colours can be used. The stitches in the first row should be made just wide enough apart for the stitches in the second row (worked from the opposite side) to lie between them. Also the length of the buttonhole stitches can be varied to form a regular pattern, or they can slope in alternate directions, to form crosses. A very pretty stitch is made when herringbone or double back stitch is laced with a different coloured thread. This is called twisted lattice stitch. Simple feather stitch can be elaborated by taking the open stitches twice or three times to each side instead of once.

#### Fine Embroidery, Various Kinds

Of the fine traditional embroidery, embroidery on white materials, embroidery on linen or canvas, embroidered laces and tapestry are among the most

important. Tapestry work is dealt with in a separate article.

For elaborate and fine work of this kind, for work where large expanses of material are to be filled, and also for appliqué work, it is advisable to use a simple embroidery frame. It not only keeps the work flat, but makes it possible, in creative work, to see the whole design in perspective while it is being done —the various colour effects and the relation of one detail of design to another. Also both hands are left free for the actual working of the stitches.

**Embroidery on White Materials.** This class of embroidery includes all openwork such as Madeira work and Broderie Anglaise, and all barred work such as Richelieu and Renaissance embroidery.

Madeira work and Broderie Anglaise need great care and accuracy of workmanship. They consist of round and oval eyelets arranged in a design, varied with solid satin stitches for stems, leaves, petals and circles. The design is transferred to the material and the eyelets are outlined by running stitches, and the running stitches are then whipped. The ovals or circles intended as eyelets are slit with fine scissors down the centre and the larger ones are slit again crosswise. The cut material is very carefully rolled back underneath until it reaches the running thread all the way round, and the outline is then overcast closely and neatly. Very small holes are pierced with a stiletto, not cut. The solid work is first padded with rows of running stitches or crossed stitches in the case of small round or oval spots, and then smoothly satin stitched. The border is usually worked in a simple or elaborate form of buttonhole scalloping. Fine embroidery cotton is usually used for this work, with a softer and thicker thread for padding. For real Madeira work a greenish blue thread is usually used against a white background, and much of the finest Swiss embroidery is worked with a blue-grey thread. Any good material can be used (linen, crêpe-de-chine, lawn or heavy Japanese silk).

Richelieu and Renaissance embroidery is usually worked entirely in buttonhole stitch, which outlines the design and forms bars to hold the pattern together. The bars are made by passing a foundation thread from outline to outline three or more times, and buttonholing over the strands without sewing the material beneath. When all the bars in each section have been made, and the outlines have been buttonholed, the surplus material beneath the bars is cut away from the back. The bars may be worked by overcasting the foundation threads, or a weaving stitch may be used. Ornamentations (picots) may be made on the outside edge of flowers and leaves by making various kinds of knots or spirals of thread drawn round into a circle, or

loops of buttonhole stitch worked on semicircles of thread, and in Richelieu work the connecting bars also may have picots.

*Embroidery. Fig. 2. Renaissance work, an effective form of embroidery for white materials, such as the tablecloth shown here.*

*Fig. 3. Cross-stitch in colour on white linen, suitable for the border of a duchesse cover.*

In Venetian embroidery, the plain linen spaces are afterwards filled in with fancy stitches and fillings. In Danish hedebo work, openwork produced by bars of buttonhole stitching, with picot ornaments, are used where the material is cut away, or the bars are worked in darning stitch and loop stitch, and the pattern in straight stitch, which is satin stitch without padding.

Piqué embroidery is done on a firm background, and the main outlines of the design are filled in with fancy stitches to represent figured materials or damask. The main outlines are chain stitched and overcast, and the interior of the designs are filled in with various embroidery stitches which are intended to represent figured material on damask. Horizontal, vertical or sloping flat stitches are used for these fillings, and the work is done closely, so that very little of the material background shows.

**Embroidery on Coarse Linen.** One of the most popular forms of embroidery on coarsely woven linen is cross stitch work, which can be done wherever the stitches can be easily counted. A specimen is illustrated (Fig. 3), where cross stitch is combined with darning stitch (used for the peacocks' tails and for the flowers on the shrubs). Most of the old samplers were worked in cross stitch, and a surprisingly wide range of designs can be adapted and executed in this useful and very easy stitch. Charts are easily obtainable showing the

position of each stitch on the counted threads of the linen or canvas, and the colours to be used are indicated.

Darning stitch also is very simple to do, and can be used to fill in designs which are outlined in stem stitch or some other bold outlining stitch. Embroidery of this kind is known as Khetha work, and a sample is illustrated at (Fig. 4). The stamens are here suggested in satin stitch. The background of the material, on the other hand, can be filled in with darning stitch, and the design left plain. In this case, the edge of the design is outlined, and French knots and single cross stitches are used to indicate the centres of flowers, etc.

*Fig. 4. Khetha work, in which the effect is chiefly produced by the darning stitch.*

Norwegian hardanger work (Fig. 5) is a form of openwork which can be done on loosely woven linen, on canvas or on any material where the threads can easily be counted. Bars of buttonhole stitching, with picot ornaments, are used where the material is cut away, or the bars are worked in darning stitch and loop stitch, and the pattern in straight stitch, which is satin stitch without padding.

*Embroidery. Fig. 5. Hardanger work. Design for a table runner worked on loosely woven linen or canvas.*

Punch work produces a drawn thread effect (Fig. 6) by means of a special punch needle, without the trouble of drawing threads. Various outline stitches may be used for the pattern and satin stitch, for flower centres, the punched holes of the background being worked with tiny hem stitches.

Hungarian embroidery is worked on coarse unbleached linen, the rougher the better, in gay colours and bold designs. By these means beautiful effects are gained.

Distinctive names are also given to other kinds of embroidery, some of which are of a national character. In all work classed as linen embroidery clear spaces of the material are left between the designs, the whole

ground never being covered as in tapestry work.

*Fig. 6. Punch work. Effective design for linen mats edged with lace, suitable for a luncheon set (Courtesy of Harrod's, Ltd.)*

**Silk and Velvet Embroidery.** Embroidery on silk and velvet requires special care. The design cannot be satisfactorily marked on the right side of velvet; it must be lightly traced on the back and the outline followed with white tacking thread, so that the tacking stitches are prominent on the right side of the material. If the work is too big to hold over the finger, an oblong frame must be used, as a pile material cannot be pressed into a round frame. A piece of stout calico should be sewn round the edges of the velvet, and by this it should be laced to the frame with long stitches, the top and the bottom edges first, getting them quite taut, and the sides last. Ordinary embroidery stitches are employed, but in the case of chenille, which cannot be drawn through the material, it must be couched down as in laid work (q.v.). Beautiful work is done by copying Japanese and Chinese designs. Chain stitch is much employed for bouquets of flowers, while needle painting is done by means of a flat embroidery stitch and colour shading.

**Gold Embroidery.** This includes all embroidery done with gold and silver threads. It is expensive work, so is only employed where very rich effects are desired, such as ecclesiastical ornaments and vestments. It requires a strong foundation, such as brocade, velvet, or thick cloth. The padding for bold designs is done with ordinary white padding cotton, only the surface stitches being worked with gold thread. The working threads should be handled as little as possible, and a fine stiletto is a great help in making small holes for coarse threads to pass through. This work requires much practice, and in some countries many years' apprenticeship is served in it.

**Appliqué Embroidery** consists of the laying of pieces of one kind of material on a foundation of another kind to form a pattern, giving the effect of patchwork, but carrying out a definite design. It comes under embroidery in its modern form, as the designs are sometimes attached by means of buttonhole and fancy embroidery stitches, while the centres are filled with ornamental stitches and lace fillings instead of the old corded edge or plain fell stitch. It stands out in bold relief, and is quick work in comparison with ordinary needle embroidery. Hence its popularity for the decoration of cushions, curtains and bedspreads.

The small pieces that form the design should be

tacked down in position before working, putting the tacking threads near the edge of the top piece and working over them when doing the embroidery. They can be drawn out afterwards from the back of the work. In the case of floral designs the veinings of leaves and the special outlines of flowers can be worked afterwards through the two materials. By this method the motifs are kept in position with embroidery stitches, which is more popular than the old method of pasting the top material to the foundation.

Embroidered laces come under the same heading as canvas embroideries, where the background is of a loose texture, and all kinds of fancy lace stitches and fillings are used, and others producing a drawn-thread effect. Colbert embroidery comes in this class, and includes imitations of Dresden lace stitches and damask stitches and open fillings. Fancy darning on net is included under the title of embroidery laces, but work done on filet net comes under a title of its own and is a special class of work. (*For embroidery delicate stitchcraft see page 756 and for instructions how to make principal stitches see page 758*)

**EMERALD.** These beautiful gems are usually set in combination with finest diamonds. The stones that are deep green and perfectly transparent are higher in value than almost any other gem of the same size or weight. Less valuable emeralds are those in a lighter shade of green in which there are white or dark quartz-like markings. These stones when closely examined have the appearance of being cracked, but notwithstanding these natural flawlike markings, they command very high prices.

Emeralds should always be set in gold claws or in gold band settings, the latter having the upper edges with milled grain finish which gives the gold band the appearance of having had a very fine file drawn across it. Though diamond ornaments may be set in platinum, emeralds used in combination with brilliants should be set in gold.

The under side of the settings of gems is invariably open, to enable light to be reflected through the facets of the stones. Therefore it is easy to keep emeralds or similar gems free from dust or soap by brushing the backs of the stones with benzine. Another method is to brush them with eau-de-Cologne or some other spirit which will easily evaporate. A soft toothbrush is best suited for the purpose. Care should be taken to prevent emeralds from becoming scratched as they are much softer than other gems.

In recent years the emerald has been so closely imitated that the stones known as synthetic emeralds are almost indistinguishable from the real gems. These copies not only reproduce the clear emerald, but also the stones with quartz markings. *See Jewelry; Ring, etc.*

**EMERY.** Emery is a very hard mineral, a variety of corundum. Owing to this quality, it is used for  
(Continued in page 758)

## EMBROIDERY: DELICATE STITCHCRAFT FOR CLOTHES AND HOUSEHOLD ACCESSORIES

Left: Place mats and glass mats in organdie and royal blue rick-rack braid. They need no transfers, and the same idea can be adapted to other uses. Right, above: Dainty edging for

lingerie. Net is placed beneath the material, and the pattern is buttonholed. Where desired, the top material is cut away, revealing the net.

Left: An exquisite flower design. The lupins are worked in pink and mauve; the harebell spray and clematis blossom and leaves in natural colours. Clever needlewomen will invent many other designs.

Right: From an old-world flower print, this exquisite honeysuckle design is worked in simple stitches, in natural colours of flowers. Stranded cotton was used. Full size about 9 in. square.

Left, above: "Shadow" work motif, worked in double back-stitch. The stems are outlined with ordinary back-stitching. Right: An original "Quarrelsome Couple" motif makes an attractive design on a tea or breakfast cloth, a tea-cosy set, or a round cushion.

# EMBROIDERY: HOW TO MAKE THE PRINCIPAL STITCHES USED IN THIS FORM OF NEEDLEWORK

## 1. Stem Stitch.

Take up a little of the material, throw the thread over to the left, and draw it through. Bring the needle out to the right at the top of the last stitch, so that the stitches overlap slightly. Continue in this way.

## 2. Raised Stem Stitch.

Work this stem-stitch as before, but first lay along the line you are working a thick thread of cotton as a foundation, and take the stem-stitches over it.

## 3. Snail-Trail.

A useful stitch for stems. Bring the needle up to the right side of the material. Hold the thread beneath the left thumb. About  $\frac{1}{4}$  inch from the beginning put in the needle again, to the left of the thread (putting the needle over the thread which is still under the thumb). Bring the needle up again the other side of the thread, and draw the thread through. A straight stitch and knot will have been formed. Continue in this way.

## 4. Back Stitch.

Make a straight stitch. Bring the needle through farther along at a distance equal to length of stitch. Make next stitch backwards to fill the gap; bring needle out, leaving another space. Continue in the same way.

## 5. Crossed Back Stitch.

This is used on transparent materials; it makes a close line of cross-stitch on the wrong side, and two rows of back-stitch on the right. It is worked on the right side. Put in the needle as if for ordinary back-stitch, pass it under the material, sloping it a little down to the second line. Draw it out and make a back-stitch on the second line. Bring the needle up again under the material, leaving enough space to make a back-stitch on the top line as before.

## 6. Satin Stitch.

Work the stitches across, placing

them close together to cover the fabric without overlapping. To get a raised effect tiny running-stitches can be put in first for padding. This stitch should be worked from left to right.

## 7. Long and Short Stitch.

One long and one short stitch taken alternately.

## 8. Buttonhole Stitch.

Working from left to right, the needle is passed downwards over the thread.

## 9. Ornamental Blanket Stitch.

Work like buttonhole-stitch, from left to right; but pass the needle two or three times into the same hole at the top, thus making little pyramids.

abrasive purposes. Emery cloth and emery sticks are made, like emery paper, by coating the particular material with powdered emery mixed with glue or with some other adhesive substance.

**Emery Paper.** This is invaluable for finishing the surface of metal work. It consists of a paper or linen back coated with an adhesive and evenly covered with powdered emery. The material is available in sheets, rolls, or narrow strips, generally known as emery tape or bands. It is made in many grades, from the finest, viz., FFFF or SF, to a very coarse grain, CF, equivalent in cutting power to a second cut file.

*Emery. How to use a strip of emery tape for cleaning up work after it has been brazed.*

A specially fine grade of emery paper is much used by jewellers and scientific instrument

makers, and sold as blue back. Emery tape is frequently used in lengths of 3 ft. or thereabouts, especially for cleaning up covered work. It is held and manipulated by both hands, one pulling on one end of the tape, the other maintaining an even pressure (*see illus.*).

**Emery Powder.** This is an abrasive; its most usual domestic application is in the form of knife powder, sprinkled on a leather covered board, against which the knives are rubbed and polished. There are a number of various grades.

Buff sticks, polishing bobs, and similar appliances are coated with emery powder, either by moistening the emery with a drain of oil or by coating the surface of the stick with glue and sprinkling the emery upon it while hot.

**Emery Wheels.** These are manufactured in a wide range of sizes and grades, from a very small size to large ones requiring a powerful engine to drive them. For amateur use a 3 in. or 4 in. wheel is quite large enough to drive by foot-power, or by means of a small bench emery grinder driven by hand. The latter are invaluable for keeping tools in good condition. *See Grinding; Polishing.*

**EMETIC.** A number of medicaments are used to induce vomiting, and are termed emetics. Examples are: mustard and water; a tablespoonful of mustard in half-glass of cold water; a full glass of warm water, in which a tablespoonful of salt has been dissolved; a tablespoonful of ipecacuanha wine. This last is a

favourite emetic for use with children. A dose of a teaspoonful may be given a child of 18 months in bronchitis where the patient is unable to cough vigorously.

*An emetic should always be the first treatment in poisoning by irritants or narcotics, but must not be given in poisoning by corrosives, such as sulphuric acid, etc.*

If there is any delay in the action of the emetic, vomiting may be hastened by tickling the back of the throat with a feather or a paper spill. *See Poisoning.*

**EMMENAGOGUE.** This is a remedy for increasing the menstrual flow when it is diminished in different diseased conditions. One of the simplest and safest means to be employed for this purpose is a very hot hip bath, to which a teaspoonful of mustard has been added for each gallon of water. There are about a dozen official emmenagogues, the most useful being ergot, potassium permanganate and apiol, the essential extract of parsley. Extracts of certain ductless glands have also been of value. Pron. E-men'a-gogue.

**EMPHYSEMA.** This is a chronic chest complaint in which the air cells of the lungs become over-distended with air, the resulting pressure leading to destruction of the walls of the air-cells. The diminution in the total lung surface thus produced means deficient aeration of the blood. The disease develops very gradually. In advanced cases the chest becomes rounded or barrel shaped, and the patient is round-shouldered. Cough becomes a marked symptom as the disease continues to advance. The patient should live, if possible, in a dry, equable, sunny climate. The bowels should be kept free. Pron. Em-fy-sē'ma.

**EMPIRE STYLE.** In furniture this name is given to the style which originated in the years after the Revolution in France. An attempt to copy Greek and Roman forms, its characteristics are classical mouldings and pediments, capitals, wreaths of laurel and of palm. Mahogany, satin wood and rosewood were used; a feature of many pieces is the bronze mounts. Tables, chairs and other pieces are also ornamented with mounts in heavy gilded designs. Much of the furniture was silvered or gilded, while the tripod and the X legs for chairs, etc., were often seen. This style succeeded the Directoire in France and then passed to England, where Sheraton made pieces in Empire and also in Directoire style. *See Dining Room; Directoire; Sheraton.*

**EMPLOYEE.** This word refers to any person who is employed by another, who is called the employer. Most of them must be insured under the national health scheme, and employers are responsible for injuries and accidents that may happen to them while at work. *See Charwoman; Chauffeur; Groom; Insurance; Servant.*

**EMPLOYERS' LIABILITY.** The liability of an employer for injuries to a servant will in most cases be determined under the Workmen's Compensation Act. In some cases, however, the employer will also be liable either at common law or under the Employers' Liability Act. The sums then recoverable will be greater than the amount of compensation under the Workmen's Compensation Act. By the common law, an employer is only liable to a servant for accidents which happen to the servant through the employer's fault or negligence. He is not liable for injuries sustained by the servant by reason of the negligence of a fellow-servant, even though the fellow-servant is in a position of authority over the one injured.

By the Employers' Liability Act, which does not apply to domestic servants, nor to any employees except those engaged in manual labour, the employer has been made responsible for injuries to a workman resulting from a negligent order given by a person whose order the workman was bound to obey; the defective condition of the ways, works, machinery, or plant; the negligence of a person having superintendence of the work; obedience to the rules or by-laws of the employer.

If an accident to a servant happens by reason of the breach by the employer or anyone for whom he is responsible of any rule or regulation laid down by Act of Parliament for the safety of the workpeople, the employer is liable, quite apart from the Employers' Liability Act. Domestic servants have the rights of any other employee under the Workmen's Compensation Act. *See* Servant; Workmen's Compensation.

**EMPLOYMENT EXCHANGE.** These institutions are found in every populous centre in Great Britain. At them the unemployed in the district register their names, and it is possible for employers to obtain there domestic servants, charwomen, and others. Application should be made, if possible, in person, to the clerk in charge, who will take down the particulars of the vacant situation and send likely persons along to the address given. No fees are charged. They were established in 1909 and until 1916 were known as Labour Exchanges.

**EMPYEMA.** Empyema is a collection of pus in a cavity of the body, particularly the pleural cavity between the lung and the chest wall. It may be a sequel to pleurisy with effusion, or it may occur as a complication in infectious diseases like typhoid and scarlet fever, or in consumption and pneumonia.

Empyema may begin suddenly with a chill and sharp pain in the side, made worse by coughing. Then the signs of fluid in the chest make their appearance. In other cases, as in scarlet fever, its onset may be very insidious, with no symptoms pointing to the chest, but it is noticed that the patient shows pallor and declining strength. If after the crisis in pneumonia the patient appears to have fever, the possibility of empyema should be suspected. This is very important in the case of young children in whom the disease, though simulat-

ing pneumonia, may be empyema from the start. When a young child supposed to have pneumonia is markedly delirious, empyema should again be kept in mind; also in obscure wasting diseases in children or when the wasting is accompanied by symptoms suggesting tuberculosis of the lungs.

In these cases the doctor diagnoses empyema by drawing pus from the chest, and treatment is to drain the cavity. If the compressed lung expands again the patient may be little, if at all, handicapped thereafter.

**EMULSION:** In Medicine. An emulsion is a watery mixture with a milky appearance due to its containing oil in fine droplets. Examples are emulsions of cod liver oil and of castor oil. Many people who have difficulty in taking plain cod liver or castor oil can take the flavoured emulsions with ease, as being more readily digestible.

**EMULSION:** In Photography. Whether on glass, film, or paper for the production of negatives or positive prints, photographic emulsion consists of a light-sensitive salt, such as silver nitrate, suspended in gelatine or collodion. *See* Ferrottype; Film; Plate.

**ENAMEL FOR THE DECORATION OF THE HOME**  
Advice on the Treatment of Furniture, Woodwork, etc.

Here are described the correct methods of using enamel paints, how to re-enamel a bath and how to apply quick drying cellulose finishes. The decoration of small wooden objects in enamel is also included. *See* Paint; Painting, etc.

The householder rightly looks upon enamel as a high-grade paint, used chiefly for the preservation and decoration of interior woodwork. Metal is extensively enamelled, but with essential differences in treatment, and the articles are usually stoved for 24 hours or so, to bake the enamel. Enamel as applied to jewelry, pottery and other articles is quite distinct from that used by the house decorator. The process is described in the article Enamelling (q.v.).

In the use of enamel for woodwork, etc., preparation of the work is of the highest importance. For new interior woodwork proceed as follows: First rub down the wood with glass-paper, unless it is already perfectly smooth, then brush over all knots with a preparation sold as knotting; when this is dry apply a coat of priming to the whole of the woodwork. Brush the priming well into the wood, and when it is dry, clean it down with sandpaper, remove all dust, and fill up all cracks with stopping and putty. Screw and nail heads, which should be below the surface, must be covered with stopping or putty well pressed in until it is level with the surface.

To close up the pores of the wood, the whole must be given one coat of a suitable under-coating. This when quite dry and hard should be smoothed with old fine sandpaper and dusted; it is followed by a second undercoating of a colour similar to that of the enamel.

This second coating must be allowed to dry thoroughly and quite hard; it should present a perfectly even colour and a good surface, but will be matt or semi-glossy in appearance. It must not be soiled, or touched with greasy hands. When quite hard give one good flowing coat of the enamel. Interior wall surfaces of plaster or cement must first be primed or filled with a good coat of reliable priming solution; this is needed to stop the suction of the plaster, as otherwise the unequal porosity of the ground work will affect the colouring, the enamel drying with a patchy effect.

New exterior woodwork should be treated in the same way as inside work, except that outside quality material should be used for the undercoats. Exterior white enamel work should be finished with two coats instead of one, the second applied after the first is thoroughly hard and dry. The amateur will probably more often be called upon to deal with existing woodwork that has already been painted. If in good condition, and when the new colour is the same as the old, it will suffice to rub down and wash the paint with soda-water, stop up holes and give one coat of matt enamel or second undercoating, finishing with the glossy enamel. When the old paint is in bad condition it can be well rubbed down, given one coat of stopping, again rubbed down when dry, all cracks filled and then treated as for new work.

Interior wall surfaces, previously painted and in good condition, can be given one coat of undercoating and one of glossy enamel. Walls in bad condition are enamelled as for new work. Distempered walls to be converted to the modern flat enamel finish can be treated as for new work, but finished with undercoating and a final coat of flat enamel.

#### Application of Enamel to Metal

Exterior ironwork should be cleaned of rust, given a coat of anti-rust priming, followed by two coats of glossy enamel, flattening the first coat of enamel by sandpapering and dusting prior to applying the final coat of glossy enamel. Bicycles and similar vehicles made of metal are preferably baked or stove enamelled. If they have to be done at home without an enamelling oven, treat them as for exterior work, taking care to clean thoroughly every part before commencing the work. Special enamels are sold for this work.

Enamel. Fig. 1. Applying putty to all holes and cracks.

Fig. 2. Sandpapering lightly to produce a level surface.

Fig. 3. Applying the undercoating.

Fig. 4. Laying off vertically.

Fig. 5. Flowing on the enamel; note grip on brush and absence of brush marks.

Fig. 6. Cutting-in edge of moulding.

The illustrations show the right and wrong ways of manipulating the brush. A useful type is a flat bristle brush ready ground, or worn in by previous use, cleaned and washed. When using proprietary enamels always use undercoatings made by the same manufacturers. Do not add anything to the enamel; simply stir it and apply it in broad, generous strokes of the brush. Do not apply too much enamel, or it will run and show ridges, nor must it be brushed out too thin, or bare places will appear, with unequal gloss. The thing to bear in mind is that a good coat of enamel should be of equal thickness everywhere on the enamelled surface, and just as thick as it can be

without sliding downwards. When enamelling a room do the prominent parts, like the door, cupboards, and windows, first, and finish with the skirting. Begin with the panels of a door; then do the muntins, top, middle and bottom rails or cross-pieces, and finally the stiles.

Enamel sets very quickly, and in half an hour from application it cannot be touched up without showing. Endeavour to apply the enamel so that the finished work is always behind the brush. Thus in covering a large area work up and down or across from side to side, so keeping the edge of the enamel always alive or workable. In dealing with windows, cut in all the small rails first, and then finish on the broad areas.

**Enamelling a Bath.** To cleanse the bath scrub it with hot water and soap extract. This will usually remove all the grease and dirt, but should these be obstinate the application of some gritty scouring powder may be necessary. When the scrubbing has been completed, two or three good scourings with cold water should follow. The next step is to wipe the bath dry and to smooth the surface by rubbing with glass paper of medium texture. Special care should be taken to rub down the parts around the exit pipe and wherever the old paint has been chipped away from the surface.

The bath must then be allowed to dry thoroughly. From now onwards until the last coat of enamel has dried no water must be permitted to fall into the bath. It is well to tie up the taps so that they cannot be turned on. Also, as taps often drip, it is a good plan to suspend an old empty paint can under each tap, or to stop the mouths with a cork. Just prior to the application of the first coat, the bath must be wiped free of dust and grit. If smuts have blown in from an open window, it may be advisable to rub them off with a rag dipped in turpentine.

Many good enamels are specially sold for bath work. The one selected should be purchased in two grades; (a) to dry with a matt or dull surface, and (b) to dry glossy. Twice as much of (a) is needed as of (b).

The first and second coats should be made with the dull-drying medium. They should be applied sparingly. Do not try to hide all the marks of discoloration with the first coat. The aim should be to obliterate a little of the discoloration as each coat goes on until none is left when the final painting has been carried out. If a non-glossy enamel be used for the two preliminary coats, each will be dry after the lapse of two days, and then the glossy enamel may be applied; this should be left for a week. As paint hardens quicker in dry weather, it is best to do the work in spring or summer. If on placing the hand firmly on the new surface there is the slightest disposition to adhere, it may be considered as still insufficiently hard.

When, however, the paint is dry, the bath should be filled with cold water, the plug should then be removed and the hot tap allowed to run. In this way, the cold water should gradually give place to warm and then hot water. The latter should be allowed to remain overnight, when the job may be considered at an end. If the plug be made of metal, it will be advisable to

replace it with a rubber one, so that it will not chip the new surface.

**Cellulose Finishes.** Cellulose enamels are on an entirely different basis from oil paints, and thus possess different properties. In the manufacture nitrocellulose is dissolved in specially prepared solvents to which plasticisers, gums and resins are added. Special pigments are incorporated to give the desired colours and tints. The drying takes place by evaporation of the liquid solvent content, and the action is very rapid.

In their first stages of development cellulose enamels were only suitable for application by spray, a method used extensively in industrial work. It has been found possible, however, to produce cellulose finishes which do not dry too rapidly in the early stages to make them impossible to brush. These modified finishes are, in fact, very suitable for application by brush, and the technique differs only slightly from that with oil paints. The products are characterised by many desirable properties such as quick-drying, good gloss and great durability. They are generally suitable both for indoor and outdoor work.

#### Special Methods for Cellulose Enamels

When using a cellulose enamel stir the paint well up from the bottom and apply with a clean rubber-set brush having soft bristles. The brush should be well charged with the paint and handled so as to distribute it evenly over the surface. The second charge of the brush should be applied at some little distance away from the first and the material laid off towards the previously painted area. By finishing the stroke with the tip of the brush lightly in a wet portion, brush marks and "drags" will be avoided. The material should not be brushed out in the manner of an oil paint, but only sufficiently to give complete and even cover. Only a small area at a time should be covered. At room temperature, the first coat should be left a minimum of 2 hours before the second is applied. The shades are mixed together to obtain any particular colour.

Brushing cellulose enamels can be applied over almost all types of surfaces, but these should, of course, always be clean and dry. All traces of polish, wax, grease and oil should first be removed with turpentine. Rust on metal should be removed by sandpaper and good quality petrol until no trace of it remains. On bare wood, plaster or wallboard a specially made undercoat is usually recommended, as this helps in building up to a good finish.

Such undercoats are usually on an oil base. The undercoat should generally be given a drying period of eight hours or more, before the finishing coat is applied.

Before applying cellulose enamels to finished surfaces these should be sandpapered smooth, and the same applies to all rough places or parts where the old paint film is broken through, when the edges should be "feathered" down. All traces of varnish must be

removed. Cellulose enamels should not be brushed over a surface that has been recently painted with varnish or enamel, or lifting may occur. When applied over surfaces which are already painted, the life of the cellulose finish will only be that of the old paint film beneath.

**Clear Cellulose Varnishes.** These are particularly suitable for use by amateurs on stained furniture, such as sideboards and dining tables, where french polish would ordinarily be employed. It is necessary to remove every trace of grease or wax polish from the surface before the clear cellulose is applied. The varnishes are not intended to be employed over a cellulose enamel to increase the gloss, as a better method is to rub the surface with a cloth moistened with a little polish supplied by the manufacturer of the enamel. An occasional rub over with this polish will ensure that the gloss is retained. Clear cellulose varnishes are only suitable for indoor work.

*The solvents in cellulose finishes are inflammable, and the material should not be used near a fire or any open flame. It can be used on geysers and fireplaces without fear so long as no flame is present while the material is being applied, or within a few hours after application. When used indoors the room should be well ventilated.*

#### ENAMEL: Flower Designs on Wood.

A modern note for small articles is struck by staining white wood brown or grey and using enamels only to paint the decorative pattern than by doing all the work in the latter material. White wood door plates, trays, blotters, boxes and book ends can be quickly transformed into charming sets by this means. The contrast of the matt background and shining flowers is attractive.

*Enamel: Trinket box in stained grey wood, with flower design in brightly coloured enamels. See key diagram.*

*Enamel: Powder jar in stained grey wood, with flower design in brightly coloured enamels. See key diagram.*

The set of powder jar (or it would do equally well for Cigarettes), trinket box and pin tray here illustrated could be stained grey, using a water stain that is obtainable in small bottles. The surface of each white wood article is first rubbed down with a piece of glass paper and then, having diluted the stain to about half its strength with water, each piece is painted. When dry the stain is rubbed down with glass paper and polished with a stiff brush in order to give a satisfactory surface on which to enamel the pattern.

*Enamel Design and key to colours on the lid of the trinket box illustrated below B, pale blue shaded with dark. O orange and pink. W white and yellow. P pink. M. mauve. BL, black. G, dark and light green.*

The chosen design is traced on tracing paper and transferred to each article, using red carbon paper, a small piece of which is placed between the design and the wooden surface. Take care not to dent the wood.

The colours are then filled in according to the chart, using small tins of enamel supplied from an arts and crafts department or studio. Outfits of 10 colours can be obtained for 4s. 6d. with medium. A boxwood stick is used to apply the enamel in a circular motion, spreading it evenly over the surface; where one part of the design intersects another, allow the underneath part to dry before colouring the rest. For example, on the pin tray the leaves are done first, then the two half-

open flowers are coloured, then the white one and last the blue, allowing each part of the design to dry in turn. The design on the trinket box only is outlined in the diagram above, but this is reproduced in actual size and can be easily adapted to suit the several pieces.

## ENAMELLING AS A DECORATIVE ART

### Methods of Using Fired and Cold Enamels

Having told how a pendant and a cigarette box can be decorated by fired enamel, this article goes on to describe the use of non-firing enamels, with designs for a trinket box in imitation cloisonné.

In most cases enamelling is used in conjunction with metalwork. In cloisonné enamels, for instance, it is inseparable, fine wires being first soldered to a base. The muffle furnace is of great importance to the enameller. This can be heated by gas or electricity. For quite small articles the jeweller's enamelling furnace shown in the photograph on page 766 could be employed. It is worked with a draught burner and does not require air blast. The following tools are needed: a small bench, a pair of furnace tongs, a porcelain pestle and mortar, a pair of small shears, an etching point, or scriber, and a set of enameller's saucers.

The other requirements are a palette knife, 6 assorted needle files, 1 half-round file (smooth), 1 flat file, safe-edge, super fine; 2 pairs of small pliers (1 snipe-nosed, 1 flat-nosed), 1 flat steel stake, 1 small planishing hammer and handle, 1 wooden mallet, a small saw frame and saws (No. 0 or 00), an upright drill stock and small drills, a wire brush, acid bowl, and a small vice.

**Enamel Pendant.** A simple pendant would form an easy job for the beginner. The design having been chosen, the following materials will be needed: A piece of fine silver sheet, gauge 10, size 2 ½ in. by 2 ½ in. Fine silver, i.e. unalloyed, should always be used for best colour results, as standard silver, i.e. alloyed, blackens when heated and dulls the enamel. Besides this there are required a sheet of silver foil, gold shell, 1 oz. gum tragacanth, a small bottle of pure sulphuric acid, and a piece of standard silver wire.

Take the piece of silver and trace upon it the shape of the pendant. Carbon paper will give a good impression on the metal. Then, with the scriber, or etching point, engrave the traced line, so that it is plainly seen when the carbon rubs away. The next operation is to saw round the engraved line.

Fix a saw in the saw frame, being careful that the teeth are pointing outwards and downwards towards the handle. Screw up, so that the saw is absolutely taut (Fig. 1). Saw a small hole in the bench peg, the small projecting part of the bench (Fig. 2). Place the silver on the peg, just above the hole. Hold it firmly with the first and second fingers of the left hand. Place the saw in the hole against the edge of the silver, moving it up and down in even strokes. It is the down stroke that cuts, and must, therefore, have slightly more pressure.

Keep the saw perpendicular. When coming round a curve, move the metal gradually round, not the saw. See that it is kept flat all the time (Fig. 3). If it is allowed to tip up it may break the saw.

*Enamelling. Fig. 1. Saw frame. Fig. 2. Bench peg. Fig. 3. How metal should lie flat on peg. Fig. 4. Right and wrong ways of twisting cord for drilling.*

Drilling the hole for the insertion of the ring needs a little practice. Place the drill in the chuck. Keep the drill-stock perpendicular placing two fingers on the cross-bar. See that the cord is not caught at the top (Fig 4). Revolve the spindle until the cord is twisted down it. Very gently press the cross-bar down, and it will come up again without a second movement (Fig. 5). When spinning, no further pressure is necessary. The metal must now be annealed or softened. If the bench is not fitted with a burner for the blow pipe, the furnace can be used.

*Fig. 5. Drilling. Note twist of cord.*

Having in the first instance obtained a good heat in the muffle, put the silver on the firing plate. With the furnace tongs place it in the muffle for a few seconds until the silver reaches red-heat. Great care must be taken to withdraw it immediately, as it will melt if left longer. The silver may be plunged into water to cool. It will now be soft and pliable, and is ready for doming. Holding the silver by the edges, place it on the steel stake and tap it with the planishing hammer, making even pits in circles until it becomes the required dome (Fig 6). Should the metal become stiff and springy, the annealing process must be repeated. Enamel applied to flat metal draws up, cracks, and flakes off. Hence the reason for doming.

Fig. 6. Doming the silver.

The pendant is now ready for cleaning. The presence of any grease or discoloration may ruin a colour; therefore too much attention cannot be given to the following: Pickle is the technical name given to the weak solution of acid used for cleaning metals.

*Particular care must be taken in the mixing, and these instructions faithfully followed, or a serious accident may result. The quantities are one part sulphuric acid (vitriol) to 20 parts water (about 10 fluid oz. of water to ½ oz. of acid). Always pour the water into the bowl first; then add the sulphuric acid gently, a few drops at a time, covering the entire surface of the water.*

Even so, the bowl will be found warm to the touch. Should this process be reversed, or the acid poured in quickly or carelessly, the sudden mixing would create heat enough to cause an explosion.

After leaving it a few seconds the pickle is ready for use. Place the bowl upon a gas ring with a small flame. Put the silver in, and heat until it is just on the boil. Remove the silver from the bowl with a match-end or piece of wood. It is not advisable to put the hands in the pickle more than is necessary. Never use iron tweezers. Iron in pickle leaves a pink deposit on the silver. Next take the silver to a tap, and with the wire brush, under running water, brush the surface briskly. When back and front are absolutely bright and free from grease it is ready for the enamel.

The grinding must now be done. Clean the mortar thoroughly. In it place, with a little clean water, a small piece of enamel of the desired colour. Experience only will teach the amount necessary to cover a surface. Take the pestle, which must also be cleaned, and tap it gently with the wooden mallet, reducing the enamel to small flakes (Fig. 7). Then grind with the pestle until it becomes a fine, even powder (Fig. 8). The water will now be milky. This milkiness must be washed away

under running water until the water is perfectly clear. Care must be taken not to wash the enamel away. This can be avoided by giving it time to sink at each rinsing. Put the enamel in one of the saucers with a little water, and cover it with the lid. Repeat this operation with each colour that is required.

Figs. 7 and 8. Grinding the enamel.

Where a thin metal is employed, a counter-enamel will have to be used. This means that the back is covered with enamel. It is done to prevent cracking, as the metal and enamel contract at different rates during cooling. Take two flakes of gum tragacanth and soak in a saucer with water. When the liquid is sticky to the touch, cover the back of the pendant with it, using a clean sable paint brush. The pendant or piece of silver to be dealt with should be held on the tips of the fingers by the edges, back upwards, to avoid marks on the silver.

This having been done, the next step is to take a small spatula or penknife, and with it convey the enamel to the back (Fig. 9). Tap the edges gently to disperse it over the surface. Then smooth it over, using a slight pressure until the whole surface is evenly and thoroughly covered. Care should be taken that the enamel is not too thick. The moisture should be soaked up with clean, white blotting paper or linen rag. To apply the enamel to the front the pendant must be turned, but still held in the same way. The colours must be blended and shaded as required, but no gum tragacanth is necessary on this side of the article. The surface should then be smoothed over with a palette knife (Fig 10), and the moisture absorbed by the method just explained.

Fig. 9. Pressing down counter-enamel.

Fig. 10. Smoothing surface of enamel.

The firing plate (Fig. 11) is now required. This is made of nickel-sheet, and must be cut in such a way as to clear the sides of the muffle, and short enough to allow the door to close. Turn the end up, so as to give a grip for the tongs. The muffle should now be an even cherry red, with no dull black spots. This is essential for good results. Place the enamel on the firing plate, lifting it carefully with a palette knife. Remove the door from the muffle and rest the plate in front and leave it there (Fig. 12). When all traces of moisture have evaporated it is ready for firing. At this stage the powdered enamel is dry and easily shaken off, so care must be taken in placing in the muffle (Fig. 13).

*Fig. 11. Nickel firing plate on which enamel is carried.*

*Enamelling. Fig. 12. Firing plate with enamel placed in front of muffle to allow moisture to evaporate.*

*Fig. 13. Placing plate into muffle for firing.*

The difference in the melting points of various colours make it impossible to say exactly how long an enamel should remain in the muffle. The enameller must watch carefully and see the changing as the enamel melts. It is not good to have the door out all the time, as it chills the muffle. When the enamel is nearing the molten state, hold the tongs over it, and when they are reflected in it, the enamel is fired and must be removed quickly. Overfiring is disastrous, and neglect at this stage may easily spoil the pendant or other

object being fired. Do not remove the pendant or other object from the plate, but put it near the muffle to cool gradually. The enamel has now had its first firing. It may happen that there are holes in the surface, or that part of the counter-enamel has dropped off. This must be patched when cold, and refired before proceeding.

*Enamelling. Small gas furnace which can be worked with a draught burner, and does not require air blast.*

Silver and gold foils are used for still brighter effects. In this pendant, silver, foil might underlie the small spots of the design to give a jewelled appearance. Take the sheet of silver foil and, holding it between the packing papers, cut small circles to the number re-quired. These are applied to the surface of the enamel by means of a spot of gum tragacanth solution. Fire again, but this time it is only necessary to reach red heat. When cold, cover the foil with spots of enamel. A small sable brush is best for this purpose. Spots of white or other light colour are also done in this operation. Again only a slight firing is given, so that these spots are glazed but do not sink to the surface level. There remains the heightening of salient features of the design with gold. For this take the gold shell and a fine sable brush. Using a little water, paint the design with a strong, clean line, and fire again.

The pendant is now finished except for the jumping for hanging. This may be made from a piece of standard silver wire, gauged to slip easily through the hole already drilled.

**Cigarette Box.** The panels of the cigarette box illustrated in Fig. 14 are simple examples of painted enamel. They are held by means of copper frames applied to a wooden box. In addition to the tools and materials already mentioned, a ground glass slab and glass muller are required, also a small bottle of oil of spike lavender, a bottle of fat oil of turps, and one gramme of iridium black. The plaques are enamelled on copper sheet, gauge 5 or 6.

*Enamelling. Fig. 14. Cigarette box in polished copper, riveted on cedar wood, with enamelled designs on inset domed plaques.*

Mark off, with the scribe, the five panels (i.e. four for the sides and one for top), seeing that they are parallel and true. They should measure about  $\frac{1}{4}$  in. each way above the actual size when finished. The doming pulls the edges inwards, and thus the design would be hidden under the frame if it were not slightly smaller than the metal. With the shears cut on the etched line and round off the corners with a file. Anneal the metal as indicated in the making of the pendant.

Dome each plaque (Fig. 6). It is important that all the edges and corners lie flat on the bench and do not rock. Next pickle and brush the plaques, making them very bright.

Coloured enamels applied directly on to copper look dark and heavy, therefore the plaques are first covered with a clear crystal enamel, called copper flux. To cover the five plaques, about  $\frac{1}{2}$  lb. of copper flux will be required.

Cover the back and front of the panels, not forgetting the gum tragacanth on the back. Remember to press the counter-enamel down well, and smooth the domed side. Enamel will not find its own level when it is molten, so if care is not taken at this point, a bumpy surface will result. Dry the plaque in front of the muffle and fire it until the flux is quite clear. While it is cooling, trace the design on tracing paper. Place over the plaque a piece of carbon paper and the tracing above it, fixing it down with four drawing pins.

Run over the tracing with a hard pencil to produce a clear carbon line on the flux. Take the ground glass slab and on it put a small quantity of iridium black, one drop of fat oil of turps, and a few drops of oil of spike lavender. Grind together with the muller. With a fine sable brush paint over the carbon line. It must be strong and distinct. If too much oil is used it will be blurred, especially after firing. Evaporate the oil in the front of the muffle, then fire until the line is glazed. The greatest heat is at the back of the muffle, therefore that end of the enamel will be fired first. The enameller must not wait for the other end to fire, but take the plaque out and turn it so that the other end gets the same temperature. This must be observed in every firing to avoid overfiring at one end.

Cut the silver foil into the required shapes between two pieces of paper. Cover the back of the foil with gum tragacanth and place it in position on the plaque, pressing it down firmly. This must also be dried before firing, as if moisture is left under the foil it will bubble. While it is cooling, grind the colours, wash each carefully, and place them in clean saucers. In applying, with an end of a palette knife or pen-knife, care must be taken not to merge one into the other. To avoid this, clean up any enamel which has gone over the outline with a sable brush. Dry and fire as before.

#### Finishing Touches with Gold Shell

Possibly the work will look blotchy and uneven in colour. Particles may have flown off when it approached the heat, leaving here and there patches of the flux exposed. These must be covered with colour and fired again. When the colour is satisfactory it is

worked on with gold shell, which is used in line and dots. Where the drawing needs improvement, e.g. on the rigging of the ship, line work is expressive, and dots are effective on the crest of the waves. After firing the gold, this panel (Fig. 15) is finished. The side and end panels are shown in Figs. 16 and 17. As regards colour and manipulation, they are repetitions of the lid panel just described.

*Enamelling. Fig. 15. Design for an enamelled plaque in the lid of a cigarette box.*

The numbers of the enamels used in the panels may be useful. They are as follows: sky—blue, 167; Ship—ruby, 115; Sails—yellow, 105; Sea—blue, 136. For the fish, ruby and yellow are employed, the sea being of the same shade (136) as in the top panel. The five panels having been completed, they are applied to the box in the following way. Sheet copper, gauge 10, is used. Cut separate pieces to cover the lid, sides, and end of the box. In the centre of each of the pieces measure the space to be cut for the panel, making it a quarter of an inch smaller each way, so giving it  $\frac{1}{8}$  in. all round to hold it when fixed. Drill a small hole to insert the saw, and saw along the line, keeping well on the inside. File up the frame until it is true and fits the enamel. Bevel the back to follow the shape of the dome sides.

*Figs. 16-17. Designs for side and end panels.*

Dome the copper frame, so that while the enamel is held in place the outside edges lie flat on the box. Bevel the edges round the enamel. Measure off the holes and drill, gauging the drill by the diameter of the pins. Fix the frame to the

box with  $\frac{1}{2}$  in. copper pins. If the wood is thin the pins must be cut to the required length before being driven. Cover the sides and the ends in the same way.

In cloisonné enamel, fine wires or cloisonnés are soldered to a metal plate. Finely ground enamel is filled in between the wires and fired. The surface is then ground evenly to the height of the cloisonnés. Opaque enamels are usually employed in this type of work. The fish design would be quite suitable for an experimental piece.

**Non-firing Enamel.** There is no comparison between the two kinds of enamel, but for many purposes liquid enamel is more practical, and it is much more quickly applied. The materials required are 8 colours in bottles, 1 bottle medium, No. 0, or 00 round sable brush, and 1 small stick with pointed end. Enamel of this kind can be used with equal success on wood, leather, glass, and metal, and its application is a simple matter.

One class of enamelling is an excellent reproduction of cloisonné work, and is not difficult, but accuracy is essential. The design illustrated in Fig. 18, with lid and side shown in outline at Fig. 19, is suitable for a trinket box. Choose a piece of copper 12 in. wide, and measure it on the box. Make a tracing of the design and fit it on the box before tracing it on the metal. Make sure that the design fits the article, and, if necessary, alter it to fit. To trace on the metal, go over the whole of the design with a steel tracer, working from the under side of the metal, and check it to see that nothing has been omitted. Most of this design can be done more accurately with a compass, but, failing this, trace it very carefully. Work on a rubber mat. The raised line thus produced serves to retain the enamel in place and to separate the colours, as in cloisonné work.

*Enamelling. Fig. 18. A copper covered box embossed and treated with brilliant coloured enamels. For design see Fig. 19.*

Turn the metal over, place on a piece of hardwood, and punch the background, using a large, round-end punch; do not punch too hard, as this buckles up the background. The next thing is to clean the metal. Scrub it well with special powder, using a nail-brush, and dry it thoroughly with a clean rag. Brush on copper patina, using a hard brush. The copper will become almost black. If it does not colour well, or the colour rubs off,

it shows that the metal is not clean. Wash it thoroughly and scrub it again, then dry it and apply the patina.

*Enamelling, Fig. 19. Design for working liquid enamel without fixing on copper, suitable for lid and side of box.*

The metal must be washed again, holding it under a tap, then be hung up to dry, allowing the water to drip off in the same direction as the water from the tap ran over it. When dry, first polish it with a rag, then burnish up the high-lights, using special powder. When the work is polished up well, it must be protected from the action of air, and for this purpose cold lacquer is used. Apply a coat evenly all over the surface, using a soft brush, and leave it until it is thoroughly hardened.

If the top and sides have been worked in one piece of copper, cut the various pieces out. Leave  $\frac{1}{16}$  in. on the bottom of the sides, and at least  $\frac{1}{8}$  in. on the end of each side,  $\frac{1}{16}$  in. being left all round the top. Fit the two short sides first, turning over the  $\frac{1}{16}$  in., and nail along the bottom of the box. Glue the rest of the metal on to the wood, using metal glue. Fit the back, turning the  $\frac{1}{16}$  in. over as before, and nailing down, then glue the rest. The front is treated in the same way. The ends of the front and back must be made neat by hammering over the edges of the side pieces.

Round the lid glue slips of copper which have been punched. The top edge can be hammered over the top of the box to about  $\frac{3}{16}$  in. Fix the top panel over this, get it into its right place and nail it down, using  $\frac{2}{5}$  copper nails. Prick a hole before inserting the nail, using a metal pricker, then insert the nail and hammer in place, using a nail-driver. This tool is employed so that the marks of the hammerhead do not show on the copper. When the whole of the box has been covered with copper, give it a hard rub with a leather, and it will be ready for enamelling.

Consult the key (Fig. 19) for the colours. Work in the enamels with the small stick sold for the purpose. Work all the colours from the centre to the edge, which is raised, and beyond which the enamel should not go.

*(Continued in page 770)*

# ENAMELLING BY FIRING: DETAILS OF WORK FOR BOX AND PENDANT

Methods of work are described under the heading Enamelling as a Decorative Art.

See page 766

Flux fired on polished copper plaque.

Design in iridium black and silver foil fired on.

Colours fired on.

Finished design with gold outlines fired on, making five firings in all.

The completed box in polished copper, riveted on cedar wood, with enamelled designs on inset domed plaques.

Front and side pieces in red and gold.

Pendant in turquoise and green.

See page 766.

# ENAMELLING WITHOUT FIRING: EXAMPLES OF THIS SIMPLE CRAFT

Instructions for this work, as for that in the previous plate, are given under the heading Enamelling as a Decorative Art. See page 766.

Glass bonbonnière decorated with liquid enamel in seven colours.

Lid of glass bonbonnière

Decoration in angles.

Copper covered box embossed and treated with brilliant cold enamels.

Centre ornament, front and back of the box.

Principal ornament on the lid of the box.

See page 766.

Mauve is obtained by mixing a little lapis blue with red. Mix it in a small container made out of a piece of scrap copper. Do not finger the enamel, as the marks of the skin show, and endeavour to work cleanly.

Key to colouring: 1, green; 2, buff; 3, mauve; 4, lapis; 5, cerulean blue; 6, pale mauve; 7, turquoise.

The enamel spreads, so leave it well inside the design, as it does not look well if the colours join up. In all enamel designs there is a division left between the different parts, so following out the idea of cloisonné, where the outlines are formed by the wire divisions. When the brushes are finished with they can be cleaned with methylated spirit. The bottles should be corked well when they are put away, and the liquid stirred before it is used. If the colours become thick, pour a little of the special medium into the bottle and stir it thoroughly.

**ENCEPHALITIS.** Inflammation of the brain substance, especially of the grey matter, which is known as encephalitis, may be due to an injury to the skull, to inflammation extending from disease of the skull bones, as in middle-ear diseases, when an abscess is likely to result, or may be due to poisoning, as in acute alcoholism. It often accompanies meningitis, and may also occur as a separate disease, which is commonest in young children, although occasionally adults are affected by it. Encephalitis is said to be microbic in origin.

In children it may follow measles, scarlet fever, pneumonia, and other infectious diseases, but more frequently the previous health has been good. The onset may be marked by drowsiness and irritability, and perhaps vomiting. Then convulsions ensue, the child going from one fit into another. The temperature rises perhaps to as high as 105°. The convulsions cease and are succeeded by deep unconsciousness or coma, which lasts for a variable time. When the patient begins to wake up it may be noticed that there is paralysis of one side of the body and face. This, after lasting for some weeks, may gradually disappear, while in other cases a certain amount may be permanent. Mental enfeeblement may also result.

Encephalitis lethargica, popularly known as sleepy sickness, is also a disease due to a microbe and is infectious, though apparently not strongly so. It is likely that some people are carriers of the disease. It is characterised by persistent drowsiness, the patient always dropping off to sleep, from which however he may be roused to answer questions. Squint is common, and a notable symptom sometimes present is persistent hiccough.

If the patient recovers he may do so completely. On the other hand there may be serious sequelae. Frequently this state resembles that of the disease known as Parkinson's, or paralysis agitans. In other cases there is a tendency to jerky movements suggestive of St. Vitus's dance. Still other cases exhibit mental and moral defects, such as lying, uncleanness, etc. The disease which may occur at any age, is notifiable, and in any form requires the prompt attendance of a doctor. Pron. En-sef-a-li'tis.

**ENDIVE.** This salad plant is of value in late summer, autumn and winter. The chief sowings are made in June, July and August. Seeds sown in June and July will furnish endive in autumn, and an August sowing will provide winter supplies. The rows should be 15 inches apart and the seedlings thinned to 12 inches from each other. If the superfluous seedlings are planted on a fresh site they will provide a later supply than those that are left to grow where sown. Seedlings raised in August should be planted in a frame or cloche in October to ensure winter produce. Endive needs well manured and deeply dug soil, which must be kept moist in hot, dry weather.

*Endive. 1. Blanching under plate.*

*2. Blanching under box.*

*3. Plants in frame during winter.*

*4. Planting on ridges.*

*5. Batavian endive.*

*6. Blanching under pots.*

*7. Soil preparation: a fine soil; b soil enriched with manure; c moisture-retain-ing rubbish. (By special arrangement with Amateur Gardening)*

The blanching process, which is essential to the production of succulent endive, takes about 4 weeks, and should be started when the plants have well developed centres. A simple method is to cover each plant with an inverted flower pot and to obscure all light by covering the hole in the pot. Plates or tiles may be used. Blanching can also be carried out by tying the leaves together to exclude light from the middle of the plants. The round-leaf varieties of the Batavian endive are excellent, and the various forms of the moss at curled endive are also to be recommended.

**Cooking.** Although principally used in salad-making, endive may also be cooked like any other green vegetable. When it is boiled, the water should be changed twice so that the natural bitterness of the plant will be reduced, and when tender, the leaves should be put into cold water, left for several minutes, and then squeezed dry. Endive cooked in this way may then be chopped and served like spinach. After a preliminary boiling in slightly salted water, endive heads may be stewed in a pan containing a small lump of butter, seasoning to taste, and a little cream. *See* Salad.

**ENDIVE:** Use on Furniture. This decoration found on certain pieces of furniture is modelled on the curled leaves of the endive. It is used on Louis XV rococo decoration, and was utilized by Chippendale in his renderings of French detail.

**Endocarditis.** *See* Heart.

**ENEMA:** Its Uses. An enema is an injection of fluid into the rectum or lower bowel and is also resorted to in supplying nourishment to the body when this cannot be given in the ordinary way.

An enema for constipation may consist of water alone or with soapsuds, olive oil, castor oil, turpentine, etc. A soapy-water enema is made by pouring a pint of boiling water over 1 oz. of soft soap and stirring well till the soap is dissolved. It is allowed to cool sufficiently. Two tablespoonfuls of castor oil, 6 oz. of olive oil, or a tablespoonful of rectified oil of turpentine may be made up to a pint with warm soapy water; or  $\frac{1}{2}$  to 1 oz. of Epsom salts may be dissolved in the same quantity of warm water. Instead of giving a large watery enema glycerin may be used and 2 or 3 teaspoonfuls will probably suffice. In obstinate cases the injection of  $\frac{1}{2}$  to 1 pint of warm olive oil will be helpful.

The enema may be administered by an ordinary douche bag or can, to which is attached a couple of yards of narrow tubing ending in a vulcanite nozzle which should be smeared with vaseline. The patient is placed on the side with the thighs bent up on the abdomen. When the bag and tube have been filled with the fluid, the nozzle should be gently inserted into the rectum. The bag should then be slowly elevated some two feet above the patient, so that the fluid may flow in. An enema may also be given by using a Higginson

syringe, a rubber tube with a bulb in the middle.

**ENGAGEMENT.** An engagement or betrothal is the formal recognition of the fact that a man and woman intend to marry. The period lasts from then until the wedding day. Almost invariably the man gives to his fiancée, as the lady is called, a ring known as the engagement ring, and sometimes one is given by her in return. Sometimes a public announcement of the engagement is made through the newspapers.

If the parents of the two are unknown to each other, steps are usually taken to bring them together. Sometimes the engagement is celebrated by a dinner party or other social function. An engagement is regarded in English law as a contract, and if either party breaks it an action for breach of promise of marriage can be begun. *See* Agreement; Breach of Promise; Marriage; Ring; Wedding.

## ENGINES AND BOILERS FOR THE MODEL MAKER

### Small Power Plants Constructed with Simple Tools

Useful hints are here given on the care and running of model steam plants. Reference should be made to the associated articles Boat; Electric Motor; Locomotive; Railway.

Most model steam engines function on one of two principles, either with the simple oscillating cylinder or with a double-action slide-valve cylinder. In the former case the cylinder itself turns about the pivot pin, and as the end of the cylinder moves from side to side, so it automatically covers and uncovers the steam port.

The steam enters the first port, forces the piston down to the bottom of its stroke, by which time the cylinder has moved over and closed the steam port, and as the piston ascends the cylinder it uncovers the exhaust port and allows the steam to escape. A small spring and adjusting nut are fitted to the pivot pin to keep the cylinder and valve face in contact.

The double-action cylinder is a fixture, and is provided with a slide valve, like a miniature box without a lid; this moves up and down by the action of the eccentric, and alternately covers and uncovers the steam ports, admitting steam first to one end of the cylinder and then to the other. At the same time it connects the steam passage in the cylinder with the exhaust port, which communicates with the exhaust pipe, and allows the used steam to escape to the open air.

**Timing the Valve.** For anything more than a toy, this type of cylinder should be adopted. An important item is the correct timing of the valve; this is accomplished by first setting the crank at its dead centre, that is, at the end of its stroke, with the piston almost touching the end or cover of the cylinder. The eccentric is set at right angles to the crank; when in this position the valve should cover both steam ports. The eccentric is slightly advanced or rotated until one

of the steam ports is just about to be uncovered. Steam is therefore admitted to the back of the piston, and the engine will function correctly. This principle is applied to model locomotives, and many other types of steam engines, but in various sizes and proportions according to the models.

All small steam engines should have regular attention in the way of lubrication and cleaning. The boiler should not be left standing after a run, but emptied of water; any surplus spirit should be emptied from the container, the body of the machine wiped dry with a cloth and all working parts lubricated. The safety valve requires to be inspected from time to time. All methylated spirit should be kept securely corked up in a can, and away from the engine. The container must be wiped dry on every occasion when it is filled.

The water in the boiler should never be allowed to get too low. Its level can be seen in the water-gauge glass, but as a rule the spirit lamp will burn out before the boiler water is all boiled away. When the spirit lamp is refilled the boiler should always be replenished at the same time. Should the pressure of steam rise to an alarming extent, turn on steam to the engine and run it at full speed; also either remove the spirit lamp or else blow it out.

**Simple Steam Engine.** The diagrams given in Fig. 1 show the parts needed for the construction of a small horizontal boiler with oscillating engine, together with a suitable lamp. It is suitable for driving a model boat, but by arranging the boiler and engine in a different manner, and making the other parts to suit, they can be adapted to drive a toy steam locomotive of the simple type shown in Fig. 2. In this model the boiler casing is made from tin, the cylinder is disposed between the main frames, and drives the wheels through simple spur gears. The boiler can be made from thin brass tubing, closed with brass ends that must be securely soldered.

The cylinder can be purchased ready for use from most of the dealers in model engine supplies, and a simple form of standard may readily be made from sheet metal. The valve face of the cylinder is soldered to the standard, and holes are made in the latter for pivot pin and main bearing. The crank is bent up to shape from a piece of steel wire. Wheels for the toy locomotive can be bought from the model shops, where also a suitable flywheel can be obtained. The locomotive wheels are simply driven on to their axles, remembering to fix the gearwheel before putting the second wheel on to the axle. By setting the boiler in a vertical position and making a circular spirit lamp, these parts can be converted into a vertical engine.

Fig. 3 shows a robust double-acting oscillating engine suitable for a small boat, or for running Meccano models or similar toys. It is larger and more powerful than the simple type just described, the bore and stroke being 7/16 in. The set of parts is sold by the makers, Stuart Turner, Ltd., Henley-on-Thames, at a trifling cost, and the engine may be built quite easily by the least experienced beginner. Cylinder and standard are of gun metal, the crankshaft, disk and crank-pin

being in one piece of steel. The boiler illustrated, which has a working pressure of 20 lb., is sold complete with lamp and funnel.

**Boilers.** A simple horizontal or vertical boiler for a stationary engine is readily made by utilising seamless copper tube of 2½ to 3 in diameter for the barrel, the ends being closed with gun-metal castings or flanged copper disks which just fit inside the barrel. The ends are silver soldered or brazed to the barrel. A casing and firebox of tinfoil or other sheet metal may be made for a horizontal type. In the case of a central flue upright boiler the lower part of the barrel may serve as a firebox, suitable air holes being made and an opening for the entrance of the lamp-tube and burner. The lower boiler end is fixed inside the barrel at the appropriate height, convex side uppermost, and is bored for the brass tube which serves as the flue. This latter passes up through the top end, and is carefully silver soldered or brazed to both boiler ends. A good boiler for larger stationary engines is the Babcock and Wilcox type shown in Fig. 4. The boiler is made in two sizes, the smaller for engines up to ½ in. bore and 1 in. stroke, the larger for engines up to ¾ in. bore and 1¼ in. stroke. The boiler of the latter is composed of seamless copper tube, 8½ in long and 3 in.

diameter, the ends closed with gun-metal castings silver soldered to the barrel. Through the bottom of the barrel five water tubes, ¼ in. in diameter, also of seamless copper, are fitted by silver soldering them to the barrel, one end being lower than the other to ensure rapid circulation. The steam is taken from the top of the boiler, through a screw-down needle valve, inside the boiler casing coiled over the top of the burner to act as a simple type of superheater, and connected to the engines by a union nut.

The casing is made from four iron castings. The castings for the casings, and the gun-metal boiler ends, tubing and fittings, are all supplied by Bassett-Lowke, Ltd., Northampton. The boiler is quite easily assembled by the amateur. All that is necessary is to drill holes for the fixing screws through each of the end castings, tapping the holes drilled in the side plates, any roughness on the castings being smoothed off with a file. The boiler sits in the circular recess cast in the front plate and rests upon pad pieces on the back plate castings; it is held by set screws through the upper portion of the back plate. The boiler fittings comprise a screw-down steam valve, a safety valve, pressure gauge and water gauge, all of which can be purchased with the castings. They are fitted by brazing the bushes, which are supplied with the fittings, into the boiler barrel, and then screwing the fittings into place, seating them on to a thin lead washer. The glands for the water-gauge glass are packed with fine cotton soaked in tallow. The holes for the gauge glass must be directly in line to avoid risk of fracture.

Two separate castings are provided in the shape of a fire door; these fit into holes cored in the front of the

*(Continued in page 774)*

Below. Fig. 6. Component parts of the Stuart mill engine.

boiler casing, and are held in place by a  $\frac{3}{32}$  in. diameter steel pin. These are simply pushed into place, and may be removed to inspect the flames from the burner. This boiler can be heated by a gas ring or by a vaporising spirit lamp.

The chimney,  $7\frac{1}{2}$  in. long, is made from stout brass tube  $1\frac{1}{8}$  in. in diameter, which presses into a hole cored into the top of the smoke stack formed in the back plate casting. The chimney is belled over at the top, and at a distance of  $\frac{5}{8}$  in. from the bottom is provided with a brass ferrule  $\frac{1}{4}$  in. thick and  $1\frac{1}{2}$  in. in diameter. The tube may be polished and lacquered, or painted in any colour. The best finish for the boiler is Brunswick black, and for the castings a brick red to represent brickwork.

**Horizontal Engine.** An excellent horizontal steam engine for amateur construction is illustrated in Fig 5, and is known as the Stuart mill engine; the castings and machined parts may be obtained from Stuart Turner, Ltd., Henley-on-Thames, or most model supply shops. It can be purchased in the form of fully machined castings, shown in Fig. 6, thus obviating the necessity for lathe work and enabling the engine to be constructed with the aid of simple hand tools. In Fig. 5 page 768, the cylinder is shown partly sectioned, to illustrate the construction.

The method of erecting this engine consists in taking the bed-plate casting, cleaning up the surface, and lining the crankshaft to the main bearings, remembering to place the eccentric sheave in place before doing so. The flywheel is fitted to the outer end of the crankshaft, and secured with a set screw. The crankshaft has a shouldered screw to act as a crank-pin, which has simply to be passed through the big-end bearing of the connecting rod and screwed in place.

The cylinder, piston, and slide, valve, are assembled and screwed in place with three screws passed through from the underside of the bed-plate casting, care being taken to see that the piston rod is in perfect alinement with the guides. These are composed of two rectangular bars of steel bolted in place, with distance pieces between them and the machined surface of the bed-plate casting. The cross-head has to be tested to see that it slides freely without shake in the guides, any roughness in the casting should be removed with a fine file or by scraping. The little end of the connecting rod should turn freely in the jaws of the crosshead, and is secured with a steel pin. The piston rod screws into the end of the crosshead, and is secured with a lock nut. The piston and glands should be packed with linen thread soaked in tallow to ensure a proper steam-tight sliding fit when the engine is working. The eccentric strap is fitted to the sheave, and the eccentric rod placed in position and secured with a lock nut. The knuckle joint at the end of the valve rod is then screwed in place, and the two connected together by a little bolt and nut.

The slide valve is timed as described earlier in this article, all bearings carefully lubricated, the remaining

bolts and nuts placed in position, and the engine is ready for use. It might be mounted upon a hardwood base and connected to the boiler previously described by fitting the steam pipe to a union screwed to the valve-chest cover, the exhaust pipe being taken to the chimney or disposed of in any convenient manner. This little plant would then drive a number of working models, or even a small-sized dynamo.

**Marine Engines.** Requirements for the power plant used in a model liner, destroyer, or speed boat are lightness, compactness, economy in steam consumption, and a low centre of gravity. A good boiler is one of the single-flue type (Fig. 7) with a number of water tubes across the flue. Since the flue is surrounded by water no outer casing is needed, and the boiler fits snugly in the hull, the weight being disposed low down.

*Engine. Fig. 7. Single flue launch boiler, with blow lamp. (Courtesy of Bassett-Lowke, Ltd.;)*

Fig. 8 shows a marine boiler made from sheet copper shaped up and riveted together. This has a dome, from which dry steam is taken off for the engine. In the absence of a dome, the steam pipe is usually made to traverse the flame before going to the engine.

Boilers of the above type are best fired with a paraffin or petrol blow lamp, preferably the former. Special lamps are made for the purpose by the leading model engineering firms (see Fig. 7), but it may be practicable to use one of the tubular commercial lamps made to heat a soldering iron.

*Fig. 8. Another type of marine boiler, made from sheet copper. (Courtesy of Whitneys)*

The engine shown in Fig. 9 may be built up from the machined set of castings and parts supplied, with the requisite bolts, nuts and screws, by Stuart Turner, Ltd., already referred to. If the worker anticipates any difficulty in drilling and tapping the

holes, this work will also be done by the manufacturers for an additional charge. The engine is enclosed in an aluminium casing, has ball bearings, and weighs, with fly-wheel, 21 oz. Other particulars are: bore  $\frac{3}{4}$  in., stroke  $\frac{5}{8}$  in. and height from bottom of crank case,  $4\frac{1}{2}$  in. The crankshaft is balanced. A displacement lubricator would be a desirable addition.

*Engine. Figs. 9 and 10. Two examples of Stuart marine engines which can be built up from sets of machined parts.*

Another engine for which a set of machined parts is sold by the above mentioned firm is that, illustrated in Fig. 10. This is an enclosed twin-cylinder engine with  $\frac{3}{4}$  in. bore and  $\frac{3}{4}$  in. stroke. The height is 4 in.; width 3 in.; and overall length  $4\frac{3}{4}$  in. It has a piston valve, and the gear wheels, with other working parts, run in an oil bath. This set is supplied with all holes drilled and tapped. The engine will propel a 4 ft. 6 in. boat.

**ENGLISH TERRIER.** This lively, intelligent and companionable dog is very similar to the black and tan or Manchester terrier, but his colour is pure white without any markings save his black nose. Any others are blemishes, according to show regulations, though the presence of a spot or two might not be considered as such by the family to which he is attached.

An admirable ratter, he does not always shine as a house guardian, his sense of hearing not being so acute as in other breeds, and often he is distinctly deaf. He has a long, narrow, flat head with fox-like muzzle; small black eyes and upright ears. The tapering tail is carried fairly level with the back. The coat is close, hard and glossy, and the weight from 12-20 lb. The English terrier is rarely seen to-day, having become almost extinct. *See Dog.*

## ENLARGING METHODS FOR AMATEURS

### How to Make and Use Photographic Enlargers

The following article covers the whole field in a fascinating department of photography, being thus one of a group that includes Developing; Exposure; Photography; Printing.

A properly exposed and developed vest-pocket negative can well be enlarged from  $2\frac{1}{2}$  in. by  $1\frac{5}{8}$  in. to a really large picture 12 in. by 10 in., or 15 in. by 12 in.

With the finest anastigmatic lenses enlargements on much greater scale than this are made.

Apart from the obvious use of getting large pictures from small negatives, the amateur will find that he can often greatly improve his photograph in enlarging it by getting rid of unnecessary or disfiguring detail, as seen in the examples in Figs. 1 and 2. The original snapshot (Fig. 1) of a harbour contains much irrelevant detail that destroys the interest of the photograph. By enlarging the centre portion of the photograph (Fig. 2), a really interesting and well-balanced picture is obtained.

*Enlarging. Figs. 1 and 2. Above, small snapshot same size as original negative. Below, enlargement of portion of negative showing the greatly improved picture obtained by getting rid of irrelevant detail such as the barrel, roof, and figure cut in half, and useless foreground and uninteresting sky. (Photo by F. J. Mortimer).*

Photographs may be enlarged either by the use of daylight or by artificial light, but more reliable results are obtained with artificial light. The simplest form of daylight enlarger is seen in Fig. 3, which consists of a box, small enough at one end to take the negative that is being enlarged, and large enough at the other end to take the sheet of bromide paper on which the enlargement is made. Near the negative end a small lens is placed controlled by the shutter: the focus is fixed, and only one size of enlargement can be made with the particular enlarger. Exposure is made by placing the enlarger out of doors, with the negative towards a clear

sky, the time necessary being found by test. An exposure meter will help in judging times.

*Enlarging. Fig. 3. Simplest form of daylight enlarger consisting of a box and a fixed focus lens.*

Artificial light enlargers are of different types. They may be grouped in two classes: (a) Those that use large and somewhat expensive condensing lenses, and (b) those that use reflected light in some form. A standard form of condensing enlarger is seen in Fig. 4, where A is the lantern house, B metal collars containing the condenser, which open and close to vary the distance between the light in the lantern house and the condensing lens, the latter being fixed to C, the carrier stage, in which D, the slide carrier holding the negative to be enlarged, is placed. Bellows E, permit the focussing of the lens F. The focussing of both lens and condenser is effected by sprockets and chains, worked by milled headed screws, G. It is necessary to be able to focus the condenser itself, since the more the enlarging lens F is racked out, the shorter must be the distance between the light source and the condensing lens.

*Fig. 4. Standard form of artificial light enlarger with condensing lenses. (Courtesy of Ensign, Ltd.)*

With apparatus of this nature it is easy to make enlargements of every size from any negative, the only limitation being the size of condensing lens. The rule is that its diameter must be equal at least to the diagonal of the negative to be enlarged.

In using an enlarging lantern it is essential to see that

the light is accurately centred and focussed. This is because the condensing lens only makes use of a point of light from the source of illumination, as will be seen in the diagram, Fig. 5, which shows the complete optical system used in an enlarging lantern. This also illustrates the necessity for accurate centring, for if the line AB does not pass through the centres of the light-condensing and enlarging lenses, it is impossible to get even illumination.

*Fig. 5. Diagram of optical system used in enlarging lanterns, showing necessity for accurate focussing of both light and negative.*

An enlarging lantern arranged in the vertical position offers distinct advantages. Adjustments are made rapidly, and in some types automatically, while no separate easel or table to take the whole apparatus is required. An efficient form, the Kodak "Auto-focus" enlarger, is illustrated in Fig. 6. The lamp-house contains a reflector with a sheet of opal glass to diffuse the light; below are the negative carrier, the bellows and an anastigmat lens. No condenser is required. A gas-filled lamp of 400 watts is recommended. An automatic focussing device gives a sharp image whatever size enlargement is chosen. The apparatus is designed to be firmly clamped to a table. If a V.P.K. negative be used (2½ in. x 1 ⅝ in.) enlargements up to 8¼ in. x 5¼ in. can be made; the largest negative which the carrier will take permits an enlargement up to 28 in. x 20 in.

*Enlarging. Fig. 6. Showing the very efficient Kodak "Auto-focus" enlarger.*

Smaller and less expensive automatic enlargers of this type are also available.

A slightly more elaborate mechanism employing a condenser, the Ensign "Magna-print," is shown in Fig. 7. Its characteristic is the speed with which enlargements are produced, a 1/1 plate enlargement from a ¼ plate negative being prepared in 3 seconds. The focussing is semi-automatic,

the whole instrument moving on the pillar and locking into position for the required degree of enlargement. The maximum is 20 in. x 16 in. from a  $\frac{1}{4}$  plate negative. This enlarger is also available for copying or photographing prints or small objects using the lamp-house as a source of light.

Various light sources may be used in enlarging lanterns so long as provision is made, where a condenser is used, for raising and lowering the light and for forward and sideward movements. The ideal form, from some points of view, is the electric arc, but this is somewhat expensive and extravagant of current. The gas-filled type of electric lamp is quite satisfactory, particularly if a lamp with a projection type filament is obtained. A 100-watt or 150-watt lamp should be used to get a strong enough light.

Where the ordinary electric supply current is not available, one of the small 6-volt gas-filled bulbs, which are used in motor headlights, run off an accumulator can be successfully adopted.

When it is proposed to take a photograph with a view to enlarging a negative afterwards, care should be taken to see that the negative is fully exposed and developed for a somewhat shorter time than usual, in order to obtain a thin negative, which gives the best results in an enlarging lantern. A thin negative of this kind should be one in which, while every detail can be clearly seen, the densest parts will allow type to be seen through them when the negative is placed upon a printed page.

**The Making of Enlargements.** The process of making actual enlargements from small negatives requires very little practice, though it needs the cultivation of an eye for picture making, i.e. the selection of the best portion of the negative to enlarge, the suppression of irrelevant detail.

*Fig. 7. Ensign "Magna-print" Enlarger for Midget and smaller sizes (Courtesy of Kodak, Ltd., and Ensign, Ltd.)*

To make an enlargement, place the negative in the negative holder, with the top end of the negative nearest the photographer's hand and the film side towards the enlarging easel. If the negative is an oblong one, place it in the holder upside down with the film outwards. By noting these points the enlarged picture thrown on to the easel will not only be the right way up, but will also be the right way round.

Next, turn on the light and, with the negative in the slide holder, focus the front lens sharply on the

enlarging easel according to the size of enlargement required. Then take out the negative and move the light backward and forward by racking the lantern house until the disk of light thrown on the enlarging easel is perfectly even. If the centre of the disk is more brightly illuminated than the rest, the light must be pushed forward; if, on the other hand, the centre is dark the light is too near the condenser and must be racked back a little. Minor inequalities of light on the easel can usually be rectified by placing a sheet of ground glass between the light and the condenser. This diffusion of the light will help to render less conspicuous in the enlargement scratches and other minor defects in the film of the negative.

Placing the orange cap over the lens, pin or otherwise fasten a piece of bromide paper on the easel in position so that the required portion of the picture falls on to it. Removing the orange cap, an exposure is made while three parts of the bromide paper are covered with a piece of card; then expose successively the three remaining parts of the bromide paper, giving each portion an equal exposure. Thus four exposures will be made on one piece of paper ranging from one to four times, and it will be easy to decide, after development, which of the four exposures was most nearly right.

No detailed guide for exposure in enlarging can be given, since the strengths of artificial light vary so greatly and the density of negatives differs so considerably. When the time of exposure for the particular negative has been found, a careful note of it should be made, either on the envelope containing the negative or in a negative record book. For details of developing and printing the reader should consult these headings.

One of the best developers for bromide enlargements is amidol. With prints that are correctly and not over-exposed development with amidol stops when the image is fully developed.

Many different types of bromide papers are available for enlarging purposes, varying from the ordinary glossy surface, used in press photography, and matt surfaces of different grades of smoothness, to very rough-surfaced papers, some giving by development warm black and brown effects. Smooth matt surface paper is more suitable to enlargements with much fine detail, while broad effects are obtained with the rougher papers. An enlarged print which is a little dull in colour, particularly in the shadows, may often be improved considerably by rubbing its surface with encaustic paste.

**Making an Enlarging Lantern.** A homemade enlarging lantern using a condensing lens, with the amateur's camera for projection and having all necessary adjustments, can be made for little more than the cost of the lens.

The body consists of 3-ply wood taken from a tea chest, the dimensions of which are shown in the sectional diagram Fig. 9. It is built up on a stout

baseboard, 16 in. long,  $7\frac{1}{4}$  in. wide, and  $\frac{3}{4}$  in. thick (Fig. 10). To this baseboard the two sides of the box which constitutes the lantern are screwed. They are 2 in. shorter than the baseboard; a removable end piece, A, carries a black velvet curtain to cover the end of the box and prevent light leaking out. The end piece fits loosely to permit the withdrawal of the lamp-house and its fittings. Its dimensions are seen in Fig. 9; the two sides are screwed at the top to a piece of wood  $7\frac{1}{4}$  in. long,  $2\frac{1}{2}$  in. wide, and about  $\frac{3}{8}$  in. thick, and braced at the bottom by a piece  $7\frac{1}{4}$  in. by  $\frac{3}{8}$  in., by  $\frac{1}{4}$  in. It is shown partly withdrawn in Fig. 8.

The box has practically no top. At the front a cover, B, about  $3\frac{1}{2}$  in. or 4 in. deep, is provided (Fig. 9). Along the top of both sides strips of tin, C,  $12\frac{1}{2}$  in. long,  $1\frac{5}{8}$  in. wide, bent along their length at right angles are nailed and screwed. These angle strips are bent so that one side is at least 1 in. wide, the other being  $\frac{3}{8}$  in. or less, and this wider side is painted underneath with dull black in order to reduce light reflecting.

On the baseboard are fitted the tubes and sliding platform for the lamp-house. Dimensions are given in Fig. 10. The long tubes are fastened at each end to blocks of wood by strips of tin bent over and screwed to the blocks. The latter are kept in position by nails or brads round them (not through them) knocked into the baseboard. They are thus independent of the baseboard and the whole of this portion is easily removed. On the long tubes are placed two shorter pieces of slightly larger tubing, which slide freely and are connected by a stout plate of copper or other metal, soldered at each end. A slot is cut in the centre. Pieces of an old tubular brass camera tripod serve this purpose, or brass curtain rods of two sizes can be used.

On the centre plate the lamp-house proper is fixed; it consists essentially of a cigar box and an adjustable lamp carrier (Fig. 11). It is fastened to the plate by a bolt and nut, which passes through the slot on the plate (Fig. 10), thus permitting a sideways movement of the lamp house to allow for the adjustment of the light. Backward-and-forward movement is supplied by the sliding tubes on which the plate is supported; upward-and-downward movement by the adjustable lamp carrier. In this case an old focussing projection piece from a disused magic lantern was made use of, the lenses having been removed. Such pieces of scrap optical apparatus can be easily picked up from optical dealers or on second-hand stalls. An alternative arrangement for raising and lowering, the light is shown in Fig. 12, where an ordinary electric bell or wireless terminal, A, slides up and down on a rod, the flex of the electric lamp being gripped, not too-tightly, between two nuts on the shank of the terminal. Similar forms of light holders can be improvised.

The lamp-house is completed by two pieces of wood (Fig. 13), screwed on to the top of the cigar box with a circular hole cut in the centre to allow the focussing piece used as the lamp carrier to pass through.

The purpose of these pieces is to provide a

covering for the light when in the lantern. The covering moves with the light, and prevents direct rays escaping from the lantern, since it moves underneath the overlapping strips of blackened tin. If further means of light exclusion are required, pieces of 3-ply wood  $7\frac{1}{2}$  in. by 3 in. or 4 in. can be placed on top of the box at either end, according to the position of the lamp-house. At the front end of the lantern a slot is cut with a keyhole saw to take a frame holding a sheet of ground glass for diffusion of light, if necessary. The slot is cut at the height of the condenser, and a strip of wood is fastened inside to provide a ledge for the diffusing glass.

The condenser box is seen in the photograph (Fig. 14) and the diagram (Fig. 15). For a  $5\frac{1}{2}$  in. condenser, such as is necessary for enlarging  $\frac{1}{4}$  plate negatives, a biscuit tin  $6\frac{1}{4}$  in. square and about  $2\frac{1}{2}$  in. deep is required, or a larger one can be cut down to fit, the cut ends being turned over and soldered. An aperture is cut in the bottom of the tin  $4\frac{1}{2}$  in. wide and  $3\frac{3}{4}$  in. deep, i.e. a little larger than a  $\frac{1}{4}$ -plate. A strip of copper the length of the condenser box and  $2\frac{1}{4}$  in. wide is taken and bent over at right angles, one side of the bend being  $1\frac{1}{4}$  in. wide, the other 1 in. A second strip of the same length  $2\frac{1}{2}$  in. wide is bent over at right angles, each bend in this case being  $1\frac{1}{4}$  in. wide. These strips are bolted on to the top and bottom of the condenser box to allow the negative carrier to be pushed in between the strips and the box, gripping it but permitting free movement. On the copper strip which is bolted on to the top of the condenser box a hooked piece is soldered on to support the camera, as shown at A (Fig. 15). Its dimensions are given in the smaller diagram (Fig. 16). This hook fits into the slot at the back of the camera in which the focussing screen slides. The condenser is wedged into the tin box with pieces of wood cut to fit, or it may be properly mounted.

The condenser box is made a light-tight fit in the front of the lantern in the manner shown in the photo (Fig. 8) and in the diagram (Fig. 9). A solid piece of wood, D, about  $\frac{1}{2}$  in. thick and  $6\frac{3}{4}$  in. wide, supplies a platform for the condenser box. It is screwed on to an upright piece, E,  $7\frac{1}{4}$  in. by 1 in. by  $\frac{1}{2}$  in. On both sides uprights, F, of  $\frac{1}{4}$  in. 3-ply wood are screwed, with a cross-piece at the top, of the depth required to make the condenser box a reasonably tight fit. When the condenser box is in position light leakages are stopped by stuffing strips of black cloth all round; these are nailed down with narrow strips of 3-ply wood (see photo Fig. 8).

To avoid moving the lantern backward and forward in enlarging different sizes the easel is arranged to slide along a plank 1 in. by 7 in. Details of its construction are seen in Fig. 17. The easel consists of an ordinary large-sized drawing board fastened to a sliding saddle-piece by means of two copper brackets, which are cut out of a piece of 2 in. square metal and folded up as

**Enteric.** *See* Typhoid.

**Enteritis.** The meaning of enteritis is inflammation of the intestine. *See* Colitis; Diarrhoea; Intestine.

**ENTRÉE.** This name is given to made-up dishes such as chicken cutlets, quenelles, fricassées, rissoles, ragoûts, soufflés, etc., and may be either hot or cold. If more than one entrée is served, the hot should precede the cold. The remains of fish, poultry, game, and meat can be used, and kidneys, sweetbreads, and livers are employed. The entrée course at dinner follows the fish, and precedes the joint.

**Entrée Dish.** These are made in silver. Sheffield plate and electro-plate, and may be purchased singly or in pairs. Such dishes are often found with a detachable handle, which enables the cover to be turned upside down and each dish made into a pair. Sometimes they have fixed liners with a space between the two parts for hot water. The entrée dish lends itself to rather elaborate ornament, and good 18th century specimens fetch high prices. *See* Sheffield Plate; Silver.

**ENTREMET.** This term is applied to a dishes of dressed vegetables, such as cauliflower au gratin, casseroles of cucumber, etc., as well as to hot and cold sweets and after dinner savouries.

**ENURESIS.** In young children enuresis or bed wetting is sometimes a very troublesome complaint. It is not wise to make a fuss about it, and in an ordinary case, there should be no threat of punishment. The bedclothes should not be too heavy, and the child should not be allowed to bury himself beneath them, nor to sleep on his back. An old method of preventing this is to tie a cotton-reel on the small of the back.

The diet should be simple, avoiding spiced food and condiments, and the last meal should not be heavy nor too near bedtime. No fluid should be allowed within an hour or two of going to bed. The bladder should be emptied just before getting into bed, and the child should be awakened in an hour or so to empty it again. A mackintosh sheet and draw sheet should be used. If constipation is present it must be corrected, and the motions should be observed for the presence of threadworms. In boys circumcision is sometimes necessary. Adenoids and enlarged tonsils are a common cause. When no obvious cause is present, suggestion may be a valuable help.

**EPACRIS.** This evergreen heather-like shrub is suitable only for cultivation in a heated greenhouse where the various kinds bloom in autumn, winter and spring. It belongs to the group known as hard wooded plants and is not an easy plant to grow well. In spring

when the flowering season is over the plants should be pruned; any repotting that may be necessary is done then. A suitable compost consists of peat (or peat two-thirds and loam one-third) with sand added freely. The pots must be well drained. Great care in watering is necessary to ensure that the soil becomes neither sodden nor dry. Propagation is by cuttings inserted in pots filled with sandy peat and placed in a propagating case under glass in summer.

**EPIDEMIC.** The name epidemic is given to a disease when it affects a large number of people at one time. The disease is usually one due to a microbe, but other causes may operate and affect large numbers of people, e.g. a poison contained in some article of food or lead poisoning from pollution of water by lead pipes. These epidemics of poisoning and of deficiency diseases, when once their nature and causation are apparent, can be easily brought to an end.

Notification and isolation have helped to limit the spread of most infectious diseases. In the case of small-pox, vaccination has been invaluable; and in the case of what are known as the water-borne diseases, e.g. enteric fever and cholera. The same may be said of control and, if necessary, the sterilization of water and milk supplies. Much may be done to limit the extension of diseases in which insects, such as the mosquito, flea, house-fly, etc., are the agents of infection, by measures of exterminating the insects or for affording protection from their bites or contamination. Protective inoculations with serums and vaccines, by increasing the resistance of the body, have proved successful.

It is not clear why some epidemics occur at more or less regular intervals. In the case of diseases which may affect the same person repeatedly, there will be a certain period of immunity after the illness and, as in the case of influenza, the epidemic may sweep over the community in a series of waves separated by varying intervals of time. Widespread meteorological conditions may be factors and lowered resistance affecting large communities because of food shortage. *See* Inoculation.

**Epidermis.** *See* Skin.

**EPILEPSY** or Falling Sickness (Grepilēpsis, seizure). Disease of the nervous system characterised by periods of unconsciousness. Epilepsy most commonly begins in childhood, before the fifth year. The fundamental cause is unknown, though fright, injury alcoholism, and an attack of illness appear to be exciting causes. The offspring of those parents who suffer from insanity or neurasthenia are more prone to exhibit epilepsy than are other children.

*The incidence of epilepsy would be much diminished if epileptics refrained from marrying and having children, every child of an epileptic need not have the taint, but in a family some members are almost sure to have it.*

Two forms are recognized. In petit mal the attacks of unconsciousness often last no longer than a few seconds and there are no convulsions. Grand mal is characterised by the occurrence of convulsive fits. The subject may have a preliminary sensation or aura, which warns him of what is going to happen. Sometimes the beginning of the fit is marked by a loud cry. At first the muscles are rigid, and suspension of respiration causes blueness of the face. After a few seconds, violent convulsions occur, and the tongue may be severely bitten. After one or two minutes the patient passes into a state of somnolence, which may be succeeded by prolonged sleep.

During an actual fit all that can be done is to prevent the patient from hurting himself. He should be allowed to remain in the recumbent posture, the clothes should be loosened round the neck, and a roll of cloth should be introduced between the teeth to prevent the tongue from being bitten. The most useful drugs are the bromides of sodium and potassium. These should be given for a long period. Careful attention must be given to the general health of the sufferer.

**Epispastic.** See Cantharides: Counter Irritant.

**EPSOM SALTS.** Sulphate of magnesium in the form of Epsom salts is much used for purgative action, the best time for taking it being immediately on waking in the morning. A moderate dose for a grown person is a teaspoonful in a tumbler of hot water. For stronger action 2 grains of calomel may be taken at bedtime and Epsom salts first thing in the morning. Some people find it easier to take the effervescing magnesium sulphate, of which  $\frac{1}{2}$  to 1 oz. may be taken in a glass of water and drunk while effervescing.

In certain cases of heart disease or Bright's disease, where the tissues are becoming waterlogged through the fluids in the blood escaping through the vessel walls, morning doses of Epsom salts sometimes give good results by removing from the system any excess of fluid. In this case the dose is dissolved in the smallest quantity of water which will take it up, in order to encourage a free escape of fluid from the walls of the bowel. See Aperient; Constipation.

**ERCILLA.** This is a self-clinging evergreen creeper, with leathery leaves and racemes of purplish flowers, which spring from the axils of the leaves. It is suitable only for walls, for it is not very hardy. Any ordinary soil suits it, but sandy loam is best. Propagation is by cuttings in summer in a frame. Another name for this plant is *Bridgesia spicata*.

**EREMURUS** (Giant Asphodel or King's Spear). These remarkable plants produce a large tuft of long strap-shaped leaves and in early summer send up tall strong spikes, the upper parts of which are covered with closely massed flowers. The large fleshy roots are of extraordinary formation: they radiate from a central bud like the spokes of a cart wheel.

*Eremurus. Giant Asphodel or King's Spear (E. himalaicus), 6-8 feet high with white flowers.*

Planting is best done in early autumn, and a shelter-ed place, e.g. among shrubs, must be chosen, for the plants start into growth early. There should be a 6-in. covering of soil above the roots, which must be handled carefully because they are brittle. Well-drained loamy soil suits them best; clayey land must be made suitable by adding old turf, sand and some leaf-mould or decayed manure. It is advisable to protect the roots in winter by placing ashes or leaves on the soil above them. The best method of propagation is by seeds sown in a frame as soon as they are ripe. *Eremurus robustus* bears pale rose-coloured flowers on a stem up to 10 feet high: *himalaicus*, with white flowers, grows 6 to 8 feet; *Warei*, reddish bronze, is 6 feet or more high. *Bungei*, 4 to 5 feet, with yellow flowers, is one of the best for small gardens.

**ERGOT.** The ergot, a fungus which sometimes appears among grasses and weeds, is very fatal to the plants attacked. The ergotted seed becomes black and elongated like the spur of a cock, from whence it derives its name. The remedy is to gather and burn all infected plants.

**Poisoning by Ergot.** Ergot is used in medicine, but should only be taken under the doctor's direction. In acute ergot poisoning following on an overdose of the drug, the chief symptoms are violent sickness and diarrhoea, headache and dizziness. These symptoms may gradually pass or may increase in severity, the patient falling into rapid convulsions, leading to loss of consciousness and death. While waiting for the doctor, an emetic, e.g. a tablespoonful of mustard in half a tumbler of water, may be given, and when the patient has vomited thoroughly, 2 tablespoonfuls of castor oil. Strong hot tea should also be given freely. Symptoms of poisoning may also appear through eating bread containing rye which has been attacked by the fungus.

**ERIGERON.** (Summer Starwort.) This is a most valuable plant for the herbaceous border; in summer it bears numerous large daisy-like flowers on stems up to 2 ft. high, in shades of lavender, purple and other colours. The plant thrives in ordinary well cultivated soil and can be increased by division in the autumn or by sowing seeds in a box of soil in a frame in spring.

The commonest kind is *Erigeron speciosus*, 2 ft. high with mauve-purple flowers; *speciosus superbus* with more richly coloured blooms is finer. Quakeress, lavender, is one of the best of all; other fine modern varieties are *B. Ladhams*, rose-pink; *Pink Pearl*, blush-

pink; Asa Gray, apricot-buff; Amos Perry, lilac; and Fontainebleau, lavender-blue. *Alpinus*, 9 in., purplish blue, and *aurantiacus*, 6-8 in., orange yellow shade, are suitable for planting in the rock garden.

*Erigeron. The Summer Starwort, a beautiful hardy border flower.*

**ERINUS.** *Erinus alpinus* is a pretty little plant of tufted growth suitable for crevices in the rock garden; it flourishes best in well-drained gritty soil. It is not as a rule long lived, but can easily be increased by seeds sown in spring in the rock garden where the plants are to flower the following year. *Erinus alpinus* is only 4 or 5 inches high, and bears rose purple flowers in early summer.

**ERMINE: For Wear.** Ermine, which is the fur of the stoat, is mostly obtained from Canada and Russia, the coat of the British stoat not changing colour to pure white in the winter to the same extent as it does in northern regions. The skins are narrow and about 10 in. long, the tail being white with a black tip, and the fur short and close. What is known as summer ermine is the beige colour fur of the stoat's coat in summer.

Ermine loses its whiteness, and becomes yellow with age: it can be cleaned, but once the yellow tinge appears, bleaching will not restore its pristine purity. This yellow colour may be kept from appearing for a considerable time if the fur is stored away in darkness when not in use.

Ermine is trying to the complexion, and looks best in the evening for coat, collar, or wrap. Being easily soiled, ermine needs to be treated with great care. After use it should be wiped over lightly with a fine white cloth and wrapped between layers of tissue paper. When badly soiled, ermine is best sent to the cleaners; but if it is to be treated at home, cornflour should be rubbed in with the tips of the fingers, and afterwards brushed out with a soft, white-bristled clothes brush. *See Fur.*

**ERMINE MOTH.** The small ermine moth is

found in nearly every orchard and garden, and the caterpillars are very destructive to trees and shrubs. The moth itself may be identified by its upper pair of wings, usually of a leaden whiteness, with small black spots on the edges of the wings, which also are fringed with livid-coloured hairs. The caterpillar is about  $\frac{1}{2}$  in. in length, the body being a dirty yellow or leadish-white and the head brownish.

*Ermine Moth, an orchard pest. 1. Mature insect. 2. Egg mass. 3. Caterpillar. 4. Cocoons. 5. Apple shoot with web. (Ministry of Agriculture and Fisheries and H. M. Stationery Office)*

The moth often selects apple, pear, plum or almost any fruit tree on which to deposit eggs in masses near leaf-bud and blossom. The caterpillars are hatched during autumn, but rest under a protective scale until trees are coming into leaf, and then spin a thick web of threads round a young shoot, enclosing foliage, within which they live, feeding upon the leaves.

When each caterpillar is full grown it encloses itself in a cocoon of white silk, in which it pupates until the month of July, when it emerges as a moth. Remedies are to kill the moths before they deposit eggs, and burning or crushing of the caterpillars while in their webs.

According to Leaflet No. 40, issued by the Ministry of Agriculture, the most satisfactory treatment for affected trees and hedges is to spray them soon after the blossom is over with lead arsenate (1 lb. of lead arsenate paste to 20 gallons of water).

**ERYSIMUM** (Fairy Wallflower). Free flowering annual and perennial plants with small wallflower-like blooms in yellow, orange and other colours. The two most popular annuals are *arkansanum*, yellow, and *peroff-skianum*, orange. They do best when sown out of doors in early autumn to bloom in spring and early summer. Seeds may, however, be sown in spring to provide plants in bloom from July onwards. They

flourish in ordinary soil, preferably that which is not clayey. *Erysimum rupestre* is a rock garden plant, 3 or 4 inches high, which bears yellow flowers in summer. It is easily grown in sandy soil.

*Erysimum*. One of the fairy wallflowers (*Erysimum arkansanum*), a hardy annual.

**ERYSIPELAS.** Erysipelas, or St. Anthony's fire, is an acute, rapidly spreading inflammation of the skin, and sometimes of the underlying tissues, accompanied by heat, swelling, redness and pain of the affected part, together with high fever and general prostration. The temperature may run up to 103° or 104° F., and the patient will very likely become delirious. The skin of the face is the most common site, and large or small blisters may be present. The patch spreads rapidly, the parts first attacked getting paler and perhaps scaling. If the eyelids or scrotum are involved, there may be much swelling owing to the laxity of the tissues in these situations.

The disease is due to a germ, a streptococcus, like those which cause suppuration, finding its way into the skin. Infection may take place through an open wound of any kind, even a slight scratch. Debilitating diseases, such as diabetes and Bright's disease, and alcoholism, by weakening the resistance of the tissues, predispose to the disease. Erysipelas is a disease notifiable to the authorities, and treatment should be in the hands of the doctor. *See Infectious Diseases.*

**ERYTHEMA.** This is a blush or reddening of the skin occurring in patches of various sizes which temporarily disappear upon pressure. It is due to many causes, such as emotional disturbances which produce blushing; external irritation in the case of chilblains; effects of heat and sunlight; friction of the skin by ill-fitting clothes, etc.; counter-irritants like mustard; nervous influences, e.g. neuralgia; and poisonous

substances in the blood, e.g. belladonna; poisons derived from the bowel, etc. Where there are no symptoms other than redness of the skin, with perhaps slight itching and burning, the application of a lotion such as the following usually gives immediate relief:

Boric acid	1 dram
Carbolic acid	40 minims
Glycerin	2 drams
Water to make	4 oz.

The lotion should be mixed with equal parts cold water and sopped on to the skin. In erythema due to chafing, the irritable parts may be dusted several times a day with a powder composed of zinc oxide 1 part, magnesium carbonate 1 part, starch powder 2 parts. The part should be washed before applying the powder.

Erythema multiforme is an acute inflammatory skin disease characterised by papules, lumps, red patches and sometimes blisters on the skin. Erythema nodosum is characterised by pinkish-red round or oval swellings chiefly over the shin bones. The treatment should be supervised by the doctor, unless it is slight. If the digestion is poor or the patient is of a constipated habit these matters should be put right.

**ESCALLONIA.** These are beautiful summer-flowering shrubs, most of them being evergreen. They are not very hardy, and in all except the mildest districts must be grown on a sunny wall. *Escallonia macrantha*, with attractive evergreen leaves and rose-coloured flowers, makes an admirable hedge in seaside gardens in mild localities, but elsewhere it needs the shelter of a wall. One of the hardiest is *Escallonia langleyensis*, a vigorous shrub 6 feet or more high, which may be grown in the open garden in southern counties and bears rose red flowers. *Exomensis* and *philippiana*, both with white flowers, are two fairly hardy sorts. *Escallonias* thrive in ordinary soil and are propagated by cuttings set in sandy compost in a frame in summer.

*Escallonia macrantha*, a crimson-flowered hedge shrub which thrives in seaside gardens.

*Eschscholtzia*. This is the botanical name of a showy hardy annual, the Californian poppy (q.v.)

**ESKIMO DOG.** Most of the Arctic and sub-Arctic dogs share certain features in common, being of a wolfish appearance. The head of the Eskimo particularly takes after that of the wild animal, but the dog differs in one respect by carrying its tail tightly curled over the back. The colour may be white, black, black and white, silver grey, etc. Opinions vary about their disposition. Some say they are uncertain in temper, others give them excellent characters. See Dog.

*Eskimo Dog. Specimen of the breed, which in appearance is closely akin to the wolf.*

**ESPAGNOLE SAUCE.** From this rich brown foundation sauce many other varieties are prepared. It can be made by melting 2 oz. of butter in a stewpan, and adding to it 3 oz. of ham or bacon cut into dice, a bunch of parsley and herbs, tied together, an onion and a carrot (sliced), 1 tablespoonful of chopped mushrooms, 3 peppercorns, and a clove. Fry all these a light brown, then add 2 oz. of flour.

When this is also brown, pour in 1 pint of brown stock, add 3 sliced tomatoes, and let the sauce simmer gently for ½ hour, stirring it occasionally and keeping it well skimmed. Add a wineglassful of sherry, with seasoning to taste, and then rub the sauce through a sieve or tammy cloth, adding a little more stock if it is too thick. The wine and mushrooms may be omitted.

**ESPALIER:** For Fruit Trees. The Horizontal espalier tree is a Convenient type for planting alongside the paths in the fruit and kitchen garden, the branches being trained on wires stretched between posts. Such trees, if correctly managed, produce exceptionally fine fruits. They are suitable also for planting against a wall. Apple, pear and plum are usually grown in this form. The trees may have one tier or, as is shown in the illustration, several tiers of branches. A fresh tier is formed by allowing a shoot at the top of the main stem to grow until it is 12-14 in. high; the top is then cut off, and when side shoots develop one on each side is selected and trained horizontal at about 12 in. above the tier beneath. Other shoots are rubbed off.

At the winter pruning the new branches should be cut back to within 12 in. of the base of the previous summer's growth; thus they will extend every year by about 12 in. The summer pruning consists of shortening all side shoots late in July to within 6 in. or so of the base; in winter these are cut back to within about three buds of the, base. *See* Apple; Cherry; Fruit; Pear; Plum, etc.

*Espalier. Example of an apple tree, the branches of which have been trained horizontally along wires bordering a kitchen garden.*

**ESSENCE.** Essences are the essential oils from aromatic plants, obtained by a process of distillation and made into solution with pure alcohol. They are much used in the preparation of sweet and savoury dishes. The commonest used are essences of vanilla, lemon, almond, cloves, peppermint and ginger. These are very strong and one or two drops are sufficient to provide the flavour required.

To make essence of lemon, 1½ cupfuls distilled water should be mixed with 1 cupful pure alcohol and ¾ oz. oil of lemon. Saffron should be used to colour. Orange essence is made from 6 oz. alcohol mixed with ½ oz. sweet oil of orange, and coloured with cochineal. Almond essence is made from ¼ oz. oil of bitter almonds, 1 tablespoonful distilled water and 1½ cups alcohol.

Essence of cloves is prepared by infusing ¼ oz. cloves in 2 oz. proof spirit for the period of a fortnight, straining it and then bottling the essence for use.

To make ginger essence, ½ oz. freshly powdered ginger, ¾ oz. lemon rind, and ½ pint brandy or spirits of wine are needed. Let the rind and ginger soak into the liquid for a fortnight. Shake the whole daily, and then strain and bottle it, when it will be ready for use. *See* Almond; Lemon; Vanilla.

**ESSENTIAL OIL.** The chief flavouring part of vegetable substances is known as the essential oil. That of lemon, for example, has the complete odour of the lemon, essential oils being distinguished from fixed oils by this characteristic property. Almond yields both an essential and a fixed oil, but it is only the former that smells of almonds. Essential oils differ from fixed oils in not leaving a greasy stain on paper.

**ESTATE DUTY.** This term is used for the duty payable in the United Kingdom on death from the estates of persons who leave property. It was first imposed in 1894 and is graduated according to the value of the estate. The value of all property left, real or personal, settled or unsettled, is added together and duty charged thereon at the rates noted next page.

In the case of small estates, i.e. those under £500, the executors can pay, if they prefer, a sum of 30s. if the value is not more than £300, and of 50s. if it is between £300 and £500. This frees them from all other charges.

The payment of the duty on estates of high value may be made in the form of real or leasehold property which is part of the deceased's estate. Certain classes of war loans are taken in payment at their face value, provided the deceased had held the stock for a certain period.

Other provisions of the law about estate duties deal with gifts made during life (inter vivos). If such were made within three years of death they are regarded as part of the estate and duty is charged thereon. If the gifts were for charitable or public purposes the period allowed is one year. Exceptions to this are gifts less than £100 in value, settlements made on marriage and those which were part of the deceased's normal expenditure, e.g. an annual allowance to a daughter.

Personal estate and real estate are valued separately for death duties. On personal property interest at the rate of 4 per cent is charged from the day of death until the settlement of the account. On real property the duty may be paid by instalments over a period of eight years. In this case interest of 3 per cent. is charged, but only from 12 months after death. *See* Executor; Legacy Duty; Probate; Will.

Exceeding £	Per cent	Exceeding £	Per cent
500	2	75,000	18
1,000	3	85,000	19
5,000	4	100,000	20
10,000	5	120,000	22
12,500	6	150,000	24
15,000	7	200,000	26
18,000	8	250,000	28
21,000	9	300,000	30

**ESTIMATE.** An estimate is a statement giving the probable cost of an undertaking by one who is prepared to do the work. Before building, repairing, or decorating a house, laying out a garden, removing furniture, it is advisable to ask builders and others for an estimate. If desirable, estimates can be obtained from two or more firms and the prices compared. The lowest estimate, however, is not always the most economical.

The success of any estimate depends to a large extent on the care and accuracy with which the inquiry is expressed; no one can quote a price for a piece of work unless the requirements are set out in sufficient detail. There should be a clear, precise, and definite statement

of the work to be done, when and how it is to be done, the materials to be used, terms of payment, and a penalty clause for failure on either side. Often when an inquiry is made the terms are ambiguous or indefinite, with the result that some misunderstanding arises later.

When a house is to be built, it often pays to engage an architect or quantity surveyor to prepare a bill of quantities. This includes a list of everything to be used in the work, and is the safest method to adopt, as the surveyor will see that the work has been done and the materials used in the right way and without waste. On the other hand, if a professional is called on to advise or quote for a piece of work, it is assumed that he will perform the task in a workman-like manner, and failure to do so is justifiable cause for complaint by the employer.

Estimates for building need to be examined with even greater care. An estimate becomes a contract when it is accepted, but it may contain a clause providing for an increase in the figure in the event of any change in the rate of wages or prices of materials, and adjustments of this kind, must be allowed for or the contractor can withdraw. *See* Architecture; Bungalow; Cottage; House.

**ETHER:** Use in Medicine. The purified form of ether is employed for producing anaesthesia. It may be sprayed on the skin to freeze it, and diminish the pain of an incision or puncture, or on tender points in neuralgia. As a general anaesthetic ether is preferable to chloroform in many cases, because it acts as a heart stimulant. It may also be used as a rapid stimulant in fainting, collapse and cardiac weakness generally, as a carminative in flatulent dyspepsia, and as an antispasmodic in asthmatic conditions. Ether should not be administered by an unauthorised person. The drug is very inflammable, and should never be handled near lamps, fires, etc.

**ETIQUETTE:** Some General Rules. The rules of etiquette which obtain in a social, business or professional environment form a safeguard in dealing with other people correctly. This is particularly the case when the surroundings are new and formality has to be observed with strangers, without any stiffness.

For instance, in the case of a family settling in a country district after living in a large town, certain differences of etiquette should be studied. Of these the two most important are that the new arrival should not call on anyone first, and should be careful to distinguish between calls and card leaving, by returning the same form of civility in each case. To call on someone of a higher social position who had only left cards would be to appear pushing, and perhaps cause a prejudice against the newly arrived family. On the other hand, to return cards where a friendly call has been made would be frigid, and be taken to mean that the acquaintance was not cared for.

Another instance where a knowledge of etiquette may be of importance is in the case of women whose husbands' profession stations them abroad. By observ-

ing the strictly correct procedure they avoid getting into a wrong set, because, by being polite but not intimate, they gain time to form a cool judgement without giving offence. The best plan is to follow the advice of someone who is already well established in the locality. A general rule which may be followed when in doubt is that it is wiser to err on the side of formality, and that if possible when confronted with a custom or anything which appears strange it is well to observe how other people meet it.

Appointments should be punctually kept, whether business or private. Letters should be answered as soon as possible. Invitations should be clearly and cordially expressed, and replied to in the same vein. A letter of introduction should always be given to the person it is intended to benefit open and delivered open. If not used the giver should be notified and the reason explained, with thanks for the kind intention. It is not necessary to introduce people to each other unless they are likely to have something in common, but where there are only one or two persons present it is better to introduce them than to allow anyone to feel awkward. Whatever the respective rank, age, or position, the man is always introduced to the woman, and unmarried women to the married, unless the former is of superior rank. The onus of future recognition rests upon the person to whom the other is introduced.

**Men and Women.** The rules of etiquette between men and women have been somewhat modified. In social life a man would rise when his hostess or other women entered the room or stood; he would open the door for them and follow their lead. In business this would be absurd. Some years ago it would have been a hard and fast rule for a man to give up his seat to a woman standing in a train or public conveyance. Now a business girl realizes that an older man may be more tired than herself, but anyone on being offered a seat should accept it graciously without argument.

When walking with a woman a man should be on the kerb side of the pavement, and should never greet or leave her out of doors without raising his hat. The rule for a man about paying fares for a woman is one which admits of variation. Many independent women think it unfair to allow a man to pay. Whatever the reason they should not argue and a woman should always be prepared to pay for herself quickly to save any awkwardness.

As far as the ballroom is concerned, it is worth while cultivating certain little courtesies, which go hand in hand with good manners. Always avoid dancing steps which draw attention to yourself, and never show off unless you happen to be an exhibition dancer. Introduction, though a simple matter, is one very few people take the trouble to perform gracefully. At a dance, or anywhere else, the man should be taken up to the girl, and the person who performs the introduction, with a slight inclination of the head towards her, should say: "Miss-----, may I introduce Mr. ----," and then, inclining the head towards the man, say: "Mr. -----, Miss-----."

Never hurry over an introduction, and pronounce

the names very distinctly.

The etiquette which governs dress is not altogether founded on fashion, and its rules are best interpreted by suitability. The most elaborate clothes might be worn at a wedding which would look out of place elsewhere in the daytime. A greater laxity obtains now in these matters.

At many informal parties evening clothes are not expected, though when in doubt it is best to be formally correct. When staying in country houses people are expected to have the right clothes for any outdoor sports in which they take part, and to wear the correct evening dress for dinner. *See At Home; Call; Cards, etc.*

**EUCALYPTUS.** Substitute for cocaine as a local anaesthetic. Solutions of the drug may be dropped into the eye or injected into the skin for operations on these parts, or injected into the gums for tooth extraction. In an ointment eucaine may prove useful in cases of intolerable itching.

**EUCALYPTUS: Medicinal Uses.** Eucalyptus oil is obtained by distillation from the fresh leaves of the Australian blue gum-tree. The dose is one-half to 3 minims, and it may be taken on lump sugar. It has been given in ague, in septic fevers, and in consumption and chronic bronchitis when the sputum is foul smelling. It is a strong antiseptic and disinfectant. The following makes a useful inhalation or spray in diseases of the air passages:

Eucalyptus oil	1 dram
Light carbonate of magnesia	½ „
Water to make	3 oz.

Add one teaspoonful of the above to a pint of hot water and breathe in the resulting vapour.

Eucalyptus ointment smeared on boracic lint is a good application for abrasions and burns. Tincture of eucalyptus is efficient in arresting bleeding.

**EUCHARIDIUM.** This is a pretty, hardy annual, belonging to the evening primrose family. It may be sown out of doors in autumn to provide spring flowers, and in spring to yield summer flowers. It likes well drained soil in a sunny position. The favourite is *Eucharidium Breweri*, 6 inches high, with pale rose-coloured flowers which are slightly scented.

**EUCHRE.** This is a card game for two, three, or four players. Here the game is described for four players, who play as partners, two against two. Three varieties of packs are used. A 32-card pack, the ordinary full pack, from which all cards from the six to the two inclusive are omitted, a 28-card pack in which the sevens are also omitted, or a 24-card pack, on which all cards from the eight to the two are omitted.

The cards rank according to trumps. In the trump suit the jack, known as the right bower, is the highest card. The second highest card is the jack of the suit the

same colour as trumps. This jack is known as the left bower. The order of the cards is then the ace, king, queen, ten, etc., of trumps, followed by ace, king, queen, ten, etc., of the suit the same colour as trumps. In the two suits of opposite colour to trumps the order is as at whist. If a joker is used it becomes the highest trump.

The deal is by cutting, low dealing, ace being low, and for cutting all other cards counting as at whist. Five cards are dealt to each player, in one round of three at a time and one round of two. The next card is turned up for trumps. The game is to take at least three tricks by the player or partners who make the trump. If the players who call trumps fail to make the three tricks they are said to be euchred.

The eldest hand begins play by ordering up the trumps or passing. If he orders up the trump, then the dealer must take up the exposed trump card and discard one from his hand. But he does not take up the exposed trump until his turn comes to play, though he must discard immediately. If eldest hand passes, then dealer's partner may say, "I assist," thus ordering the dealer to take up the trump, or he may also pass, and so with the third player. Finally the dealer himself may take up the trump or pass. If he passes he turns the trump card face downwards on the top of the pack. If all have passed, the eldest hand has the right to name a fresh trump suit or pass, and each player in turn will have the privilege as long as the player before has not named the trumps. If all players again pass there is a fresh deal by the next player, eldest hand.

If a new trump is named of the same colour as the one rejected, it is called making it next, but if of the opposite colour it is called crossing the suit. If joker is played, it is customary to say before a deal what suit the joker shall represent if turned up. When the trump is made, eldest hand leads and each player in turn follows suit if possible. If not, he may trump or discard. The winner of each trick leads for the next trick. As each trick is made it is turned face downwards, and is not allowed then to be examined. A player who has named a trump may elect to play alone against his opponent, in which case his partner places his hand face downwards on the table and takes no further part in the play of that hand. The ordering up of the trump, the taking up of the trump by the dealer, or the making of a fresh trump, all come under this rule.

**Rules on Revoking.** If a player revokes and it is not discovered till the trick is turned over, the hand is abandoned as soon as the revoke is claimed and proved. Players must allow tricks to be examined at the end of the game when a claim for revoke is made, or they suffer the penalty of a revoke. If the revoke is discovered before the trick is turned the player's adversaries may take back their cards and play fresh ones if they wish, but the player's partner cannot. Exposed or cards dropped face upwards must be played at the first opportunity. A player who holds the incorrect number of cards cannot claim a misdeal after the first trick has been played, nor can he or his partner score that hand.

The players or partners who made the trump and win three tricks score one point. If they win five tricks they score 2 points. Failure to take three tricks is euchre, and the opponents score 2 points. A lone hand scores 4 points for five tricks; one point for three or four tricks; and his opponents 2 points if he is euchred. Two points are scored by a player's opponents for a revoke, and 4 points by lone hand if his adversaries revoke. The game is 5, 7 or 10 points up as may be agreed upon by the players. In three-handed euchre the maker of the trump plays against the other two players. He scores 3 points for a five-trick win, and one point for three or four tricks, and loses 2 points to each of his opponents for euchre.

**EUGENOL.** This is a colourless oily liquid smelling like oil of cloves, of which it is the chief constituent. It is strongly antiseptic and is not poisonous. When applied to mucous membranes it diminishes sensation. Eugenol makes a useful application in neuralgia and toothache, and is much used in dentistry. Eugenol may also be used to relieve itching, 10 grains in 1 oz. of lanoline.

**EUONYMUS.** This is a group of hardy evergreen and leaf losing shrubs, suitable for various purposes in the garden. *Euonymus japonicus* is a well known hedge shrub, which is particularly useful in seaside gardens, where it is less liable to be attacked by the magpie moth, which often disfigures euonymus hedges in inland gardens. *Euonymus radicans* and its variegated leaved variety are trailing shrubs which will thrive beneath trees and provide a useful evergreen ground covering. The common spindle tree (*Euonymus europaeus*) is very handsome in autumn when its brightly coloured fruits are at their best. All thrive in ordinary soil and are increased by cuttings set in a frame in late summer, or by seeds sown out of doors. *Euonymus radicans* is increased by division in autumn. From the bark of this shrub a dried extract, known as euonymin, is made, and frequently employed in medicine as a purgative.

**EUPHORBIA** or Spurge. The genus of plants of this name includes annuals found in gardens and hedgerows, e.g. *E. peplus* and the common sun spurge, some shrubs, and plants which resemble cactus. When cut they exude a milky juice. The *Euphorbia peplus*, also known as petty spurge or devil's milk, is useful in asthma. *Pilulifera*, found in Australia and S. America, also known as Australian snake weed or cat's hair, is also used for asthma and for hay fever and coryza. *Euphorbia* obtained from an American species is a remedy for bronchitis.

In poisoning by a species of *euphorbia* there is vomiting and purging, the face becoming dusky. Give an emetic of mustard and water and a dose of castor oil, or, if the patient is vomiting, encourage by draughts of tepid water. Thereafter give demulcent drinks, thin arrowroot, etc. Keep the patient warm and if breathing ceases resort to artificial respiration. *See* Poisoning.

**EUSOL.** The compound solution of hydrochlorous acid known as Eusol is an antiseptic fluid made by mixing bleaching powder and boracic acid together in water. It loses its strength fairly rapidly, especially, in hot weather. It will be found useful in most conditions where an antiseptic lotion is necessary. It is too irritating for the eyes, though it may be sprayed on the throat.

Dakin's solution is a similar preparation and keeps better. It is prepared in two strengths. The stronger will keep for a month and should be diluted with six parts of water before used; the weaker is not suitable for use after a week. All these solutions can be obtained freshly made up from a chemist. *See* Antiseptic.

**EUSTACHIAN TUBE.** The Eustachian tubes are narrow passages about 1½ in. long, leading from the back of the throat near the posterior opening of the nose into the cavity of the middle ear. Each tube is lined with a delicate mucous membrane, and in health is always opened in swallowing, allowing the free passage of air into the middle ear cavity. The importance of this is that it allows the air pressure in the middle ear cavity to keep the same as that outside the ear drum, and thus a free movement of the latter is kept.

*Eustachian Tube.*  
*Diagram showing anatomy of passages running from ear to nose and throat.*

Sometimes in catarrh of the nose and throat the catarrh spreads along the Eustachian tubes, blocking it up and so preventing the free entrance of air to the middle ear. Partial deafness and buzzing sounds in the ear are frequently due to this cause. *See* Ear.

**EVENING DRESS.** Setting aside court dress, which is a matter of uniform or regulation costume, evening dress for men resolves itself into a well-cut dress suit and a dinner jacket suit. The swallow-tail coat and white tie are worn for the formal house or restaurant dinner, theatre or evening party. Either a white or black waistcoat is permissible, though the former gives a smarter, brighter appearance to the wearer. The dinner jacket, always with black bow tie, is worn for informal dress at home or out. It frequently makes its appearance now at smaller dances, is usual in the country house when a dinner party is not being given, at bridge parties, and for quiet theatre-going occasions.

When dining with formal acquaintances it is best to wear full evening dress if in doubt as to what is expected. Where the invitation is received through the post well in advance of the date of the party it is usually a sign that it will be a formal one, and require the regulation swallow-tails. For outdoor wear in large towns a black overcoat, crush hat, and white silk scarf are correct with evening dress.

**EVENING PARTY.** The formal evening party is often merely a reception, beginning about 9.30 and going on till after midnight. It may follow a dinner party to enable a larger circle of the hostess's acquaintances to meet some distinguished person in whose honour the evening's entertainment is given. In this case, those who are invited arrive at any moment within the time limits and stay as long as they wish, in just the same way as at an afternoon At Home. On the other hand, should there be a special feature, such as music, bridge, roulette, cinema show or lecture, it is usual to put this on the invitation so that the guests may arrive at the hour stated. Dancing also, if intended to form the staple attraction, would be mentioned. Evening dress is the rule.

For a mixed party including children, which might be given at Christmas or for a birthday, games are often introduced, card and conjuring tricks are popular if well done, charades are a never-failing attraction when thought out beforehand and dressing facilities are arranged, while such games as clumps and musical chairs have a perennial appeal. In the country the parties of such a description often start early in the evening.

For light refreshments or suppers at all these entertainments selections from the same kinds of food are served; sandwiches in all their varieties, meat jellies, mayonnaises, eggs or prawns in aspic, every sort of galantine, terrine, pie, cold sweet, savoury and ice. In the winter hot soups, served in cups, and in the summer iced drinks are in special demand. Iced drinks; and ices should be available throughout the evening, and where there is no staff to distribute them the guests should be asked to help themselves to refreshments.

**Informal Parties.** Some hostesses specialise in small Sunday evening parties, only inviting those who are

likely to enjoy each other's society, and without any formality. It is usual to serve a sit-down or help-yourself supper about eight o'clock at this type of party, and evening dress would be optional.

Informal after-dinner parties are useful methods of entertainment where accommodation is limited, and give opportunity for introducing people whom one is anxious should meet each other. In such cases the invitation may be by telephone or sent in a friendly note, asking the prospective guest to come in after dinner on such and such an evening.

Nothing elaborate in the way of refreshments is needed. Usually coffee is handed round as soon as the company is assembled, and liqueurs may be offered at the same time. Fruit, cakes and cocktails or other drinks may be offered during the course of the evening.

Entertainment during such an evening can take the form of cards, music, or merely conversation, according to the tastes and talents of the guests. If any of the guests can contribute items, a cabaret performance is devised, the room for dancing can be cleared except for chairs, small tables set round the walls, and the necessary piano.

For a more important musical evening a concert may be arranged either to introduce talent or for a charity. If for the latter purpose, the preliminary work involved in getting up a concert, includes some advertisement of the forthcoming event in the local newspapers, by the distribution of handbills among residents and for exhibition in shop-windows, arranging and numbering the seats, and providing tickets and programmes. *See* Bridge Party; Cocktail Party; Dinner; Amateur Theatricals.

**EVENING PRIMROSE.** Some of the evening primroses are perennial, but others are biennial. The latter perish after they have flowered, and must be raised from seed every year to ensure an annual display of bloom; the perennials live on from year to year. The common evening primrose, *Oenothera biennis*, of which the flowers do not open during the daytime, soon becomes a weed in gardens, for it sows itself freely. It is not nearly so attractive as some of the perennial kinds, although useful for odd corners and in the shrubbery.

*Evening Primrose, the flowers of which are closed during the day and open in the evening.*

The best of the perennials is *Oenothera fruticosa* or *Fraseri*; this is a splendid border plant, 18 inches to 24 inches high, which bears bright yellow flowers that are open during the daytime. *Speciosa*, 2 feet, has beautiful white flowers, and *missouriensis*, a trailing plant for the rock garden, has large yellow blooms. The new *Oenothera trichocalyx*, 2 feet high, with white flowers, blooms in

summer from seeds sown in spring under glass.

The evening primroses suitable for planting in borders flourish in ordinary soil; *missouriensis* thrives best in well-drained sandy loam. The perennials can be propagated by division of the clumps in autumn or spring, or by sowing seeds out of doors or in boxes of soil in a frame in April-May.

There are several annual evening primroses, of which the most striking are *taraxacifolia*, blush, 6 to 8 inches high; *rosea*, rose colour, 6 to 8 inches; and *bistorta Veitchii*, yellow and crimson, 12 inches. The two first named are hardy annuals to sow out of doors in April; the last should be sown under glass in March.

**EVERGREEN.** The term is applied to the innumerable trees, shrubs and flowers which retain their leaves all the year round, instead of shedding them in the autumn, as deciduous or summer leafing shrubs do. With the exception of the holly, box, and some varieties of the oak, there are few evergreen native trees, but notable instances of other popular evergreens are to be found in the laurel, privet, ivy, and rhododendron. *See* Andromeda; Aspidistra; Bouvardia; Box; Butcher's Broom; Ceanothus; Ivy, etc.

**EVERLASTING FLOWER.** The so-called everlasting flowers are useful in the garden during the summer months and for room decoration in the autumn and winter. If they are required for use in winter they should be cut during dry weather before the blooms are fully expanded; after having been set out in a cool room to dry they should be bunched and hung, flowers downwards, indoors until required for vases.

*Everlasting Flower. One of the everlasting flowers, Helichrysum, which flowers in summer and may be dried for winter decoration.*

Those chiefly grown are hardy and half-hardy annuals—*helichrysum*, *acroclinium* and *rhodanthe*. *Helichrysum* is a hardy annual, and should be sown out of doors in early April where the plants are to grow; it reaches a height of 2 feet or more and bears large blooms in crimson, orange, yellow and other colours. *Rhodanthe* and *acroclinium*, with rose or white flowers, are of slender growth and reach a height of about 12 inches; they may be raised from seeds sown out of doors in April-May or under glass in March: they are often grown in pots for the summer decoration of the greenhouse.

**EVERLASTING PEA.** This is a useful climbing summer-flowering plant for covering a trellis, porch or other support. They are hardy, thrive in ordinary soil and reach a height of 6 to 8 feet. The best way of raising a stock is to sow seeds in a box of soil in a frame in spring or out of doors in April. The commonest kind, *Lathyrus latifolius*, bears rose-red flowers; the variety White Pearl is more attractive. *Lathyrus grandiflorus* has rose crimson flowers.

**EWER.** This name is given to a wide spouted jug made in earthenware and glass. The early ewers were used for holding water to pour over the hands after meals. These were usually of silver or other metal, and some were made with a basin to match. *See* Crockery; Cream Jug; Jug.

**EXCHANGE: Of Goods.** Many persons wish, instead of selling and buying, to exchange one article for which they have no use for one which they want. Furniture dealers, especially those who sell antique and second-hand goods, frequently take one article in payment or part payment for another. A popular way of bringing about an exchange is to advertise in one of the newspapers, say the "Daily Telegraph." The articles to be exchanged should be described as clearly as possible in the limited space available, and it should be stated when they can be seen.

**EXECUTOR: His Duties.** An executor is a person who is appointed by a will to see that it is carried out; on him devolves the duties of seeing that the testator's debts are paid, and his property disposed of as he has directed. It is well to appoint two executors in a will, for one may die before the testator or immediately after him, and before the duties have been completely carried out. If the estate is a small one, and can be wound up quickly, it is better to appoint two in the alternative, thus: "I appoint as executor of this my will John Smith, or if he dies before me or refuses to act then I appoint William Jones." It is best for a testator to nominate as executors people who are younger than himself.

An executor's first duty is to prove the will, either at Somerset House or at one of the local Probate Registries. It is wise to employ a solicitor to do this, and to pay the necessary death duties. The next duty is to collect the property.

All debts should be got in as promptly as possible for reasons which will be shown below. The first debts to be paid are the funeral and testamentary expenses incurred by the executor. Next the debts owing by the deceased in his lifetime should be paid; and after that, when all debts are discharged, the executor begins to pay legacies, and to distribute the property.

An executor should be diligent in collecting debts—that is, he should not delay so long that the debt becomes statute barred. Debts should be paid in the following order:

(1) Funeral expenses and expenses of proving will and getting in property.

(2) Debts preferred by special statutes.

(3) Rates and taxes and wages to certain servants; compensation due under Workmen's Compensation Act; contributions to Insurance Acts.

Next, the ordinary debts must be paid, but certain debts are deferred until all others have been met, e.g. money lent to wife by husband, or vice versa, for purpose of trade; money lent to deceased on terms that lender should receive a rate of interest varying with profits of deceased's business.

If the deceased left plenty of assets to pay all his debts, it does not matter in what order the executor pays them; but if there is not enough to go round, the executor should adhere strictly to the order given above.

As between the people to whom money or property has been left by the will, the executor often has to make a choice; he has to take some of the property to pay debts, thus leaving not enough to pay all the legatees. He must apply the assets towards payment of debts in this order:

(1) Property not disposed of by will, subject to a fund for pecuniary legacies.

(2) Property included in a residuary gift, subject to a fund as aforesaid.

(3) Property specifically appropriated for payment of debts.

(4) Property disposed of subject to a charge for payment of debts.

(5) Any fund for pecuniary legacies.

(6) Property specifically disposed of in will.

(7) Property appointed by will under a general power of appointment.

An executor is liable personally to the estate if he wilfully neglects to collect or realize the property. He is personally liable to a creditor if he admits assets by paying a debtor of an inferior class when that creditor is of a superior class. He may be liable if he personally promises a creditor to pay his debt; but the promise cannot be enforced unless it is in writing signed by the executor or his agent.

If the executor gives notice to creditors by means of advertisement in certain newspapers calling for claims, he is not liable for debts notified after that time.

Occasionally a legacy is bequeathed to someone who cannot be found, e.g. a relative who has emigrated, address unknown. In such a case the executor would be well advised to pay the money into the chancery division of the high court, and then await the claim. *See* Death; Estate Duty; Legacy; Will.

**EXERCISE.** A healthy child rejoices in exercising its muscles, and the more vigorously the better. Children who are cooped up in cramped and badly ventilated rooms are prone to develop rickets. Their bones become soft, bend easily, giving rise to misshapen chests, bandy legs and other bony deformities. A large number of girls, mostly amongst the poorer classes, show a faulty development, the reason being that they are very frequently kept indoors for household duties.

Games, therefore, are the natural right of the young, being necessary to their growth. If a child is indisposed for games by lack of bodily vigour, attention should be given to its health, and suitable gentle exercise should be selected, to lead gradually to something more strenuous. In adolescence games provide a safe means whereby a superabundance of energy may be expended. Apart from their usefulness in developing the body, games should be encouraged as a means of developing character and of enabling the child to come into easy relationship with his fellows.

Nor is exercise less necessary for those whose bodily development is complete. The sedentary worker who neglects exercise becomes stale, his vigour is diminished, he suffers from a lack of elasticity, and his digestion is apt to be sluggish. If he also lives well in the way of food and drink, these evils will be intensified and he may become obese or gouty, suffering from arterial disease or a combination of these, and break up comparatively early in life. Exercise improves the tone, the size, and the firmness of the muscles, strengthens the heart and lessens its work, increases the excretion of waste products by the lungs, the skin, the kidneys and the bowels, and so makes possible a free, untrammelled activity of all the body tissues.

Nothing can compensate wholly for the lack of exercise in the open air, but in the case of town dwellers whose opportunities in this respect are limited, an hour once or twice a week in a well-appointed gymnasium will be of the utmost value, or carefully chosen exercises may be done regularly at home in a well-ventilated bedroom. Exercises involving much strain should not be undertaken by those whose hearts are weak, or who are much older than 30.

Walking provides good exercise if one walks sufficiently fast, and more particularly if the walk is uphill; but as the value of exercise is largely enhanced by the extent to which interest is excited, the superior claims of golf are apparent, apart from the additional exercise to the arms. For the same reason any other suitable game should be played whenever it is at all possible to do so. *See Beauty Culture; Breathing; Diet; Drill; Figure.*

**EXHAUST:** From the Engine. This word is used for the waste steam or burnt gases ejected from an engine, and also for the exhaust piping. In internal combustion engines the waste gases are expelled through the exhaust valves and the exhaust port into the exhaust pipe. Most motor cycles are provided with a device known as an exhaust lifter, usually controlled from the left-hand side of the handlebars. This raises the exhaust valve when required, releases the compression of the engine and prevents firing.

The fumes from the exhaust of a petrol engine may contain the highly poisonous gas known as carbon monoxide, produced by imperfect combustion of petrol in the cylinders.

*If the engine is allowed to run while the car is standing in the garage, the exhaust pipe must be connected to the outer air, and the building ventilated by opening doors and windows.*

**EXOPHTHALMIC GOITRE.** Over-action of the thyroid gland, which is situated in the neck just below the Adam's apple, is the cause of a disease to which the name exophthalmic goitre has been given. It may be contrasted with myxoedema, which is due to under action of the same gland. Its chief characteristics are prominence of the eyeballs, enlargement of the thyroid gland, rapid heart action, and a continuous fine tremor. The disease is more common among women, and it is possible that worry or excitement may help to bring it on.

The symptoms are very gradual. The heart beat is quickened and may range between 100 and 120 instead of the normal 65 to 75. The action is abnormally forcible and the vessels in the neck, the pulses at the wrists and in front of the ears, etc., become readily visible. As a rule the patient loses flesh and becomes anaemic.

Everything should be done to secure mental as well as physical rest, and in the case of a town-dweller she should be sent if possible to live in the country for a time, avoiding excitement and getting plenty of fresh air and plain food. Ten hours' sleep is not too much in such cases. The drugs mostly given are iodine, arsenic, digitalis, belladonna, and the bromides. Attacks of diarrhoea and vomiting should at once be brought to the notice of the physician. The application of X-rays has proved a successful cure in many cases of exophthalmic goitre. In severe cases an operation is undertaken.

**EXPECTORANT.** A drug used to promote easier expulsion of expectoration from the air passages in disease by altering the character of the secretion or otherwise is termed an expectorant. Among these are sodium or potassium bicarbonate, ammonium chloride, ammonium carbonate, iodide of potassium, ipecacuanha, squills, volatile oils (e.g. camphor), balsams (e.g. compound-tincture of benzoin), and a variety of others. Some expectorants are depressant to the heart, e.g. ipecacuanha and antimony, and care has to be taken in giving them to the aged and debilitated, for whom stimulating substances like ammonium carbonate, ammoniacum, and camphor are preferable.

The following is a typical expectorant mixture such as might be prescribed in a case of chronic bronchitis. The dose is 2 tablespoonfuls every 4 hours:

Ammonium carbonate	30 grains
Wine of ipecacuanha	1½ drams
Infusion of senega	4 oz.
Water to make	8 oz.

**EXPECTORATION** or Sputum. Material coughed up or got rid of by spitting may come from the mouth, nose, throat, air passages, or lungs. A clear, sticky sputum, like white of egg, occurs in the early stages of bronchitis, pharyngitis, and of lung conditions such as phthisis and pneumonia. In chronic catarrhal conditions of the nose and throat greenish-grey, sticky

material is hawked up in "clearing the throat," frequently stippled with black specks due to inhaled dust. A brownish or yellowish-red sticky sputum constitutes the rusty sputum of developed pneumonia.

Streaks of blood in the sputum may come from the mouth in spongy conditions of the gums, etc., the throat from adenoids, etc., or the air passages generally when inflamed. When in larger or smaller quantities of pure or almost pure blood, it is termed haemoptysis. The commonest cause is consumption. The blood is coughed up, it is bright red and is mixed with air, these circumstances distinguishing it from haematemesis, or blood from the stomach, which is vomited and is usually dark in colour and intermixed with food.

In diseases in which there is expectoration this should not be received in a handkerchief, otherwise it dries and is shaken off into the air, carrying with it the disease microbes. In cases of consumption a pocket spittoon or spitting bottle is always insisted on for this reason, but there are others than consumptives whose expectoration is dangerous, and it is their duty also to use a bottle and protect their neighbours. Within doors the sputum may be received in pieces of paper, which are immediately burnt, or if they are received in a receptacle this should contain some antiseptic solution, e.g. of lysol. *See* Bronchitis; Pneumonia, etc.

**EXPOSURE:** In Photography. Correct exposure is the key to success in all forms of photography and without it good results cannot possibly be obtained. The camera cannot be treated as an instrument in which only a button has to be pressed and the machine does the rest. The simple roll film camera with a lens of an aperture of  $f\ 8$  or  $f\ 11$  (U.S. numbers 4 or 8 or Kodak No. 1 for V.P.K.) will give satisfactory results for most subjects on sunny days in midsummer without any special consideration of exposure times, for it is designed to do this, but at other times of the year or on dull days and with certain kinds of subjects a knowledge of the conditions to be observed is absolutely essential.

There are four conditions which govern the exposure: The actinic, or photographic, value of the light; the sensitiveness, or speed, of the plate or film used; the kind of subject being photographed; the aperture, or speed, at which the lens works. Taking the last condition first, it will be assumed in this article that a lens working at an aperture of  $f\ 8$  (as explained under F Numbers) is used. For a lens of  $f\ 11$ , such as is found on the ordinary V.P.K. and other cheap roll film cameras, all the calculations must be doubled.

The actinic value of the light varies very considerably according to weather conditions, time of day and time of year. It does not necessarily follow that because the light appears to be bright it is good in the photographic sense; for what has to be considered is not the appearance of the light to the eye, but its chemical action on the sensitive film. Some forms of light which are hardly perceptible to the eye have very definite action on the photographic plate. Again, winter sunshine, which may appear to be strong, is photographically weak, and even on an August day the

light is not quite so strong in the afternoon as it is in the morning.

Small variations in the chemical strength of the light do not matter, because the latitude allowed by modern films permits exposures which may be two or three times the theoretically correct figure without impairing the result. In fact, for the amateur working with a roll film camera it may be broadly stated that the one thing he has to guard against is under-exposure; he is hardly likely in taking snapshots to over-expose.

*Exposure. Left, a Leudi visual extinction meter, small and very light. Below, a Weston meter with Photronic photo-electric cell, for all cameras.*

The second consideration, the speed of the plate or film used, is one that will give the amateur very little trouble if he will adopt the plan of finding the plate or film that suits his purpose best and sticking to it. Determining the speed of a plate is a very complex matter. For even different batches of the same plate will vary. Experienced workers in photography, therefore, find that the best results are obtained if they confine themselves, as far as possible, to one brand of plates or films whose speed they know.

As to the third consideration, the kind of subject that is photographed, the novice soon learns that a white object requires a shorter exposure than a dark one. He does not always recognize that darkness of colour is not the same as darkness in lighting, and that a white object poorly lighted may actually require a longer exposure than a dark object well lighted.

The most satisfactory method of calculating exposure is to use either an actinometer, a visual extinction, or a photo-electric meter. An actinometer makes use of a small piece of printing-out paper which is exposed to the light through an aperture. The time of darkening of the paper is taken as a measure of the light intensity, and is applied to the calculating device incorporated to find the exposure required.

In the case of the visual extinction meter, light reflected from the subject illuminates either one or a series of contrasted letters or figures. The eye views the field, and if one letter or figure is visible, part of the meter is rotated until this letter or figure is only just visible. The amount of rotation needed to reduce the

intensity of the light to this point is a measure of the intensity of light reflected from the subject, and the reading is applied to a calculator on the meter.

The photo-electric exposure meter measures light intensity by means of a light-sensitive cell, which generates an electric current whose strength is proportionate to the intensity of the light falling upon the cell. The current is passed through an extremely sensitive galvanometer, or micro-ammeter, which moves a pointer along a calibrated scale, the reading of which indicates the value of the light intensity.

The photo-electric exposure meter is more expensive than the other types, but is the most reliable of the various kinds of exposure meter. It can be used in all kinds of light, and is subject to smaller errors than most other meters in the determination of the light intensity.

Cameras with single speed shutters marked as working at 1/25th sec. usually give an exposure of about 1/15th to 1/20th sec., which is about the longest exposure that can safely be given with the camera held in the hand if movement is not to show itself in the picture. Cheaper shutters marked as giving an exposure of 1/100th of a second generally give about 1/50th. These variations are all to the good, as they result in longer exposures.

Longer exposures can easily be given. Rest the camera on a fence, a gate post or the top of a chair, and by setting the shutter to "Bulb" give short-time exposures. Thus, with the shutter set at "Bulb" the release is pressed and let go again instantly. If this is done as quickly as possible without shaking the camera an exposure of about a  $\frac{1}{4}$  sec. will have been given. For  $\frac{1}{2}$  sec. do the same with a perceptible pause between pressing the release and letting it go, or by pressing the release while the words "one, two" are said sharply. Doing the same while saying sharply "one, two, three, four" will give a 1 sec. exposure. *See* Developing; Snapshot; etc.

**EXPRESS DELIVERY.** Packages and letters can be sent from most post offices for express delivery by special messenger. The charge is 6d. for each mile or part of a mile, and a 1d. for each package in addition to the first up to a maximum of ten. Packages over 1 lb. in weight pay a further 3d. By this service live animals, liquids and loose cash can be sent and persons conducted to and from any given place. Packages may also be posted and then sent by special messenger at the charges mentioned from the post office to the address thereon.

On payment of 3d. to a servant of any of the chief railways, in addition to postage at the ordinary rate, letters not exceeding 2 oz. will be forwarded, and passed on from one company to another at a junction, by the next available train or steamship, to be called for at the station to which the letter is addressed, or to be transferred to the nearest letter-box for postal delivery. The letter may be taken to a passenger station of the railway company, or sent there by express delivery on week days. By the new "Railex" door-to-

door system there is an inclusive charge of 2/6 for 2 oz. letters, or 3/- for letters between 2 oz. and 1 lb.

**EXTRACT.** Meat extracts are obtained from lean meat by various processes, which include the use of heat. They contain a very small amount of nutritive material, their chief constituents being extractives, substances which result from the breaking down of proteins, and mineral salts. They act as stimulants and help to remove fatigue. They also improve appetite and digestion, so that other food which is taken at the same time proves of more use to the body. Meat extracts are useful flavouring agents. Extract is sold in bottles of various sizes, and, with hot water, soup or broth may be quickly prepared.

Malt extracts contain a large percentage of carbohydrates, which are readily dissolved and digested, and one also finds in them active diastase, the ferment which converts starch into sugar. Thus they provide an additional and suitable supply of carbohydrate, and also assist in the digestion of starchy food. *See* Beef Tea; Food, etc.

## THE EYES AND THEIR CARE

### Hints on the Preservation of the Eyesight

The subject of sight is dealt with in this Encyclopedia under a number of headings, e.g., Eyeglass; Sight Testing; Spectacles. *See* also the entries on Astigmatism; Blind; Cataract and other eye affections.

Of all the organs of the human body the eye is the most delicate in structure, the most susceptible of injury by disease, accident or overstrain, and any affliction of this organ calls for expert treatment at the earliest possible moment. In no case is this more essential than in ophthalmia of the newly-born, a disease which makes its appearance within a day or two after birth and is the cause of the great majority of cases of blindness. It is characterised by the discharge of pus from the eyes; any such discharge calls at once for skilled attention if total blindness is to be prevented.

**Visual Defects in Children.** During childhood various faults of vision, such as short-sight, long-sight, squint and astigmatism, may make their appearance, and parents and guardians should be on the alert to have the eyes of children examined at once if they observe any signs of visual defect. The child suffering from short-sight will hold objects which he wishes to see nearer to his eyes than is normal and cannot identify objects that are at a distance. The child who is long-sighted will complain of pains in the eyes and of headache when reading or writing, due to overstrain of those muscles by which the eyes are focussed on near objects. In all such cases glasses are essential.

Squint is most frequently due to over-strain of the focussing muscles, and is a sign either of weakness of these muscles or of longsightedness. Astigmatism is generally caused by irregularity in the curvature of the front of the eyeball, and demands the provision of specially ground glasses. Its presence may be suspected

where the subject complains of eyestrain or of headache, especially after a visit to a kinema, theatre, etc.

*Eye. Sectional diagram showing the anatomy of the organ.*

**Eye Changes in the Elderly.** After middle-age difficulty may be experienced in viewing objects clearly which are near at hand. This is due to hardening of the internal structures of the eye and weakness of the muscles of focussing, and assistance must be rendered by glasses, which will require to be strengthened as the disability increases with advancing years. If it is found necessary to obtain stronger glasses more frequently than every five years, and especially if at night-time street lights or candles are seen surrounded by rainbow-coloured rings, it is possible that the subject is suffering from a dangerous disease known as glaucoma, which, even in its chronic form, demands immediate surgical treatment. When acute, glaucoma is ushered in with intense pain in the eyeball, frequently radiating around the eye, and sometimes accompanied by headache and vomiting. Its onset, therefore, is liable to be mistaken for a bilious attack, and valuable time is wasted in securing treatment. In all cases where glasses are required, they should only be obtained on the prescription of a qualified oculist.

In order to avoid the occurrence or aggravation of visual defects, it is of importance that all close work should be done in a good light. Excessive light is equally harmful. In reading or writing, a position should be adopted in which the source of light is, if possible, behind and from the left. This is particularly important at the school age. Undue stooping when writing should be avoided as tending to increase tension within the eyeballs, and therefore to aggravate any existing, predisposition towards short sight. For the same reason tight neckwear and excessive physical exercises may be harmful. Reading in bed is injurious, and children should never indulge in it.

**Diseases and Injuries.** A sty is a small abscess which forms at the root of an eyelash. It should be treated by pulling out the eyelash involved, and by bathing the eye frequently with a hot lotion made by dissolving a teaspoonful of common salt in a pint of water which has been boiled. This lotion is also useful

for all simple inflammatory diseases of the eyelids. Chronic inflammation, however, demands drastic treatment by an oculist, as the condition may be due to trachoma, a condition which is dangerous alike to the patient, owing to the possibility of blindness supervening, as well as to others who may become infected.

*Soiled towels in public lavatories should never be used to dry the eyes, as the infection of trachoma, as well as of many other contagious diseases, may readily be conveyed by such means.*

To prevent the sealing of the lids which is so frequent in inflamed eyes, and does harm by imprisoning the discharges, the eyes should be well smeared at bedtime with a salve or ointment. Useful ointments are 10 grains of boracic acid powder in 1 oz. of soft paraffin or vaseline, and equal parts of yellow oxide of mercury ointment and vaseline. A little glass rod with a rounded end is a convenient instrument to use for applying. The lower eyelid is drawn down and some ointment, picked up on the end of the rod, is put on its inner surface. The patient closes his eye, and by gently rubbing over the surface of the lids the ointment is spread over the eyeball.

A lotion or collyrium (q.v.) should always be used comfortably warm. It may be applied by soaking a piece of cotton wool in the lotion and squeezing this out into the eye, or by means of an eyebath (*see below*).

Foreign bodies in the eyes may usually be removed by brushing with a camel-hair pencil, or the moistened corner of a pocket handkerchief. If simple measures fail, instil a drop of castor oil into the eye, place a soft pad, as of cotton wool, over the closed eyelids and secure this in position by applying a bandage lightly. A doctor should be consulted without delay.

Wounds of the eyeball are extremely dangerous, no matter how trivial they may appear, as they may be productive of blindness. A blow on the eye, as in boxing, may cause serious internal injury even though no external signs are visible. It is of importance to remember that failing vision may be the first symptom of grave diseases, such, for example, as Bright's disease or diabetes.

**Hygienic Measures.** When in perfect health, the whites of the eyes should be of a clear bluish-white. Redness shows that the eye is suffering from a slight cold or a strain. Give the eyes a warm boric lotion bath three or four times a day, using a teaspoonful of boric acid powder to every  $\frac{1}{2}$  pint of hot water. To remove a yellowish tint from the whites of the eyes, drink a glass of hot water to which the unsweetened juice of a lemon has been added. In all treatment with bandages and pads, medicated cotton wool and butter muslin are the most hygienic materials to use, since they can be thrown away. Sponges should never be used unless they are certain to be destroyed immediately afterwards.

People who write or read a great deal often suffer

from eye strain. This may be relieved by bathing the eyes in a solution of salt and water, a teaspoonful of salt and a quart of water. Pure cold water is in itself a good eye wash, or a weak solution of zinc sulphate will be made up by any chemist and is very good for tired eyes. After extra fatigue a strip of lint, moistened with water and laid on each eye and kept in place by a bandage for about ten minutes, is very helpful.

An eyebath is a convenient appliance for washing the eyes. This is a little vessel of glass or some other material, with its edge shaped to fit into the socket of the eye. It is filled with the lotion and the patient bends forward the head and applies the edge of the bath firmly round the eye. He then throws his head back and opens the eye widely. The lotion is kept in contact with the eye for a minute or two. The cleansing may be facilitated by opening and closing the eye several times while the bath is in position.

**EYEBROW.** If eyebrows are too thin a little vaseline or olive oil can be applied nightly with a small eyebrow brush, which is like a minute toothbrush in form.

In applying any strengthening lotion care must be taken not to encourage the growth of hairs between the eyebrows. Some eyebrows have a tendency to meet over the nose. The use of tweezers keeps the line of the brows in good trim, unless the hairs are abnormally coarse, when electrolysis may be employed by a good operator. Brushing the eyebrows with a clean brush lightly smeared with a little brilliantine each morning tends to darken them and give them a silky appearance. It is possible to have the eyebrows and lashes tinted in any desired shade of brown or black. *See Beauty Culture; Face.*

**EYEGLASS.** Eyeglasses are usually worn by persons who do not require glasses constantly, but only for a particular purpose or for part of the day. For such persons eyeglasses are perhaps more suitable than spectacles.

Excluding the single eyeglass, or monocle, there is not a great deal of variety in the eyeglasses worn by men and women in ordinary life. There are slight variations in the nature and strength of the spring that keeps the glasses in position on the nose and in the shape of the bridge that unites the two glasses; there are glasses with rims and glasses without, and there are glasses that fold up and glasses that do not, but that is practically all. The frames, however, vary in quality and material, ranging from the cheaper ones of nickel or steel to the expensive ones of solid gold. Silver is rarely used for these frames, but rolled gold is frequently seen. Some persons have eyeglasses with horn or tortoiseshell frames. Some wear a cord to attach the eyeglass to some part of the person; others prefer to carry them in a case.

The eyeglass has usually a rim of metal round the glass proper, but many persons wear glasses without rims, and for these certain advantages are claimed. Their weight, it is said, is about one half that of

ordinary eyeglasses; they are, when properly fitted, almost invisible, and they have no rims to interfere with the vision if they get slightly out of place.

**The Frames.** The frames of eyeglasses are often made in other material than metal, and those fashioned of tortoiseshell or horn are not easily repaired. When the nature of the damage permits, the fracture can be mended with Canada balsam, using this as a cement. The parts are held together with fine binding wire, or with a strong paper-clip of the John Bull type, and left for 24 hours to set hard.

A common fault with eyeglasses is for the frames to become distorted and forced out of line. In bending the parts and bringing them into place, keep the fingers of each hand close together with the bent part of the frame between them, thus localizing the strain. If a small pair of pliers is used, remember not to exert too much pressure and smash the glasses. When viewed in plan the lenses should be in line, and likewise when viewed from the front. The plaquets, or nose grips, are often faced with cork, and this can be cleaned with petrol, or new pieces cut from a good quality bottle cork and cemented in place. See that the plaquets are in line and at equal angles to a vertical centre line.

Eyeglasses with astigmatic clips, or those in which a spring draws the two parts together, will benefit by cleansing with petrol, and the spring be retensioned by drawing it through the fingers and thus increasing its length. Replacement parts are generally obtainable from manufacturing opticians. *See Sight; Spectacles.*

**EYELASH.** The beauty of the eye depends to a great extent upon the eyelashes. They should be as dark or a shade or two darker than the hair. They can be painted at night with castor oil applied with a camel's hair brush. If the eyelashes are inclined to be very straight they should be gently brushed upward over an orange stick laid along the edge of the upper eyelid. The use of a slightly astringent eye lotion containing witch hazel tightens the eyelids and prevents fall of the lashes.

**EYELET.** An eyelet is a small round hole in cloth, sailcloth, etc., which is worked like a buttonhole for the passage of a lace, ring or rope. In needlework it is best known as the open hole which is used in various forms of embroidery for working berries and similar small round parts of the design. *See Embroidery; Stiletto.*

## FACE: CONTOUR AND SKIN TREATMENT

### The Use of Simple Cosmetics and Massage

For related information see the articles *Beauty Culture; Diet; Hair; Neck; Skin.* Consult also the entries *Powder; Soap, etc.*

A good facial contour ranks next to a fine complexion in creating a general impression of beauty. The skin is of first importance, because no matter how handsome the features they will not be admired if

blemished by surface defects. Correct diet and exercise are essential factors, but local treatments are also integral to the preservation of a fine skin. It is quite easy to call to mind many healthy women and girls who do not possess beautiful complexions for the simple reason that they take no care of them.

On the other hand, the athletic movement of the past twenty years has undoubtedly improved the skin, eyes and hair of the sex in general. The sports girl breathes more deeply, and so possesses a bigger supply of oxygen in her blood, expressed in greater physical beauty, owing to her better circulation. This combined with saner views on diet and fresh air has also lessened digestive troubles and constipation which have a directly adverse effect on the facial appearance.

A frequent cause of a sallow, wilted look is simply the neglect of drinking sufficient water. The normal body requires three or four pints a day, some of which is taken in food. A glassful should be drunk at night and in the morning. A free use of water combined with plenty of fruit, green vegetables, a nourishing diet, fresh air and the regular performance of breathing exercises will remove premature hollows under the eyes and round any unbecoming facial angles.

**Facial Contour.** Superfluous flesh in a youthful face will often respond quickly to correct diet and massage, when the desire to reduce is strong enough to make certain sacrifices, such as cutting down sweets, pastries, and not giving way to laziness. The muscles which preserve the contour of the face must be kept healthy because on their vitality mature good looks depend.

The upright carriage of the head has a good effect on these muscles. Exercises to assist in preserving the contour of the jaw are given in the entry on Neck. The pursing of the lips as if for whistling, when exhaling during breathing exercises, smoothes out lines from nostrils to the corners of the mouth and helps to correct a sagging tendency towards the points of the jaw. A simple little exercise which wards off a double chin is to protrude the lower lip and blow as if trying to blow away something from the tip of the nose.

The following hints are also useful for the preservation of the contour of the chin, the most important line of the face. After applying a skin cream, smartly pat along under the chin with the back of the hand (or a rubber patten) for about two minutes to stimulate the muscles. After washing dab an astringent lotion composed of one part of toilet vinegar to two of rosewater, under the chin. A daily treatment which is said to remove a double chin is to use an emollient cream and an astringent on alternate days with a chin strap which is worn for fifteen minutes. Soak a pad of cotton wool in the astringent and after kneading and patting the muscles, place this under the chin and keep it in position with the strap. The next day massage with a skin-food and wear the strap for the same length of time.

**Astringents and Creams.** The face should always be thoroughly cleansed before applying an astringent or massage. A good method is to squeeze a pad of

cotton wool out of cold water, sprinkle it with a lotion composed of 2 oz. extract of witch hazel and 10 oz. rose water, and then spread over it a cleansing cream, and with upward strokes of the pad thoroughly wash the face and neck. A pleasant cream for this purpose is made as follows:

Take  $\frac{1}{2}$  oz. each of white wax and spermaceti and 4 oz. white vaseline; melt together and pour into a heated bowl. Very gradually add 3 oz. orange flower water and 1 oz. witch hazel, stirring all the time, and continue stirring until the emulsion is cold.

This way of cleansing the face is satisfactory during the day, after a journey, or exposure to wind and sun, or when the complexion is intolerant of soap and water. It may be used at night before an astringent or if any makeup has been applied to the skin during the day. The value of an astringent is that it braces the skin by closing relaxed pores, and it is essential that any foreign surface matter should be first removed. Nearly every skin benefits by washing daily with soap and water, massaging the lather over the face with both hands. A good rubbing with a turkish towel across the back of the neck and behind the ears stimulates the circulation after the final cold sponge in the morning.

There are many degrees of astringents, and discretion must be used in choice for the individual skin. (*See Complexion.*) Sponging in the morning with cold water to which a few drops of simple tincture of benzoin have been added is sufficient for the fresh complexion. The use of a complexion milk, after washing, containing benzoin and cucumber is suitable to most skins. It is not worth the trouble of procuring the many ingredients which go to the making up of these milks, when excellent preparations are on the market at a small cost.

#### For a Relaxed Skin

If  $\frac{1}{2}$  oz. simple tincture benzoin is added to the 2 oz. witch hazel extract and the 10 oz. rosewater this makes an excellent mild astringent for dabbing on the face with cotton wool, and also for tired eyelids if a pad of cotton wool is squeezed out of cold water, soaked in the astringent, and laid on each eyelid for 20 minutes during a short rest. Should the facial condition be really flabby a stronger astringent is composed of 2 oz. toilet vinegar to 4 oz. rosewater. This can be used at night and an emollient applied afterwards to prevent undue dryness of the skin. The patting movements with the pad of cotton wool moistened with an astringent stimulate the circulation and help the removal of waste matter before closing the pores. This process tones up the skin.

Lanolin is the basis of many so-called "skin foods." An inexpensive but satisfactory cream is made by melting 2 oz. hydrous lanolin with 2 oz. white vaseline and stirring in 1 oz. each of olive and almond oils, and 2 dr. each boracic powder and zinc oleate. For anyone afraid that lanolin will encourage superfluous hair (used in such proportion it is quite unlikely to do so) a

cream with a casein basis may be used. Casein is prepared from the albuminoid matter of milk, and a simple emollient is composed of 3 oz. casein, 6 dr. boracic acid, 3 dr. cocoa butter. Occasional massage with olive oil may also be necessary to counteract dryness. This oil is soothing for treating, temporary conditions of dry skin caused by exposure to wind and sun.

For a sunburnt skin relief can be obtained by a piece of lint saturated in warm water to which a few drops of cloudy ammonia have been added, care being taken to keep the eyes closed while holding the lint to the scorched skin. To remove tan a mixture made of two parts peroxide of hydrogen, one part lemon juice, and one part rosewater can be applied to the face, after using the cleansing cream, and allowed to dry on. If this treatment should be too drastic at first, dilute the mixture with more rosewater. Freckles, which are pigmentary discolorations of the skin, are not unsightly unless they are too numerous and deep in colour. They may be hidden, and to some extent the rays of the sun may be counteracted by the use of a calamine lotion and face powder.

The formula for calamine lotion is as follows: Prepared calamin, 6 dr.; powdered oxide of zinc, 2 dr.; glycerin, 1½ dr.; rectified spirit of wine, 1½ oz.; elderflower water to make the lotion, up to 8 oz. This lotion deposits a fine powder. To keep it on the face of a child a soft muslin mask is necessary.

The following ointment may be rubbed sparingly in at night, but should not be used for children. It produces a peeling of the skin which usually leads to the disappearance of the freckles. Mercury perchloride, 1 gr.; powdered starch, 2 dr.; powdered oxide of zinc, 2 dr.; soft paraffin, 4 dr.

The treatment for blackheads is described under that heading. The application of calamine lotion, after sponging the affected area with hot water, is useful for both this unhealthy state of the pores and for a spotty condition of the face.

**Facial Packs.** From earliest days of beauty culture, facial masks or packs have been used. These are said to embody cleansing and astringent properties. Special mud and clay packs are variously recommended for clearing the skin and eliminating acidity. A simple and efficacious pack is made by placing a tablespoonful of fuller's earth in a cup, and mixing with it sufficient rosewater and witch hazel lotion to make a thin paste. Oatmeal may be used as a pack mixed with buttermilk, which possesses whitening properties when it is applied to the skin.

A facial mask which bleaches is made with almond meal mixed to a paste with the sunburn lotion containing peroxide, lemon juice and rosewater. Another pack is of half a cupful of cooked oatmeal into which 2 tablespoonfuls of milk and one of glycerin have been thoroughly stirred. Yet another is of egg. The beaten white is first applied with a camel-hair brush and allowed to dry on the face. A second painting with the white is followed, when this is thoroughly dry, with the application of the beaten yolk. This egg mask and

the other packs described are left on for an hour and then washed off with pure soap and warm water. Afterwards, a light facial massage with an emollient should be given. A thin muslin mask cut to the shape of the face with eye-holes and tied on with ribbons is often used to keep these applications on the skin.

**Helpful Massage.** Some women are afraid of facial massage as they think it stretches the skin. This is only the case if wrongly or too hurriedly applied. All four movements, stroking, friction, pétrissage and tapotement can be used with advantage. The first starts the treatment with firm upward strokes when using the cleansing cream. Then, having wiped this off with an absorbent tissue, an emollient cream is applied and light friction given with the cushion part of the finger-tips, working the cream with circular spiral movements over the face. Facial massage should have an upward and outward tendency to correct the droop of the muscles. Then with the wrist held loosely the percussing movement already described is performed with the back of the hand under the chin. Next, more cream is applied, and the chin and cheeks are lightly pinched with the cushions of the finger-tips. Then, with fingers placed on the cheekbones, the thumbs meeting under the chin should stroke upwards to meet the fingers with a firm pressure, returning lightly under the chin. Repeat this movement for two minutes. Next, stroke the finger tips from the point of the jaw past the corners of the mouth to the nose and very lightly across the closed eyelids to the roots of the hair and across the forehead.

Lines should be followed and not rubbed across. Should there be a vertical furrow between the brows, it may be stroked gently upwards. The cream must be very lightly patted in round the eyes with the third finger, as the slightest rubbing will stretch the sensitive skin there. After this the massage cream may be wiped off. If the massage is performed at night a little emollient may be left on round the eyes and along any deep lines; if during the daytime, the skin may be toned with a mild astringent before powdering.

**FACEACHE.** Pain occurs in the face in inflammatory and suppurative conditions, e.g. dermatitis, gumboil, mumps, etc., and the cause of the pain is indicated by the redness and swelling which are also present. In the absence of such plain indications, an explanation for the pain should be sought for in disease affecting the teeth, eyes, nose and the cavities leading from it, the ear, etc., and in the general state of health of the patient, as anaemia, constipation, gout, hysteria, rheumatism, and other disorders frequently underlie the occurrence of pain. *See* Neuralgia; Toothache.

**FACE PLATE.** A face plate is a contrivance used on a turning lathe as a means of mounting work to be turned. It comprises a circular disk, generally of cast iron, with a projecting boss at the back. A hole is

drilled through the centre and screwed to correspond with the size of the screw thread on the mandrel. The plate is, as a rule, provided with holes or slots through which bolts are passed, which, in conjunction with clamp plates, bolts, and nuts, are used to fasten the work to the face plate. *See* Chuck; Lathe.

*Face Plate. Contrivance invaluable to the metal worker for mounting work to be turned.*

**FACING:** In Dressmaking. This is the name given to a strip of material laid along the edge of a garment, either on the wrong side, for neatening and strengthening, when it is sometimes termed a "false hem," or else on the right side, as an ornamentation, this often being of a contrasting material. The name is also applied to the top layer of such portions of a garment as are made of double material, i.e. the collar and cuffs.

As regards the cutting of facings, the rule for the first mentioned type is that, the strip can be cut on the straight if the edge to which it is to be applied is straight. A curled or rounded edge, however, is either faced with a strip cut on the cross, which can be pulled to shape, or else with a strip cut to the exact shape of the garment, and of the same way of the grain, these shaped pieces always being used for the facings laid inside the front edges of a coat, and also for the top layers of collars and cuffs, etc. One way of attaching a facing of the strip type is to set it over the garment, with the right side downwards, and to stitch it on just within the top edge; then to turn the strip over to the wrong side, and to hem the unattached edge down.

Another plan employed is to turn in the edges of the garment, set the facing over it, turn in the facing edges and hem or slip stitch down. When attaching a coat from facing, the inner edge is left detached.

**FAGGOT:** In Cooking. This is the name given to a preparation made from calf's liver, or the inferior parts of a sheep, such as the liver, lights, pluck, and heart.

To make faggots from the intestines of a sheep, procure the liver, lights, pluck, heart and sweetbread and some of the skin. These must be well washed, put in a saucepan with cold water poured over them, brought to the boil and simmered gently for about 15 min. Add salt and pepper and pour off the liquid. Boil an onion in a little water and chop it. Chop the liver, lights, etc., and pound them well with the onion. Then add a sprinkling of mixed herbs and a pinch of nutmeg, and stir in sufficient breadcrumbs to make a firm paste.

Mould the mixture into squares and wrap each square in a piece of skin. Place them in a baking-tin that has been well greased, and leave it in a moderate

oven until they are a pale brown. Make a gravy to serve with the faggots from the liquid in which they are boiled. Add pepper and salt, and thicken with a tablespoonful of flour made into a paste with a little of the cold liquid. Bring it to the boil and add a little caramel or gravy colouring if necessary.

**FAGGOTING:** The Trimming. This is sometimes used for beading to make an open seam for a dress or underwear. A slightly different variety of faggot stitch is used in drawn-thread work. The two edges to be joined should be sewn to stiff paper or toile cirée, about  $\frac{1}{4}$  in. apart. The tacking threads should be about  $\frac{1}{4}$  in. in from the edge of the hems to allow room for working the stitch under them.

*Faggoting. An example of this useful trimming.*

The following plan will keep the stitches even. Place a ruler along the edge of one hem, and at every  $\frac{1}{4}$  in. mark put a dot on the material with a lead pencil. Repeat this operation on the opposite hem, but let the first dot come half-way between the first and second dot of the opposite edge, then the other dots will follow in order. To work the faggoting, join the thread on the wrong side of the hem at the top left-hand corner, holding the work so that the seam is in a perpendicular line before you, the stitching proceeding downwards. Bring the needle up from the underside of the hem on the opposite side, through the first dot.

Now put the needle under the stitch just made, which lies across the opening between the two hems; put the needle under the opposite hem and bring it through at the dot. It is important that the needle should be put down behind the thread last made so that the stitch comes under it. The illustration shows this position. Repeat this operation down the whole seam, then cut the tackings and take away the paper. *See* Drawn Thread Work.

**FAHRENHEIT.** This is one of the two chief ways of measuring heat by a thermometer. On a Fahrenheit thermometer the distance from the freezing-point of water to the boiling-point is 180°. The freezing-point is marked 32° and the boiling-point 212°. *See* Centigrade; Thermometer.

**FAIENCE.** This name is applied to various kinds of earthenware pottery and tiles having a highly glazed or emmelled surface. The word comes from the name of the Italian town Faenza, which made a speciality of this pottery from the time of the Renaissance. The art of the Moorish potters who established themselves in

Spain and left, among other examples of their skill, the tiles of the palace at Seville, spread to Sicily, and from there prepared the way for the Italian masters of majolica faience. Luca della Robbia is the best known of these. In the 15th century he created the most beautiful examples of this tin-glazed ware.

*Faience. Persian bas-relief in polychrome faience brick, approximately of the period of Darius (500 B.C.)*

Damascus enamelled earthenware also is believed to have helped to inspire ceramic art in Europe, as it was largely imported during the 15th century. Holland made the delft ware which was a compromise between majolica and Chinese porcelain, its methods being taken from the former and its designs from the latter. In 1676 a Dutch potter settled at Lambeth and started delft faience ware in England. Some varieties of Josiah Wedgwood's ware are styled English faience.

Germany developed faience methods for stove tiles and beer tankards, while in France the best known faience was the blue Rouen ware developed afterwards at Moustiers in a variety of colours. Enamelled brickwork was used in the days of Darius, and was the forerunner of the splendid glazed tile decoration which is extensively employed in Persian architecture.

Modern fabrics of Doulton, Minton and Ault are among those classed as faience, also some makes of Japanese pottery. The decorative effect may be in form, the beauty of monochrome glaze, as seen in certain tiles, or through polychrome designs heightened by applied reliefs. Many modern reproductions of majolica are good, but others tend to be crude in ornament and colour.

For this reason pieces which bear the sign manual of creative artists, or, as in the case of Della Robbia reproductions, aim at preserving the best traditions of the past, may be sought for as satisfactory notes of decoration in a sitting room. Sometimes one may rejoice in the possession of pieces that ought to be safeguarded, such as a fine Satsuma vase, a Rhineland tankard, a Leeds bowl, and even a piece of Valencia lustreware or Urbino majolica. *See* Delft; Lambeth Ware; Majolica; Pottery; Terra Cotta; Tiles.

**FAILLE.** Heavy taffeta woven with a pronounced rib is sold as faille. It also makes the most serviceable of ribbons, and is more hard-wearing than ordinary taffeta.

**FAINTING:** How to Treat. The cause of fainting is a deficiency of blood in the brain, which produces

a temporary loss of consciousness. The fainting fit lasts usually for less than 1 min., but may be prolonged when it follows severe loss of blood or disease of the heart. In people predisposed to fainting any sudden strong emotion may tend to bring on a fit. A blow on the abdomen or on the head, intense internal pain, standing up quickly from a sitting posture, or getting suddenly out of a hot bath may cause fainting, especially if the heart is weak.

When one feels faint one should get into the fresh air or close to an open window and lie down or sit with the head bent forward between the knees. A few sips of cold water or a little spirits or sal volatile in water will assist recovery. If a person faints, lay him on his back with the head low, loosen the clothing about the neck, chest and waist, and let him lie still until he recovers. He should have as much fresh air as possible, and when necessary may be carried into the open air, the head being kept low.

Recovery can be helped by the following measures: Sprinkle the hands and face freely with cold water. Gently slap the face and hands with a soft, wet cloth. Put a bottle of smelling-salts or eau-de-Cologne to the nose. After recovery the person should rest lying down for a few minutes. In severe cases the legs should be raised well above the body and massaged in the direction of the heart. If breathing is not resumed, artificial respiration (q.v.) should be carried out. *See* Dizziness.

**FAIRY RING.** This popular and superstitious name is given to rings of toadstool-like fungi which establish themselves in grass, and sometimes assume considerable dimensions. The grass in and around the rings is generally of luxuriant growth, because it benefits by the nitrogenous matter in the decaying fungi. A fairy ring can be exterminated by watering it with a solution of sulphate of iron or copper, 1 lb. in 3 gallons of water. Afterwards, a little fresh soil may be applied and grass seed sown in spring or September to cover the bare spot. *See* Fungicide.

**FAIRY ROSE.** This is a dainty dwarf form of the Polyantha type of rose, compact in habit, with elegant leaves, and bearing bunches of pretty blossoms. It is suitable for pot culture, as it does not grow more than 1 ft. high. Plants raised from seed generally flower three months after sowing. If grown outdoors they demand well-drained soil in a sunny position. *See* Rose.

**FALSE ACACIA.** The name of false acacia is given to Robinia pseudacacia, a familiar tree with pinnate leaves and drooping clusters of white, pealike flowers. It does well in town gardens.

**FALSE HEM.** This is a strip of material sewn at the extreme edge of the part which requires additional length, turned over to the wrong side and hemmed at the required depth. In cases where there is not enough

material to allow for a deep hem to be turned up, a false hem can be added of sateen or any material the same colour as the garment itself, taking care that the facing does not show on the right side.

A double hem can be made by folding a piece of the same material over and attaching it to the edge of the garment, covering the join with a trimming or fancy stitching. In the case of a thin material the false hem can be joined to the garment by means of faggot stitching. *See Faggoting; Hem.*

**FAMILY COACH.** Family coach is an old-fashioned game which is popular among small children. The players sit round the room and each chooses some part of the coach to represent. Thus one will be the box, another the lamps, another the wheels, and so on. If there are a great many players, each part may be taken by two or three children.

Somebody tells a story about the journeyings of the coach and its adventures on the road, mentioning the various parts in the course of the narrative. As each part is mentioned, the child who represents it has to get up and turn round, and when the coach itself is mentioned the whole party has to do the same. Any player failing to respond to his or her name in the story has to pay a forfeit, which is redeemed at the end of this amusing game in the usual manner.

**FAN: Uses and Ornament.** Fans are of two distinct types, the folding and the non-folding. The non-folding kind, in use with evening dresses, consists of one or more plumes. The stick or handle may be of tortoiseshell or mother-of-pearl, or of composition to imitate either of these, of jade, amber or coral.

*Fan of cream coloured lace, mounted on an amber frame (Courtesy of Selfridge & Co., Ltd.)*

The folding fan was invented by the Japanese, and is said to have been suggested by a bat's wing. From Japan it spread to China and thence to Italy, and was introduced into France by Catherine de Medici in the 16th century. The non-folding fan was inspired by the palm leaf, and dried palm leaves are still used for the cheapest kind of oriental fan. The earliest known fans were of this straight shape, and are recorded in stone on the walls of an Egyptian tomb at Thebes, where a Pharaoh of the 18th dynasty is surrounded by fan bearers.

Spanish fans have the advantage of expanding from right or left, and are most usual in black lace with

black bog oak carved mounts. Beautiful fans, painted, feather, or lace, still come from France. Interesting Chinese and Japanese fans can sometimes be picked up in curio shops. They may be made entirely of carved ivory, tortoiseshell or wood, the blades being strung together with coloured ribbons, or of folded, painted silk.

*Fan. Black lace fan, with painted centre in the Watteau style.*

The principle of Japanese fan painting is worth noting, because it has inspired the most successful designers of all nations. As the fan is invented for cooling purposes, patterns should be light and airy. The Japanese carry out this idea often by suggesting flowers, rushes, or branches of shrubs waving in the breeze, with, birds, butterflies or fish introduced to balance the design. These Japanese designs can be copied successfully by an amateur on a plain silk or gauze fan. Quite a success has been achieved by a straight Japanese fan, shield-like in shape, gold designed and varnished with red lacquer, handsome tassels depending from its stick; this is carried by the wearer of a black evening dress.

A charming idea from an old French fan is a centre medallion of pansies bordered with a ribbon knotted at the top and festooning to border a smaller medallion on either side containing the monograms of giver and receiver. Under the centre medallion the words "Thoughts of you" are painted. The three medallions connected by some kind of light ornamentation is a favourite design in fan painting. they can be placed to suit the arc of the fan, and filled with landscapes, classical figures or heads after the style of cameos.

If the fan is to be painted, the fabric must be painted before it is made up. It must be cut to the desired size, leaving a good margin for turning in. Stencil colours suitable for painting on silk, georgette or gauze should be used. If a pale coloured silk is chosen, the design looks very well in liquid Mandarin inks applied with a fine brush. The design must be carefully drawn on the silk before painting. Further inspirations for designs may be obtained from looking at the notable collection of beautiful 18th century fans, to be seen at South Kensington Museum. Designs painted on these fans were the work of Watteau and other genre painters. *See Stencilling.*

FANS: RARE AND HISTORICAL SPECIMENS OF INTEREST TO THE  
CONNOISSEUR

1. Korean fan. 2. Ancient Egyptian fan. 3. Chinese feather fan. 4. Indian fly fan. 5. Japanese water fan. 6. Ancient Egyptian state fan. 7. Indian hand fan of sandalwood. 8. French Merveilleuse fan. 9. Flabellum of Tournus Abbey, France. 10. Italian painted fan (18th century). 11. Cingalese state fan. 12. Ancient Greek fan. 13. French fan with a scene after Rosa Bonheur (19th century). 14. English fan (18th century). 15. Japanese war fan. 16. Chinese kingfisher fan. 17. Modern Sudanese fan. 18. Papal flabellum. 19. Burmese regalia fan. 20. Japanese Court lady's fan.

## FANCY DRESS FOR JUVENILES AND ADULTS

### Suggestions which Improve Attractive Costumes

In this Encyclopedia related information will be found under the headings Children's Party; Dance; Dancing. See also Making-up; Amateur Theatricals.

A costume which is out of the common, that does not cost too much, and is comfortable to dance in is what most people desire in the way of a fancy dress. English or French costumes of the powder periods are always dignified and becoming, and though they can hardly be said to be uncommon are required for a 'Powder Ball,' and are often favoured by men and older women who do not care for the exaggerated type of costume seen at any fancy dress dance. Adapted by modern designers, dresses that are suitable for wear with powder and patches may be quite original.

Whatever the style, if a white wig is to be worn, care should be taken not to hire one with a woolly, wispy appearance. It ought to be well dressed, with that crisp formality in each curl which marks the finest designs, and is better, especially if it is to be worn with a strictly period 'square cut' 18th century costume such as is shown in Fig. 1, when it is not made of pure white hair, but with a slight mixture of grey. Patches placed on the cheek and chin should not be forgotten. These cost 1s. 3d. for a box of assorted sizes. Women require a dainty pink and white make-up with accentuated eyebrows and lashes for wear with a powdered or white wig.

*Fancy Dress. 1. Powdered wig and period costume. (Claude Harris)*

Shepherd and shepherdess or other rustic china figures furnish models, copies of which can be carried out by the clever amateur dressmaker. Such picturesque ideas are more charming for children than grown-up persons, and can be carried out inexpensively in printed and plain sateens. Success lies in matching the delicate colouring and approximating the various patterns of the painted materials; also in copying the details of the oblong birdcage with stuffed bird emerging, the oval basket of mixed flowers, the straw hat full of pink roses, or the ribboned lamb, one of which typical objects should be carried, except when dancing.

*2. Christmas Tree fairy. (Bassano)*

Very small girls look attractive as Christmas-tree fairies. A pretty design is shown in Fig. 2. Small

boys may favour a pierrot or harlequin costume (Fig. 3), unless they set their hearts on a wooden soldier, pirate or Red Indian design. Patterns for many good fancy dresses are obtainable from the best pattern services.

*3. Harlequin pierrot. (Bassano)*

The topical costume often finds favour with men; a clever idea from a newspaper cartoon or caricature, a popular play or book title travestied. These are necessarily whims of the moment, and their value lies in being apt and well done. Other inspirations may come from studying the posters on the hoardings, either of plays or advertised goods. Characters out of fiction and drama of present and bygone times always make their appearance, more or less effectively, at fancy dress dances, and this class opens up a wide field. Sometimes a dance is arranged when all the dresses have to be of a period or out of a book—as, for instance, a Victorian, or an Arabian Nights' ball. The Victorian jockey (Fig. 4) is a suggestion for a man's costume for the former.

National dresses offer a variety of distinctive designs, of which many beautiful examples are illustrated in such a work as "Peoples of All Nations." Such costumes look well in pairs, and attract the eye to both partners.

*4. Victorian jockey, for a "character" dance.*

**Oriental Make-up.** Oriental costumes open up a wide field of choice and can be dignified, beautiful, piquant, mysterious or comic according to design and suitability. A beautiful Chinese princess dress is shown in Fig. 5. Such costumes need a special make-up for the skin and eyes to render them effectively in keeping with the character represented. This is not a difficult task according to the following directions.

*5. Chinese princess design suitable for an oriental ball; it is carried out in Chinese embroidery.*

Having cleansed the face thoroughly with cold cream and wiped it with an absorbent tissue or soft towel, apply grease paints Nos. 5½ and 6 for a dark

**EGG MOULD.** To make Egg Mould, dissolve  $\frac{1}{2}$  oz. gelatine in  $\frac{1}{2}$  gill water, then mix with 2 gills white sauce and 1 gill unsweetened condensed milk. When thoroughly mixed, stir in 4 chopped hard-boiled eggs, 4 oz. boiled rice, 1 teaspoonful chopped parsley, salt and a few grains cayenne. Decorate bottom of plain china mould with shapes of beetroot and some green peas, and pour in egg mixture. When set, turn out and serve with green salad round base of mould.

**EGG FRICASSÉE.** For Egg Fricassée, melt 3 oz. butter and add 3 or 4 slices cucumber, 3 shallots cut small, and 4 or 5 small pieces celery. Cook for 10 min.; then add 1 dessertspoonful flour, 1 tablespoonful prepared proteid food, and stir. Pour in 1 pt. milk and simmer for 15 min., stirring continuously. Strain, add a little ground mace, pepper, salt and 1 tablespoonful cream. Cut 6 shelled, hard-boiled eggs into slices, drop these into the sauce and serve with mashed potatoes.

**FISH TOAST.** Break 6-8 oz cooked white fish into small flakes, season with salt, pepper and a little chopped parsley, and add lemon-juice to taste. Melt 2 oz. butter in a pan over the fire, put in fish and a small teaspoonful of curry or fish sauce, and heat through. Serve the mixture on hot buttered toast cut in long finger-shaped pieces. Garnish with chopped parsley.

**FRUIT CASTLE.** To make Fruit Castles, stamp some slices of stale cake into rounds about 2 in. thick. Then with smaller cutter stamp out the centres, but not right through. Put rounds on plate and pour over a little wine or fruit syrup. Fill insides with stewed, fresh or bottled fruit. Whip some cream, sweeten, flavour, and heap on top.

## 'E' AND 'F' RECIPES: A SELECTION SHOWN IN ACTUAL COLOUR

**Easter Cakes.** Beat 5 oz. butter to a cream, mixing in same quantity of sugar, beaten yolks of 3 eggs and a little brandy. Stir in 1 lb. flour, moistening mixture with a little milk if too dry, and add 3 oz. currants. Leave paste in cool place for an hour, roll out thinly, and cut into rounds. Bake in warm oven. A few minutes before ready, brush over with beaten white of egg and sprinkle with castor sugar. **Floating Island.** Cut a round sponge cake into slices, spread these with apricot jam and soak in a little liqueur. Put them together again in a large glass dish, cover with whipped cream, sweetened and flavoured. Decorate with chopped almonds and pistachio nuts and pour custard round base of cake. Sherry may be used if preferred to liqueur.

foundation, blending the colours evenly over the face; a few strokes from each stick of paint will suffice, then working them in with the finger-tips. If the effect is too dark a little No. 2 grease paint well worked in will remedy this. Having thoroughly smoothed the foundation tint apply a grease rouge (or a little grease paint No. 9) and smooth carefully. Now soften a piece of white soap and place it over the eyebrows. When this is dry, smooth the grease paint very gently up to it and the hairs will be invisible. Apply an eyebrow pencil, drawing the ends of the eyebrows in an upward slanting curve, slightly or exaggeratedly according to the requirements and character of the costume.

To give the oriental effect to the eyes a line is drawn from the outer corners upwards, about half an inch long, with a black lining pencil, and after powdering the face with a dark shade of powder, a woman should make up her lashes heavily with black mascara, and a man lightly, just sufficiently in his case to remove any powder from them. To give a dark-eyed effect the upper eyelids should be shaded with a deep blue lining pencil. A brilliant but rather dark red shade of lipstick should add the finishing touch for a woman.

**Some Quaint Costumes.** Many variations of black and white fancy costumes are seen at a big dance. A chimney sweep design, with a stove-pipe hat made of cardboard and covered with black paper, the bodice of white sateen with bricks marked on it in black stencil paint, trousers of black velveteen fringed in long strips below the knees, black gloves and a sweep's brush in place of a fan, supplies an idea for a quickly made costume. A chessboard design is also striking for either a man or a girl. The long trousers are made in black and white check sateen with braces to match over a white silk shirt. The headdress or cap is ornamented with chessmen in black and white.

Polka dots of black on white sateen make up into an attractive pierrot costume with ruffles half-black and half-white. A silk wig can be worn with such a costume, which is made of black silk knitting yarn on one side of the parting and of white silk yarn on the other. Another beautiful black and white dress is shown in Fig. 6. The body part of this butterfly and the skull cap can be made of black velveteen, while the wings can be of white silk with a batik dyed design which is outlined with silver sequins.

6. *Butterfly, a beautiful design for a black and white costume.*

Mascot dresses are easy to make at home. They may be in pierrot style for a boy or a white sleeveless blouse and a short striped skirt may be worn as the foundation for a girl. The object is to adorn them with as many charms and symbols of luck as possible; some of these may be

embroidered on the material, others applied with buttonhole stitching, hung on a chain round the neck, worn as a headdress or attached to a waistbelt in the manner best suited to the style of the costume. Sometimes dresses are based on decorative things. Fig. 7, "Feathers," embodies such an idea.

7. *Feathers, consisting of a softly draped silver gauze bodice with skirt of white feathers and georgette. (Henri Manuel)*

Strange wigs may form an important part in quaint designs. They are best and coolest made on a foundation of embroidery canvas shaped to the head. Wigs are effective in wool or knitting silk left in loops or the loops cut and frayed to form a fringe; another way is to make them of tiny blossoms and leaves. Small roses, jessamine, violets, and lilies of the valley are suitable with leaves skilfully introduced to soften the face line, and each dress carrying out the colour and petal shapes of the flower chosen. Other wigs are made completely of coloured feathers.

In wool and silk these wigs give a touch of originality to the many variations of the pierrot and pierrette, and all the harlequinade characters. Such costumes and many flower costumes can be effectively made up in crêpe paper for children's fancy dress dances, when the object is to have bright and original designs with a small outlay.

**FANLIGHT.** Originally this term meant a glazed sash filling the arched head of a door or window opening, and was so called from the fact of its having bars radiating upward like a fan. Nowadays it denotes any sort of small window at the top of a door or larger window.

Most fanlights are bottom hung, on stout butt hinges, the casement opening inwards from the top. A simple quadrant of iron, with double cords, pulleys and a cleat, is cheap to buy and easy to install.

**FARAD.** An electro-magnetic unit of capacity. It is the capacity of an electrical condenser charged to a potential of one volt by one coulomb of electricity. A microfarad ( $\mu\text{F}$ ) is one millionth of a farad.

The application of electricity produced by an induction coil is known as faradism or faradization. It is more stimulating than the constant current, and may be applied to the whole body or to any part. *See Capacity; Electricity.*

**Farcy.** *See Glanders.*

**FARINACEOUS FOOD.** Farinaceous foods consist very largely of starch: bread, 50 per cent.; oatmeal, 63 per cent.; maize, 64 per cent.; macaroni, 77 per cent.; and rice, 84 per cent.; and in the last-named the amount of proteid is small. Wholemeal and standard bread contain the fat soluble vitamin A, and are richer in organic phosphorus compounds than white bread, and possess obvious advantages for children unless white bread is supplemented by milk, butter or animal or fish fats. Margarine of the vegetable variety does nothing to improve the food value of white bread in respect of vitamin, though it supplies fat. Wholemeal bread is less easily digested than white bread, however, and may give rise to symptoms of indigestion. Maize in the form of cakes or porridge is a good food, but the flavour is too coarse to make it a food of choice. Its derivatives, hominy, oswego and cornflour, have not this disadvantage and are often used in this way.

Farinaceous foods provide the starch which is a necessary constituent of diet, and some provide proteid also, and to a less extent fat; but, to balance all these constituents to our requirements, their use must be supplemented by other things. *See* Diet; Flour; Food; Maize; Oatmeal; Rice, etc.

**FARTHINGALE CHAIR.** Chairs of this, kind were made for women in the days when farthingales were worn. The specimens in existence date mainly from the 17th century, and are valued by collectors. They are without arms, and are much higher in the seat than ordinary chairs. Most are upholstered, and some have a squat, padded back, with a horizontal top rail. *See* Chair.

*Farthingale Chair of 17th century make (Courtesy of Waring & Gillow)*

## FAST COLOUR.

Colours should not be called fast if they are liable to change seriously upon exposure to sunlight, but cloth so dyed or printed that its colour is substantially un-altered after a fortnight's exposure to sun and air can reasonably be so described. Colours are not fast unless they will bear washing, and a test in this respect is to boil a sample for 10 min. in soap and water, with a handful of common washing soda to the pint.

The crucial test of fastness is the readiness of the seller to give the money back should the colour fade, and certain cloths can be guaranteed in this way. Lacking definite guarantees, the assumption must be that fast colour does not mean unalterable fastness under all conditions of wear and laundering. The matter is really important, for in some circumstances the garment is useless when the colour has gone. Articles made in mixed colours cannot invariably be

redyed, and as a general rule re-dyeing, whether done at home or at the dyers' and cleaners' works, is less fast in colour than a good dye applied while the cloth is being made. *See* Colour; Dyeing; Laundry.

**FASTING.** Properly speaking, fasting means complete abstention from nutritious food for a shorter or longer time. It is sometimes a useful remedy when carried out under the supervision of a doctor, but for the great majority of people a prolonged fast is exceedingly risky and nearly always injurious. The temporary deprivation of food will frequently lower the resistance to infection by the germs of disease. After a long fast the digestive organs are in a debilitated state, so food should at first be liquid, and taken in very small quantities.

In cases of acute gastritis fasting for at least 24 hours is required to give the stomach a rest; and a short fast will also be useful when, from over-indulgence in rich food, the liver is overloaded and biliousness has been induced. Abstinence from certain kinds of food, or a large reduction in the quantity taken, is beneficial in many conditions. Thus, in diabetes and in obesity, starchy and sugary foods are much curtailed, and in certain forms of rheumatism and in other diseases marked benefit may accrue by omitting butcher meat from the diet. *See* Diet; Obesity, etc.

**FAT: Its Food Value.** Fat is found in the body in adipose tissue, bone marrow, and elsewhere. Adipose tissue is widely distributed amongst the tissues and, with the exception of a few situations, e.g. the eyelids, exists as a layer of varying thickness beneath the skin. The stored-up fat forms an important fuel reserve for the use of the body.

Fat is made up of carbon, oxygen and hydrogen. No nitrogen being present, it cannot take part in the building-up of the muscles or organs, but it supplies heat and energy to the body, an ounce of fat giving more than twice as much as an ounce of starchy food.

Fat alone cannot support life, but it is a necessary ingredient of any diet. Fats that are derived from vegetable substances and sold as margarine do not provide a suitable source of fat for growing children, on account of their not containing fat soluble vitamin. This is present in mother's milk and is derived from the cow's milk and animal fat included in the mother's food. Fish oils also contain it. Infants require a larger proportion of fat than adults. When a child is fed on cow's milk, the whole of the natural fat should be present. On skimmed condensed milk a child will starve.

The standard proportion of fat in the diet of an adult is as follows:

Fat	5
Protein	12
Carbohydrate	50

While proteins and carbohydrates (sugar and starch) are digested by the juices of the stomach and pancreas and absorbed into the blood vessels, fat is emulsified

**FARINACEOUS FOOD.** Farinaceous foods consist very largely of starch: bread, 50 per cent.; oatmeal, 63 per cent.; maize, 64 per cent.; macaroni, 77 per cent.; and rice, 84 per cent.; and in the last-named the amount of proteid is small. Wholemeal and standard bread contain the fat soluble vitamin A, and are richer in organic phosphorus compounds than white bread, and possess obvious advantages for children unless white bread is supplemented by milk, butter or animal or fish fats. ### FAST COLOUR.

Colours should not be called fast if they are liable to change seriously upon exposure to sunlight, but cloth so dyed or printed that its colour is substantially un-altered after a fortnight's exposure to sun and air can reasonably be so described. Colours are not fast unless they will bear washing, and a test in this respect is to boil a sample for 10 min. in soap and water, with a handful of common washing soda to the pint.

The crucial test of fastness is the readiness of the seller to give the money back should the colour fade, and certain cloths can be guaranteed in this way. Lacking definite guarantees, the assumption must be that fast colour does not mean unalterable fastness under all conditions of wear and laundering. The matter is really important, for in some circumstances the garment is useless when the colour has gone. Articles made in mixed colours cannot invariably be

redyed, and as a general rule re-dyeing, whether done at home or at the dyers' and cleaners' works, is less fast in colour than a good dye applied while the cloth is being made. *See Colour; Dyeing; Laundry.*

**FASTING.** Properly speaking, fasting means complete abstention from nutritious food for a shorter or longer time. It is sometimes a useful remedy when carried out under the supervision of a doctor, but for the great majority of people a prolonged fast is exceedingly risky and nearly always injurious. The temporary deprivation of food will frequently lower the resistance to infection by the germs of disease. After a long fast the digestive organs are in a debilitated state, so food should at first be liquid, and taken in very small quantities.

In cases of acute gastritis fasting for at least 24 hours is required to give the stomach a rest; and a short fast will also be useful when, from over-indulgence in rich food, the liver is overloaded and biliousness has been induced. Abstinence from certain kinds of food, or a large reduction in the quantity taken, is beneficial in many conditions. Thus, in diabetes and in obesity, starchy and sugary foods are much curtailed, and in certain forms of rheumatism and in other diseases marked benefit may accrue by omitting butcher meat from the diet. *See Diet: Obesity, etc.*

**FAT: Its Food Value.** Fat is found in the body in adipose tissue, bone marrow, and elsewhere. Adipose tissue is widely distributed amongst the tissues and, with the exception of a few situations, e.g. the eyelids, exists as a layer of varying thickness beneath the skin. The stored-up fat forms an important fuel reserve for the use of the body.

Fat is made up of carbon, oxygen and hydrogen. No nitrogen being present, it cannot take part in the building-up of the muscles or organs, but it supplies heat and energy to the body, an ounce of fat giving more than twice as much as an ounce of starchy food.

Fat alone cannot support life, but it is a necessary ingredient of any diet. Fats that are derived from vegetable substances and sold as margarine do not provide a suitable source of fat for growing children, on account of their not containing fat soluble vitamin. This is present in mother's milk and is derived from the cow's milk and animal fat included in the mother's food. Fish oils also contain it. Infants require a larger proportion of fat than adults. When a child is fed on cow's milk, the whole of the natural fat should be present. On skimmed condensed milk a child will starve.

The standard proportion of fat in the diet of an adult is as follows:

Fat	5
Protein	12
Carbohydrate	50

While proteins and carbohydrates (sugar and starch) are digested by the juices of the stomach and pancreas and absorbed into the blood vessels, fat is emulsified

into a soapy fluid in the intestine and is absorbed into the lymph vessels.

The following table shows the percentage of fat in various articles of food:

FOOD	PERCENTAGE OF FAT
Rice	0.1
Bread	1½
Milk	3½
Oatmeal	5
Beefsteak	5
Eggs	10
Mutton (medium fat)	20
Cheese (average)	25
Butter	90
Pork (medium fat)	26
Bacon	65

*See Diet.*

**FATHER: His Legal Position.** By father, in law, is meant the father of a legitimate child, as the father of an illegitimate child has no rights or duties towards it, save in so far as he may be ordered to contribute by an affiliation order. While father and mother are living together the father is the sole guardian of the children. If they are separated and any question arises, the court will decide.

A father is responsible for supplying his children with food, clothing, lodging and medical attendance up to the age of 16. If a child of any age—even grown-up—becomes chargeable to the Poor Law the father may be compelled to pay. A father is not responsible for the consequences of any wrong done by the child, nor is he liable for its debts unless they were incurred with his authority. In certain cases of offences committed by his child, the father may be ordered to pay the fine. A father has the right to choose in what religion his child shall be brought up. *See Affiliation; Child; Guardian; Illegitimacy; Mother.*

**FATIGUE.** After a hard day's work, mental or physical, the vigour of the whole body is lowered. Waste matters have accumulated in the system, and until they are carried off by the circulating blood a greater or less sense of fatigue remains.

It is a mistake, when in this state, to eat a full meal, even if food has not been taken for some hours. A tired person should lie down for half an hour, or longer, before taking a meal. Recovery will be all the quicker if one neither talks nor reads. Massage, when obtainable, is the best of all restoratives when one's muscles are tired and clogged with waste matter. Alcohol only disguises fatigue, in no way removing it. *See Brain Fag.*

**FATSIA.** This is an excellent room plant with large, handsome, indented evergreen leaves. In warm showery weather the plant may be placed out of doors.

Tall growth may be remedied by the process known as stem-rooting, by which the top of the plant is converted into a dwarf. Repotting, when necessary, is

done in March, using a compost made of two parts loam, one part leaf-mould, and one of silver sand. This plant is hardy in the southern and other mild counties.

**FAUCET.** This is a term usually applied to the socket of a cast-iron pipe. It is also used to describe a spout with a plug or spigot used for drawing liquor from a cask. The name is also, in some districts, used as a description for any kind of tap from which water can be drawn, for a hot or a cold water system. *See Stop-cock; Tap.* Pron. Faw-set.

**FAVUS.** In human beings favus or honeycomb ringworm is a contagious disease which may appear anywhere on the skin, but oftenest on the scalp. Its chief characteristic is the formation of bright sulphur-yellow, irregular, cup-shaped crusts, pierced on the scalp by the hairs. They are easily broken off, and when removed a reddish surface is seen, which leaves a scar on healing. The cause of the disease is a vegetable parasite or fungus.

In treatment, the hairs piercing the crusts must be pulled out, and the rest of the hair should be cut close. The crusts are softened by applying lint wet with olive oil, and covered with gutta-percha tissue, and removed by washing with soap and water. A germicidal application should be applied morning and evening, composed of precipitated sulphur, 4 drams, and purified lard, 2 oz. Treatment must be continued for many months where the scalp is attacked. X-ray treatment sometimes gives excellent results. *See Ringworm.*

**In Poultry.** The disease favus or white comb in poultry is due to a parasitic fungus, *Lophophyton gallinæ*, which is distinct from that causing favus in mammals. This fungus attacks the comb and wattles of birds, and spreads from the naked parts of the head to parts covered by feathers. The breast and more often the rump may be attacked. One side only of the neck may be quite denuded of feathers, whilst the other shows no signs of the disease. As a rule, however, it is the comb that suffers first and most from the attack.

The first signs of an attack are small, pale, irregular, cup-like spots on the comb or wattles, generally appearing on the comb first. These spots grow together, and sooner or later form a crust of a dirty yellowish-grey substance, which is often arranged in concentric layers. When the feathered areas become invaded the disease is more persistent and may end fatally. The feathers may become erect, dry, and somewhat brittle, and fall off, the naked skin being covered with crusts. The affected birds exhale a mouldy odour.

The treatment consists in bathing the infected parts with warm water and soft soap, and then applying some ointment to destroy the parasite. An ointment made of sulphur and lard, mixed in equal proportions, is a simple remedy. Another more effective but more expensive remedy is nitrate of silver, which, when

rubbed into the comb and wattles, has been found of great benefit. An ointment of 5 p.c. of nitrate of silver in soft paraffin (vaseline) is recommended for the purpose in Bulletin No. 8 issued by the Ministry of Agriculture—from which these particulars of the disease and its treatment are taken. Red oxide of mercury 1 part, to lard 8 parts, is an excellent remedy if persistently used for several days. Before applying the ointment the diseased parts should be carefully fomented, and all the crusts removed as far as possible with a blunt knife.

**FEATHER BED.** When feather beds are made, care should be taken to see that the feathers are thoroughly stoved and sterilized in the first instance; they may then be enclosed in a case of ticking, the inside of which is rubbed with beeswax to prevent feathers from pushing through.

The dressing may be done at home or by the firm responsible for the manufacture of the bed. The process consists of separating the light feathers from the quills, and returning the cleared or loosened bulk to the case. *See Bedding; Bedstead; Mattress.*

**FEATHER EDGING.** In furniture this is a method of using marquetry so as to give a frame of special character round a central panel. It is found especially on walnut pieces of the reign of Queen Anne. It is made by cutting two thick strips of wood so that, when they are placed side by side and glued down, the grain of each piece meets in a feather-like formation. It is also known as herringbone. *See Marquetry; Queen Anne Style.*

**FEATHERED JOINT.** A feathered joint is one in which the joint between two pieces of wood is secured by means of a narrow strip of relatively thin wood known as a feather. To a large extent it is similar to the groove and tongue joint, except that the latter is formed from the solid.

Featheredge boards, such as weather-boarding, where one edge is thinner than the other, are laid overlapping, and the joint is sometimes known as a feathered joint. *See Joint.*

**FEATHER GRASS.** This is the English name of *Stipa pennata*, an ornamental hardy perennial grass worth growing in a border for the sake of its graceful, nodding plumes. Propagation is by seed, sown in a frame in spring or by division in autumn. *Stipa gigantea*, the giant feather grass, grows 3 feet high.

#### **FEATHERS: Their Care and Cleansing.**

The feathers of poultry, when, they have been properly cleansed and preserved, provide the household with material for stuffing cushions, beds, bolsters, and pillows. They are also useful to make good deficiencies when remaking such articles.

To achieve the best results, care in plucking the birds is essential. There must be no skin or flesh adhering to the feathers, and in the case of geese the coarse feathers should be removed first, so that the fine inner down

may be kept separate. This down forms the most valuable kind of feather. Chickens are sometimes plucked too young for their feathers to be of any value, and only those of mature fowls should be used. The same applies to pigeons. Game feathers, too, are seldom worth preserving, as they are apt to be tainted, and likely to remain so indefinitely.

There are two methods of preserving feathers, viz., wet and dry, the former being adapted to small feathers and quills, and the latter to small feathers only. To prepare by the wet process, place the feathers in water heated to a temperature of 100° F. into which sufficient white curd soap has been dissolved to form a milk-like emulsion. Then stir and let soak for an hour, after which stir again, and then collect on a sieve to drain off. After similar treatment in a second warm bath, using Castile soap instead of white curd soap, rinse the feathers in two baths of tepid water, made slightly alkaline with a little ammonia, and finally in a bath of clear cold water. The feathers should then be placed in paper bags and dried in a mildly heated oven.

Preserving by the dry process is effected by sprinkling the feathers slightly with a dilute non-corrosive disinfectant, and packing them loosely in paper bags. The bags should then be placed in an oven sufficiently hot to scorch paper in 5 or 6 min., and left there until the bags begin to brown. In both processes the feathers must be subsequently beaten lightly to get rid of dust, after which they may be stored in waxed paper bags until ready for use. After five years the feathers usually require re-dressing.

**Ornamental Feathers.** Ostrich feathers that are dirty and straight can be washed and recurled. The feathers are dipped in and out of a warm lather of soapy water. They are then well rinsed, shaken out, and dried in front of the fire. They burn very easily, so, although heat is essential, it must not be too great. The feathers should be shaken constantly and when dry recurled by drawing a blunt penknife or ivory paper knife along each strand. Great care must be taken not to cut the feather; the point of the knife can be used if blunt, otherwise it is better to use the back of the blade. This is held obliquely, and drawn across the strand until it curls.

Feathers that may have got damp and straight through exposure to rain can be curled in the same way. In the case of a feather rucking, it is enough to shake the trimming before the fire immediately after exposure to damp. The feathers must not be allowed to dry straight. If they do, the process of recurling becomes much more difficult.

Feathers are bleached by washing them in warm soapy water, and then exposing them to fumes of sulphur. To dye feathers, first put them into hot water, and allow them to drain. When they are lifted out of the dye, they should be rinsed at least twice in clean, cold water, and then dried before the fire. If red, however, one rinsing will be sufficient.

Marabout trimmings are washable in warm soapy water, and resume their soft, fluffy appearance if constantly shaken during the drying process. Swansdown trimming can be washed in the same way, and dried before a fire, with constant shaking. When not in actual use, valuable feathers should be wrapped in tissue paper and stored in boxes with either camphor or naphthaline balls as a protection against moth.

**FEATHER STITCH.** This is a useful trimming, as it can be executed with coarse cotton, fine silk, or any other medium in order to suit the foundation. There are three forms of feather stitch, single, double, and treble, formed with one, two, and three stitches in succession to the left, and the same order to the right, of a centre line.

*Feather Stitch. Left to right: single, double and treble forms of this decoration.*

The beauty of this work depends on its regularity, and this can be ensured by dots or by running a centre line. For ordinary purposes the stitches should be about  $\frac{1}{8}$  in. apart and about the same depth.

**FEBRIFUGE.** A febrifuge is a remedy used to bring down the temperature in fever. A cold bath in typhoid acts as a febrifuge. Drugs like sweet spirits of nitre and mindererus solution, and the free use of liquids, by encouraging perspiration help to reduce temperature.

**FEE: Of Professional Men.** This word is chiefly used for payments made for services rendered by professional men, e.g. doctors, solicitors and architects.

**Fees of Doctors.** Doctors usually charge a certain amount per visit, which sometimes includes medicine, but sometimes does not. It varies with the size of the house visited and the standing of the patient. An ordinary middle-class family will be charged anything from 5s. to 10s. 6d. per visit. Double fees are charged for night visits, but much less when the patient visits the doctor. The class of patient accustomed to do this is, however, dealt with under the National Health Insurance scheme.

There are various special fees. For instance, in cases

of childbirth it is usual to charge an inclusive fee of perhaps £5 5s., which includes attendance at the time of delivery and until the patient is well again, unless unexpected developments occur. The fees of specialists, both for consultation and for operations, depend almost entirely on the standing of the man employed. In the ordinary way a first visit to a London specialist will cost £3 3s., and subsequent visits one or two guineas each. Larger fees are charged if the patient is visited, and still larger if an operation is performed.

Doctors do not usually, give any details of their visits when they render their accounts, usually half-yearly, so in most cases the householder can only surmise whether or not the total is approximate, in his opinion, to the services rendered. Nursing and maternity homes charge fees, but these vary very much indeed.

**Solicitors' Charges.** The fees charged by solicitors are laid down in a scale which was drawn up under an Act of Parliament. This scale chiefly relates to sales, purchases and mortgages, and is based upon the value of the property or the amount of money involved. The fees charged are intended to cover the services of the solicitor and his clerks, but not any outlay for stamps, duties, etc. Very few solicitors charge on the full scale, but on the other hand it is almost impossible for a layman to check his solicitor's bill. He can, however, make a bargain for a fixed sum when he commissions the work, or if dissatisfied he can have the bill of costs taxed. This, however, may involve him in considerable expense.

**Fees of Architects.** Architects charge usually on the amount of the contract. A charge of 10 p.c. on the cost of a house of moderate size is generally regarded as reasonable. Fees or commissions are also charged by house agents and auctioneers. For selling furniture by auction a usual charge is 5 p.c. on the amount realised. For selling property a smaller percentage is usually charged, especially if the amount involved is considerable. A charge of 5 p.c. is also made for letting houses and furnished flats, the amount being paid on the first year's rental. These fees are paid by the seller or owner, the buyer or tenant usually paying nothing. Valuations of furniture, etc., are also charged on a percentage basis, which varies from  $2\frac{1}{2}$  to 5. There is usually a minimum fee of five guineas.

**FEEBLE-MINDED:** Care of Children who are mentally weak may be greatly improved as a rule by intelligent careful training and attention to their health. On the other hand, if neglected or otherwise improperly treated, they may remain permanently backward, and find it very hard to earn a living or go through life with ordinary success. There are innumerable grades of mental weakness.

From the earliest age the mother must try to arouse the child's interest in his surroundings. Little things that healthy children notice and learn about for

## What to do in the Garden

### Flowers

Syringe azaleas, heaths, and other hard-wooded plants

Keep calceolarias, fuchsias, and other summer bedding plants at a temperature of about 50° F.

Take off tops of fuchsias and start them in gentle heat to increase supplies

Pot up another lot of lilies

Sow half-hardy annuals in boxes

Plant the herbaceous border with hardy perennial plants. Plant leaf-losing trees and shrubs. Prune winter jasmine. Transplant autumn-sown annuals

Give gravel paths a first and strong dose of weed-killer

Finish planting hardy roses

Patch and edge turf on playing lawns

Plant hedges of leaf-losing shrubs

Knock off snow, if any, from branches of evergreens with a broom or rake

Towards end of month, lower slightly the temperature in which summer bedding stuff is growing

Sow annuals in boxes for transplanting later

### Fruit

Finish pruning fruit trees of every description

Give top dressing of farmyard manure, where available, to hardy fruit borders

Cut back stocks for grafting

Use the knife only lightly upon black currant bushes

Wash indoor vines, and paint them with a mixture of sulphur, soot, lime, and soap-suds

Plant a new strawberry bed

Spray fruit trees with lime sulphur

### Vegetables

Sow early peas on a warm border

Sow any kinds of early salad crops in frames that can be spared

Look over stored vegetables, and take out any that show signs of decay

Set seed potatoes in a light, frost-proof place

Plant Jerusalem artichokes in an unwanted corner

Sow broad beans for early crop

Bend the leaves of flowering broccoli inwards, to protect them from frost

Give the cabbage patch a dressing of lime

Sow short horn carrots for an early crop on a warm border

Sow onions for spring thinnings

Plant seakale and rhubarb; also shallots and onion sets

## Food in Season

### Fish

Barbel; bream; brill; carp; cod; dory; eels; flounders; gurnet; had-dock; hake; halibut; herring; ling; mac-kerel; mullet (red); perch; pike; plaice; salmon; skate; smelts; soles; sprats; tench; turbot; whitebait; whiting

### Shellfish

Crab; crayfish; lobster; mussels; oysters; prawns; scallops; shrimps

### Meat

Beef; house lamb;

mutton; pork; veal; venison

### Poultry and Game

Capons; capercailzie; chicken; duck; fowl; geese; hares; larks; landrails; partridges; pheasants; pigeons; pintail; plover; ptarmigan; pullets; prairie-hen; quails; rabbit; snipe; teal; turkey; wild fowl; widgeon; woodcock

### Vegetables

Artichoke; beetroot; broccoli; Brussels sprouts; cabbage; cardoons; carrots;

celeriac; celery; chervil; chicory; cress; cucumber; endive; horseradish; leeks; lettuce; mushrooms; onions; parsnips; potatoes; radishes; salsify; savoy; Scotch kale; seakale; spinach; tomatoes; turnips; turnip tops

### Fruit

Almonds; apples; bananas; Brazil nuts; chestnuts; cob nuts; cranberries; grapes; lemons; limes; med-lars; oranges; foreign peaches; pears; pine-apple; rhubarb; walnuts

## Notes for the Month

FEBRUARY 8 .. Half-quarter Day  
FEBRUARY 14 .. S. Valentine's Day

themselves the feeble-minded child must be taught. As he becomes old enough to understand, habits of cleanliness and self-control must be impressed upon him. Threats and scolding and punishment are worse than useless. The child must not be ridiculed or cowed, but encouraged. Bad habits must be corrected. In this matter it is necessary to explain why certain practices are objectionable. If he steals, explain that he will not be trusted, and that things will be locked up; if he is untruthful, tell him that no one will believe what he says in future, and that people will dislike him. This is better than punishing or threatening or scolding.

The weak-minded child must be taught regular habits. He should go to bed and get up much about the same time every day, and have meals at fixed hours. He should be taught to make full use of all his senses—sight, hearing, touch, smell, and taste. Physical exercises, when supervised, and massage, will help in developing and training in the proper use of the muscles.

In many cases it is better not to send the feeble-minded child to school until he is at least six years old. If a special school or institution for children of feeble mind is available, he will be much better there than at an ordinary school. Much has been done by legislation to safeguard the interests of the mentally deficient.

**FEEDER:** For the Baby. This serves the same purpose as a bib, but is larger. It usually takes the form of a square or oblong piece of material, from one side of which a semicircular piece is cut out for the neck, tapes being secured to the shoulders to fasten it round the back of the neck, while often tapes are sewn to the base of the sides, to pass round the waist and tie at back, so that the feeder does not move out of position. Sometimes, however, the back is made exactly like the front, so that the feeder can be reversed as needed.

Feeders are made of good white washable materials, and the favourite trimming consists of animals, such as bunnies or chicks, done in appliqué work. Feeders are generally made of single material, hemmed at the edges, or buttonholed. Pretty designs can be worked in cross-stitch, the feeder bound with a contrasting colour, which matches the embroidery.

**Making a Pattern.** A pattern for a feeder may be drafted thus: Cut a piece of paper to measure 13 in. long and 5 in. wide. Mark one of the shorter edges with the word top. Measure from this top edge down one of the longer edges some 2 in., and make a mark there; then measure from the first point across the top edge some 2 in., and make another mark. From the mark in the longer edge now cut through in a nicely curved line to the mark in the top edge, and so hollow out the neck part. The pattern, when drafted, consists of half the feeder, and the shorter of the two long edges is the centre front. When cutting it in material, this front edge should be put to a fold in a piece of doubled fabric, so that a whole feeder can be cut out. The neck should be faced in with a strip of material. *See Embroidery.*

**FEEDING BOTTLE.** The best type of feeding bottle is the upright type without a valve, as it is easy to

clean and the mixture can be poured directly into it when prepared once in the 24 hours. The teat should have a bulb at the end and be of good quality rubber. The hole in the teat should be large enough to allow the infant to draw out the milk without too much difficulty, but not large, or the milk will be bolted with subsequent indigestion and sickness. For this reason it is useful to have two teats, one with a small hole to use at the beginning of the feed when baby is hungry and sucking vigorously; and one with a slightly larger hole to use towards the end of the feed if baby becomes tired and feeds too slowly.

It is best to have five bottles, one for each feed; in this way the mixture can be prepared once in the 24 hours and poured into all bottles at the same time. Stand bottles in a cool place covered with muslin.

Before giving to the baby, stand the bottle containing milk in hot water to warm it. Heat to 100° Fahrenheit and cover with a flannel bag to maintain the temperature during the feed. When the feed is over any milk left in the bottle should be thrown away and the bottle rinsed with cold soda water, shaken well and rinsed. The teats should be turned inside out, rubbed with dry salt inside and out, then rinsed in cold boiled water, drained, and kept dry standing on a saucer under a cup or mug. Before using again the bottles should be boiled. The teats should be scalded once a day—never boiled. Old-fashioned bottles and feeding methods should be carefully avoided. The above suggestions are approved by the Truby King school of thought. *See Baby.*

**Feet.** *See Foot.*

**FELLOE.** A felloe, or felly, is the outer rim of a wooden wheel, or the curved pieces of which it is composed. A simple example is the wooden wheel of a garden wheelbarrow, which generally has four separate pieces or fellies forming the rim. These pieces are separately sawn from suitable timber, and when made up in this way the grain of the wood is more nearly concentric with the wheel, which is much stronger than if the rim was sawn from a solid piece of board.

Should a small wheel be broken at the felly, the damaged part may be sawn out, the joint faces of the remaining parts cleaned up true, and a new felly cut to shape from timber of a corresponding thickness, the joint faces being carefully fitted to the old work and secured with short dowels rounded at the end. The steel rim will have to be removed and replaced in the usual way.

**FELT: Varieties and Uses.** There are many uses for the various kinds of felt in house furnishings and in the manufacture of hats. In the latter the two chief kinds of felt are fur and wool, the former being, the more expensive. Rabbit hair obtained by paring away the skin from the fur is the chief material used in

making fur felts, and hare fur is employed for velours felt. Specially fine surfaces are put upon hat felts by using a little of such fine hair as nutria.

Felts proper have no thread structure, but are made by matting together fibres which exhibit peculiar powers of cohesion. Goods, however, are sold as felts, notably for carpet or mattress underlays, in which there is an upper and a lower surface of hairy felt and an intermediate woven layer. Felts of this type are practically stretchless and retain their original dimensions, where other kinds may tread out larger, or run up in size. Felt is not designed to take much pulling strain, but if necessary to stretch it tight the pull should be in the direction of the length rather than the width. Fine felts closely compacted from soft wool are made into bedroom slippers with a thicker, coarser felt for the soles.

Roofing felt, which is the coarsest kind, is composed of hair, wool, jute waste, and other rough fibre. Used under corrugated iron roofing it tends towards coolness in summer and warmth in winter. Nailed upon wood and treated with tar and shingle, it makes an inexpensive non-conducting weatherproof roof. Odd lengths make excellent packing material, and strips serve for draught-excluders. Refrigerators can be improvised with felt as a covering. Felt is useful to protect pipes of a house from freezing.

**Felt Appliqué.** This decoration is effective for floor cushions, work bags, coverlets, nursery cushions and mats. Bundles containing a number of good-sized pieces of different coloured felt are obtainable at handicraft shops, or it may be bought by the yard. As it costs 4/- the yard and  $\frac{1}{8}$  will cut out quite a number of flowers, animals, etc., it is sometimes better to buy it in this way if several articles are to be made or decorated.

Motifs are cut from the pieces of coloured felt and applied to hessian, cloth, canvas, crash or to a groundwork of the felt itself. Designs and transfers are easily obtainable from a needlework department, or can be originated to form motifs without much difficulty. Wool or matching silk is used to stitch the appliqué. Sometimes flowers are worked in the wools, while leaves and a jar or vase containing the bouquet are cut out in the felt and applied with coarse buttonhole stitch. If a thick wool is used it can be couched on the edge of the felt with small stitches in a matching silk (*see Laid Work*). This method looks particularly well for conventional flower or geometrical designs. Circular holes are usually cut in the centres of flowers and filled in by darning across, using a colour contrast for the horizontal and vertical stitches. *See Appliqué; Embroidery; Woolwork.*

**FENBERRY.** The name is sometimes given to the cranberry, a hardy evergreen trailing plant bearing deep red globular fruit of sour flavour. It requires an open position on marshy peat, and may be propagated by cuttings, layering, or by division of the plants. *See Cranberry.*

## Efficient Varieties and How to Erect Them

This article, which concludes with a section on the law about fencing, is supplemented by other entries on Gate; Post; Wire Netting, etc.

The object of a fence is to define a boundary and to serve as a protection against intruders. It should be strong, efficient, and pleasing in appearance, and can be made ornamental in character. Oak is by far the best wood to use for a fence, not only on account of its long life, but on the score of appearance, and the very small cost of upkeep, an occasional coat of wood preservative being all that is necessary. The construction should be simple, and preferably the posts should stand above the top line of the fence. It is a wise precaution to put such fences together with galvanized iron nails, as an ordinary nail quickly rusts and so will cause unsightly stains.

Oak pales nailed to triangular section cross bars let into strong oak uprights make an effective fencing if the pales are overlapped by a  $\frac{1}{2}$  in., 4 pales being usually reckoned to cover 1 ft. of length. Fig. 1 shows an oak pale fence in process of repair, with new gravel boards being fixed.

*Fence. Fig. 1. Repairing a cleft oak pale fence with new gravel boards.*

**Chestnut Pale Fence.** A cheap and effective type of fence is made of cleft chestnut pales, fastened together by galvanized wire. This fencing, which is supplied in 10 yd. lengths and can be rolled up into a bundle, is excellent for enclosing woodlands and for small gardens. The chestnut fencing is made up in a variety of styles with the pales of uniform height; or, slightly more ornamental in appearance, with adjacent pales of unequal length. Stock heights vary from 2 ft. to 6 ft., with 2 or 3 rows of wire. This fence can be rapidly fixed in any position, even over rough and undulating ground. The straining or end posts should have butt ends and be properly bedded into the ground. Intermediate posts can have pointed ends, and be driven into the ground by means of a wooden beetle or mallet.

Before fixing the fencing the straining post and gate posts should be securely strutted, to prevent them being pulled over. One end of a length of fencing is then fastened to the first post, and the whole piece strained tightly with a simple block and tackle, or with the aid of a 6 ft. pole used as a lever in the manner indicated in Fig. 2. The wires are then secured to the posts with galvanized iron staples, driven in tight.

The assistance of a second person is necessary for this. To join up the lengths, wire them together with the ends of the galvanized wire, which are left protruding. A simple type of fence is made by using prepared timber framed together and completed by nailing slats of wood on to two or more longitudinal rails (Fig. 3).

*Fence. Fig. 2. Fence of cleft pales, showing use of lever for straining the wire when securing the fencing to the straining post.*

*Fig. 3. Simple fence made from prepared timbers.*

**Wire Fences.** An extremely durable fence is made of galvanized hard steel wire woven together to form a network. The horizontal and vertical wires are secured in the process of manufacture by an immovable knot. It is available in rolls of 55, 110, and 220 yd. The horizontal wires are at unequal intervals, varying from 7 to 10 in. at the top to 3 to 6½ in. at the bottom, according to the type of fence and its purpose. The vertical wires are spaced 11 in. to 22 in. apart. The type with smaller mesh makes a strong pig fence. In erecting such a fence it is absolutely necessary that it should be tightly stretched, for which purpose it is desirable to obtain the regulation straining tools supplied by the manufacturers. The posts may be of iron, wood, or reinforced concrete, and all corner, gate, and end posts should be properly strutted.

A similar fence made with horizontal wires only is suitable for cattle, and can be erected without trouble by straining and fixing it to posts by staples. Besides the straining posts and intermediates there are iron spacers ("droppers") which do not enter the ground. The wires are secured to these by a form of iron clip which passes through a hole in the dropper and is closed on to the wire by a special hand tool. This type of fence is especially adapted for undulating ground. Fig. 4 shows a strong fence made of concrete straining posts and standards, to which are attached six horizontal wires. The posts could be cast in a simple mould, the holes for the wires being made at the same

time.

*Fence. Fig. 4. Example of a concrete post and wire fence, showing the method of bracing the straining post with a strut.*

The shape of the posts may vary, but a pattern which tapers on two sides will be found satisfactory, and is more economical in concrete. Immediately before the concrete is placed in the mould the reinforcements should be fixed in place. For ordinary sized posts, steel rod ¼ in. in diameter, placed one at each corner of the post, within about 1 in. of the outer surface, is suitable. The ends may be bent over at right angles, and if bound together in the middle with a piece of stout wire, the reinforcing strength will be greatly increased. The rods should first be wired together in the form required, and the concrete then placed around them in the mould.

After the concrete has been properly cured, which will take a month or so, the fence may be erected in the ordinary way. A post about 7 ft. long should be sunk in the ground to a depth of about 2 ft. 6 in. to 2 ft. 9 in. or so, according to the nature of the soil and the strain to which it is likely to be subjected.

The corner posts will be rendered stronger than the ordinary line posts by making them of larger dimensions, and reinforcing them with larger rods, say, of ⅜ or ½ in. rod, placed on each of the four sides, as well as in the corners. These corner posts should be securely braced up by struts, in order to withstand the constant strain to which they will be subjected by the wire.

**Points of Law.** Except in certain special circumstances there is no legal obligation on the owner or occupier of land to erect a fence. At the same time everybody is bound to keep his own animals from trespassing on his neighbour's premises, and is liable for the consequences if he does not.

If a fence is put up, there is not any right in anybody to have it kept up, apart from contract. But a contract of tenancy usually implies a legal obligation on the tenant to maintain existing fences. Sometimes a duty is cast on the owner of a fence to maintain it as between himself and his neighbour.

Where land adjoins a highway, if the owner chooses not to fence it, he cannot complain if damage is done

by straying cattle which are being driven along the highway, but if cattle stray about the highway and damage property the owner can claim damages. The owner of land adjoining a highway must fence off anything dangerous and likely to cause damage to travellers. Thus it is negligent to leave unfenced a hole or pit near a dark country road. A wall or fence adjoining the highway is a nuisance if it is in a dangerous condition, and the owner is liable not only to pay damages to anyone who may be injured in consequence of his neglect, but also to be indicted for a public nuisance.

It is dangerous to use barbed wire for external fences. If one erects a barbed wire fence as a boundary between his own field and a neighbour's, and any of his neighbour's cattle are injured by it, he will be liable. So also if he places a barbed wire fence next to a public road, and if such a fence is blown down by a sudden gust of wind, he will be liable to any member of the public who sustains damage. It has even been held that the owner of such a fence adjoining a public footpath is liable to pay damages to a person whose coat is blown by a gust of wind against the fence and torn.

The local authority, if satisfied that a barbed wire fence adjoining a road is a nuisance to the highway, may give notice requiring the wire to be removed; and if it is not removed they may summon the owner before the magistrates. The latter may make an order for the owner to remove the wire, or, if he does not, the local council may remove it and recover the expenses from him. A barbed wire fence includes a fence on which any barbed wire is placed.

**FENDER.** This piece of household furniture came into use when the open fireplace was abandoned. Fenders are made of brass, steel, or iron, and are either solid or pierced, often with fire irons to match. Some are freely decorated, the Adam style being used as well as other artistic patterns. Apart from these is the familiar kitchen fender.

*Fender. Antique examples. 1. Polished steel fender with applied brass ornaments, mid-18th century. 2 and 3. Pierced brass fenders, mid-18th century. 4. Pierced brass fender with serpentine front, late 18th century. (Courtesy of Gill & Reigate, Ltd.)*

Of antique fenders the best date from, the 18th century, some being beautiful examples of craftsmanship. Of the four illustrated, No. 1 is of polished

steel, pierced with ovals showing roses and thistles, with applied brass ornaments of conventional tulips. It stands on brass ball feet, and dates from the middle of the 18th century. Nos. 2 and 3 are of pierced brass. The former has a middle band of fine tracery and upper and lower bands of scroll work; the latter shows plain moulded bands top and bottom, the centre being pierced in rosette patterns with applied circular bosses. Both stand on paw feet, and are middle 18th century work. No. 4, which is later 18th century, is also of pierced brass. It has a serpentine front, the piercing being in two biers of inter laced arches with a central embossed band of roping.

These designs are copied in modern examples and are more in keeping with a panelled Georgian style room than are the various kind of metal, marbled or tiled flat curbs. With electric and gas fires the tendency is to do away with the fender as a superfluous piece of furniture. *See Chimney Piece; Curb; Fireplace, etc.*

**FENNEL.** This is a tall, vigorous, hardy and herbaceous perennial. With finely cut ornamental leaves and yellow flowers in summer, it thrives in ordinary soil and takes up a good deal of room. *Ferula communis*, 5 ft. high, is one of the most decorative: it is increased by seeds or division. *Ferula assafoetida* and other species supply the assafoetida of commerce. The fennel used for garnishing and other purposes in cookery is *foeniculum vulgare*, a hardy perennial which can be raised from seeds sown out of doors in early summer. The seeds are employed for flavouring and also in the making of liqueurs.

**Fennel Sauce.** This sauce will give an added flavour to mackerel. Prepare it by picking some fennel leaves from the stalks, washing them thoroughly, and then putting them into a pan of boiling water over the fire. When tender, drain and chop them as finely as possible. Melt 2-3 oz. of butter in another pan, mix in 1¾ tablespoonfuls of flour, and blend the two for a minute or so over a gentle heat.

Take the pan from the fire before adding 1½ pints of milk, then boil up the whole again, stirring all the time. Put in 3 tablespoonfuls of the chopped fennel, together with seasoning to taste, continue boiling for a few minutes, and the sauce is then ready to be served.

**FERN: The Varieties.** Ferns embrace many species of stove, greenhouse, and hardy kinds, ranging from the wild bracken of woods and common, to the exquisite varieties grown in stovehouse and greenhouse. They are propagated by division of roots, by young buds on the fronds, and by spores. The fronds are wonderfully varied in size, texture and colour, and some idea of their wide diversity of shape may be gathered from the diagram, which shows the following ferns:

- |                                   |                       |
|-----------------------------------|-----------------------|
| 1. Maidenhair                     | 3. Spleenwort         |
| 2. <i>Nipholobolus augustatus</i> | 4. Alpine hare's foot |

- |                          |                           |
|--------------------------|---------------------------|
| 5. Australian spleenwort | 9. New Zealand fern       |
| 6. Silvery brake         | 10. Actiniopteris radiata |
| 7. Tunbridge filmy fern  | 11. Hart's tongue         |
| 8. Bird's foot           | 12. Elk horn              |

*Fern.* Examples of fern foliage showing some of the many varieties of frond. A key to the drawing will be found in the text.

Hardy ferns are admirable plants for a shady border providing the soil is moist; they do not flourish in dry ground. There are many crested and tasselled varieties of the male fern, lady fern, hart's tongue and others which are very beautiful in summer and should be planted in preference to the commoner forms. Planting is best done in autumn, though it may be carried out in spring. If the soil is clayey, leaf-mould and sand should be dug in freely and an annual top dressing of leaf-mould or decayed manure in March will do good.

Some ferns do well in room windows, for instance the holly fern (*Cyrtomium falcatum*), *Pteris cretica* and its varieties, *Asplenium bulbiferum* and the ladder fern (*Nephrolepis*). Some of the less vigorous hardy ferns also make good window plants. A suitable compost consists of half leaf-mould or peat with sand added.

There are many charming ferns suitable for cultivation in a heated greenhouse having a minimum winter temperature of about 55 degrees. The ferns must be shaded from hot sunshine in summer and the soil kept moist. The maidenhair ferns (*Adiantum*) are great favourites; some of the most attractive are *cuneatum*, *gracillimum* and *pacotti*. Other suitable ferns are the bird's nest fern (*Asplenium nidus*), lace fern (*Cheilanthes*), squirrel's foot fern (*Davallia bullata*), gold and silver ferns of which the fronds are covered with gold and silver powder, and the ladder fern or *Nephrolepis*. The stag's horn fern (*Platycerium*) is of remarkable appearance with fronds like the antlers of a stag, it is grown in peaty soil fastened on a block of wood or board which is suspended against the greenhouse wall.

**The Fernery.** An indoor fernery requires comparatively little labour and skill to provide a source of constant attraction. A position where other plants will fail can be utilised, and there is such great variety that it is not difficult to find a large number of the loveliest ferns which will flourish. Give them plenty of

root room and avoid any accumulation of stagnant water.

An outdoor fernery built of rockwork is always attractive. Sandstone is preferable for construction. Use the pieces as sparingly and as naturally as is possible, endeavouring to convey the idea that they are cropping out of the ground. Loam, leaf-mould or peat and sand form a suitable compost.

**Fern Case.** Filmy ferns, which have thin, almost transparent fronds, are very beautiful and can be grown in a closed case in a cool shady greenhouse or in a shady room window. They need very moist conditions, though moisture must not be provided by watering from above. The ferns should be planted in a drained soil compost of sandy peat and loam; it is wise to cover the compost with moss, for this remains moist and thus helps to maintain suitable conditions. The chief filmy ferns are *Hymenophyllum*, *Trichomanes radicans* (Killarney fern) and others. See *Aquarium*; *Asparagus Fern*.

**FERN ROOT.** The liquid extract of the root of the male fern is very frequently prescribed for tapeworm, as it destroys the worm and leads to its expulsion from the intestines. The dose of the liquid extract of male fern is 45 to 90 minims; but the drug should only be used under the supervision of a doctor.

Before taking the fern extract the bowels should first be thoroughly emptied by the use of some purgative such as one to two tablespoonfuls of castor oil or a dose of Epsom salts taken overnight. The next morning the dose of male fern is taken on an empty stomach. About four hours later this is followed by a second dose of the purgative, if necessary. The patient should make certain that the head of the worm (and not only portions of the body) has come away, and to help in determining this it has been suggested that the receptacle used should be lined with crape. The head is about the size of a pin's head, and is at the end of a tapering neck. The diet should be light for two or three days preceding the treatment, and it may be advisable to keep the patient in bed. See *Worms*.

**Ferric Salts.** The name is given to compounds of iron, like perchloride of iron and citrate of iron and ammonium.

**FERRIER'S SNUFF.** This is an old remedy sometimes used for cold in the head. It consists of subnitrate of bismuth, powdered gum acacia and morphia. A pinch sniffed into the nose allays pain and greatly diminishes the discharge. As this preparation contains morphia, it can only be obtained on a doctor's prescription, and Ferrier's snuff should not be used indiscriminately or too often, or a morphia habit may be developed.

**FERRO-CONCRETE.** In modern building ferro-concrete consists of a framework or skeleton of

steel encased in walls of concrete. The term is applied generally to any structure made of concrete with internal steel strengthening members. Ferro-concrete is extensively used in all classes of building. *See Concrete.*

**FERROTYPE.** Ferrotypes is a method of obtaining direct positive photographic images very rapidly on thin iron plates or cards. Though principally used by itinerant photographers on seaside beaches and elsewhere, it can be employed to provide entertainment in the home.

The thin iron or cardboard plates are coated with collodion emulsion. A special form of camera is used with a magazine holding 50 or 100 plates. It is so arranged that by working a lever the plate is brought into position for exposure, and after exposure carried into a combined developing and fixing bath. At ordinary temperatures the plate is developed and fixed in about 1 min. or  $1\frac{1}{2}$  min. It is then rinsed in water and allowed to dry: the result is a positive image (not a negative as in an ordinary camera), with a not unpleasing appearance. With a reasonably good lens the detail is perfectly sharp and the image clear, although, owing to the iron or cardboard backing, a pure white ground is not possible. Only one copy of each picture is possible, but as it can be produced complete within 2 min. of the moment of making the exposure it is quite feasible to make a series of exposures if a number of copies of the picture is required.

An improved apparatus of this nature is the Prismotype camera. With the ordinary ferrotypes camera the image is reversed, so that any lettering that may appear is unreadable. This camera overcomes this disadvantage by the provision of a prism over the lens. Combined fixing and developing salts are sold by the makers of the camera, the formula being a proprietary one.

Insufficient exposure of ferrotypes plates gives dark pictures, and too long an exposure gives light ones. If white streaks appear on the photograph development is incomplete, and the plate should be returned to the tank. After the plate has been in the developer-fixing solution for 30 or 40 seconds it is comparatively insensitive to light. *See Developing.*

**FERTILIZER.** This name is commonly employed for artificial or chemical manures, which are largely used in gardening. The main elements of plant food are nitrogen, phosphates, and potash; and these are present in artificial manures suitable for general use in the garden.

Fertilizers containing nitrogen are sulphate of ammonia, guano, and nitrate of soda. Phosphatic manures are basic slag, bonemeal, and superphosphate. Potash fertilizers include wood-ashes, kainit, nitrate, muriate, and sulphate of potash. Green manures, dead fish, weeds, garden refuse, and animal matter are very rich in plant food essentials, but they need proper preparation by being placed in a heap and turned over occasionally.

Lime and soot are valuable agents; the former is of

special value in improving and sweetening soil as well as unlocking inert fertility. Slow-acting fertilizers, such as bone-meal, basic slag, and kainit, are best applied during autumn; and soluble manures as sulphate of ammonia, nitrate of soda, sulphate of potash, superphosphate, and guano, during the spring.

Never apply these fertilizers to sickly plants, as benefit can only be derived during healthy growth. Moderation should govern the use of any fertilizer, as excess encourages rank growth rather than fine crops, and if a proprietary compound is being used careful regard should be given to the instructions supplied by the maker. *See Basic Slag; Lime; Manure; Potash.*

**FESCUE.** The fescue grasses (*Festuca*) are often present in the mixtures sold by seedsmen for pastures and sports grounds, and are especially useful for sowing on light land, *Festuca glauca*, which has blue-grey leaves, is a pretty edging plant.

**FESTOON.** As used in architecture and on furniture a festoon is an ornament made to resemble a wreath of flowers. The festoon was used by the Adam brothers, and a similar decoration is sometimes found on silver. *See Adam Style; Anaglypta Christmas; Swag.*

**FEVER: Its Occurrence.** The normal temperature of the human body is  $98^{\circ}$ - $99^{\circ}$  F., and anything above that means that fever is present. It is slight if the temperature does not rise above  $101.5^{\circ}$ ; when it rises above  $106^{\circ}$  there is a state of hyperpyrexia, which may prove dangerous. In cases of fever the temperature usually reaches its highest point in the evening.

Fever occurs in infectious diseases, and is due to the poisons produced by microbes; in inflammatory disorders, e.g. pleurisy; in some digestive disorders, in heat stroke, etc. There are certain symptoms which are found in association with a rise of temperature, whatever its cause. The patient feels out of sorts, and there may be a general soreness or aching, headache and backache. Children frequently have convulsions at the beginning. Sleeplessness is common, and delirium may be present. The mouth feels dry, there is thirst and usually constipation. The appetite is impaired, and there may be nausea and sickness. The pulse rate and the breathing rate are increased.

Unless the fever is slight the patient should be put to bed in a quiet room. The diet must be liquid only, diluted milk, etc., and water or fresh lemonade may be drunk freely. The following remedy will help to keep a mild attack of fever in check. The dose for a child is 1-2 teaspoonfuls every 3-4 hours, for an adult 2 tablespoonfuls every 3 hours. In the case of children half the mixture only should be given at a time.

Sweet spirits of nitre	$\frac{1}{2}$ oz.
Solution of acetate of ammonia	2 „
Syrup	$1\frac{1}{2}$ „
Water	4 „

When the temperature tends to be high, or the patient is restless or delirious, the body should be sponged with tepid water, a part only being exposed at a time; or a cold pack (q.v.) may be employed. The treatment should be supervised by the doctor, and until it is clear that there is no infection the patient should be isolated. *See* Infectious Disease; Scarlet Fever; Thermometer; Typhoid Fever, etc.

**FEVERFEW.** The popular name of *chrysanthemum parthenium* (known also as *matricaria* or *pyrethrum*), of which the double flowered variety is a useful garden plant, 2 feet high, bearing a profusion of small double white flowers. It will thrive in shade and sow itself freely. The name feverfew is also applied to that popular bedding plant, golden feather.

*Feverfew. Golden feather, or feverfew, a popular summer bedding plant with yellow leaves.*

**FIBROID.** Fibroids of the uterus are tumours composed of muscle and fibrous tissue which may arise in any part of that organ, but are most common in the body of the uterus.

The commonest symptom is excessive loss of blood at the periods, and it is of great importance that advice should be sought early. The tumours enlarge just before the menstrual periods, and the occurrence of difficulty in passing water for 2 or 3 days before a period should incite suspicion of their presence.

The period of maximum frequency is between the ages of 35 and 45. Although the presence of a fibroid or fibroids may not prevent conception, it nearly always renders dangerous, and sometimes impossible, the birth of the child, or even its development to full time. If the growth becomes infected by germs, general blood poisoning and the death of the patient will ensue. The only treatment of any avail in the great majority of cases is the removal of the uterus.

**Fibroma.** *See* Tumour.

**FIBROSITIS.** This term is applied in medicine to swelling of fibrous tissue from inflammation and is the condition present in muscular rheumatism, where the fibrous sheaths and intersections of the muscles are affected. Where the swellings occur nerves may be compressed or dragged upon, and this is especially so when movements are made, hence the acute pain associated with this complaint. The lumps can sometimes be felt.

Fibrositis may follow exposure to cold and damp, injury or poisoning from sepsis in the mouth, intestine

or elsewhere. In some cases rest in bed is necessary. Aspirin may be useful in relieving the pain, and the bowels should be cleared with a dose of Epsom or Rochelle salts. A course of sulphur may also be beneficial. Heat, either in the form of a hot water bag or of poultices or fomentations will be found comforting. Massage is an all-important part of the treatment, and after the rubbing the patient should make such movements of the part as are possible without pain, and in most cases he rapidly gains freedom in doing this. To prevent recurrences he should keep a clean mouth, pay attention to the regularity of the bowels, and by extra clothing, etc., take precautions against exposure. *See* Lumbago; Massage, etc.

**Fibula.** *See* Leg.

**FIDDLE PATTERN.** Tablespoons and forks are very often made in this pattern, which came in vogue in the 19th century. Its main features are the round end and straight side, the handle having sharp corners where it rounds away into the stem. *See* Fork; Spoon.

**FIDGETS.** Elderly people frequently suffer from sleeplessness and troublesome fidgets. This is probably due to a general failing of all the organs, which hinders the purifying processes of the blood. The patient should eat very moderately and be kept a good deal in the open air, even when unable to take much active exercise. An occasional warm (but not hot) bath before going to bed will soothe the nerves.

A form of fidgets to which other than elderly people are prone is due to muscle fatigue, the limbs feeling nerveless and out of control. The treatment noted above may give relief, but if not, a doctor should be consulted.

*Fig. The ripe fresh fruit highly prized for dessert.*

**FIG:** Growing and Cooking. The edible fig is borne upon hardy trees of varying sizes belonging to

the genus *Ficus*, of which the indiarubber plant is a member. Except in mild districts, figs are best grown under glass, or on a sunny wall. They strike readily from cuttings of ripe wood placed in sandy soil, in bottom heat in late autumn. When rooted, the young plants should be given separate pots, and then either repotted as required if they are to be fruited under glass, or planted out against a wall. As the habit of the tree is naturally gross, rich soil must be avoided. If the soil is deficient in lime, mortar rubbish or chalk may be added liberally, and the soil rammed well down. Propagation may also be effected by drawing suckers away from the base of established plants. Pruning, which is done in summer chiefly, is directed towards preventing overcrowding. Suckers (shoots that grow from the base) should be pulled up. The best variety for general cultivation is Brown Turkey.

**How to Cook.** The fresh fruit of the fig-tree is useful for dessert. These are always called "green figs," and are sometimes made into jam, or a compôte cooked as follows: To about  $\frac{3}{4}$  pt. of water add  $\frac{1}{2}$  lb. of sugar, and let them boil together for about 10 min. Add 1-1 $\frac{1}{2}$  lb. of figs, and simmer them slowly until they are tender. Then take them out, and let the syrup boil briskly until reduced to about  $\frac{1}{2}$  pt. Pour it over the figs, and leave them to get cold. Lemon peel added to the water, and a little lemon juice or wine added when the fruit is soft, will improve the flavour.

In stewing, use the small figs, and soak them overnight in cold water. Then put into an enamelled saucepan 4 oz. of sugar, 1 $\frac{1}{4}$  pint of cold water, and the thinly peeled rind of a lemon. When the sugar is dissolved, add 1 $\frac{1}{2}$  lb. of figs, and stew them slowly for about 1 $\frac{1}{2}$  hours. They are usually served with a milk or custard pudding. If liked, the juice of a lemon may be used as flavouring for the figs instead of the peel.

The fruit for eating as dessert should be quite ripe, and must not be kept too long or it loses its delicate flavour and bloom. The finer kinds of dried or Turkey figs serve also as a dessert dish. In appearance they should be slightly moist, and have a whitish tint outside and a rich yellowish brown inside. The smaller figs are drier in appearance, but should be clean and without black patches. They are mostly used for stewing, and are useful for various kinds of puddings. They may take the place of raisins in a cake, and in that case should not be soaked in water.

**Fig Cake.** A rich cake can be made by sifting  $\frac{1}{2}$  lb. of flour with a pinch of salt, 1 teaspoonful of ground ginger, and  $\frac{1}{4}$  teaspoonful of baking powder. In a separate basin cream 3 oz. of lard and 2 oz. of butter with 5 oz. of brown sugar, adding the rind of  $\frac{1}{2}$  a lemon. When these ingredients have been well worked, add 3 eggs one by one, and beat them well in. Clean and cut up into small dice  $\frac{1}{2}$  lb. of figs, add them to the flour and then mix them with the butter and eggs, taking care to work the dry ingredients in lightly. Lastly, add  $\frac{1}{2}$  gill of sour milk, turn the mixture into a

lined cake-tin, and bake it for about 1 $\frac{1}{4}$  hours.

**Fig Jam.** To make fig jam, weigh some small green figs, which should not be quite ripe, wipe them, and score them across the top. Lay them in a brine of salt and water for 10 days, then wash them and boil them in fresh boiling water till a skewer will easily pierce them. Put the figs into cold water and leave them for 4 days, changing the water each day. For every lb of figs bake 1 lb. of granulated sugar and make it into a syrup, allowing one gill of water to every lb of sugar. Cool the syrup after straining it, pour it over the figs, and leave them all night. The next day boil the jam till the fruit is quite clear, put it into jars and tip it down securely. (See Jam.)

**Fig Pudding.** Chop  $\frac{1}{2}$  lb. of dried figs very finely, and add to them  $\frac{1}{2}$  lb. of breadcrumbs, 4 oz of finely chopped suet or dripping, and 4 oz. of sugar. Beat up 2 eggs, pour them, with a good breakfastcupful of milk, over the dry ingredients, and mix well. A little grated nutmeg or powdered allspice might also be added. Turn the mixture into a well-greased pudding basin, twist some greased paper over the top, and steam it for about 4 hours.

*Fig Pudding. Another variety can be made by using equal quantities of chopped figs and raisins.*

**FIG MARIGOLD.** Few of the mesembryanthemums or fig marigolds are hardy in Great Britain except in specially favoured places. One of the hardiest is the ice plant, *Mesembryanthemum crystallinum*, an annual which is raised from seeds under glass in spring; it has succulent stems and leaves and white or red flowers in summer and should be planted in a sunbaked spot. One named *Mesembryanthemum cordifolium variegatum*, with green and yellow leaves, is often used in carpet bedding; it is, raised from cuttings in a frame in August. In spring and summer the points of the shoots must be pinched off several times to keep the plants dwarf.

*Fig Marigold, annual suitable for a sunny garden.*

**FIGURE:** How to Improve. The foundations of a

good figure are laid in early youth. With ordinary health, if hygienic rules have been observed, a strong, graceful body may be developed which with a little care will retain correct lines.

Diet, fresh air, proper breathing, sufficient relaxation and exercise all contribute toward moulding a good figure. Outdoor games should be encouraged for normal children to develop healthy growth of bone and muscle. Swimming and classical dancing, particularly in the open air, are especially beneficial as they exercise every muscle with rhythmic perfection. Skipping improves breathing, balance and carriage. Tennis, when played vigorously, is a good form of exercise.

While perfectly controlled muscles are essential, over-development of these to some extent destroys elasticity and coarsens the limbs. To acquire symmetry and to preserve the good lines of the body a short course of exercises, which flatten and strengthen the back and abdomen, deepen the chest and keep the body supple, should be performed daily. Suppleness and symmetry are the keynotes of beauty. They mean fluent grace of line and movement.

**Suitable Exercises.** In addition to the exercises given under Beauty Culture and Breathing, the following three would make up the daily dozen of an excellent course suitable for either sex.

(1) A lunge exercise is good for all the muscles of limbs and trunk. Stand erect with hands on hips. Take a step forward with the right leg, bending the right knee. At the same time lunge forward and upwards with the right arm to the full extent, following the arm with the eyes. The left arm is simultaneously carried backwards and downwards. Spring back to the original position, then lunge with left arm, bringing the left leg forward. Spring back and repeat the exercise, lunging with right and left arms alternately.

(2) This exercise should be practised gradually. Lie flat on floor, face downwards. Support the weight of the body on the toes and hands, palms flat on the ground at the side of the body, fingers pointing forwards. Raise the body by straightening the arms and keeping the trunk rigid without bending at the waist. Slowly lower the body and try to touch the floor with the chin. Raise and lower the body alternately, touching the floor only with the toes, the palms of the hands and the chin. This is a splendid exercise for the arm, thigh and abdominal muscles.

(3) Stand with feet apart, arms extended to the sides at shoulder height, palms downwards. Bend the body forward from the hips until at right angles, keeping the knees stiff. Then bend down and touch the ground between the feet with the right hand, left arm raised to a vertical position above head, keeping the body bent the whole time. Repeat ten successive movements each side. Digestion is stimulated by this exercise, the liver and kidneys toned up by using the back muscles, and, in addition, the abdominal muscles strengthened.

Do not hold the breath during the exercises, but breathe deeply and evenly throughout. The movements should be repeated until there is a slight feeling of fatigue. It is surprising how speedily strength is

improved by persistent practice. *See* Beauty Culture; Breathing Exercises; Diet; Obesity.

**FIGURE OF EIGHT MOTH.** Although this moth is exceedingly common and fairly large, it rarely comes under the notice of the gardener; but the caterpillar is often evident to him. The perfect insect is less than  $1\frac{1}{2}$  in. in the spread of its greyish-brown forewings, which bear the distinctive mark from which the moth takes its name. There are two whitish blobs on each wing, and the one nearer to the base of the wing takes the shape of a crudely formed 8. Flying by night, it is rarely seen, except occasionally by watching the street lamps which attract it. The eggs, laid in September, hatch about April, and the caterpillars which out in the open feed upon hawthorn, blackthorn and crab, in the garden attack apple, plum and other fruit trees. They often appear in great numbers, and may be recognized easily by their characteristic blue backs which have a yellow line down the middle. Each segment of the body of this moth bears four black warts on the back, and the warts bear bristles.

*Figure of Eight Moth, an orchard pest.*  
1. male; 2. female; 3. caterpillar.

By late June the larvae are full grown—about  $1\frac{1}{4}$  in. long; but they are large enough to be noticeable early in May. When full-fed they descend the trunk to spin a cocoon near the ground, attached to the bark or sticks or stones. As soon as their presence is detected, a large sheet of some sort should be spread under the tree where they are thickest, and the branches should be jarred by rapping them sharply with a stout stick, bringing the caterpillars down in a shower.

#### **FILAMENT: In Wireless Apparatus.**

In a wireless receiving valve of the battery operated type the filament is a metal wire enclosed by the grid and anode. Upon being heated by the flow of current from a low tension accumulator the filament emits electrons from its surface. In this type of valve the filament constitutes the cathode, in contrast to an indirectly heated mains valve, in which the filament (i.e. heater), and cathode are separate.

A directly heated mains valve is fundamentally similar to a battery valve, but the electron-emitting filament is heated by the mains current. The difference is that whereas the resistance of a battery valve filament is kept as high as possible in order to reduce

current consumption to the lowest practical level, that of a directly heated mains valve is low to minimise hum of voltage variations.

The filament of a modern battery operated valve is usually connected direct to a low tension accumulator of suitable voltage, the current supply being controlled by an "on-off" switch inserted in either the positive or negative leads. *See Cathode; Valve.*

**FILBERT.** Belonging to the genus *Corylus*, the filbert will flourish in ordinary well drained soil. On the chalky soil of Kent the filbert flourishes excellently, and it may be used as a hedge, instead of privet or thorn, or as a screen, or in groups. The tree may be raised from nuts planted in the autumn, or from layers or suckers. Popular varieties are white-skinned, red-skinned, Webb's prize, and Cosford. The best crops are obtained from trees that are closely pruned to the shape of a vase. Pruning must not be done until after the catkins have faded: side shoots, other than those bearing the small red-tipped female flowers, are then shortened.

*Filbert. Leaves and fruit of a tree useful to the gardener.*

They are best freshly gathered, and will then peel easily when removed from the shell. To blanch the nuts for cooking, or any other purpose boil the shelled nuts for a second or two, then turn the kernels into a clean rough cloth, and by rubbing remove the brown skins. *See. Nut.*

**FILE: Its Uses.** A file is provided with a spike called a tang at one end, to which a wooden file handle can easily be fitted. When in use, the file is grasped by the handle in the right hand, with the length of the file pointing forward across the top of the work to be filed; the finger tips of the left hand are laid down on the top of the file close to the point end. Vertical downward pressure is applied equally with both hands, and at the same time the file is driven forward in the direction of its length by force exerted principally by the right hand. On the recovery stroke the downward pressure is entirely relaxed, or the file may be lifted off the work.

Exert the downward pressure principally with the left hand at the commencement of the stroke, transferring it gradually during the stroke, so that at the finish of the stroke the principal pressure is exerted by the right hand. This must not be overdone, or rounding instead of flatness will appear; properly done,

the gradual transferring of the duty of pressing down from the left to the right hand just keeps the file dead level, and level work is the result.

It is essential for the work to be held in a vice or otherwise rendered absolutely as firm as possible. The above description applies particularly to the use of a flat file on a flat surface (*see illustration*).

*File. Correct position in use: thumb on handle, weight on both arms, file horizontal.*

Files are classified according to size, shape, and roughness of surface. The only shapes which are required for daily use are known as hand, half round, square, round, and three square. The grades of roughness are known as rough, middle, bastard, second cut, smooth and dead smooth. The amateur will find the following assortment of files useful: a 10 in. bastard, an 8 in. second cut, and a 6 in. smooth hand file, an 8 in. second cut half-round, an 8 in. and a 6 in. second cut square, an 8 in. and a 6 in. second cut round, and a 6 in. second cut three-square file.

**FILET LACE WORK.** This lace derives its name from the French filet or net which forms the background on which the pattern is darned. It is a square mesh varying in size from 1/16 to 1/4 in. for the standard filet nets, although larger meshes have become fashionable for window curtains, table centres, cushions, chairbacks, and other articles of the kind.

Real filet lace has a hand-made background made with the ordinary netting stitch used by fishermen, but with a much finer needle and mesh, a round steel knitting needle being used for the latter where a mesh of less than 1/8 in. is required. Many English filet laces are worked on a machine-made background, the designs being darned on the net by hand.

*Filet Lace. Fig. 1. Showing hand-made net attached to wire frame, and method of making darning stitch.*

Fig. 1 shows a square of hand-made net lashed firmly to a square filet frame of thick wire, bound with green silk. With a small piece of work, the ground net should be sewn to strong calico, and the latter sewn or lashed to an ordinary frame bound with strong calico. A round embroidery frame could be used for small motifs, by sewing the latter to a piece of

material each side so that the net in the middle is quite free.

The stitch employed is the ordinary darning stitch, passing the needle under and over the meshes of the net in an up-and-down direction until the space is filled. A specimen of this is shown in the lower part of Fig. 1.

The most expensive filet laces are worked in cloth darning, shown in the top left corner of Fig. 1. To do this, darn up and down as described above, but work only half the number of threads required to fill the space, then darn in the opposite direction, going under and over every thread in turn, including the net background.

**FILLET: Of Meat and Fish.** *See* Beef; Fish; Mutton; Veal, etc.

**FILM: In Photography.** Celluloid films have many advantages as compared with glass plates. They are lighter, not liable to breakage, and less liable to halation than unbacked glass plates. In the roll form as cartridges for daylight loading they are extremely convenient for snapshot work. Roll films suffer from a liability to longitudinal scratches, probably caused by rolling too tightly; care should be taken when the film is in the camera to see that both top and bottom spools revolve easily.

Modern super-speed films are of many different varieties. One or two still make negatives by full exposure and normal development that are on the soft side. But at least two of Continental make give distinctly vigorous negatives. The amateur photographer should stick to one make whose peculiarities he understands. Both auto-chromatic and high speed panchromatic roll films are now obtainable.

Films are also available in flat form, six or a dozen exposures being carried in a film pack. These are exactly similar in characteristics to roll films, but are designed for use with plate cameras. For more advanced photographers flat films of a stouter kind are made which have all the advantages of plates and none of their disadvantages. These flat or cut films are carried separately in plate holders or dark slides.

Lately, however, photography has been revolutionized by the use for miniature cameras of standard cinematograph film whose emulsion uses the whole experience of the cinema and photographic industries. In general, films are so convenient that the Kodak company temporarily abandoned the manufacture of glass plates, whether for amateur or professional use. These plates, however, may shortly be reintroduced.

As films are more liable than plates to surface damage by scratches and finger marks, it is a sound plan to harden them by immersion for  $\frac{1}{4}$  hour in a solution of one part of formalin in 25 parts of water. After removing the surface water with fluffless blotting paper the film can be dried before a fire. If dried thus without hardening it would melt.

**The Clearing Bath.** Stains on a film caused during development, both on the front and sensitive side and

on the gelatine back, can usually be removed by a clearing bath. The film should be thoroughly washed to get rid of the slightest trace of hypo, and then immersed in the following solution:

Alum	2 oz.
Citric acid	$\frac{1}{2}$ „
Water	20 „

If chrome alum is used the quantity should be  $\frac{1}{2}$  oz. and 1 oz. citric acid. This solution can be used two or three times, and it brightens the negative considerably. To remove the film from useless glass or gelatine negatives, soak them for several hours in strong soda water and place them in water which is nearly boiling; they should then come off quite easily.

The "multi-coated" film consists first of a comparatively slow emulsion capable of giving considerable density and of recording a very wide range of contrast. On top of this is a thin emulsion of high speed, which responds to illumination far too faint to produce any developable change in the slower emulsion. Yet the "multicoated" film has a disadvantage: it produces slightly blurred pictures; and many photographers to whom the utmost possible sharpness is a vital matter are returning to a single-coated film. *See* Cinematography; Developing; Fixing; Negative.

**FILM PACK.** This is a means of using flat films in a plate camera with the advantage of daylight loading. Six or 12 films are placed together in a cardboard holder, each film being backed with black paper, the end of which projects at the top of the pack and carries a number. The whole pack is placed in a film-pack adapter fitted to the particular camera, taking the place of the ordinary dark slide or plate holder. When a film is exposed it is changed by pulling out the numbered tab steadily and without excessive force: this pulls the exposed film round a roller at the bottom of the pack so that it is changed from the front to the back of the pack, and the next film is ready.

When the last paper tab is pulled out a shield is brought in position in front of the last exposed film, protecting it from light and allowing the whole pack to be removed from the adapter in daylight. If it is desired to develop single exposures the adapter containing the pack can be taken into the dark room and the required films removed, care being taken to close the pack properly before replacing. *See* Developing; Fixing; Photography.

**FILTER: For Drinking Water.** When drinking water is suspected of being contaminated it should be carefully filtered before use. As an extra precaution, it is well to boil it first. Water loses its contained air by boiling and becomes flat, but the process of filtration restores more or less air. The water supplied to city people is thoroughly filtered, but in country districts, where the supply comes from wells and streams, the process must be carried out in the home. Where disease

germs are present, however, reliance should not be placed on filters; the best safeguard is to boil drinking water.

*Filter. Fig. 1. A non-pressure type, showing upper and lower chambers and (left) filter candles. (Courtesy, Pasteur Chamberland Co.)*

Several filters suitable for use in the home are on the market. The Pasteur Chamberland is made in several types, the largest being pressure filters for attaching to the main water supply. A smaller one, of the non-pressure type, made to stand in the house, is of earthenware or enamelled iron. Its size varies, the largest being able to deal with 16 gallons of water a day and the smallest with three. A filter of this kind is illustrated in this page.

Another useful type is the silicated carbon filter, made in various sizes and styles.

**FINGER BOWL.** Finger bowls may be of plain or cut glass, those of the former type being often coloured. If coloured ones are used they should harmonise with the dessert service and the table decorations generally.

Finger bowls of old glass can occasionally be purchased, and are usually of greater beauty than modern ones. Some are of the double-lipped type, and are found in a variety of patterns, cut and engraved. More rare are the barrel-shaped ones, austere decorated with raised lines. *See Glass: Table Laying.*

*Finger Bowl. 1. Early moulded Irish finger bowl, c. 1780. 2. Bowl of Bristol blue glass with gilded edge, c. 1800. 3. Irish cut glass work, c. 1800. 4. Finger bowl decorated with flute cutting, c. 1820-30*

*(Courtesy of Cecil Davis).*

**FINGER STALL.** Rubber finger stalls may be bought from any chemist, but ordinary ones can be made from an old pair of gloves. Cut off the glove

finger corresponding to the finger for which the dressing is required, leaving a triangular piece of material extending from the base. This is then pierced and a piece of tape inserted. The tape should be long enough to cross over the back of the hand and take a turn round the wrist, being then fastened. *See Bandage; Dressing.*

**FIR.** This name is commonly used in reference to various conifers, e.g. abies, picea, pinus and others.

**Fir Cone.** Fir cones make excellent fuel for an open grate. They should be collected and dried, and then stored in a log basket. When the fire has burned up well and is bright and clear, put on the cones. They burn briskly and give out a pleasantly fragrant smoke.

A large fir cone makes a reliable weather glass. It should be hung up in the porch or hall. When wet weather is to be expected the cone will close up tightly, owing to the moisture in the air. When a spell of dry weather is coming the cone will open and spread out. *See Deal; Fire; Fuel; Wood.*

**FIRE: How to Lay.** Much depends upon the correct laying of a fire, but no difficulty should be experienced if a sufficient supply of dry wood is kept ready for use.

The kitchen fire is generally the first to be lighted in the morning, by raking out the dead cinders and ashes from the grate, placing crumpled paper in the bottom, with the finest kindling on top of it. Upon this is placed slightly larger wood, with a fairly large piece, and a few knobs of coal on the top. The top of the range should then be replaced, or the kettle placed over the opening, the dampers adjusted correctly for draught, and a match applied to the paper. The paper may be saturated with paraffin oil before it is placed in the grate; to tip paraffin over the whole fire is risky.

In the case of an anthracite stove, the same procedure may be followed, except that, instead of the damper, the small door at the bottom of the stove should be opened when the fire has been lit, in order to provide more draught, and a fairly large quantity of anthracite placed on the wood. For open grates no damper is provided, but the grate is generally larger, and more wood can be laid on it. Open grates are more common in the country, and a wood fire is easily made up before coal is placed upon it. The same procedure may be followed in the case of barless stoves and fireplaces, although in the latter case it is generally wood that is burnt.

Where the fire is open, that is, not enclosed, as in a range or slow combustion stove—care should be taken to see that the register is opened before the fire is lit, or the room will be filled with smoke. Essentials are that there shall be room for the flames from the paper and kindling and a sufficiency of air for proper combustion, for which reason there must be a space for the air to get through. It is useless trying to light

any fire if the kindling be so tightly packed that the air cannot pass all through it, a good draught being a great help to speedy and effective fire lighting.

**Fire Lighter.** Special compositions, generally of pitch and sawdust, are sold for fire lighting. In some cases the composition is placed on kindling wood all ready for use, and in others it is sold in blocks, divided up into squares, one of which is used at a time. They are very useful when the kindling wood is damp, but care should be taken that they are stored in a place that is not greatly exposed to heat, as they are liable to catch alight.

Pine cones are converted into fire lighters by soaking them in a mixture of 8 parts of resin to 1 part of tallow. This is done while the mixture is hot; the cones are improved by sprinkling them with sawdust. As they are very inflammable they should be stored in a safe place, preferably out of doors, but protected from the elements. *See Anthracite; Coal; Gas; Grate, etc.*

**FIRE: Precautionary Measures.** One of the first duties of the householder is to ensure that proper precautions are taken against fire, and while much has been done by legislation so far as the building of the house is concerned, the interior arrangements must be carried out by the inmates themselves. Various safeguards and emergency measures to be adopted in case of fire are outlined in this article, together with a brief description of some of the fire appliances on the market. Such measures include the provision of extinguishers and ladders, the immediate closing of doors and windows, and the application of water, sand, or a chemical extinguisher.

Open fireplaces ought to be protected by an efficient fireguard at night, or on occasions when the house is left unattended for any length of time. The storage of inflammable oils should be in an outbuilding, and not in the house itself. Oil used for lamps should be kept in a safe place away from any heat, and the lamps themselves wiped dry at the time of refilling. Candles and nightlights should never be left burning unless properly protected by a holder of adequate size or housed in a candlestick with a glass shade. Never put a lighted lamp in any position where the heat from it may be a source of danger. A lamp is usually alight for a considerable time, and while the heat at the start may not amount to much, the cumulative effect may be enough to scorch, and finally to fire, adjacent woodwork. The airing of clothes at an open fire should only take place under supervision, as a cat or a dog may easily overthrow a clothes-horse and cause a fire. Another wise precaution is the provision of metal ash-trays: many fires have started from a dropped cigarette-end.

#### Importance of Instant Action

The greatest safeguards against fire are those which can be quickly applied. Speed is everything; the biggest fire starts as a tiny one, and therefore if a fire occurs act at once. A tumblerful of water applied at the instant of the outbreak may suffice, or the prompt application

of a thick rug or mat.

If the bedroom curtains catch fire, seize a pillow and beat out the flames, and if assistance be at hand, let the doors and windows be at once closed, and apply the water from the toilet jugs thrown forcibly into the heart of the fire. An outbreak can sometimes be suppressed by the prompt application of a wet blanket.

When it is necessary to enter a burning building it is better for two persons to go in company, so that if the first is overcome by the smoke the other may be able to effect a rescue. If the smoke is very dense the entrance should be made on the hands and knees. A wet handkerchief, towel, or a damp sponge gripped in the teeth is an aid to breathing, as it acts as a sort of filter for the air.

Many excellent fire-fighting appliances are on the market, and their purchase should be looked on as an investment. The chemical extinguishers are probably the most effective for domestic use. They are made in many sizes and types, but those of two or three gallons capacity are as good as any in an ordinary house. They work in various ways. In some there is a handle to be turned; in others the appliance is turned upside down, struck a blow on the floor, and the liquid at once directed into the heart of the fire. Whatever the type adopted, its method of use should be demonstrated in the presence of all those normally resident in the house, so that all may be familiar with it. The appliance should be kept in a well-known and accessible position.

**Insurance Against Fire.** A policy insuring a house and its furniture against fire should be taken out by every householder. The rates vary, but 1s. 6d. for each £100 insured is a fair average. It is more economical in most cases to take out a policy that covers other risks, e.g. burglary and employers' liability as well.

A fire insurance policy is essentially an agreement in good faith. A failure to disclose any material fact necessary to estimate the risk properly vitiates the policy, and the same is true if anything is done without permission of the insurer whereby the risk of fire is increased after the contract has been made. The risk of fire as a result of invasion, riot, strikes, or civil commotion is not covered by an ordinary fire policy.

Fire insurance policies are issued either subject to average or without average, and those who take one out should make inquiries on this point. In the former case, if the full value is not insured, the insurer must bear a proportion of the loss. For instance, A insures his house for £1,000, but its total value is £2,000. A fire damages it to the extent of £800, but the insurance company will only pay him £400, or half the amount of his loss, as his house was only insured for half its value. If, however, property is insured without average, the full amount of the damage is payable up to the limit of the amount insured. *See Insurance.*

**Fire Alarm.** Fire alarms are of two classes. Those installed in the public streets are set going by breaking

the glass and pulling a handle or knob; an electric circuit is completed, and a bell rings in the fire station. Those installed in the building to be protected are of two kinds, those which merely indicate that an excessive temperature has been reached in some part of the building, and those which release a jet of water about the place where the fire is.

The first kind generally consist of mercurial thermometers. When the mercury reaches a predetermined limit it will touch a wire fixed in the glass and thus complete an electric circuit which causes a bell to ring or a steam whistle or "syren" to go off. The second consists of fusible metal disks which are fixed generally in the ceiling, and melt when a dangerous temperature is reached in their neighbourhood, letting down a spray of water; an audible alarm is usually combined with the disk apparatus.

**FIREBRICK.** Firebricks are manufactured from various kinds of earth and treated to render them fire resisting. Moreover, they have the property of radiating heat, and are an excellent non-conductor of heat. For this reason it is an ideal material for the back of a fireplace, or any other location where great heat has to be resisted.

Firebricks are obtained in a wide range of sizes and shapes. Modern grates which are made on the barless principle often have a firebrick back extending the full height of the grate. *See Grate.*

**FIREBUSH.** This is the common name of *Crataegus pyracantha*, a type of evergreen hawthorn, bearing white flowers in May, followed by bright scarlet berries in autumn. Ordinary soil is suitable for the firebush, but a sunny aspect away from the shade of other trees is desirable. There is a superior variety called *Lelandi*, of more compact growth, and bearing dark-green leaves with clusters of white flowers, followed by bright orange-scarlet berries.

**FIRECLAY.** A variety of clay that will withstand extreme heat is used in making firebricks, for setting parts of a grate or stove, and for other purposes where resistance to great heat is essential. The best qualities come from the neighbourhood of Stourbridge. It is obtained in powder form, has to be moistened with water, and applied in a plastic state with the aid of a trowel, or pressed into place with the fingers, according to circumstances.

Many excellent compositions are on the market that have fireclay as a base. They are sold under different trade names, and have much to recommend them for amateur use as, being purchasable in small tins, they are economical in use and of a proper consistency for such work as the repair of a damaged fireplace. Fireclay is very useful for luting the joints around a stove-pipe, for making good any defective places in an anthracite stove, or in fact any place which is subjected to the heat of a fire. *See Firebrick; Grate.*

**FIRE GUARD.** An essential piece of hearth

furniture where there are children, a fire guard is also useful as a protection against flying sparks which might cause damage during absence from a room after a fire has been lighted. A useful form which will save many anxious moments in the nursery is of wire netting and shaped so that it completely masks the grate opening. By the Children Act, 1908, any person over the age of 16 years who has the custody, charge or care of any child under the age of 7 years is liable to a fine of £10 if he allows that child to be in any room containing an open, fire grate that is not sufficiently guarded so as to protect the child against the risk of being burnt or scalded—that is, if the child actually suffers serious injury or is killed. It is a defence that the adult person in charge took reasonable precautions against the risk; as, for example, by having someone else in the room to look after the child. It may even amount to manslaughter to leave a child in a room with an open fire grate left unguarded.

*Fire Guard in wire, essential in the nursery (Courtesy of Selfridges).*

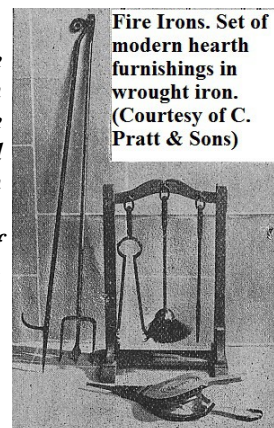

## FIRE IRONS.

These articles, used for tending a fire, consist of poker, tongs and shovel. They are usually

sold in sets to match the fender or other fittings, and some sets include a hearth brush. They are made of brass, iron and steel; also of copper and oxidized silver. The older types of fire irons rest on two fire dogs, a development of the old andirons or dogs, but a modern fashion is to hang them from a stand made to match. Newer than a stand with the implements clustered round it is the wrought iron frame, with tongs, poker, hearth brush and bellows all to match the log irons, as shown in the illustration.

*Left, fire irons in Adam style in polished steel, 18th century (Courtesy of C. Pratt & Sons)*

*Fire Irons. Set of modern hearth furnishings in wrought iron. (Courtesy of C. Pratt & Sons)*

These oldest existing examples, known of log irons, were implements used for moving logs from the fire, consisting of a fork and a roller. Smaller ones of similar type came later into use. Afterwards fire irons were designed in the Adam style, and a beautiful set is shown here. These are of polished steel with engraved urns on the top of the handles. The panel of the shovel with its honeysuckle decoration is in keeping with the remarkable grace of this set.

The methods of cleaning and caring for fire irons vary to some extent with the metal. Polishing is necessary from time to time, and those in unoccupied rooms should be guarded from damp. *See* Andirons; Coal Box; Poker; Tongs, etc.

### FIREPLACES, HOMELY AND BEAUTIFUL

**Principles of Design and the Best Styles Described**  
For related information see Anthracite Stove; Chimney Piece; Grate; Range. See also Cottage; House; and the entries on Coal; Coal Box; Curb; Fender; Fuel.

Fireplaces are so linked up with traditions of British home comfort that, whatever the methods of heating used to supplement them, there is little likelihood of their going out of fashion in living-rooms. This is particularly the case with forms of fireplaces which are structurally good and designed in fabrics eminently suitable for their purpose.

Brick fireplaces endure for several reasons. They are right in many styles of rooms and different periods of architectural decoration; they suggest complete comfort and please the eye. The warm tones and harmonious colours of good bricks, combined with their delightful texture, render them a particularly suitable material when built up in simple but effective designs. British brickwork has had a good revival in this century, and for fireplaces mixtures of old English 2 in. handmade bricks are often chosen, which are well burned to a pleasing variety of tints. In many of the newer houses the bricklayer has put his craft to a specially artistic use in carrying out excellently designed fireplaces.

Where coal fires are not desirable, gas stoves of architectural character to resemble a coal fire, or one made of imitation logs, and burning in a dog grate can be reasonably associated with a brick fireplace of the less heavy type. An anthracite stove may also be suitably framed by the simple treatment for a hall fireplace shown in p. 410, though such a design would be equally pleasing for a small sitting room or country bedroom, with either a gas or coal fire.

**Attractive Examples.** Many larger modern living-room fireplaces are based on designs taken from genuinely old examples such as that seen in Fig. 1. This beautiful fireplace with its massive oak shelf, beam, square tiled hearth and stone curb is many centuries old. Interesting details are the fireback, dog grate and fire-dogs or andirons which support the antique fire irons. Firebacks look their best in such a setting. Modern adaptations of these are copied in cast iron or can be made from sheet metal with applied ornament.

The design can be carved in wood or modelled in plaster on a canvas backing, and the finished casting obtained from an iron founder. Various sizes of cast iron firebacks were commonly in use in the fireplaces of the 17th, 18th and 19th centuries, and were made in Sussex during the 15th century. The earliest designs were very simple, but those of the 17th century reproduced to-day are decorated with flowers, fruit, figures and various heraldic emblems.

*Fireplace. Fig. 1. Antique brick fireplace in a Sussex residence. The built-in massive oak beam and the fireback are noteworthy (Humphrey, Joel)*

Brick and tilework fireplaces in bold simple designs are an excellent choice for oak panelled or half panelled rooms, and are quite suitable in the country type of drawing room, where the keynote is comfort and the furnishing of a somewhat solid character. Brick looks particularly well with carpets and rugs in mellow oriental colourings and with curtains and covers of linen printed in a Jacobean design or in conjunction with chintz hangings. Such a fireplace may provide cosy nooks on either side for winter evenings, and immediately produces a feeling of welcome and homeliness with a wide hearth and curb in one with the chimney piece and with brass accessories to enhance the glowing warmth.

In modern adaptations of Tudor style the stone arch, open hearth with its herring-bone brickwork and simple treatment of the mantelpiece are seen. Nothing is more easy to keep clean than the hearth of this period, either during the day when the fire is burning, or when relaying. The firebrick interior with canted, forward back is very efficient; burning little coal and throwing out a good heat, but by its size admitting of a big fire on a cold day, while rough logs can be burnt instead of the specially cut ones necessary for some types of grates. The beauty of copper or brass wall and hearth fitments add to the attraction of such a fireplace. Fig. 3 shows an adaptation of Tudor style in

*Fireplace. Fig. 2. Design suitable for a small flat. The pull-out coal box fitted below the bookshelves should be noted. (Humphrey & Vera Joel)*

Bath stone and old English bricks. Tiles surround the outer part of the hearth finished by a solid oak curb. Even in these days of electric fires most people really prefer a genuine coal fire, especially the down fire in the modern rendering of a Tudor room either wood panelled or oak-beamed.

While a Tudor stone or a brick fireplace seems ideal for the dining room or lounge hall, the Georgian style shown in Fig. 4 is perfect for the 18th century period type of drawing room with painted panelled walls. The curved steel fender, steel basket grate and fire irons, pale green tiles, white marble surround and ornamented shelf are beautiful features of the whole.

*Fireplace. Fig. 3 Adaptation of Tudor style in Bath stone and old English bricks. (E. F. Collins)*

Modern fireplaces of small type abandon such architectural treatments and adopt rectangular designs and receding planes usually without ornamental moulding. Such a design is shown in Fig. 2, with a dove-

grey marble surround and black marble curb. This fireplace is particularly suitable for a small flat. The coalbox is in the lower part of a built-in bookcase, the companion cupboard containing wood. In this example the mantelshelf is very narrow; often in such a fireplace it is absent.

In many modern fireplaces slow combustion grates are found, or they are merely settings for gas and electric fires. A gas fire needs a flue only a quarter of the area necessary to that for a coal fire, and it is possible to use flue blocks built into the partition wall.

Space can thus be saved by doing away with the chimney breast and setting the gas fire direct against the wall. Electric fires, which need no flue, can be placed anywhere in the room, but as a rule they are decoratively best in a modern fireplace setting, though when of the kind which simulates an ordinary fire, they are seen in various period settings.

*Fig. 4. Drawing room fireplace, in Georgian style in panelled setting. (Courtesy of Country Life, Ltd.)*

In other fireplaces which are both decoratively and practically designed to suit all sizes of rooms, the coal burns in a bowl-shaped interior of special fireclay which is manufactured to

radiate intense heat, and with the help of a clay fireback set at a forward angle the heat collected from the burning coal is sent out into the room. The brick fireplace seen in Fig. 5 possesses a barless slow combustion grate. Various other forms of fire or fireplace interior will be described in the article on Grate.

*Fig. 5. Hob fireplace constructed of brick. The interior is not attached to the canting firebrick, and can be replaced in summer by some decorative scheme. (Courtesy of Bratt, Colbran & Co., Ltd.)*

**Structural Details.** In designing a house, it is important to locate the fireplaces as far as possible on the internal walls. Every fireplace in an outside wall involves a separate chimney and stack to itself, and the multiplication of stacks is an extravagance.

Fireplaces are formed by building projections, generally of brick, either into the room or outward into an external chimney stack. These projections are known as jambs. The usual size of a fireplace opening is about 3 ft. sq. when intended to be fitted with the usual register-stove or grate. A charming effect can be obtained by removing the mantel register-stove

and building a fireplace with bricks. These can be set in front of the walls of the jambs, and the work can be carried out by the amateur bricklayer, all that is necessary being some bullnose bricks with which to form the face of the jambs, and some nicely coloured stock or facing bricks. These must be set in cement-mortar. The diagram at Fig. 6 illustrates the chief points of such a fireplace. The jambs should not be carried to the top of the opening, but only to a height of some 24 in., according to the height of the room and the size of the desired opening. A strong iron bar about 2 in. wide and  $\frac{1}{4}$  in. thick is then set on the top of the brickwork and 1 in. from the front.

On this the facing bricks are set in an upright position, and well flushed with mortar. The back of the fireplace may need facing with the same coloured bricks, or firebricks may be obtained and set at the back, and the upper bricks carried over towards the front in order to act as a throating to the fire, in the manner shown in the diagram below. The fireplace opening should be small in relation to the size of the room, as a small opening and a large room accord well, while a large opening in a small room is never a success. The width of a fireplace depends so much on the room that any definite rules are impossible, but 12 in. will suit most rooms up to 12 ft. sq. The opening is governed, of course, by the size of the stove. A 16 in. or 18 in. stove will be suitable for a room about 16 ft. long by 12 ft. wide, but much will depend on the geographical position, number and size of windows, and number of outside walls.

*Fireplace. Fig. 6. Diagram showing section through a simple brick-built fireplace.*

**FIREPROOFING.** There are various methods of treating an article or piece of material so as to render it partially or wholly non-inflammable. In the case of fabrics the treatment consists in immersing the articles in a liquid, or of spraying them, and is obviously limited to those materials which are not liable to

damage by being so treated.

For example, fancy dresses made from muslin and other common materials may well be fireproofed, but a rich evening frock would sustain damage if immersed in chemicals. Various formulae have been published from time to time for the fireproofing of fabrics, and these vary very much as regards their efficacy. The following are applicable to materials of the classes mentioned:

- a. A strong solution of tungstate of soda.
- b. Ammonium borate, 1 part.  
Potassium carbonate, 3 parts.  
Water, 33 parts.

Wood is rendered fire-resistant by the use of any of the recognized fireproof paints, these being applied in much the same way as ordinary paint. Fireproofing compositions may also be brushed into the wood, or the articles may be entirely immersed, either plan being adopted according to the nature of the work. In addition to the use of fireproof paint, whitewash is a good protective for woodwork. It is made by dissolving lime in water with the addition of a little whiting, and is simply brushed over the work. Two or three coats will act as an efficient fire-retarding medium. The following are effective fireproofing compositions for wood:

- a. A strong solution of tungstate of soda.
- b. Ammonium borate, 2 parts.  
Potassium carbonate, 6 parts.  
Water, 60 parts.

**FIREPROOF WARE.** Cooking utensils made of fireproof china, earthenware and glass have now largely replaced metal pans and pots, especially for braising, stewing and soup making. Casseroles can be bought in all sizes, from the large type capable of holding a family stew, to the smaller ones used in the preparation of ragoûts, salmis and hot pots. Ramequin cases in brown or green fireproof china are also sold for making small soufflés, creams, etc., also white china shells for holding scallops of meat, fish, game or vegetables.

Au gratin and other baking dishes are obtainable in the same wares, and are invaluable in houses where meals have to be kept waiting, for they can be left in a hot oven without fear of breakage. Green china entrée dishes, also fireproof, are equally useful, while even more attractive are the ones in glass. Brown earthenware casseroles and square baking dishes look well on an oak table. All fireproof ware can be kept clean by washing it in warm, soapy water, and burn marks may be removed with fine sand. Stains caused by fruit or vegetables are best treated with soap and water. The dish should be soaked in this solution and then washed in the usual way. *See Casserole.*

**FIRE SCREEN.** Of the two types of small screens known as fire screens one only, the shield on a stand, which can be fixed into position to protect the face from the fire, is true to its name. The other is really an

empty grate screen with a purely decorative value.

*Fire Screen. Left, early 18th century screen in mahogany and tapestry. Right, screen consisting of colour print on silk with a carved and gilt limewood frame and stand; late 18th century.*

*(Left, by courtesy of Waring & Gillow, Ltd.; right, by permission of the Director, Victoria and Albert Museum, S. Kensington)*

The first is rarely seen except in the genuine or reproduced styles of the eighteenth and the first half of the nineteenth century. The second type should be carefully chosen. A well-blackened grate is preferable to the cheaper and less artistic forms of bought screens.

The mahogany Chippendale style fire screen, with glazed brocade, or needlework panels, is always correct with furniture of the same character, and so is the Louis XV type of ornate gilt panels, and the Empire model with ormolu decoration. Screens in decorative leather work are suitable for a living-room, while furnishing jaspé and linen are quickly and effectively embroidered in coloured wools to make panels for wooden frames. A piece of Chinese embroidery, glazed and framed in narrow black, looks well if nicely fitted to the grate opening of a small fireplace.

A pretty screen for a sitting room grate is made by ferns or flowering plants arranged in a simple two-tier flower box to suit the size of the fireplace, but it is often impossible to exclude the down draught from the chimney without a sheet of glass fitted to the opening behind the flowers. Another idea of the same type is an arrangement of cut flowering shrubs or foliage in a pottery vase. Metal screens, chromium plated or in rustless steel or oxidized silver or copper, have the merit of not tarnishing. These usually match the curb or fender and fire irons, and are sold in a suite or separately. *See Flowers; Leather Work.*

**FIREWOOD.** Firewood can be bought ready for use in bundles, but is cheaper when bought as rough wood from a grocer and chopped up as required. In country districts local supplies can be obtained. If the wood is cut when green it will have to be dried and stored for some months.

If the oven has been used during the day, wood may be left in it all night, and will thus dry quickly and thoroughly. Logs of wood are useful to supplement coal and to burn with slack. Sometimes opportunities occur of buying discarded blocks of wood paving. These are

an excellent form of fuel for the house on account of the tar with which they are soaked. *See Coal; Fuel, etc.*

**FIRMER.** A firmer chisel is an ordinary carpenter's chisel, having a blade of normal proportions, neither thin, as in paring chisels, nor of exaggerated thickness, as in mortise chisels; the blade has a tang and shoulder to take a wooden handle.

The firmer gouge is the ordinary form of gouge as used by carpenters and joiners; the blade is more or less curved, and may vary from practically flat to a semicircle in cross section. It is sharpened on the back by grinding on a grindstone, and whetting on an oil stone, in the usual way. Firmer gouges are employed for all classes of curved work and, in addition, for some forms of carving, such as hollowing and shaping a model boat hull. *See Chisel; Gouge.*

**FIRST AID: How to Render.** Everyone should know how to give some aid in cases of accident and sudden illness. A few simple measures promptly carried out will often prevent serious developments, and may save life.

It is a common incident to see would-be helpers lifting a fainting person into a sitting posture. The fainting is due to insufficiency of blood in the brain, and this manoeuvre still further reduces the supply, thus prolonging the fainting fit. Indeed, when the heart is very weak or the patient has lost a great deal of blood death may be caused by lifting him.

In cases of unconsciousness the first essential is to loosen all the patient's tight clothing and provide for a free current of air. To assist this other people should not be allowed to crowd around him. When the face is pale, the patient should be laid flat on the ground and the legs slightly raised; when flushed, the head should be raised. In both cases the head should be turned to one side. Nothing of any description should be given by the mouth until consciousness is restored.

*On no account should those rendering first aid make any attempt to force brandy or other stimulant down the throat of an unconscious person, as this may result in choking him.*

It should be the rule not to move a person who has been hurt or becomes suddenly ill, except so much as is necessary to permit of his breathing easily, until some opinion has been formed as to what is the matter with him. Urgent conditions like bleeding and shock should be attended to first, the former by taking the necessary steps to arrest haemorrhage, and the latter by applying warmth. In cases of severe burns, especially in children, a shock-like condition may be present. By putting a child in a warm bath not only is the shock treated, but the removal of clothing is made easier.

Before beginning artificial respiration, in all cases where it is necessary, the mouth and the back of the throat should be examined to make sure that they are clear. Clothing should not be removed unnecessarily in the case of accidents out of doors. In the case of bleeding, the wound may be exposed by slitting a seam

with a knife, but while this is being done pressure should be put on the main artery. If a person's clothes are on fire, some heavy fabric, a rug, a blanket, or coat, should be thrown round, and he should be rolled on the floor in this.

In sending for the doctor, it may save valuable time if he is told, preferably in writing, the general nature of the emergency, e.g. bleeding, broken bone, poisoning, etc., and details, as to the part injured, the poison suspected, and so on.

**First Aid Cabinets.** First-aid cabinets for service in the home in plain deal, fumed oak, and white enamel are sold in various sizes. They contain all the dressings and bandages necessary in case of accident, while some of them, finished with nickel-plated fittings and plate-glass shelves, may serve also as bathroom cabinets. The doors of these cabinets, when closed, provide good shaving mirrors. Smaller first-aid outfits are sold in cases containing ointment, adhesive plaster, bandages, lint, etc. These can be easily carried in the pocket. *See Artificial Respiration; Asphyxia; Bandage; Bleeding; Burn; Epilepsy; Fracture; Poisoning; etc.*

*First Aid Cabinet in fumed oak, which can be hung on a wall or set upon a shelf. The contents comprise everything which may be needed for the relief of common ailments and accidents. (Courtesy of Boots Pure Drug Co., Ltd.)*

## **FISH: CHOICE, COOKING, FOOD VALUE, ETC. Some Facts of Daily Interest to Every Housewife**

This article describes the several ways of cooking fish, gives information about various fish dishes, and contains other facts of value in the home. See the entries on fish ordinarily eaten, e.g. Cod; Haddock; Halibut; Salmon; also Diet; Food.

Next to meat we must rank fish as one of the most valuable sources of the proteid, or body-building material, and fat. This food may be used, with benefit to health, by persons who do not require a full meat diet for the repair of bodily waste. Even those workers whose occupation requires a liberal diet can thrive upon a little meat and a moderate allowance of fish. For townspeople of sedentary employment or for those

engaged in light manual work, fish constitutes one of the best proteid foods.

Cod, haddock, smelts, and flounders are among the lean fish, and very little fat can be derived from them. But cod has a high percentage of proteid, and is therefore nutritive.

For energy, as well as the restoration of tissue, we need a varied fish dietary, and fat fish should be chosen by persons whose labour demands muscular exertion. One of the virtues of a fish diet is its full absorption in the body. Only about five per cent of the solid matter of fish is lost in digestion. All the lean fish are readily digested, and are therefore recommended to invalids; and any fairly normal digestive system can absorb salmon or the more oily kinds.

**Cost and Food Value.** It must not be supposed that the cost of some kinds of fish has any relation to their nutritive value. A dozen oysters yield only a small amount of fat, and about as much nourishment as a single herring. A sole may please the palate more than a plaice, but it contains considerably less fat; halibut is almost as nourishing as turbot. Mackerel have much less fat than eels, but more proteid. Tunny, sold in tins, has over 30 per cent. of fat.

One great advantage in a fish diet is its digestibility as compared with meat. Cod is perhaps the least digestible fish and mackerel the most digestible. Lean fish, such as whiting, can be digested readily by many invalids. When a food is cheap it is often refused on the ground that cheapness and a lack of nourishment go together. This is not the case with any of the fat fish—herrings, bloaters, sardines, sprats, and eels.

Some kinds of fresh fish may contain as much as 70 per cent. of water. Oysters have over 77 per cent. of water and about 22 of nutriment. In a salt herring there is 53 per cent. of nutrients. The difference between the amount of fat in fish is shown by comparing a hake with a mackerel. In the former the fat is only about 5 per cent, and in the latter 25 per cent. But the lean fish are by no means devoid of nourishing matter. Cod contains 91 per cent. of body-building material but very little fat. Turbot yields rather over 84 per cent. of proteid, and halibut contains 79 per cent.

**Varieties of Fish.** There are unreasonable prejudices against eating several kinds of valuable fish. One of the blennies, known as the cat-fish or wolf-fish, is often despised as a table fish, but it is very good eating. Some of the British sharks and dogfish are quite edible. They are rejected because of their unattractive appearance. One of the tastiest fishes that swim is the gurnet or gurnard.

The handsome lythe or pollack is not a good fish for keeping, and must be eaten soon after it is caught. The edible quality of this fish is not sufficiently known, and the same may be said for the coal-fish or saithe and sea bream.

The choice of fish may be largely determined by its

appearance. Fresh fish is stiff, plump and firm, has bright, firmly attached scales, clear eyes, and red-coloured gills. When the freshness wears off the fish becomes flabby, the flesh is easily indented with the finger, the eyes are dull and glazed, while the scales fall off easily. Growths about the head or fins, unsightly blotches and scaleless patches are well-known signs of disease.

In stale fish the gills change to a dark red or a whitish colour; but this test is not infallible, for trawl-caught fish are suffocated often in the process of hauling in the nets, and the gills become congested and dull-looking. Oysters should be firmly closed, but if slightly open, the shells should meet instantly and tightly on the blade of a knife being inserted between them. If the shells gape, the fish are unwholesome.

**Tinned Fish.** Tinned fish should be turned out of the tin as soon as the latter is opened, and consumed as quickly as possible. Lobster, in particular, keeps badly. Tins which show signs of rust, of being soldered in many places, or which give a hollow drum-like sound when tapped or shaken, should be rejected. Sardines, small herrings and tunny which are preserved in oil should be taken out of their tins and kept in a covered china or glass dish. When air reaches the open tin, chemical action is set up, and the oil becomes impregnated with the metal. A wholesome smell characterizes cured fish which is in good condition. In case of doubt, make a small incision with a knife near the backbone and test the odour.

Fish should be kept in a cool, dark place, and whenever possible in prepared paper bags placed in ice. If the bags are fastened down the fish should keep fresh.

**Cooking Directions.** Fish are usually fried or boiled, but there are other methods, such as steaming and grilling and baking. Boiled fish lose some of their nutritive value in water, but steamed fish retain the nutrients, and are more agreeable to the palate. Most fish that can be boiled can be steamed.

The general rule in boiling all kinds of fish is the avoidance of haste. The water should be heated until it is near the boiling point, and the fish, wrapped in muslin, placed in it and boiled quickly for 2 or 3 min. only. The heat must then be reduced, and the fish allowed to simmer; 3 lb. of fish will require 20 min. for boiling, and 35 for steaming; 1 lb. of fish will require about 12 min. boiling. Casserole cooking is a good method with large fish, which should be placed in the casserole in fillets with a little butter. An onion, pepper, and any kind of spice that is approved, such as cloves, should be added. After stewing for 5 min., a glass of white wine will give an additional flavour, or a teaspoonful of Worcester sauce, and some slices of lemon. Take the fish up on to a hot dish and allow it to drain well still wrapped in muslin. Remove muslin and pour away the liquid that has collected before serving.

Two or three of the coarse freshwater fish are scarcely worth cooking. Barbel is an example, though in Spain this fish is cooked with onions and spices, and

eaten by the peasantry. Chub are insipid and very bony. Bream from fresh water are edible, but cannot be considered luxuries, and the same may be said for roach. Carp and tench have slightly more flavour, and may be stewed or fried in olive oil, butter, or beef dripping. Pike may be cut into collops and fried, or stuffed and baked. Perch should be skinned to remove the rough scales. Gudgeon are rather more flavoured than many river fish, and may be fried like perch. Trout of over 1 lb. should be filleted and fried or grilled. Large lake trout and sea trout are best boiled. Kedgerees, curries, and rissoles can be made with almost any kind of fish as the main ingredient.

The flat fish—skate, soles, plaice, and dabs—are best cooked by frying, either whole or in fillets. Cod, large haddock, and pollack should be cut into steaks before frying. Fish are often stuffed with forcemeat and baked.

In the preparation of fish it is essential that each cloth or cookery utensil should be thoroughly cleansed after use, or the next article of food which comes in contact with it will contract a fishy flavour. A saucepan or kettle in which fish has been boiled, or one used in making fish soup must be washed separately from other pans. After touching fish it is sufficient to wash the hands in the ordinary way to remove all odour.

**Curing Fish.** Fish cured in the following way will keep for a long time. Clean and carefully wash and scale the fish, and, if large, split it down the back. Rub it thoroughly inside and out with finely powdered common salt, and hang it in a cool, draughty place for 24 hours. Next rub into it a mixture of 1 oz of bay-salt and  $\frac{1}{2}$  oz each of coarse brown sugar and saltpetre.

Lay the fish on a dish, cover it with more salt, and leave it for at least 48 hours. Then turn it, cover it again with fresh salt, and leave it for a further period of 24 hours. Drain of the brine after this time, dry the fish, fix it on thin sticks, and hang it in a cool, dry, airy place. If kept for long soak the fish in cold water for 24 hours before cooking it.

**Filleting Fish.** Large fish are seldom filleted unless a portion is purchased that can with advantage be boned and cut into strips or pieces. Flat fish, such as soles and plaice, make the best fillets, although haddock and whiting are frequently used for this purpose. To fillet flat fish, lay it down upon a board and with a sharp-pointed cook's knife cut off the head and fins; also cut the tail across. Score a line down the spine and, pressing the knife against the bones and taking long, even cuts, take off one side of the fish. Then turn it round and remove the other side. Turn it over, and repeat the process.

Haddock and whiting are treated in the same manner, but in these cases there are only two fillets, instead of four, to be removed. It is economical to fillet fish, for the bones can be used to make fish stock for the sauce.

*(Arranged by Mac Fisheries Ltd.)*

**Frying Fish.** Frying is the quickest way of cooking most fish. Small fish are usually fried in the frying basket; and fillets and steaks of fish are fried either in deep fat or in just sufficient fat to cover. In all cases the fat must be very hot when the fish is immersed; so hot that it has ceased to bubble and a blue smoke is rising from the pan. All fish before being fried must be well dried, and this is best accomplished by rolling it in flour seasoned with salt and pepper.

Fillets and steaks of fish are usually dipped into beaten egg and coated with breadcrumbs before being fried, or dipped into batter. When the outside is of a pale brown colour the fish is cooked. The fish is lifted out of the pan with a fish slice to prevent the flesh from breaking. Fried fish must be well drained before being served. This is done by placing it on a sheet of kitchen paper or on a cloth. It is served up on a dish paper, and the usual garnish for fried fish consists of pieces of cut lemon and sprigs of fried parsley.

The fat most commonly used in Great Britain for frying fish is lard or dripping, although some prefer the continental custom of frying in olive oil. Frying oil can be bought at provision shops, and is not so expensive as pure olive oil but equally efficacious.

**Fish Stock.** This stock forms a good basis for fish soups or sauces. Make it by putting 1 lb. of bones, heads, and trimmings of any fresh fish into a saucepan containing 1 quart of cold water., a blade of mace, a small peeled onion, 4 cloves, 6 peppercorns, and a pinch of salt. Bring it to the boil, let it simmer for 10 min., then strain it. If the stock is allowed to boil too long it will become bitter. Fish stock must not be kept from day to day as it soon turns sour.

**Using Cold Fish.** There are many ways in which the remains of cold cooked fish can be made into appetising breakfast, luncheon, and supper dishes. Any cold, left-over sauce should be used for mixing these dishes, and they should always be well seasoned. The following five recipes will be found useful.

**Fish Cake.** Any cooked white fish and some cold cooked potatoes, in the proportion of 1 lb. of fish to  $\frac{1}{2}$  lb. of potatoes, are needed to make these cakes. Skin, bone and flake the fish, rub the potatoes through a sieve, and in the meantime melt 1 oz. of butter in a pan over the fire and add to it a tablespoonful of milk. When these are hot, put in the fish and potato, the beaten yolk of an egg and seasoning to taste, and stir the whole over a low heat for a few minutes. Spread the mixture evenly on a plate, mark it with a knife into a dozen even-sized divisions, and form each into a neat, round cake about  $\frac{3}{4}$  in. thick. Brush these over with beaten egg, coat them with breadcrumbs, and fry till brown in a pan of smoking hot fat. The mixture may also be formed into balls and fried.

**Fish Galantine.** Take the skin and bone from 1 lb. of any cooked white fish, break it into flakes, and mix them with two teaspoonfuls of chopped parsley, the

beaten yolk of an egg, seasoning to taste, and enough egg, anchovy, or shrimp sauce to bind the whole. Make the mixture into a roll, place this on a greased baking-sheet, brush it over with the white of egg, then sprinkle it with breadcrumbs or maize meal, and bake it in a fairly hot oven till brown. This galantine can be served hot with the same kind of sauce as is used for mixing, or cold with salad.

**Fish Moley.** Chutney and grated coconut should be served with this Indian dish. To prepare it, cover  $\frac{1}{4}$  lb. of desiccated coconut with boiling water, and leave it to soak. In the meantime, fry 2 oz. of sliced onion in the same quantity of dripping. Add  $\frac{1}{2}$  teaspoonful of powdered tumeric or saffron, the strained coconut water, a small piece of green ginger, 1 teaspoonful of sliced chillies, 1 lb. of cooked fish, cut up into small pieces, a tablespoonful of vinegar, and a little salt. Simmer the whole till it thickens, and then heap it on to the centre of a dish, arranging round it a border of boiled rice.

**Fish Mould.** These moulds can be made from the remains of any cold fish. Remove all skin and bone from about 3 heaped tablespoonfuls of fish, put the flesh in a mortar, add 1 tablespoonful of fresh crumbs, 1 teaspoonful of chopped parsley, 1 oz. of warmed butter, a beaten egg, 4 tablespoonfuls of milk, and seasoning, and pound all well.

Well butter some small dariole moulds, fill them with the mixture, cover them with pieces of greased paper, and steam them gently for  $\frac{1}{2}$  hour in a pan containing enough boiling water to reach half-way up the moulds. Turn the moulds on to a hot dish, pouring round them  $\frac{1}{4}$  pint of parsley sauce.

**Fish Pie.** Any kind of cooked fish can be used for making this pie. Prepare it by rubbing 2 heaped breakfastcupfuls of mashed potatoes through a sieve, and adding to them 1 oz. of melted butter, a tablespoonful of milk, and salt and pepper to taste. Then mix all well together. Remove the skin and bone from one heaped breakfastcupful of cooked fish, chop it up coarsely, and place it in a pie-dish.

Melt 1 oz. of butter in a saucepan, stir in the same quantity of flour, and then add 1 pint of fish stock. Stir this sauce over the fire until it boils and thickens, add 1 hard-boiled egg chopped in large pieces and seasoning to taste. Add sufficient of this sauce to the fish to moisten it well, and cover the dish with the potato mixture, smoothing it evenly over the top, and marking it with a fork. Scatter small lumps of butter over the whole, and bake the pie in a moderately hot oven until it is brown. Salt cod may be used after soaking and preparing.

**Uses of Fish Bones.** Fish bones provide valuable manure for the garden if placed in the ground immediately before or at the time of seed sowing. They

are usually mixed with other manure before use, and succeed best in dry soil. Bones left over from meals may be used in this way, but uncooked bones are better.

**Bones in the Throat.** In most cases where a fish-bone is caught in the gullet, it is either spat out or swallowed later on with a bolus of food. A scratch may then remain and give the mistaken idea that the bone is still there. When the bone effects a lodgment it is a good plan to swallow large mouthfuls of bread not much masticated. Small bones may sometimes be gradually dissolved by taking occasional sips of lemon juice or lemon juice and water. If the bone is not removed by these measures a doctor should be consulted, or the results may be serious.

**Poisoning by Fish.** Several varieties of fish are poisonous by reason of substances that are manufactured by certain of their glands, e.g. liver, ovary, etc. Some are always poisonous, some at certain periods, and some only to persons who are peculiarly susceptible.

In Great Britain mussels, mackerel, and sometimes oysters, as well as tinned salmon, crab, lobster, eels, etc., occasionally produce severe symptoms of poisoning. This is usually due to their having been invaded by microbes, e.g. that of botulism. Oysters, have been responsible for carrying enteric fever and allied disorders. Mussels, especially those taken from docks, harbours, and the mouths of rivers, where the water is contaminated with sewage, are frequently poisonous.

**FISHER FUR.** Long-haired and dark brown in colour, fisher fur, or fisher marten, as it is also called, is obtained from the largest of the marten tribe, an animal measuring 2 to 3 ft, in length. Fisher fur, like all other dark-coloured pelts, may be cleaned with silver sand. Put the sand into a dish in the oven, and when it is thoroughly warmed rub it into the fur. It may then be shaken or, if necessary, brushed out. *See Fur.*

*Fish Kettle of blue enamel fitted with wire strainer. It can also be used for frying, roasting, etc. (Courtesy of Staines Kitchen Equipment Co., Ltd.)*

**FISH KETTLE.** This is a utensil for cooking fish. It is generally oval and fitted with a strainer or drainer, and is made of block tin or aluminium, while some of the better kind are lined with copper. The drainer is essential for several reasons. It enables the fish to be lowered gently into the kettle, and to be taken out again without breaking, and may also be used to keep fish warm when it is not to be served immediately. The drainer is placed across the kettle, and the fish, which should be covered with a clean cloth, is put upon it and is thus kept warm by the steam. Fish kettles may be cleaned in the same way as other aluminium or tin pans. *See Aluminium; Tin.*

**FISH KNIFE.** The blades of these knives are of silver or electro-plate, not of steel, and are therefore blunter than the ordinary table knives. Fish knives and forks are made either in two pieces, the handles being of ivory, mother of pearl, or silver, or they are made in one piece entirely of metal.

Plated fish knives and forks or fish servers should be washed immediately after use, with hot soap suds, to which a small lump of whitening should be added. If there has been any delay, after washing, rub the surface of the knives and forks lightly and quickly with cut lemon, then rinse in the suds again and wipe the articles dry.

**FISH SLICE or Server.** This article of table use, now represented by fish carvers, was introduced into England in the 18th century and is valued by collectors. It has two main shapes, one in the form of a trowel, i.e. having a triangular blade, and the other with a curved edge on the working side. They were made in silver and Sheffield plate.

A somewhat similar slice, suited to kitchen use, is made of tinsplate or sheet aluminium, and the handle formed in one with the blade. This is used for lifting and turning fish when frying it. It has holes for draining the fat.

**FISH STRAINER.** This is a perforated metal plate with handles, upon which fish is placed when it is boiled in a fish kettle. The handles are perpendicular to the plate and reach to the top of the pan, so that the fish can be lifted out of the water and drained without fear of its breaking. *See Fish Kettle.*

**Fit.** *See Apoplexy; Convulsions; Epilepsy; Fainting; Hysteria.*

**FITCH.** Fitch fur, obtained from a small animal of the marten species known both as fitch and pole-cat, has long black top hair and yellow underwool. It is used as a trimming and is often dyed satisfactorily to imitate sable.

The word fitch is somewhat loosely used in connexion with artists' brushes made of ox hair and used for painting in oils.

**FIXATIVE.** Any material used to make something permanent or fixed is a fixative, as, for example, that used in the form of a spray to fix the crayon or pencil lines on a drawing. This is perhaps the most usual application in a domestic sense, and such a fixative may be composed of dry white shellac dissolved in pure alcohol, sufficient of the shellac being used to form a thin film when it is sprayed on to the paper that is used for the drawing.

The fixative can be obtained at any artists' colour shop and is put up in a convenient form in a small

bottle. The sprayer is an L-shaped tubular device sometimes known as an atomizer. One end is inserted into the bottle of fixative and the other end used as a mouthpiece, and as the wind is blown into it, the fixative is drawn out and deposited on the paper in the form of a fine spray.

**FIXING:** Photographic. The photographic negative or print is fixed when those portions of the sensitive chemicals in the film which have not been acted upon by light and the developer are dissolved out. This is usually effected by a solution of hyposulphite, or thiosulphate, of sodium, commonly called hypo, in water.

For fixing negatives and films a solution should be made of 4 oz. or 6 oz. of hypo in 1 pint or 20 oz. of water. It should not be weaker than 4 oz. to the pint for negatives, but may be stronger. In making up the solution warm or hot water should be used; hypo in dissolving reduces the temperature of the water considerably, and if cold water is used it will take an inconveniently long time to dissolve. The solution should be cold before it is used.

It is not possible to say at what precise point the fixation of a negative is complete. It is certain that the process is not complete when the creamy emulsion has been dissolved away; negatives must be left in the fixing solution for double the time that it takes to remove this creamy appearance from the back of the negative. Stains, dark patches and other markings which cannot be removed from negatives are the result of incomplete fixing.

When the fixing solution has been used two or three times it is likely to become discoloured and stain negatives. It is therefore desirable to use only fairly fresh solutions. A pint of the solution given above will fix efficiently about a dozen  $\frac{1}{4}$ -plate negatives. An acid fixing solution is particularly desirable for bromide prints. It is made up in the following proportions:

Hypo	4-6 oz.
Potassium metabisulphite	$\frac{1}{2}$ oz.
Water	20 oz.

The potassium salt should not be added to the hypo solution while it is hot, or sulphurous acid may be given off and the solution thereby weakened. This bath gives clear and brilliant negatives; it can be used for all fixing purposes, except for P.O.P. or daylight printing papers.

It is essential after fixing negatives and prints to remove every trace of the hypo, or the print will gradually fade. Washing may be done in running water or by frequent changes of water. More than 90 per cent. of hypo is washed away in the first 10 min., but considerably longer is required to remove the remainder, and for this purpose it is essential that the negative or print should be in perfectly fresh water. It is useless to expect to wash a negative effectively by placing it at the bottom of a basin under the tap with water overflowing at the top; what happens is that while the larger portion of the hypo is dissolved and washed away, the negative lies in a weak solution at the bottom of the basin.

Various forms of washing apparatus for both negatives and prints can be obtained. In freely-running water negatives and bromide prints should be washed for at least 30 min.; prints on thick paper or card and P.O.P. prints should be washed for an hour. *See* Bromide Paper; Developing; Gaslight Paper.

**FIXTURES:** The Law About. Legally fixtures and fittings are those articles affixed or joined to property in such a manner that while so attached they become part of it, e.g. gas or electric light fittings, tapestry on the walls, etc. They may belong either to the landlord or the tenant. In the ordinary case a tenant is not allowed to remove fixtures even though he has himself put them up. Where, however, they are fixed for ornament, or for the convenience or pleasure of the tenant, or for the purposes of his trade or business he may remove them so long as he does not injure the landlord's property in doing so.

After a tenant is in occupation he may put up over a doorway a wood or plaster ornament, panel, or frieze. These may be removed by the tenant if by so doing it will not damage the landlord's property. Otherwise they remain in the house and become the landlord's, although the tenant paid for their erection. Blind rollers, towel rails, fireplace accessories which were in a house when the tenant entered into possession remain the landlord's property. Blind rollers are often removed by an outgoing tenant under the mistaken idea they are his perquisites. To take away fixtures unlawfully is larceny at law. Trees, shrubs, etc., which were in the garden when the tenant entered into possession remain the landlord's fixtures.

In another sense a tenant can remove certain fixtures from their places, but must not take them from the house when giving up possession., Hangings, blinds, grates, stoves, may be taken down or removed to make room for similar articles of the tenant's own; but here again no damage must be caused to the landlord's property, and on leaving, all such fittings must be replaced, or the substituted ones left.

It should be particularly noted that a cupboard built into a house is the landlord's fixture, as distinct from a movable one provided by the tenant.

A tenant should remove any fixtures he is entitled to take at the time of quitting the premises, as he cannot re-enter the house for the purpose of removing them.

Trade fixtures are removable by the tenant, unless there is any stipulation to the contrary in the lease or agreement. In agricultural tenancies, such as farms, small holdings, allotments, the tenant is entitled to compensation for any improvements. For example, if he walls off part of his garden and plants fruit-trees, so that in the course of a few years there is a valuable orchard, he will demand and receive compensation, as he cannot take the orchard with him on removing. On the other hand a town tenant must leave all fruit trees in his garden as fixtures of the landlord.

Much trouble is saved if the tenant asks for and

receives from the landlord a complete list of fixtures, as it often happens that these get lost or destroyed, and the landlord demands payment or damages in respect of them. For example, he finds a kitchen raker is missing, and accuses the tenant of removing it. Probably it was missing when the latter entered upon the tenancy, having been taken by a previous tenant. A list in duplicate agreed upon by landlord and tenant at the commencement of a tenancy would avoid much misunderstanding. *See* Blinds; Bracket; Cupboard; Curtains.

**FLAG.** This is the popular name given to some varieties of the family of iris. It is also known as the poor man's orchid. The word flag is generally intended to refer to the wild yellow iris, or to the purple iris, which blooms in such a prolific fashion in June in suburban gardens. It is not, strictly speaking, a bulbous plant, but has rhizomatous roots, which may be separated in the autumn if increase of stock is desirable. Its botanical name is *Iris germanica*. *See* Iris.

**FLAGEOLET:** In Cookery. The small green beans of French or kidney beans, known as flageolets, are cooked in several ways. In Great Britain they are generally sold in a dried state, though they are also excellent when fresh and cooked in the same manner as green peas. Dried flageolets need to be washed and soaked overnight before being put into a saucepan containing just enough cold water to cover them. A small quantity of mixed herbs and an onion should be added to give flavouring, and the whole brought to the boil.

The beans require about 2 hours' cooking before they are tender, when they should be drained and tossed over the fire in a pan containing a little butter. They are then ready to be seasoned and served. Flageolets may also be served in egg, or parsley, or any other suitable sauce, in which case they should be cooked until tender according to the directions already given, drained, and then reheated in the sauce.

**FLAGON.** This word is employed for a vessel used for holding liquid, one somewhat taller than the tankard and fitted with a lid. In England flagons are found in the 16th century or earlier. The lid was hinged at a point well back on the handle, and was provided with a thumb-piece, so that when drinking, the drinker could keep the lid quite clear of his mouth.

*Flagon. Left, flagon of serpentine marble mounted in silver-gilt; about 1630. Right, flagon of silver-gilt, repoussé with tulip flowers, leaves and animals; 1663 (Courtesy of the Director, Victoria & Albert Museum, S. Kensington).*

Flagons were made of silver, as well as of pewter and

cheaper metals. One example, illustrated in the next page, dating from 1663, is of silver gilt. It is cylindrical in shape, with a flat cover and a scroll handle. The thumb-piece represents a pierced heart, and is beautifully chased and embossed. It stands 15 ½ in. high. To-day the word is used for the glass bottle in which certain kinds of wine are sold. *See* Silver; Tankard.

**FLAGS:** The Game. Also known as French and English, this is an excellent game for large parties of children, such as picnics, school treats, and the like. It is played out of doors or in a large schoolroom, as a good deal of space is required. The players are divided into two sides, which are chosen in the ordinary way.

A line is marked across the middle of the ground; one side occupies one half of the ground and the other side the other half. At each end of the ground are laid handkerchiefs—stones, caps, or any other portable objects do equally well—which represent the flags of the side, and are to be defended against the enemy. The sides then take up their position in their own camp, and the game begins.

It is the object of each side to capture the flags of the other, but the moment a player steps across the dividing line he can be caught by any member of the opposing side. If caught he is a prisoner, and must stand behind the flags with outstretched hand awaiting rescue. If he succeeds in reaching a flag without being caught, he can carry it back in safety. No flag may be taken while there are prisoners to be rescued. The game continues until one side has captured all the flags of the opposing side.
